Consider an open quantum system with (discrete-time) Markovian dynamics. Our task is to store information in the system in such a way that it can be retrieved perfectly, even after the system is left to evolve for an arbitrarily long time. We show that this is impossible for classical (resp. quantum) information precisely when the dynamics is mixing (resp. asymptotically entanglement breaking). Furthermore, we provide tight universal upper bounds on the minimum time after which any such dynamics 'scrambles' the encoded information beyond the point of perfect retrieval. On the other hand, for dynamics that are not of this kind, we show that information must be encoded inside the peripheral space associated with the dynamics in order for it to be perfectly recoverable at any time in the future. This allows us to derive explicit formulas for the maximum amount of information that can be protected from noise in terms of the structure of the peripheral space of the dynamics.

I. INTRODUCTION

Systems of relevance in quantum informationprocessing tasks are typically open, i.e. they have unavoidable interactions with their surroundings. The external system modelling the surrounding of the original system is usually called its environment or a bath. An interesting scenario, which is amenable to rigorous analysis, is one in which the interaction between the system and the bath is assumed to be weak. In this so-called weak*coupling limit*, the decay times of correlation functions of the bath are much shorter than the typical time scale over which the state of the system changes significantly. In other words, the bath 'forgets' about its interaction with the system and returns to its steady state quickly relative to the speed at which the system evolves. Since in subsequent interactions, the bath does not remember the details of the previous interaction, the dynamics of the system becomes Markovian. Mathematically, the reduced dynamics of the system can be modelled by a (discreteor continuous-time) quantum Markov semigroup [1-5].

In this paper, we consider a finite-dimensional open quantum system A which undergoes such a Markovian evolution. Our task is to encode information in A in such a way that it can be recovered *perfectly* without any error, even after the system is left to evolve for an arbitrarily long time. We can think of A as a quantum memory in which we wish to store information so that it can be perfectly retrieved in the future. We focus on the discrete-time scenario, in which the evolution of the system is given by a discrete-time quantum Markov semigroup (dQMS). If \mathcal{H}_A is the Hilbert space of the system A, then any dQMS is of the form $\{\Phi^n\}_{n\in\mathbb{N}}$, where $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is a quantum channel (i.e. a linear completely positive trace-preserving map between linear operators acting on \mathcal{H}_A) and

$$\Phi^n := \underbrace{\Phi \circ \Phi \circ \ldots \circ \Phi}_{n \text{ times}}$$

is the n-fold composition of the channel with itself. The nomenclature arises from the fact that compositions of the channel clearly satisfy the semigroup property: $\Phi^{n+m} = \Phi^n \circ \Phi^m$, for all $n, m \in \mathbb{N}$. The task described above can be thought of as perfect transmission of information across time, i.e. through channels Φ^n , where $n \in \mathbb{N}$ plays the role of the time parameter. Such tasks form the core of zero-error communication theory [6– 10]. However, both in the classical and quantum settings, the focus till now has been on information transmission through *parallel* uses (i.e. tensor products) of a channel [11–14]. In fact, originally, capacities of channels were evaluated in the so-called *asymptotic*, *memoryless* setting in which it was assumed that the channel was available for an infinite number of (parallel) uses and that there was no correlation (or memory) between successive uses of the channel. For a channel Φ , this was modelled by considering information transmission through $\Phi^{\otimes n}$ and then taking the limit $n \to \infty$. In this paper, we instead focus on how the capacities behave under *sequential* concatenations of channels, thereby studying how information propagates over time under a Markovian evolution.

For a quantum channel, its zero-error communication ability is quantified by the one-shot zero-error capacity of the channel. This can be either the classical or quantum capacity, depending on whether the information to be transmitted is classical or quantum. For example, in order to transmit M classical messages perfectly through Φ , one must encode the M messages in pure states $\{\psi_m\}_{m=1}^M \subset \mathcal{L}(\mathcal{H}_A)$ such that

$$\forall m \neq m': \ \Phi(\psi_m) \perp \Phi(\psi_{m'}), \tag{1}$$

where two states ρ, σ are orthogonal ($\rho \perp \sigma$) if their supports are orthogonal as subspaces. The interpretation here is that for any choice of encoding of the *M* classical messages on the input side, the set of output states have to be perfectly distinguishable in order for the receiver to decode the intended message via a measurement without error, which is possible if and only if the output states are pairwise orthogonal. The maximum number of bits that can be transmitted in this fashion through Φ is called the *(one-shot) zero-error classical capacity* of Φ (denoted $C_0^{(1)}(\Phi)$). Similarly, in order to send an *M*-dimensional quantum state perfectly through Φ , one must find an encoding subspace $\mathcal{C} \subset \mathcal{H}_A$ with dim $\mathcal{C} = M$ such that there exists a recovery channel \mathcal{R} satisfying

$$\mathcal{R} \circ \Phi(\rho) = \rho, \quad \forall \rho \in \mathcal{L}(\mathcal{C}).$$
 (2)

The maximum number of qubits that can be transmitted in this fashion through Φ is called the *(one-shot) zero*error quantum capacity of Φ (denoted $Q_0^{(1)}(\Phi)$).

A. Main results

We now summarize the primary contribution of our work. Consider a quantum system A whose time evolution is governed by a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, where Φ : $\mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is a quantum channel. We address the following questions/problems.

- Does there exist a finite time $n \in \mathbb{N}$ at which the one-shot zero-error classical (resp. quantum) capacity of Φ^n vanishes? If yes, we say that the dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ is eventually c-scrambling (resp. q-scrambling)). In this case, the dynamics is so noisy that no matter how cleverly we encode information in A, eventually, that is after enough time has passed, we will not be able to perfectly recover it.
- For an eventually scrambling dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, we denote the minimum time $n \in \mathbb{N}$ at which Φ^n loses its ability to perfectly transmit classical (resp. quantum) information by $c(\Phi)$ (resp. $q(\Phi)$) and refer to it as the classical (resp. quantum) scrambling time (or the scrambling index) of Φ . This is the minimum time after which any encoded information in the system will get 'scrambled' beyond the point of perfect recovery. Finding bounds on the scrambling times $c(\Phi)$ and $q(\Phi)$ of the dynamics is a natural problem to consider.
- Finally, if the dQMS is not eventually scrambling, what is the optimal way to encode information in the system in such a way that it is protected from noise for an arbitrarily long time?

Our main results provide full solutions to all of the above. Firstly, we completely characterize the class of eventually scrambling dQMS.

Theorem I.1. A dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ governing the dynamics of an open quantum system A is

- eventually q-scrambling if and only if it is asymptotically entanglement breaking, *i.e.*, if and only if all the limit points of the semigroup $\{\Phi^n\}_{n\in\mathbb{N}}$ are entanglement breaking.
- eventually c-scrambling if and only if it is mixing, i.e., if and only if there exists a state $\rho \in \mathcal{L}(\mathcal{H}_A)$ such that

$$\forall X \in \mathcal{L}(\mathcal{H}_A) : \lim_{n \to \infty} \Phi^n(X) = \operatorname{Tr}(X)\rho.$$

Note that Theorem I.1 provides an information theoretic interpretation to the entanglement-breaking and mixing behaviours of quantum Markov semigroups, which have been extensively studied in the literature [15– 17].

Secondly, we provide a universal upper bound on the scrambling times of all eventually scrambling dQMS that scales quadratically with the dimension of the system. Moreover, we show that this quadratic dependence is optimal in the classical case by exhibiting an explicit class of dQMS whose classical scrambling time scales quadratically with the system dimension.

Theorem I.2. For an eventually c-scrambling dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ governing the dynamics of a d-dimensional system, the scrambling times satisfy $q(\Phi) \leq c(\Phi) \leq d^2$. Moreover, there exists a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ acting on a d-dimensional system such that

$$c(\Phi) = \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil.$$

Theorem I.3. For an eventually q-scrambling dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ governing the dynamics of a d-dimensional system, the scrambling time satisfies $q(\Phi) \leq d^2$.

The above results are special cases of a more general phenomenon. It turns out that for a d-dimensional system, there exists a universal time scale $n \sim O(d^2)$ after which the zero-error capacities of any dQMS acting on the system stabilize.

Theorem I.4. For any dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ governing the dynamics of a d-dimensional system, $\exists N \leq d^2$ such that

$$\begin{aligned} \forall n \in \mathbb{N} : \quad Q_0^{(1)}(\Phi^N) &= Q_0^{(1)}(\Phi^{N+n}), \\ C_0^{(1)}(\Phi^N) &= C_0^{(1)}(\Phi^{N+n}). \end{aligned}$$

Finally, if the dynamics $\{\Phi^n\}_{n\in\mathbb{N}}$ of the system is not eventually scrambling, we show that the optimal way to encode information in order to protect it from noise is to do it inside the peripheral space $\chi(\Phi)$ of the channel Φ , which is defined as the span of all its peripheral eigenoperators:

$$\chi(\Phi) := \operatorname{span}\{X \in \mathcal{L}(\mathcal{H}_A) : \Phi(X) = \lambda X, |\lambda| = 1\}.$$

The structure of this space is well understood: for any channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$, there exists a decomposition $\mathcal{H}_A = \mathcal{H}_0 \oplus \bigoplus_{k=1}^K \mathcal{H}_{k,1} \otimes \mathcal{H}_{k,2}$ and positive definite states $\rho_k \in \mathcal{L}(\mathcal{H}_{k,2})$ such that [5, Theorem 6.16]:

$$\chi(\Phi) = 0 \oplus \bigoplus_{k=1}^{K} (\mathcal{L}(\mathcal{H}_{k,1}) \otimes \rho_k).$$
(3)

Moreover, there exist unitaries $U_k \in \mathcal{L}(\mathcal{H}_{k,1})$ and a permutation π which permutes within subsets of $\{1, 2, \ldots, K\}$ for which the corresponding $\mathcal{H}_{k,1}$'s have the same dimension, such that for any $X = 0 \oplus \bigoplus_{k=1}^{K} x_k \otimes \rho_k$:

$$\Phi(X) = 0 \oplus \bigoplus_{k=1}^{K} U_k^{\dagger} x_{\pi(k)} U_k \otimes \rho_k.$$

From the above peripheral decomposition, it is not too hard to deduce that any information encoded inside the $\mathcal{L}(\mathcal{H}_{k,1})$ blocks is shielded from noise for an arbitrarily long time. Furthermore, in the asymptotic limit, it turns out that this is the best one can do.

Theorem I.5. For any dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, we have

$$\lim_{n \to \infty} C_0^{(1)}(\Phi^n) = \log \sum_{k=1}^K \dim \mathcal{H}_{k,1}.$$
$$\lim_{n \to \infty} Q_0^{(1)}(\Phi^n) = \log \max_k \dim \mathcal{H}_{k,1}.$$

Note that because of Theorem I.4, the limits above are actually attained at a finite time $n \leq d^2$. Two special cases of this result are worth highlighting. If Φ is a classical channel given by a stochastic matrix M:

$$\Phi(X) = \sum_{i,j} M_{ij} X_{jj} |i\rangle\langle i|$$

the $\mathcal{H}_{k,1}$ blocks in Eq. (IA) become one-dimensional (since otherwise the channel would have non-zero quantum capacity, which is impossible). Hence, $\sum_k \dim \mathcal{H}_{k,1} = \dim \chi(\Phi) =$ number of peripheral eigenvalues of M (counted with multiplicities). Similarly, if Φ is a quantum channel with a unique fixed state, the $\mathcal{H}_{k,1}$ blocks become one-dimensional [5], and we get

$$\lim_{n \to \infty} C_0^{(1)}(\Phi^n) = \log \dim \chi(\Phi).$$

B. Proof ideas

Two main ingredients are employed in the proofs of our results. The first is a reformulation of the zero-error capacity of any channel Φ in terms of its operator system. If $\{K_i\}_i$ is a set of Kraus operators of $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$, the operator system $S_{\Phi} := \operatorname{span}_{i,j}\{K_i^{\dagger}K_j\}$ is a \dagger -closed subspace of $\mathcal{L}(\mathcal{H}_A)$ containing the identity. The error correction condition in Eq. (I) can be restated as

$$\forall m \neq m': \quad |\psi_m\rangle\!\langle\psi_{m'}| \perp S_{\Phi} \quad [10]$$

A similar reformulation can be done for the quantum case in Eq. (I) by exploiting the Knill-Laflamme error correction conditions [18]. Hence, the zero-error capacities of any channel Φ are purely a function of its operator system. Now, for any dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, we show that the corresponding operator systems form an increasing chain of subspaces in $\mathcal{L}(\mathcal{H}_A)$ which stabilizes at time $N \leq (\dim \mathcal{H}_A)^2$:

$$S_{\Phi} \subset S_{\Phi^2} \subset \ldots \subset S_{\Phi^N} = S_{\Phi^{N+1}} = \ldots = S_{\Phi^{N+n}} = \ldots$$

This immediately shows that the zero-error capacities must also stabilize after time N (Theorem I.4). The second key ingredient we use is the fact that for any dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, there exists an increasing subsequence $(n_i)_{i \in \mathbb{N}}$ such that $\Phi^{n_i} \to \mathcal{P}_{\chi}$ as $i \to \infty$ [5, Prop. 6.3], where P_{χ} is the channel that projects onto the peripheral space $\chi(\Phi)$. This shows that the capacities of Φ^n must stabilize to the corresponding capacities of P_{γ} , which can be explicitly computed in terms of the block structure of $\chi(\Phi)$ (Eq. (IA)). The characterization of eventually scrambling dQMS follows easily from this. Clearly, a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ is eventually c-scrambling $\iff \sum_{k=1}^{K} \dim \mathcal{H}_{k,1} = 1 \iff \dim \chi(\Phi) = 1 \iff \Phi$ admits a unique fixed state and no other peripheral eigenoperators, which is equivalent to the dQMS being mixing in the sense of Theorem I.1. The quantum case follows similarly by exploiting the results derived in [16] on asymptotically entanglement-breaking channels. We refer the readers to the supplementary material for complete proofs of all the results [19].

C. Auxilliary Results

We derive several auxilliary results in the supplemental material, which might be of independent interest [20]. We list a couple of them below. We prove that if a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$ is eventually c-scrambling, then even the oneshot zero error *entanglement assisted* classical capacity of Φ^n vanishes for some $n \in \mathbb{N}$. Moreover, the entanglement assisted classical scrambling time $c_E(\Phi)$, defined analogously to $c(\Phi)$, also satisfies $c_E(\Phi) \leq d^2$.

We also exhibit a close link between the Wielandt index [21-24] of a channel and its scrambling time. It turns out that if Φ is a mixing channel as in Theorem I.1 with a full rank fixed state, $\exists n \in \mathbb{N}$ such that Φ^n sends any input state to a full rank output state, and the minimum such n is called the Wielandt index of Φ (denoted $w(\Phi)$). For any mixing channel with a full rank fixed state, it is easy to check that $c(\Phi) \leq w(\Phi)$. In case Φ is also unital, we obtain a reverse inequality: $w(\Phi) \leq (d-1)c(\Phi)$.

II. DISCUSSION AND OUTLOOK

Ever since the inception of information theory from Shannon's seminal work [25], the task of information transmission via a noisy communication channel has been a focal point of enquiry. Much of the effort in this regard has been in the so-called *parallel* setting, where the task is to transmit information across many parallel copies of a given channel [11–14]. In contrast, we initiate the study of information transmission in the *sequential* setting, where we analyze how information can be transmitted across sequential concatenations of a channel.

Physically speaking, we investigate how information stored in an open quantum system propagates over time as the system evolves according to a discrete-time Quantum Markov Semigroup $\{\Phi^n\}_{n\in\mathbb{N}}$. We show that information stored inside the peripheral space $\chi(\Phi)$ of the channel Φ is protected from noise for an arbitrarily long time. Furthermore, in the asymptotic time limit $n \to \infty$, we prove that the block structure of $\chi(\Phi)$ dictates the maximum amount of information that can be protected from noise. This allows us to derive explicit formulas for the information transmission capacities of any dOMS in terms of the structure of $\chi(\Phi)$. Here, it would be interesting to analyse whether the decomposition of $\chi(\Phi)$ in Eq. (IA) is efficiently computable, which inturn would make the capacity formulas of Theorem I.5 efficiently computable. We also show that a system is asymptotically useless for storing classical (resp. quantum) information if and only if the dQMS governing its dynamics is mixing (resp. asymptotically entanglement breaking). Interestingly, we exhibit a universal time scale $n \sim O(d^2)$ after which the information transmission capacity of any dQMS acting on a d-dimensional system stabilizes. While the quadratic dimension dependence here is tight for classical capacity, we do not know if this is true for quantum capacity.

The sequential view of information transmission that we consider opens a host of exciting research directions. While we have considered a simple discrete-time Markovian model for the dynamics of the open system, it would be interesting to perform the same analysis for other kinds of dynamics, such as continuous-time Markovian models [1–4] and repeated interaction systems [26–28]. Apart from the standard classical and quantum capacities, other kinds of transmission rates can also be considered, such as those where assistance from external resources like correlations and entanglement are supplied to aid in communication [29–32]. Finally, it would be interesting to drop the zero-error constraint and analyse approximate capacities, where information is required to be recovered only approximately with a certain error threshold.

III. ACKNOWLEDGEMENTS

We thank Omar Fawzi for insightful comments on the first version of this manuscript and for conjecturing that the results in Theorem I.5 should hold true.

SI. PRELIMINARIES

In this paper, we always work with finite-dimensional Hilbert spaces and denote them by \mathcal{H} . $\mathcal{L}(\mathcal{H})$ denotes the algebra of linear operators acting on \mathcal{H} . The set of quantum states (density matrices) on \mathcal{H} is denoted by $\mathcal{D}(\mathcal{H}) := \{\rho \in \mathcal{L}(\mathcal{H}) : \rho \geq 0, \operatorname{Tr}(\rho) = 1\}$. The identity operator on \mathcal{H} is denoted by $\mathbb{1} \in \mathcal{L}(\mathcal{H})$. Note that if dim $\mathcal{H} = d, \mathcal{H} \simeq \mathbb{C}^d$ and $\mathcal{L}(\mathcal{H}) \simeq \mathbb{M}_d(\mathbb{C})$, where $\mathbb{M}_d(\mathbb{C})$ denotes the matrix algebra of all $d \times d$ complex matrices. We denote the Hilbert space associated to a quantum system A by \mathcal{H}_A . Pure states of the system A are denoted either by normalized kets $|\psi\rangle \in \mathcal{H}_A$ or by the corresponding rank one projections $\psi := |\psi\rangle\langle\psi| \in \mathcal{L}(\mathcal{H}_A)$.

A quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ is a linear, completely positive, and trace-preserving map. Φ is said to be unital if $\Phi(\mathbb{1}_A) = \mathbb{1}_B$. The adjoint of the channel Φ , with respect to the Hilbert-Schmidt inner product, is the linear map $\Phi^* : \mathcal{L}(\mathcal{H}_B) \to \mathcal{L}(\mathcal{H}_A)$ defined through the relation $\operatorname{Tr}(\Phi^*(X)Y) = \operatorname{Tr}(X\Phi(Y))$, for any $X \in \mathcal{L}(\mathcal{H}_A)$ and $Y \in \mathcal{L}(\mathcal{H}_B)$. It is completely positive and unital. In this paper, all logarithms are taken to base 2.

A discrete quantum Markov semigroup (dQMS) associated with a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is the sequence $\{\Phi^n\}_{n\in\mathbb{N}}$. Here, the 'semigroup' terminology simply refers to the fact that the sequence $\{\Phi^n\}_{n\in\mathbb{N}}$ is closed with respect to compositions: $\Phi^n \circ \Phi^m = \Phi^{n+m}$. We can think of a dQMS as governing the time evolution of an open quantum system A, with $n \in \mathbb{N}$ acting as the discrete time parameter.

Remark 1. As mentioned in the Introduction, we are interested in studying zero-error communication through discrete quantum Markov semigroups. Hence, we will mostly focus on quantum channels $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ whose input and output spaces are the same $\mathcal{H}_A = \mathcal{H}_B = \mathcal{H} \simeq \mathbb{C}^d$. Using the isomorphism $\mathcal{L}(\mathbb{C}^d) \simeq \mathbb{M}_d(\mathbb{C})$, we will interchangeably denote such channels by $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$ or $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ and use $\mathbb{S}_d(\mathbb{C})$ to denote the set of quantum states $\mathcal{D}(\mathcal{H})$.

A. Spectral and ergodic properties

Every quantum channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$ admits a quantum state $\rho \in \mathcal{D}(\mathcal{H})$ as a fixed point: $\Phi(\rho) = \rho$ [13, Theorem 4.24]. In other words, $\lambda = 1$ is always an eigenvalue of Φ . The spectrum (denoted spec Φ) of Φ is contained within the unit disk $\{z \in \mathbb{C} : |z| \leq 1\}$ in the complex plane and is invariant under complex conjugation, i.e., $\lambda \in \operatorname{spec} \Phi \implies \overline{\lambda} \in \operatorname{spec} \Phi$. The peripheral spectrum of Φ consists of all peripheral eigenvalues $\lambda \in \mathbb{T} \cap \operatorname{spec} \Phi$, where $\mathbb{T} := \{z \in \mathbb{C} : |z| = 1\}$. It is known that the geometric and algebraic multiplicities of all peripheral eigenvalues of a quantum channel are equal [5, Proposition 6.2]. A peripheral eigenvalue is called simple if it has unit multiplicity. A quantum channel and its adjoint both share the same spectrum, spec $\Phi = \operatorname{spec} \Phi^*$.

We now introduce the notions of ergodic and mixing quantum channels. For a more detailed study of the ergodic theory of quantum channels, the readers should refer to [5, 15, 34]

Theorem SI.1. For a quantum channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$, the following are equivalent.

- $\lambda = 1$ is a simple eigenvalue of Φ .
- There exists a state $\rho \in \mathcal{D}(\mathcal{H})$ such that for all $X \in \mathcal{L}(\mathcal{H})$,

$$\lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \Phi^k(X) = \operatorname{Tr}(X)\rho.$$

A channel Φ (or a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$) satisfying these equivalent conditions is said to be **ergodic**. The unique fixed point $\rho \in \mathcal{D}(\mathcal{H})$ of Φ is called the invariant state of Φ . If, in addition, the unique invariant state has full rank, then the channel and the associated dQMS are said to be **irreducible**.

Theorem SI.2. For a quantum channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$, the following are equivalent.

1. $\lambda = 1$ is a simple eigenvalue of Φ and there are no other peripheral eigenvalues of Φ .

2. There exists a state $\rho \in \mathcal{D}(\mathcal{H})$ such that for all $X \in \mathcal{L}(\mathcal{H})$,

$$\lim_{n \to \infty} \Phi^n(X) = \operatorname{Tr}(X)\rho.$$

A channel Φ (or a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$) satisfying these equivalent conditions is said to be **mixing**. If, in addition, the unique invariant state of Φ has full rank, then the channel and the associated dQMS are said to be **primitive**.

The peripheral space of a channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$ is defined as the span of all its peripheral eigenoperators:

$$\chi(\Phi) := \operatorname{span}\{X \in \mathcal{L}(\mathcal{H}) : \Phi(X) = \lambda X, |\lambda| = 1\}.$$

For any channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$, there exists a decomposition $\mathcal{H} = \mathcal{H}_0 \oplus \bigoplus_{k=1}^K \mathcal{H}_{k,1} \otimes \mathcal{H}_{k,2}$ and positive definite states $\rho_k \in \mathcal{L}(\mathcal{H}_{k,2})$ such that [5, Theorem 6.16]:

$$\chi(\Phi) = 0 \oplus \bigoplus_{k=1}^{K} (\mathcal{L}(\mathcal{H}_{k,1}) \otimes \rho_k).$$
(S1)

Moreover, there exist unitaries $U_k \in \mathcal{L}(\mathcal{H}_{k,1})$ and a permutation π which permutes within subsets of $\{1, 2, \ldots, K\}$ for which the corresponding $\mathcal{H}_{k,1}$'s have the same dimension, such that for any $X = 0 \oplus \bigoplus_{k=1}^{K} x_k \otimes \rho_k$:

$$\Phi(X) = 0 \oplus \bigoplus_{k=1}^{K} U_k^{\dagger} x_{\pi(k)} U_k \otimes \rho_k.$$

A channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is called entanglement-breaking if local action of Φ on any bipartite system breaks all entanglement in the system, i.e., for all states $\rho \in \mathcal{D}(\mathcal{H}_A \otimes \mathcal{H}_B)$, $(\Phi \otimes \mathrm{id})(\rho)$ is separable.

- A channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$ (or a dQMS $\{\Phi^n\}_{n \in \mathbb{N}}$) is called
 - eventually entanglement-breaking if there exists an $n \in \mathbb{N}$ such that Φ^n is entanglement-breaking.
 - asymptotically entanglement-breaking if all the limit points of the set $\{\Phi^n\}_{n\in\mathbb{N}}$ are entanglement-breaking.

It is known that for any channel $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$, the limit points of the set $\{\Phi^n\}_{n \in \mathbb{N}}$ are either all entanglementbreaking or none of them are [16]. Moreover, the following result was derived in [16, Theorem 32].

Theorem SI.3. Let $\Phi : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$ be a quantum channel. The following are equivalent:

- Φ is asymptotically entanglement-breaking.
- All the $\mathcal{L}(\mathcal{H}_{k,1})$ blocks in the peripheral decomposition in eq. (SIA) are one-dimensional.
- All peripheral points of Φ commune with one another, i.e. $\forall X, Y \in \chi(\Phi), [X, Y] = XY YX = 0.$

For an elaborate discussion of eventually entanglement-breaking and asymptotically entanglement-breaking quantum channels, the readers should refer to [16, 17].

B. Fixed points and multiplicative domains

Given a channel Φ on $\mathbb{M}_d(\mathbb{C})$, the set of fixed points of Φ is the set

$$\operatorname{Fix}_{\Phi} = \{ A \in \mathbb{M}_d(\mathbb{C}) | \ \Phi(A) = A \}.$$

Note that it is a vector subspace of $\mathbb{M}_d(\mathbb{C})$ which is closed under taking adjoints. If the channel Φ is unital, then the set Fix_{Φ} is also closed under multiplication and hence is a C^{*}-subalgebra ([35]). Recall that a (operator) norm-closed subset of $\mathcal{L}(\mathcal{H})$ that is closed under addition, multiplication, and the *-operation is called a C^{*}-algebra.

The multiplicative domain of Φ is defined to be the following set

$$\mathcal{M}_{\Phi} = \{ A \in \mathbb{M}_d(\mathbb{C}) | \ \Phi(AX) = \Phi(A)\Phi(X), \ \Phi(XA) = \Phi(X)\Phi(A), \forall X \in \mathbb{M}_d(\mathbb{C}) \}.$$

For unital channels, it holds that

$$\operatorname{Fix}_{\Phi} = \mathcal{A}',$$

where \mathcal{A} is the C*-algebra generated by the Kraus operators of Φ and \mathcal{A}' is the algebra that commutes with \mathcal{A} . Also, it is known that for unital channels one has

$$\mathcal{M}_{\Phi} = \operatorname{Fix}_{\Phi^* \circ \Phi}.$$

The multiplicative domain shrinks under the iterations of a unital channel. Indeed, let \mathcal{M}_{Φ^k} denote the multiplicative domain of Φ^k for each $k \ge 1$, then it holds that ([36])

$$\mathcal{M}_{\Phi} \supseteq \mathcal{M}_{\Phi^2} \supseteq \cdots \mathcal{M}_{\Phi^n} \supseteq \cdots$$

The above chain stabilizes at a set which we denote as $\mathcal{M}_{\Phi^{\infty}} := \bigcap_{k \ge 1} \mathcal{M}_{\Phi^k}$ and call the *stabilized multiplicative domain* of Φ and it is invariant under repeated applications of the channel.

C. Contraction coefficient

The contraction coefficient of a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ with respect to the trace norm is defined as follows [37]:

$$\eta^{\mathrm{Tr}}(\Phi) := \sup_{\substack{\rho, \sigma \in \mathcal{D}(\mathcal{H}_A)\\ \rho \neq \sigma}} \frac{\|\Phi(\rho) - \Phi(\sigma)\|_1}{\|\rho - \sigma\|_1}.$$

Lemma SI.4. [38, Theorem 2] For a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$,

$$\eta^{\mathrm{Tr}}(\Phi) = \sup_{\substack{\rho, \sigma \in \mathcal{D}(\mathcal{H}_A) \\ \sigma \mid \sigma}} \frac{1}{2} \|\Phi(\rho) - \Phi(\sigma)\|_1.$$

Moreover, the states in the supremum above can be taken to be pure.

D. Zero error communication

Let Alice and Bob be linked via a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$. Suppose Alice wants to communicate $k \geq 2$ classical messages to Bob perfectly without error. This is possible if and only if she can encode the k messages in states

$$\{\rho_i\}_{i=1}^k \subset \mathcal{D}(\mathcal{H}_A)$$
 such that $\forall i \neq j : \Phi(\rho_i) \perp \Phi(\rho_j),$

where we say that two positive operators $X, Y \ge 0$ are orthogonal $(X \perp Y)$ if their supports are orthogonal as subspaces, which is equivalent to saying that $\operatorname{Tr}(XY) = 0$. The interpretation here is that for any choice of encoding of the k classical messages on the input side, the set of output states would have to be perfectly distinguishable in order for Bob to decode the intended classical message via a measurement without error, which is possible if and only if the output states are pairwise orthogonal. Note that if $\rho \in \mathcal{D}(\mathcal{H}_A)$ is a mixed state and $|\psi\rangle \in \operatorname{supp}\rho$, there exists an $\varepsilon > 0$ such that $\psi \le \varepsilon \rho$. Therefore, $\Phi(\psi) \le \varepsilon \Phi(\rho)$ and $\operatorname{supp}\Phi(\psi) \subseteq \operatorname{supp}\Phi(\rho)$. Thus, without loss of generality, all the encoding states in the above scheme can be taken to be pure. With this background, we can introduce the following definition.

Definition SI.5. The one-shot zero-error classical capacity $C_0^{(1)}(\Phi)$ of a channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ is defined as follows:

$$C_0^{(1)}(\Phi) := \sup_C \log |C|,$$

where the supremum is over all collections C of pure quantum states $\{\psi_i\}_{i=1}^{|C|} \subset \mathcal{D}(\mathcal{H}_A)$ such that

$$\forall i \neq j : \quad \Phi(\psi_i) \perp \Phi(\psi_j).$$

Suppose now that Alice and Bob share some entanglement beforehand, say in the form of a pure bipartite state $\psi \in \mathcal{D}(\mathcal{H}_{A_0} \otimes \mathcal{H}_{B_0})$. Alice can now come up with a more general encoding scheme by pre-processing her share of ψ with arbitrary quantum channels $\{\mathcal{E}_i : \mathcal{L}(\mathcal{H}_{A_0}) \to \mathcal{L}(\mathcal{H}_A)\}_{i=1}^k$. She then sends her share of the resulting states through $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$. As before, the condition for perfect distinguishability on Bob's end is equivalent to the following orthogonality relations:

$$\forall i \neq j: \quad (\Phi \circ \mathcal{E}_i \otimes \mathrm{id}_{B_0})(\psi) \perp (\Phi \circ \mathcal{E}_j \otimes \mathrm{id}_{B_0})(\psi).$$

Definition SI.6. The one-shot zero-error entanglement assisted classical capacity $C_{0E}^{(1)}(\Phi)$ of a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ is defined as follows:

$$C_{0E}^{(1)}(\Phi) := \sup_{\psi,C} \log |C|,$$

where the supremum is over all pure bipartite states $\psi \in \mathcal{D}(\mathcal{H}_{A_0} \otimes \mathcal{H}_{B_0})$ and collections C of quantum channels $\{\mathcal{E}_i : \mathcal{L}(\mathcal{H}_{A_0}) \to \mathcal{L}(\mathcal{H}_A)\}$ such that

$$\forall i \neq j: \quad (\Phi \circ \mathcal{E}_i \otimes \mathrm{id}_{B_0})(\psi) \perp (\Phi \circ \mathcal{E}_j \otimes \mathrm{id}_{B_0})(\psi).$$

If Alice wants to send quantum information to Bob through $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ perfectly without error, she must find an encoding subspace $\mathcal{C} \subseteq \mathcal{H}_A$ such that Bob can reverse the action of Φ on \mathcal{C} , i.e., there exists a recovery channel $\mathcal{R} : \mathcal{L}(\mathcal{H}_B) \to \mathcal{L}(\mathcal{H}_A)$ such that

$$\forall \rho \in \mathcal{D}(\mathcal{C}) : \quad \mathcal{R} \circ \Phi(\rho) = \rho$$

If $\{K_i\}_i$ are the Kraus operators of Φ , the Knill-Laflamme error correction conditions [18] show that a subspace $\mathcal{C} \subseteq \mathcal{H}_A$ as above exists if and only if $P_{\mathcal{C}}K_i^*K_jP_{\mathcal{C}} = \lambda_{ij}P_{\mathcal{C}}$ for all i, j, where $P_{\mathcal{C}}$ denotes the orthogonal projection onto \mathcal{C} and $\lambda_{ij} \in \mathbb{C}$.

Definition SI.7. The one shot zero-error quantum capacity $Q_0^{(1)}(\Phi)$ of a channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ is defined as follows:

$$Q_0^{(1)}(\Phi) := \sup_{\mathcal{S}} \log \dim(\mathcal{S}),$$

where the supremum is over all subspaces $S \subseteq \mathcal{H}_A$ such that there exists a recovery quantum channel $\mathcal{R} : \mathcal{L}(\mathcal{H}_B) \to \mathcal{L}(\mathcal{H}_A)$ satisfying

$$\forall \rho \in \mathcal{D}(\mathcal{S}) : \quad \mathcal{R} \circ \Phi(\rho) = \rho$$

It is possible to recast the above channel capacity definitions in terms of an operator system that one can associate with the channel.

Definition SI.8. Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ have a Kraus representation $\Phi(X) = \sum_{i=1}^{n} K_i X K_i^*$. The operator system (also called the non-commutative (confusability) graph) of Φ is defined as [10]

$$S_{\Phi} := \operatorname{span}\{K_i^* K_j, 1 \le i, j \le n\} \subseteq \mathcal{L}(\mathcal{H}_A).$$

One can check that the above definition is independent of the chosen Kraus representation of Φ . Moreover, $\sum_{i=1}^{n} K_{i}^{*}K_{i} = \mathbb{1} \in S_{\Phi}$, since Φ is trace-preserving. Furthermore, $X \in S_{\Phi} \implies X^{*} \in S_{\Phi}$. Such *-closed subspaces $S \subseteq \mathcal{L}(\mathcal{H}_{A})$ containing the identity are called *operator systems* [39].

For an operator system $S \subseteq \mathcal{L}(\mathcal{H})$,

• the maximum size k of a set of mutually orthogonal vectors $\{|\psi_m\rangle\}_{m=1}^k \subseteq \mathcal{H}$ such that

$$\forall m \neq m': \quad |\psi_m\rangle \langle \psi_{m'}| \perp S,$$

is called the *independence number* of S (denoted $\alpha(S)$).

• the maximum number k such that there exist Hilbert spaces $\mathcal{H}_{A_0}, \mathcal{H}_R$, a state $\rho \in \mathcal{D}(\mathcal{H}_{A_0})$, and isometries $\{V_m : \mathcal{H}_{A_0} \to \mathcal{H} \otimes \mathcal{H}_R\}_{m=1}^k$ such that

$$\forall m \neq m': \quad V_m \rho V_{m'} \perp S \otimes \mathcal{L}(\mathcal{H}_R),$$

is called the entanglement-assisted independence number of S (denoted $\tilde{\alpha}(S)$).

• the maximum number k such that there exists a subspace $C \subseteq \mathcal{H}$ with dim C = k satisfying $P_{\mathcal{C}}SP_{\mathcal{C}} = \mathbb{C}P_{\mathcal{C}}$, (where $P_{\mathcal{C}}$ denotes the orthogonal projection onto C) is called the *quantum independence number* of S (denoted $\alpha_q(S)$).

Theorem SI.9. [10] For any channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$, the following relations hold:

$$C_0^{(1)}(\Phi) = \log \alpha(S_{\Phi})$$
$$C_{0E}^{(1)}(\Phi) = \log \tilde{\alpha}(S_{\Phi})$$
$$Q_0^{(1)}(\Phi) = \log \alpha_q(S_{\Phi})$$

Moreover, $0 \leq Q_0^{(1)}(\Phi) \leq C_0^{(1)}(\Phi) \leq C_{0E}^{(1)}(\Phi)$, where the inequalities can be strict.

Remark SI.10. The terminology in Definition SI.8 is motivated by the notion of confusability graphs of classical channels [6]. A discrete classical channel $\mathcal{N} : \mathcal{X} \to \mathcal{Y}$, where \mathcal{X} and \mathcal{Y} denote two finite alphabets, is defined by a transition probability matrix, A, with elements $\mathcal{N}(y|x)$ that express the probability of observing the symbol y given that the symbol x was sent. In order to send different messages through the channel \mathcal{N} with zero error, they should be encoded in the symbols of \mathcal{X} in a manner such that the corresponding outputs of the channel have disjoint support. One can associate a confusability graph $G_{\mathcal{N}}$ with the channel; it has vertex set \mathcal{X} and edges between any pair $x, x' \in \mathcal{X}$ which can be confused, i.e. for which there is a $y \in \mathcal{Y}$ such that $\mathcal{N}(y|x)\mathcal{N}(y|x') > 0$. The one-shot zero error capacity of \mathcal{N} is the maximum number of bits of classical information that can be transmitted without error through a single use of \mathcal{N} . This is given by $\log \alpha(G_{\mathcal{N}})$, where $\alpha(G_{\mathcal{N}})$ is the independence number of the confusability graph, and is equal to the maximum number of vertices in $G_{\mathcal{N}}$ which do not have any edges between them.

We now collect some results from the literature which describe equivalent conditions for the various zero-error oneshot capacities of a channel to be zero. Let us first introduce the following terminology. A channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ is called

- *c*-scrambling if $C_0^{(1)}(\Phi) = 0$.
- q-scrambling if $Q_0^{(1)}(\Phi) = 0$.

Theorem SI.11. The following are equivalent for a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$:

- 1. Φ is c-scrambling.
- 2. $\eta^{\rm Tr}(\Phi) < 1.$
- 3. $\operatorname{Tr}(\Phi(\psi)\Phi(\varphi)) > 0$ for any pair of orthogonal pure states $\psi, \varphi \in \mathcal{D}(\mathcal{H}_A)$.
- 4. $\operatorname{Tr}(\Phi(A)\Phi(B)) > 0$ for all non-zero positive operators $A, B \in \mathcal{L}(\mathcal{H}_A)$.
- 5. There are no rank one elements in S_{Φ}^{\perp} .

The equivalence of (1), (2), (3) and (4) above was obtained in [37, Proposition 4.2] and the equivalence of (1) and (5) was obtained in [40].

Proposition SI.12. [10] For a quantum channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B), C_{0E}^{(1)}(\Phi) = 0$ if and only if S_{Φ}^{\perp} is the zero subspace.

Proposition SI.13. [41] Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_B)$ be a quantum channel. Then, $Q_0^{(1)}(\Phi) > 0$ (i.e. Φ is not q-scrambling) if and only if there are unit vectors $|\xi\rangle, |\eta\rangle \in \mathcal{H}_A$ such that

 $\forall X \in S_{\Phi} : \quad \langle \xi | X | \eta \rangle = 0 \quad and \quad \langle \xi | X | \xi \rangle = \langle \eta | X | \eta \rangle.$

Moreover, the following implications hold:

- $[S_{\Phi}]'$ is non-abelian $\implies Q_0^{(1)}(\Phi) > 0.$
- $[S_{\Phi}]'$ is non-trivial $\implies C_0^{(1)}(\Phi) > 0.$

If S_{Φ} is an algebra, the reverse implications also hold:

- $[S_{\Phi}]'$ is non-abelian $\iff Q_0^{(1)}(\Phi) > 0.$
- $[S_{\Phi}]'$ is non-trivial $\iff C_0^{(1)}(\Phi) > 0.$

In the above statements we used the notation $[S_{\Phi}]'$ to denote the commutant of $[S_{\Phi}]$, i.e.,

 $[S_{\Phi}]' = \{ X \in \mathcal{L}(\mathcal{H}_A) : XY = YX, \, \forall Y \in S_{\Phi} \}.$

SII. MAIN RESULTS

A. Characterization of all eventually c-scrambling dQMS

Consider an open quantum system A whose time evolution is governed by a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, where $\Phi: \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is a quantum channel. We call $\{\Phi^n\}_{n\in\mathbb{N}}$ eventually c-scrambling if there exists an $n \in \mathbb{N}$ such that Φ^n is c-scrambling. These are precisely the kind of evolutions which eventually become useless for zero-error classical communication. Since any non-trivial Φ models some inherent noise in the system, one might naively reason that any (non-trivial) dQMS is eventually scrambling, i.e., if one waits for a long enough time $n \in \mathbb{N}$, Φ^n will become too noisy to communicate any classical message perfectly. However, the following theorem shows that this is the case only for the class of mixing evolutions (see Theorem SI.2). Moreover, we prove that if a dQMS is eventually scrambling, then it will eventually become useless for classical communication even if entanglement is present to aid the process.

Theorem SII.1. Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ be a channel and $\{\Phi^n\}_{n \in \mathbb{N}}$ be the associated dQMS. Then, the following are equivalent.

- 1. $\exists k \in \mathbb{N}$ such that $C_{0E}^{(1)}(\Phi^k) = 0$.
- 2. $\exists k \in \mathbb{N}$ such that $C_0^{(1)}(\Phi^k) = 0$, i.e., $\{\Phi^n\}_{n \in \mathbb{N}}$ is eventually c-scrambling.
- 3. $\{\Phi^n\}_{n\in\mathbb{N}}$ is mixing.

Proof. (1) \implies (2) This implication is trivial, since $C_0^{(1)}(\Phi) \leq C_{0E}^{(1)}(\Phi)$ for any channel Φ . (2) \implies (3) Assume that $\exists k \in \mathbb{N}$ such that Φ^k is scrambling, i.e., $\eta^{\mathrm{Tr}}(\Phi^k) = c < 1$. Let $\rho \in \mathcal{D}(\mathcal{H})$ be a fixed state of Φ . Then, for any (non-zero) positive semi-definite operator $X \in \mathcal{L}(\mathcal{H})$, we have

$$\left\| \Phi^{nk}(X/\operatorname{Tr} X) - \rho \right\|_{1} = \left\| \Phi^{nk}(X/\operatorname{Tr} X) - \Phi^{nk}(\rho) \right\|_{1} \le c^{n} \|X/\operatorname{Tr} X - \rho\|_{1} \to 0 \text{ as } n \to \infty.$$

Hence, for all positive semi-definite $X \in \mathcal{L}(\mathcal{H})$, we get $\lim_{n \to \infty} \Phi^n(X) = \operatorname{Tr}(X)\rho$. Since any $X \in \mathcal{L}(\mathcal{H})$ can be written as a linear combination of positive semi-definite operators, it is clear that Φ is mixing.

(3) \implies (1) Assume that $\exists \rho \in \mathcal{D}(\mathcal{H})$ such that $\forall X \in \mathcal{L}(\mathcal{H})$, $\lim_{n \to \infty} \Phi^n(X) = \operatorname{Tr}(X)\rho$. Since pointwise and uniform convergence are equivalent in finite dimensions, for every $\varepsilon > 0$, $\exists N \in \mathbb{N}$ such that $\forall X \in \mathcal{L}(\mathcal{H})$, $\|\Phi^n(X) - \operatorname{Tr}(X)\rho\|_1 \leq \varepsilon$ for $n \geq N$. In other words, $\lim_{n \to \infty} \Phi^n = \Phi_\infty$, where Φ_∞ is the completely depolarizing channel defined as $\Phi_\infty(X) = \operatorname{Tr}(X)\rho$, and the convergence is with respect to the induced trace norm defined as

$$\|\Phi\|_1 := \sup_{\|X\|_1 \le 1} \|\Phi(X)\|_1.$$

(In fact, since any two norms on a finite-dimensional space are equivalent, we can also think of this convergence in terms any other norm, say the diamond norm for instance.) It is then easy to see that $\lim_{n\to\infty} \Phi^n \otimes \operatorname{id}_{B_0} = \Phi_\infty \otimes \operatorname{id}_{B_0}$. Put differently, for every $\varepsilon > 0$, $\exists N \in \mathbb{N}$ such that $\forall X \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H}_{B_0})$, $\|(\Phi^n \otimes \operatorname{id}_{B_0})(X) - (\Phi_\infty \otimes \operatorname{id}_{B_0})(X)\|_1 \leq \varepsilon$ for $n \geq N$. Hence, for any pure state $\psi \in \mathcal{D}(\mathcal{H}_{A_0} \otimes \mathcal{H}_{B_0})$, channels $\mathcal{E}_i : \mathcal{L}(\mathcal{H}_{A_0}) \to \mathcal{L}(\mathcal{H})$ for i = 1, 2, and $n \geq N$, we have that

$$\begin{aligned} &\frac{1}{2} \| (\Phi^n \circ \mathcal{E}_1 \otimes \mathrm{id}_{B_0})(\psi) - (\Phi^n \circ \mathcal{E}_2 \otimes \mathrm{id}_{B_0})(\psi) \|_1 \\ &= \frac{1}{2} \| (\Phi^n \otimes \mathrm{id}_{B_0})(\psi_1) - (\Phi^n \otimes \mathrm{id}_{B_0})(\psi_2) \|_1 \\ &\leq \frac{1}{2} \| (\Phi^n \otimes \mathrm{id}_{B_0})(\psi_1) - (\Phi_\infty \otimes \mathrm{id}_{B_0})(\psi_1) \|_1 + \frac{1}{2} \| (\Phi^n \otimes \mathrm{id}_{B_0})(\psi_2) - (\Phi_\infty \otimes \mathrm{id}_{B_0})(\psi_2) \|_1 \leq \varepsilon \end{aligned}$$

where $\psi_i = (\mathcal{E}_i \otimes \mathrm{id}_{B_0})(\psi)$ for i = 1, 2 and $(\Phi_\infty \otimes \mathrm{id}_{B_0})(\psi_1) = (\Phi_\infty \otimes \mathrm{id}_{B_0})(\psi_2)$ were added and subtracted to obtain the second inequality. This clearly implies that $C_{0E}^{(1)}(\Phi^k) = 0$ for $k \ge N$.

B. Zero-error classical encodings for non-mixing dQMS

Let us now discuss the conclusion of Theorem SII.1 in more detail. The theorem shows that the semigroups $\{\Phi^n\}_{n\in\mathbb{N}}$ that are able to send classical messages perfectly for arbitrarily long times are precisely of the non-mixing type:

$$\forall n \in \mathbb{N}: \quad C_0^{(1)}(\Phi^n) > 0 \iff \{\Phi^n\}_{n \in \mathbb{N}} \text{ is non-mixing.}$$

It is then natural to ask what kind of encoding states $\rho_1, \rho_2 \in \mathbb{M}_d(\mathbb{C})$ can be used to perfectly transmit a 1-bit classical message through Φ^n ($\forall n \in \mathbb{N}$) for a given non-mixing dQMS { Φ^n }_{$n \in \mathbb{N}$}. Since { Φ^n }_{$n \in \mathbb{N}$} is non-mixing, the following two cases can arise:

Case I. $\lambda = 1$ is not a simple eigenvalue of Φ , i.e., Φ is not ergodic. To tackle this case, let us first note a lemma.

Lemma SII.2. [15, Section 3.1] [5, Proposition 6.8] The fixed-point vector space $\operatorname{Fix}_{\Phi} := \{A \in \mathbb{M}_d(\mathbb{C}) : \Phi(A) = A\}$ of a quantum channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is spanned by quantum states.

Proof. Let $A \in Fix_{\Phi}$ and consider its canonical decomposition into Hermitian parts:

$$A = \frac{A + A^{\dagger}}{2} + i\frac{A - A^{\dagger}}{2i}.$$

Since Φ is Hermiticity preserving, $(A + A^{\dagger})/2$ and $(A - A^{\dagger})/2i$ are also fixed by Φ . Thus, it suffices to show that a Hermitian fixed point $A = A^{\dagger} \in \operatorname{Fix}_{\Phi}$ lies in the span of quantum states. Since A is Hermitian, we can write its Jordan decomposition: $A = A^+ - A^-$, where $A^{\pm} \ge 0$ and $\operatorname{Tr}(A^+A^-) = 0$. Let Π^+ be the projector onto support of A^+ . Then, we have $A^+ = \Pi^+A = \Pi^+\Phi(A) = \Pi^+\Phi(A^+) - \Pi^+\Phi(A^-)$, so that

$$\operatorname{Tr}(A^+) = \operatorname{Tr}(\Pi^+ \Phi(A^+)) - \operatorname{Tr}(\Pi^+ \Phi(A^-)) \le \operatorname{Tr}(\Pi^+ \Phi(A^+)) \le \operatorname{Tr}(\Phi(A^+)) = \operatorname{Tr}(A^+).$$

Hence, the inequalities above must be equalities, implying that $\Pi^+\Phi(A^-) = 0$ and $\Pi^+\Phi(A^+) = \Phi(A^+)$. This shows that $A^+ = \Pi^+A = \Pi^+\Phi(A^+) = \Phi(A^+)$, which clearly also implies $A^- = \Phi(A^-)$. Hence, A lies in the span of quantum states $A^+/\operatorname{Tr} A^+$ and $A^-/\operatorname{Tr} A^-$.

Let us now consider a channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ for which $\lambda = 1$ is not a simple eigenvalue. This means that there are two distinct states $\rho, \sigma \in \mathbb{S}_d(\mathbb{C})$ that are fixed by Φ . Let $A = \rho - \sigma$. Then, the proof of Lemma SII.2 shows that the orthogonal positive and negative parts A^{\pm} of A are also fixed by Φ . Thus, we can transmit a 1-bit classical message through Φ^n for all $n \in \mathbb{N}$ by encoding it in the states $\gamma_1 = A^+ / \operatorname{Tr} A^+$ and $\gamma_2 = A^- / \operatorname{Tr} A^-$.

Case II. $\lambda = 1$ is a simple eigenvalue of Φ but there are other peripheral eigenvalues as well. In other words, Φ is an ergodic quantum channel with $|\mathbb{T} \cap \operatorname{spec} \Phi| \geq 2$.

In order to tackle this case, we need to study the peripheral spectrum of ergodic quantum channels. The structure of the peripheral spectrum of such channels is well-understood.

Lemma SII.3. The following is true for an ergodic quantum channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$:

- The peripheral spectrum of Φ is a cyclic subgroup of \mathbb{T} , i.e., $\exists q \in \mathbb{N}$ such that $\mathbb{T} \cap \operatorname{spec} \Phi = \{\omega^m : m = 0, 1, \ldots, q-1\}$, where $\omega = e^{2\pi i/q}$.
- All the peripheral eigenvalues of Φ are simple.
- There exists a unitary $U \in \mathbb{M}_d(\mathbb{C})$ such that $\Phi^*(U^m) = \omega^m U^m$ for $m = 0, 1, \ldots, q-1$.
- U admits a spectral decomposition $U = \sum_{m=0}^{q-1} \omega^m P_m$ such that $\Phi^*(P_{m+1}) = P_m$.

Proof. We recall that a quantum channel and its adjoint have the same spectrum, and also that if Φ is ergodic, then Φ^* is also ergodic. Also recall that the adjoint of any quantum channel is unital and completely positive. This means that for an ergodic channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the adjoint map $\Phi^* : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ has a unique positive definite fixed point: $\Phi^*(\mathbb{1}) = \mathbb{1}$. The peripheral spectrum of such maps has been studied in detail in the literature, and the statement of the lemma follows directly from the results in [42], see also [5, Theorem 6.6].

The next proposition provides a lower bound on the number of classical messages that can be sent without error through any iteration of an ergodic channel.

Theorem SII.4. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be an ergodic quantum channel. Then,

$$\forall n \in \mathbb{N}: \quad C_0^{(1)}(\Phi^n) \ge \log |\mathbb{T} \cap \operatorname{spec} \Phi|.$$

$$\forall m \in \mathbb{Z}_q : \quad \operatorname{Tr}(\Phi^*(P_{m+1})P_m) = \operatorname{Tr}(P_m) = \operatorname{Tr}(P_{m+1}\Phi(P_m)), \\ \quad \operatorname{Tr}(\Phi^*(P_{m+1})P_{m'}) = \operatorname{Tr}(P_m P_{m'}) = 0 = \operatorname{Tr}(P_{m+1}\Phi(P_{m'})) \quad \text{for} \quad m \neq m'.$$

In other words,

$$\forall m \in \mathbb{Z}_q: \quad \operatorname{Tr}(\Phi(P_m)P_{m'}) = \begin{cases} \operatorname{Tr}(P_m) & \text{if } m' = m+1\\ 0 & \text{if } m' \neq m+1. \end{cases}$$

This shows that sequential action of Φ on the encoding states ρ_m just cyclically permutes the output supports: supp $\Phi(\rho_m) \subset$ supp P_{m+1} for $m \in \mathbb{Z}_q$. Clearly, the output states $\{\Phi^n(\rho_m)\}_{m \in \mathbb{Z}_q}$ are thus mutually orthogonal for all $n \in \mathbb{N}$, which proves our claim.

More generally, we can prove that for any dQMS $\{\Phi^n\}$, the peripheral space $\chi(\Phi)$ of the channel Φ serves as the right space to encode information in order for it to be recoverable for an arbitrarily long time. Recall that the peripheral space of a channel $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is defined as the span of all its peripheral eigenoperators and there exists a decomposition $\mathcal{H}_A = \mathcal{H}_0 \oplus \bigoplus_{k=1}^K \mathcal{H}_{k,1} \otimes \mathcal{H}_{k,2}$ and positive definite states $\rho_k \in \mathcal{L}(\mathcal{H}_{k,2})$ such that [5, Theorem 6.16]:

$$\chi(\Phi) = 0 \oplus \bigoplus_{k=1}^{K} (\mathcal{L}(\mathcal{H}_{k,1}) \otimes \rho_k).$$
(S2)

Moreover, there exist unitaries $U_k \in \mathcal{L}(\mathcal{H}_{k,1})$ and a permutation π which permutes within subsets of $\{1, 2, \ldots, K\}$ for which the corresponding $\mathcal{H}_{k,1}$'s have the same dimension, such that for any $X = 0 \oplus \bigoplus_{k=1}^{K} x_k \otimes \rho_k$:

$$\Phi(X) = 0 \oplus \bigoplus_{k=1}^{K} U_k^{\dagger} x_{\pi(k)} U_k \otimes \rho_k.$$
(S3)

Using this decomposition, we can prove the following result.

Theorem SII.5. Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ be a quantum channel and $\{\Phi^n\}_{n \in \mathbb{N}}$ be the associated dQMS. Then, $\exists N \leq (\dim \mathcal{H}_A)^2$ such that

$$\forall q \in \mathbb{N}: \quad \lim_{n \to \infty} C_0^{(1)}(\Phi^n) = C_0^{(1)}(\Phi^N) = C_0^{(1)}(\Phi^{N+q}) = \log \sum_{k=1}^K \dim \mathcal{H}_{k,1}.$$

Proof. Note that the first two equalities follow from Theorem SII.10, which shows that there exists $N \leq (\dim \mathcal{H}_A)^2$ such that the operator systems of the semigroup stabilize after time N:

$$S_{\Phi} \subset S_{\Phi^2} \subset \ldots \subset S_{\Phi^N} = S_{\Phi^{N+1}} = \ldots = S_{\Phi^{N+q}} = \ldots$$

To show the final equality, first note that the stated action of a channel on its peripheral space (Eq. (SIIB)) clearly implies that the set of states $\{|i_k\rangle\langle i_k|\otimes \rho_k\}$ for k = 1, 2, ..., K and $i_k = 1, 2, ..., \dim \mathcal{H}_{k,1}$ forms a zero-error classical code for Φ^n for all $n \in \mathbb{N}$ in the sense of Definition SI.5. Here, for each k, the state $|i_k\rangle\langle i_k|\otimes \rho_k$ is supported on the $\mathcal{H}_{k,1} \otimes \mathcal{H}_{k,2}$ block in Eq. (SIIB). This shows that

$$\forall n \in \mathbb{N}: \quad C_0^{(1)}(\Phi^n) \ge \log \sum_{k=1}^K \dim \mathcal{H}_{k,1}.$$

To show the reverse inequality, suppose that $\{\psi_m\}_{m=1}^M$ is a zero-error classical code for Φ^N . Since the operator systems of the semigroup stabilize after time N, $\{\psi_m\}_{m=1}^M$ is also a zero-error classical code for Φ^{N+q} for all $q \in \mathbb{N}$, i.e.,

$$\forall q \in \mathbb{N}, \ \forall m \neq m': \quad \langle \Phi^{N+q}(\psi_m), \Phi^{N+q}(\psi_{m'}) \rangle = 0.$$

From [5, Proposition 6.3], there exists an increasing subsequence $(n_i)_{i \in \mathbb{N}}$ such that $\lim_{i \to \infty} \Phi^{n_i} = \mathcal{P}_{\chi}$, where \mathcal{P}_{χ} is the channel that projects onto the peripheral space $\chi(\Phi)$. Thus, $\{\psi_m\}_{m=1}^M$ is also a zero-error classical code for \mathcal{P}_{χ} :

$$\forall m \neq m': \quad \lim_{i \to \infty} \langle \Phi^{n_i}(\psi_m), \Phi^{n_i}(\psi_{m'}) \rangle = 0 = \langle \mathcal{P}_{\chi}(\psi_m), \mathcal{P}_{\chi}(\psi_{m'}) \rangle$$

where we have used the continuity of the Hilbert-Schmidt inner product on $\mathbb{M}_d(\mathbb{C})$. Thus, $\{\mathcal{P}_{\chi}(\psi_m)\}_{m=1}^M$ forms an orthogonal set of states in $\chi(\Phi)$, which from the structure of $\chi(\Phi)$, clearly implies that $M \leq \sum_{k=1}^K \dim \mathcal{H}_{k,1}$. Since $\{\psi_m\}_{m=1}^M$ was an arbitrary zero-error classical code for Φ^N , this shows that

$$C_0^{(1)}(\Phi^N) \le \log \sum_{k=1}^K \dim \mathcal{H}_{k,1}.$$

Remark SII.6. We urge the readers to check that for an ergodic channel Φ , dim $\mathcal{H}_{k,1} = 1$ for all k in Eq. (SIA) [5, 42], so that $\sum_k \dim \mathcal{H}_{k,1} = \dim \chi(\Phi) = |\mathbb{T} \cap \operatorname{spec} \Phi|$ and we get

$$\lim_{n \to \infty} C_0^{(1)}(\Phi) = \log |\mathbb{T} \cap \operatorname{spec} \Phi|$$

C. Zero-error quantum communication through dQMS

In this subsection, we consider the task of storing quantum information in a system A whose time evolution is governed by a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, where $\Phi: \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ is a quantum channel. We take a slightly different route here than what was taken in the classical case in previous subsections. We first prove the analogue of Theorem SII.8 for the quantum capacity, from which the characterization of dQMS that eventually become useless for perfect quantum communication will follow naturally. The peripheral space $\chi(\Phi)$ will again play a crucial role in our discussion. Let us recall that there exists a decomposition $\mathcal{H}_A = \mathcal{H}_0 \oplus \bigoplus_{k=1}^K \mathcal{H}_{k,1} \otimes \mathcal{H}_{k,2}$ and positive definite states $\rho_k \in \mathcal{L}(\mathcal{H}_{k,2})$ such that:

$$\chi(\Phi) = 0 \oplus \bigoplus_{k=1}^{K} (\mathcal{L}(\mathcal{H}_{k,1}) \otimes \rho_k).$$
(S4)

Moreover, there exist unitaries $U_k \in \mathcal{L}(\mathcal{H}_{k,1})$ and a permutation π which permutes within subsets of $\{1, 2, \ldots, K\}$ for which the corresponding $\mathcal{H}_{k,1}$'s have the same dimension, such that for any $X = 0 \oplus \bigoplus_{k=1}^{K} x_k \otimes \rho_k$:

$$\Phi(X) = 0 \oplus \bigoplus_{k=1}^{K} U_k^{\dagger} x_{\pi(k)} U_k \otimes \rho_k$$

Using this decomposition, we can prove the following result.

Theorem SII.7. Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ be a quantum channel and $\{\Phi^n\}_{n \in \mathbb{N}}$ be the associated dQMS. Then, $\exists N \leq (\dim \mathcal{H}_A)^2$ such that

$$\forall q \in \mathbb{N}: \quad \lim_{n \to \infty} Q_0^{(1)}(\Phi^n) = Q_0^{(1)}(\Phi^N) = Q_0^{(1)}(\Phi^{N+q}) = \log \max_k \dim \mathcal{H}_{k,1}.$$

Proof. As in the proof of Theorem SII.8, we initially note that the first two equalities follow from Theorem SII.10, which shows that there exists $N \leq (\dim \mathcal{H}_A)^2$ such that the operator systems stabilize after time N :

$$S_{\Phi} \subset S_{\Phi^2} \subset \ldots \subset S_{\Phi^N} = S_{\Phi^{N+1}} = \ldots = S_{\Phi^{N+q}} = \ldots$$

To show the final equality, first note that the action of a channel Φ on its peripheral space is reversible [5, Theorem 6.16], i.e., there exists a channel $\mathcal{R} : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ such that $\mathcal{R} \circ \Phi = \mathcal{P}_{\chi}$, where \mathcal{P}_{χ} is the channel that projects onto the peripheral space $\chi(\Phi)$. Thus, in the language of [43], all the $\mathcal{H}_{k,1}$ sectors in the decomposition in Eq. (SII C) are correctable for Φ^n for all $n \in \mathbb{N}$. Corresponding subspaces $\mathcal{C}_k \subseteq \mathcal{H}_A$ with dim $\mathcal{C}_k = \dim \mathcal{H}_{k,1}$ can then be constructed using [43, Theorem 3.7] that are correctable for Φ^n for all $n \in \mathbb{N}$ in the sense of Definition SI.7. This shows that

$$\forall n \in \mathbb{N} : \quad Q_0^{(1)}(\Phi^n) \ge \log \max_k \dim \mathcal{H}_{k,1}.$$

Conversely, suppose that a subspace $C \subseteq \mathcal{H}_A$ is correctable for Φ^N in the sense of Definition SI.7. Since the operator systems of the semigroup stabilize after time N, the subspace C is also correctable for Φ^{N+q} for all $q \in \mathbb{N}$. A reformulation of the Knill Laflamme error correction conditions in terms the relative entropy [44–47] shows that:

$$\forall q \in \mathbb{N}, \ \forall \rho, \sigma \in \mathcal{D}(\mathcal{C}): \quad D(\rho || \sigma) = D(\Phi^{N+q}(\rho) || \Phi^{N+q}(\sigma))$$

Since there exists an increasing subsequence $(n_i)_{i\in\mathbb{N}}$ such that $\Phi^{n_i}\to \mathcal{P}_{\chi}$ as $i\to\infty$, we have that

$$\forall \rho, \sigma \in \mathcal{D}(\mathcal{C}): \quad \lim_{i \to \infty} D(\Phi^{n_i}(\rho) || \Phi^{n_i}(\sigma)) = D(\rho || \sigma) = D(\mathcal{P}_{\chi}(\rho) || \mathcal{P}_{\chi}(\sigma)),$$

which is equivalent to saying that the subspace C is correctable for \mathcal{P}_{χ} as well. This means that \mathcal{P}_{χ} acts like a *-homomorphism on the algebra $\mathcal{L}(\mathcal{C})$ [48, Theorem 3], upto smearing by a fixed operator. The structure of *-homomorphisms between matrix algebras is well-understood [49]. In particular, this means that the image $\chi(\Phi)$ of P_{χ} must be able to accommodate atleast one copy of the full matrix algebra $\mathcal{L}(\mathcal{C})$, which is only possible if there exists a k such that dim $\mathcal{C} \leq \dim \mathcal{H}_{k,1}$. Since \mathcal{C} is an arbitrary correctable subspace of Φ^N , we get

$$Q_0^{(1)}(\Phi^N) \le \log \max_k \dim \mathcal{H}_{k,1}.$$

Using the above theorem, we can easily characterize the class of eventually q-scrambling dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, i.e., the ones for which there exists $n\in\mathbb{N}$ such that $Q_0^{(1)}(\Phi^n)=0$.

Theorem SII.8. Let $\Phi : \mathcal{L}(\mathcal{H}_A) \to \mathcal{L}(\mathcal{H}_A)$ be a quantum channel and $\{\Phi^n\}_{n \in \mathbb{N}}$ be the associated dQMS. Then, the following are equivalent:

- Φ is eventually q-scrambling
- Φ is asymptotically entanglement-breaking.
- All the $\mathcal{L}(\mathcal{H}_{k,1})$ blocks in the peripheral decomposition in eq. (SIIC) are one-dimensional.
- All peripheral points of Φ commune with one another, i.e. $\forall X, Y \in \chi(\Phi), [X, Y] = XY YX = 0.$

Proof. From the previous theorem, it is clear that Φ is eventually q-scrambling if and only if dim $\mathcal{H}_{k,1} = 1$ for all $k = 1, 2, \ldots, K$ in Eq. (SII C). The rest of the equivalences then follow from [16, Theorem 32].

D. Bounds on scrambling times

We have completely classified channels $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ (or dQMS $\{\Phi^n\}_{n \in \mathbb{N}}$) that eventually lose their ability to send classical or quantum information perfectly. We now consider upper bounds on the minimum time after which such dQMS lose their information transmission capacity. We refer to this as the scrambling time (or the scrambling index) of the dQMS.

Definition SII.9. For a channel Φ (or a dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$), we define

- (quantum scrambling time) $q(\Phi) := \min\{n \in \mathbb{N} : Q_0^{(1)}(\Phi^n) = 0\}.$
- (classical scrambling time) $c(\Phi) := \min\{n \in \mathbb{N} : C_0^{(1)}(\Phi^n) = 0\}.$
- (entanglement-assisted classical scrambling time) $c_E(\Phi) := \min\{n \in \mathbb{N} : C_{0E}^{(1)}(\Phi^n) = 0\}.$

Here, we adopt the convention that the minimum of an empty set is $+\infty$.

Since for any channel Φ , $Q_0^{(1)}(\Phi) \leq C_0^{(1)}(\Phi) \leq C_{0E}^{(1)}(\Phi)$, it follows that $q(\Phi) \leq c(\Phi) \leq c_E(\Phi)$. Moreover, the inequalities here can all be strict. The separation between $q(\Phi)$ and $c(\Phi)$ can be illustrated by considering a non-mixing channel Φ that is entanglement-breaking, so that $q(\Phi) = 1$ and $c(\Phi) = c_E(\Phi) = +\infty$. Examples of this kind can be easily constructed: any classical channel $\Phi_A : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ of the form

$$\forall X \in \mathbb{M}_d(\mathbb{C}): \quad \Phi_A(X) = \sum_{i,j} A_{ij} X_{jj} |i\rangle \langle i|, \qquad (S5)$$

where A is an entrywise non-negative column stochastic matrix, works. Intuitively, since this channel completely decoheres its input, no quantum information can be sent through it. However, since spec $\Phi_A = \operatorname{spec} A \cup \{0\}$, we can easily choose A so that Φ_A is non-mixing. To show the separation between $c(\Phi)$ and $c_E(\Phi)$, we note that there exist channels Φ such that [40]

$$C_0^{(1)}(\Phi) = 0$$
 and $C_{0E}^{(1)}(\Phi) > 0$

We now prove the central result of this subsection: for any dQMS $\{\Phi^n\}_{n\in\mathbb{N}}$, its zero-error transmission capacity stabilizes after time $n \sim O(d^2)$.

Theorem SII.10. For any channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C}), \exists N \leq d^2 - \dim S_{\Phi}$ such that

$$\forall n \in \mathbb{N} : \quad Q_0^{(1)}(\Phi^N) = Q_0^{(1)}(\Phi^{N+n}), \\ C_0^{(1)}(\Phi^N) = C_0^{(1)}(\Phi^{N+n}), \\ C_{0F}^{(1)}(\Phi^N) = C_{0F}^{(1)}(\Phi^{N+n}).$$

Proof. Let $\{K_i\}_{i=1}^p \subseteq \mathbb{M}_d(\mathbb{C})$ be a set of Kraus operators for Φ . Recall that $S_{\Phi} = \operatorname{span}\{K_i^{\dagger}K_j; 1 \leq i, j \leq p\}$. It can be easily checked that for any $n \in \mathbb{N}$, we have

$$S_{\Phi^{n+1}} = \operatorname{span}\{K_i^{\dagger} X K_j : X \in S_{\Phi^n}, 1 \le i, j \le p\}.$$

We thus obtain an increasing chain of operator systems $S_{\Phi} \subseteq S_{\Phi^2} \subseteq \ldots$. Furthermore, if $S_{\Phi^n} = S_{\Phi^{n+1}}$ for some n, then $S_{\Phi^n} = S_{\Phi^{n+k}}$ for all $k \in \mathbb{N}$. In other words, the increasing chain of operator systems stabilizes at some point. Let N denote the minimum $n \in \mathbb{N}$ such that $S_{\Phi^n} = S_{\Phi^{n+1}}$. We then obtain the following chain

$$S_{\Phi} \subset S_{\Phi^2} \subset \ldots \subset S_{\Phi^N} = S_{\Phi^{N+1}} = \ldots = S_{\Phi^{N+k}} = \ldots$$

Note that the inclusions above are all strict. This is because if $S_{\Phi^n} = S_{\Phi^{n+1}}$ for some n < N, the above stabilization argument would contradict the minimality of N. Moreover, since all the operator systems are inside $\mathbb{M}_d(\mathbb{C})$ which is of dimension d^2 , the maximum length of the above chain is $d^2 - \dim S_{\Phi}$. Hence, $N \leq d^2 - \dim S_{\Phi}$. Recall that all the one-shot zero-error capacities can be characterized in terms of the operator system (Theorem SI.9). Since the operator system stabilizes after N iterations, all the one-shot zero-error capacities also stabilize after N iterations. \Box

The above result immediately yields an $O(d^2)$ upper bound on the scrambling times of all eventually scrambling evolutions.

Corollary SII.11. For any mixing channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the following bound holds:

$$q(\Phi) \le c(\Phi) \le c_E(\Phi) \le d^2 - \dim S_{\Phi}.$$

Furthermore, for any asymptotically entanglement-breaking channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, we have $q(\Phi) \leq d^2$.

Proof. We know that for a mixing channel Φ , $\exists k \in \mathbb{N}$ such that $C_{0E}^{(1)}(\Phi^k) = 0$. Hence, $C_{0E}^{(1)}(\Phi^{k+n}) = 0$ for any $n \in \mathbb{N}$. By the above proposition, we must have $k \leq d^2 - \dim S_{\Phi}$, which implies that $c_E(\Phi) \leq d^2 - \dim S_{\Phi}$. Since $q(\Phi) \leq c_E(\Phi)$ for any channel Φ , we have the required chain of inequalities. The result for asymptotically entanglement-breaking channels follow similarly. \Box

Let us take a moment to note that the dimension factor of d^2 in Proposition SII.10 and Corollary SII.11 is optimal for the classical scrambling times. To show this, consider the $d \times d$ stochastic matrix

$$A_d := \begin{pmatrix} 0 & 1/2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1/2 & 0 & 0 & 0 & 0 \end{pmatrix}.$$
 (S6)

Firstly, observe that for a classical channel Φ_A of the form defined in Eq. (SIID), the two scrambling times $c(\Phi_A)$ and $c_E(\Phi_A)$ are equal.

Lemma SII.12. For a classical channel $\Phi_A : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C}), c(\Phi_A) = c_E(\Phi_A)$

Proof. It suffices to show that $C_0^{(1)}(\Phi_A) = 0 \implies C_{0E}^{(1)}(\Phi_A) = 0$. Hence, assume that $C_0^{(1)}(\Phi_A) = 0$. This means that the operator system S_{Φ_A} is such that there are no rank one matrices in $S_{\Phi_A}^{\perp}$. However, since the operator system is 'graphical' [10], i.e.,

$$S_{\Phi_A} = \operatorname{span}\{|i\rangle\langle j| : i = j \text{ or } i \sim_A j\}$$

where the notation $i \sim_A j$ is used to denote that i and j are confusable under the transition probabilities defined by A, the absence of a rank one element in $S_{\Phi_A}^{\perp}$ implies that $S_{\Phi_A}^{\perp} = \{0\}$, which shows that $C_{0E}^{(1)}(\Phi_A) = 0$. \Box

The results in [50] then show that

$$c(\Phi_{A_d}) = c_E(\Phi_{A_d}) = \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil$$

Remark SII.13. The optimal upper bound on the scrambling times of classical stochastic matrices $A \in \mathbb{M}_d(\mathbb{C})$ is already known in the literature [50, 51]. It is of the form noted above:

$$c(A) \le \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil$$

where $\lceil \cdot \rceil$ denotes the ceiling function and equality is attained for $A = A_d$. However, this result is derived in a purely combinatorial framework, with no reference made to any zero-error information transmission task. Moreover, the proof is long and uses a variety of intricate graph-theoretic techniques. In contrast, the proof of Proposition SII.10 proceeds via a simple operator theoretic chain argument, yields an upper bound with the same optimal d^2 dimension factor, and works not only for classical channels but also for quantum channels.

SIII. AUXILLIARY RESULTS

A. Ergodicity and invariant subspaces

In this section, we study equivalent descriptions of ergodic and mixing quantum channels in terms of their invariant subspaces.

Definition SIII.1. A subspace $S \subseteq \mathbb{C}^d$ is said to be invariant under $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ if for all states ρ with $\operatorname{supp}(\rho) \subseteq S$, $\operatorname{supp} \Phi(\rho) \subseteq S$. A subspace $S \subseteq \mathbb{C}^d$ is a minimal invariant subspace of Φ if for any subspace $S' \subseteq \mathbb{C}^d$ which is invariant under Φ , $S \subseteq S'$.

The following characterization of ergodicity was obtained in [15, Theorem 1].

Theorem SIII.2. A channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is ergodic if and only if Φ admits a non-zero minimal invariant subspace S_* . Moreover, S_* is precisely the support of the unique invariant state of Φ .

In what follows, we provide a similar characterization for the class of mixing quantum channels.

Theorem SIII.3. For a quantum channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the following are equivalent.

- 1. Φ is mixing.
- 2. Φ admits a non-zero minimal invariant subspace $S_{\star} \subseteq \mathbb{C}^d$ and $\exists N \in \mathbb{N}$ such that $\forall \rho \in \mathbb{S}_d(\mathbb{C})$ and $n \geq N$, supp $P_{\star}\Phi^n(\rho)P_{\star} = S_{\star}$, where P_{\star} denotes the orthogonal projector onto S_{\star} .
- 3. Φ admits a non-zero minimal invariant subspace $S_{\star} \subseteq \mathbb{C}^d$ and $\exists N \in \mathbb{N}$ such that for $n \geq N$, $P_{\star}\mathcal{K}_n(\Phi) = P_{\star}\mathbb{M}_d(\mathbb{C})$, where $\mathcal{K}_n(\Phi) := \text{span} \{K_{i_1} \dots K_{i_n}\}$. Here, $\{K_i\}_i$ denotes a set of Kraus operators of Φ and P_{\star} is the orthogonal projector onto S_{\star} .

Remark SIII.4. Note that if $P_{\star}\mathcal{K}_n(\Phi) = P_{\star}\mathbb{M}_d(\mathbb{C})$, then $P_{\star}\mathcal{K}_m(\varphi) = P_{\star}\mathbb{M}_d(\mathbb{C}) \ \forall m \geq n$, since

$$\forall X \in \mathbb{M}_d(\mathbb{C}): \ P_{\star}X = \sum_{i_1\dots i_n} c_{i_1\dots i_n} P_{\star}K_{i_1}\dots K_{i_n},$$

and for each term in the sum, $P_{\star}K_{i_1} \dots K_{i_{n-1}} \in P_{\star}\mathbb{M}_d(\mathbb{C})$, and so can also be written as

$$P_{\star}K_{i_1}\ldots K_{i_{n-1}} = \sum_{j_1\ldots j_n} d_{j_1\ldots j_n} P_{\star}K_{j_1}\ldots K_{j_n}.$$

Proof. (1) \implies (3): Assume Φ is mixing. Then Φ is ergodic and hence admits a non-zero minimal invariant subspace $S_{\star} = \operatorname{supp}(\rho_{\star})$, where $\rho_{\star} \in \mathbb{S}_d(\mathbb{C})$ is the unique invariant state of Φ (Theorem SIII.2). On the contrary, assume that $\forall n \in \mathbb{N}, P_{\star}\mathcal{K}_n(\Phi) \subset P_{\star}\mathbb{M}_d(\mathbb{C})$ with the containment being strict. Let us choose an operator $X_n \in \mathbb{M}_d(\mathbb{C})$ such that

$$0 \neq P_{\star} X_n \in \left(P_{\star} \mathcal{K}_n(\Phi) \right)^{\perp}$$

where the orthogonal complement is taken inside $P_{\star}\mathbb{M}_d(\mathbb{C})$, so that $\forall P_{\star}K^{(n)} \in P_{\star}\mathcal{K}_n(\Phi)$,

$$\langle P_{\star}X_n, P_{\star}K^{(n)}\rangle = \operatorname{Tr}\left(X_n^*P_{\star}P_{\star}K^{(n)}\right) = 0.$$

Note that $P_{\star}X_nX_n^*P_{\star}$ is a non-zero positive operator supported in S_{\star} . Hence,

ł

$$\forall n \in \mathbb{N} : \quad \operatorname{Tr}\left(\rho_{\star} P_{\star} X_{n} X_{n}^{*} P_{\star}\right) \geq \frac{1}{||\rho_{\star}^{-1}||_{\infty}} \operatorname{Tr}\left(P_{\star} X_{n} X_{n}^{*} P_{\star}\right).$$
(S7)

However, we can also write

$$\left|\operatorname{Tr}(\rho_{\star}P_{\star}X_{n}X_{n}^{*}P_{\star})\right| = \left|\sum_{i_{1},\ldots,i_{n}}|\operatorname{Tr}(X_{n}^{*}P_{\star}P_{\star}K_{i_{1}}\ldots K_{i_{n}})|^{2} - \operatorname{Tr}(\rho_{\star}P_{\star}X_{n}X_{n}^{*}P_{\star})\right|.$$
(S8)

Let us consider the two terms on the RHS of (SIII A) separately. Using cyclicity of the trace and the following elementary relations for $A \in \mathbb{M}_d(\mathbb{C})$:

$$\operatorname{Tr} A = \operatorname{Tr}[(A \otimes I)\Omega],\tag{S9}$$

$$\operatorname{Tr} A \operatorname{Tr} A^* = \operatorname{Tr} \left[\Omega(A \otimes I) \Omega(A^* \otimes I) \right], \tag{S10}$$

$$(A \otimes I) |\Omega\rangle = (I \otimes A^T) |\Omega\rangle, \qquad (S11)$$

where $|\Omega\rangle = \sum_{i=1}^{d} |ii\rangle$ is the unnormalized maximally entangled state and $\Omega = |\Omega\rangle\langle\Omega|$, we can write

$$\sum_{i_1,\dots,i_n} |\operatorname{Tr}(X_n^* P_\star P_\star K_{i_1} \dots K_{i_n})|^2$$

$$= \sum_{i_1,\dots,i_n} \operatorname{Tr}(P_\star K_{i_1} \dots K_{i_n} X_n^* P_\star) \operatorname{Tr}(P_\star X_n (K_{i_1} \dots K_{i_n})^* P_\star)$$

$$= \sum_{i_1,\dots,i_n} \operatorname{Tr}\left[\Omega(P_\star K_{i_1} \dots K_{i_n} X_n^* P_\star \otimes \mathbb{1})\Omega(P_\star X_n (K_{i_1} \dots K_{i_n})^* P_\star \otimes \mathbb{1})\right],$$

$$= \operatorname{Tr}\left[\Omega(\tilde{\Phi}_n \otimes \operatorname{id})(X_n^* P_\star \otimes \mathbb{1})\Omega(P_\star X_n \otimes \mathbb{1})\right].$$

Here, $\tilde{\Phi}_n : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is the CP map defined as follows:

$$\tilde{\Phi}_n(X) = P_\star \Phi_n(X) P_\star = P_\star \left(\sum_{i_1, \dots, i_n} (K_{i_1} \dots K_{i_n}) X(K_{i_1} \dots K_{i_n})^* \right) P_\star$$

To deal with the second term in (SIII A) we further define a completely depolarizing map $\Phi_{\infty} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ through the relation $\Phi_{\infty}(X) = \operatorname{Tr}(X)\rho_{\star}$, so that $\tilde{\Phi}_n(X) \longrightarrow \Phi_{\infty}(X)$ as $n \to \infty$, since

$$\forall X \in \mathbb{M}_d(\mathbb{C}): \quad \tilde{\Phi}_n(X) = P_\star \Phi^n(X) P_\star \longrightarrow P_\star(\operatorname{Tr} X) \rho_\star P_\star = (\operatorname{Tr} X) \rho_\star \quad \text{as } n \to \infty.$$

Then, once again using the relations (SIII A), (SIII A), (SIII A), it can be shown that

$$\operatorname{Tr}(\rho_{\star}P_{\star}X_{n}X_{n}^{*}P_{\star}) = \operatorname{Tr}\left(\Omega(\Phi_{\infty}\otimes \operatorname{id})(X_{n}^{*}P_{\star}\otimes I)\Omega(P_{\star}X_{n}\otimes I)\right)$$

Thus, we can express Eq. (SIII A) as follows:

$$\left| \operatorname{Tr}(\rho_{\star}P_{\star}X_{n}X_{n}^{*}P_{\star}) \right| = \left| \operatorname{Tr}\left[\Omega((\tilde{\Phi}_{n} - \Phi_{\infty}) \otimes \operatorname{id})(X_{n}^{*}P_{\star} \otimes I)\Omega(P_{\star}X_{n} \otimes I) \right] \\ \leq \|\Omega\|_{\infty} \|(\tilde{\Phi}_{n} - \Phi_{\infty}) \otimes \operatorname{id}\|_{1} \operatorname{Tr}(P_{\star}X_{n}X_{n}^{*}P_{\star}).$$

Note that, $\|(\tilde{\Phi}_n - \Phi_\infty) \otimes \operatorname{id}\|_1 \to 0$ as $n \to \infty$ since $\tilde{\Phi}_n \mapsto \Phi_\infty$ in this limit, which contradicts Eq. (SIII A). This concludes the proof of (1) \Longrightarrow (3).

(3) \implies (2): Assume that $P_{\star}\mathcal{K}_n(\Phi) = P_{\star}\mathbb{M}_d(\mathbb{C})$ for some $n \in \mathbb{N}$. Hence, $\forall |\psi\rangle$,

$$P_{\star}\Phi^{n}\left(|\psi\rangle\!\langle\psi|\right)P_{\star} = \sum_{i_{1},\ldots,i_{n}}P_{\star}K_{i_{1}}\ldots K_{i_{n}}\left|\psi\rangle\!\langle\psi|\left(K_{i_{1}}\ldots K_{i_{n}}\right)^{*}P_{\star}.$$

This implies that

$$supp P_{\star} \Phi^{n} (|\psi\rangle\langle\psi|) P_{\star} = span\{P_{\star}K_{i_{1}} \dots K_{i_{n}} |\psi\rangle\}$$
$$= P_{\star}span\{K_{i_{1}} \dots K_{i_{n}}\} |\psi\rangle$$
$$= P_{\star}\mathcal{K}_{n}(\Phi) |\psi\rangle = P_{\star}\mathbb{M}_{d}(\mathbb{C}) |\psi\rangle = S_{\star}$$

(2) \implies (1): Assume that Φ admits a minimal invariant subspace $S_{\star} \neq \{0\}$ and $\exists N \in \mathbb{N}$ such that for any $\rho \in \mathbb{S}_d(\mathbb{C})$ and $n \geq N$, supp $P_{\star}\Phi^n(\rho)P_{\star} = S_{\star}$. Since Φ admits a minimal invariant subspace, it must be ergodic. Assume on the contrary that Φ is not mixing. Then, there must exist a peripheral eigenvalue different from 1. Hence,

$$\mathbb{T} \cap \operatorname{spec} \Phi = \left\{ e^{\frac{2\pi i m}{q}} : m = 0, 1, \dots, q - 1 \right\}$$

for some $q \in \mathbb{N}$, $q \geq 2$ (see Lemma SII.3). This implies that Φ^q has q distinct fixed points. Let us consider two of them, say $\rho_{\star}, \sigma \geq 0$, where $\operatorname{supp} \rho_{\star} = S_{\star}$. If $\operatorname{supp} P_{\star} \sigma P_{\star} \neq S_{\star}$, we can choose k large enough such that $kq \geq N$ and $\operatorname{supp} P_{\star} \Phi^{kq}(\sigma) P_{\star} = \operatorname{supp} P_{\star} \sigma P_{\star} \neq S_{\star}$, leading to a contradiction. So, we can assume that $\operatorname{supp} P_{\star} \sigma P_{\star} = S_{\star}$. Now, consider $\omega = \rho_{\star} - \varepsilon \sigma$, which is again a fixed point of Φ^q . Clearly,

$$P_{\star} \omega P_{\star} \ge 0 \iff \rho_{\star} \ge \varepsilon P_{\star} \sigma P_{\star}$$
$$\iff P_{\star} \ge \varepsilon \rho_{\star}^{-1/2} \sigma \rho_{\star}^{-1/2}$$
$$\iff \varepsilon \le \frac{1}{\left\| \rho_{\star}^{-1/2} \sigma \rho_{\star}^{-1/2} \right\|_{\infty}}$$

Let us choose $\varepsilon = 1/\left\|\rho_{\star}^{-1/2}\sigma\rho_{\star}^{-1/2}\right\|_{\infty}$ and $0 \neq |v\rangle \in S_{\star}$ such that $\rho_{\star}^{-1/2}\sigma\rho_{\star}^{-1/2}|v\rangle = |v\rangle/\varepsilon$. Then,

$$\varepsilon P_{\star} \sigma \rho_{\star}^{-1/2} \left| v \right\rangle = \rho_{\star}^{1/2} \left| v \right\rangle = \rho_{\star} \rho_{\star}^{-1/2} \left| v \right\rangle \implies (\rho_{\star} - \varepsilon P_{\star} \sigma P_{\star}) \rho_{\star}^{-1/2} \left| v \right\rangle = 0.$$

This means that $P_{\star}\omega P_{\star} = \rho_{\star} - \varepsilon P_{\star}\sigma P_{\star}$ has a kernel in S_{\star} , so $\operatorname{supp} P_{\star}\omega P_{\star} \neq S_{\star}$. Since ω is fixed by Φ^{q} , its positive and negative parts $\omega_{\pm} \geq 0$ are also fixed by Φ^{q} . Finally, by choosing k large enough such that $kq \geq N$, we get $\operatorname{supp} P_{\star} \Phi^{kq}(\omega_{\pm})P_{\star} = \operatorname{supp} P_{\star}\omega_{\pm}P_{\star} \subseteq \operatorname{supp} P_{\star}\omega P_{\star} \neq S_{\star}$, which contradicts our original assumption. Hence, Φ must be mixing, and the proof is complete.

It is easy to see that if the quantum channel is primitive, the equivalences obtained in Theorem SIII.3 reduce to those given in [21, Proposition 3], which we restate below.

Corollary SIII.5. For a quantum channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the following are equivalent.

- 1. Φ is primitive.
- 2. $\exists N \in \mathbb{N}$ such that $\forall \rho \in \mathbb{S}_d(\mathbb{C})$ and $n \geq N$, $\Phi^n(\rho)$ is of full rank.
- 3. $\exists N \in \mathbb{N}$ such that for $n \geq N$, $\mathcal{K}_n(\Phi) = \mathbb{M}_d(\mathbb{C})$, where $\mathcal{K}_n(\Phi) := \operatorname{span} \{K_{i_1} \dots K_{i_n}\}$. Here, $\{K_i\}_i$ denotes a set of Kraus operators of Φ .

B. Connection with the quantum Wielandt index

Consider a primitive channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$. Then, Corollary SIII.5 informs us that $\exists N \in \mathbb{N}$ such that Φ^n is strictly positive for $n \geq N$. This leads naturally to the definition of the Wielandt index [21–24] of Φ :

$$w(\Phi) := \min\{n \in \mathbb{N} : \Phi^n \text{ is strictly positive}\}.$$

Note that if a channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is strictly positive, then $\operatorname{Tr}[\Phi(\rho)\Phi(\sigma)] > 0$ for all $\rho, \sigma \in \mathbb{S}_d(\mathbb{C})$. Thus, Φ is also scrambling. Hence for a primitive channel Φ , it holds that

$$q(\Phi) \le c(\Phi) \le w(\Phi).$$

In this section, we obtain a converse bound $c(\Phi) \leq w(\Phi) \leq (d-1)c(\Phi)$ for primitive channels $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ that are also unital, thus establishing a close link between the scrambling times and Wielandt indices for such channels. We do this by relating the notions of scrambling and strictly positivity. We show that for unital channels that are scrambling, there is a linear universal bound (depending only on the system dimension) for the channel iterations to become strictly positive. In order to prove this result, we first need some new definitions.

Two projections $P, Q \in \mathbb{M}_d(\mathbb{C})$ are said to be (Murray-von Neumann) equivalent (denoted $P \sim Q$) if there is an operator $V \in \mathbb{M}_d(\mathbb{C})$ such that $P = VV^*$ and $Q = V^*V$. Hence, $P \sim Q$ if and only if $\operatorname{Tr} P = \operatorname{Tr} Q$. Further, we say that a projection $P \in \mathbb{M}_d(\mathbb{C})$ is *non-trivial* if $P \notin \{0, 1\}$. Let $P^{\perp} := I - P$. The following definition is from [22] (see also [33]).

Definition SIII.6. A quantum channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is said to be fully irreducible[20] if there does not exist any pair of non-trivial, equivalent projections, $P \sim Q$, such that $\Phi(P) \leq \lambda Q$, for some $\lambda > 0$.

Proposition SIII.7. If a unital channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is scrambling, then it is fully irreducible.

Proof. We prove that if Φ is not fully irreducible, then it cannot be scrambling. To do this, let us assume that there exists a pair of non-trivial, equivalent projections $P \sim Q$ such that $\Phi(P) \leq \lambda Q$ for some $\lambda > 0$. This implies that $Q^{\perp}\Phi(P)Q^{\perp} = 0$. Let $\{K_i\}_i$ denote a set of Kraus operators of Φ . Then, since P is a projection (i.e. $P = P^*$ and $P^2 = P$), we get

$$Q^{\perp} \left(\sum_{i} K_{i} P K_{i}^{*} \right) Q^{\perp} = 0$$

i.e.
$$\sum_{i} (Q^{\perp} K_{i} P) (Q^{\perp} K_{i} P)^{*} = 0$$
$$\implies Q^{\perp} K_{i} P = 0 \quad \forall i$$
$$\implies K_{i} P = Q K_{i} P \quad \forall i$$
(S12)

Hence,

$$\Phi(P) = \sum_{i} K_i P K_i^* = \sum_{i} K_i P (K_i P)^* = Q \left(\sum_{i} K_i P K_i^* \right) Q = Q \Phi(P) Q \le Q,$$

where the third equality follows from (SIII B), and the last inequality follows from the fact that $P \leq 1$ and since Φ is unital, $\Phi(P) \leq \Phi(1) = 1$. Thus we have established the following:

$$\Phi(P) \le \lambda Q \implies \Phi(P) \le Q. \tag{S13}$$

From (SIII B) we have $\operatorname{Tr} \Phi(P) = \operatorname{Tr} P \leq \operatorname{Tr} Q$, since Φ is trace-preserving. However, by assumption, $\operatorname{Tr} P = \operatorname{Tr} Q$ (since $P \sim Q$). Hence, by faithfulness of the trace we get $\Phi(P) = Q$. However, this equality implies that Φ violates the property of scrambling, as is shown explicitly below.

Set $\rho = P/\operatorname{Tr} P$ and $\sigma = \mathbb{1}/d = \frac{P+P^{\perp}}{d}$. Then,

$$\begin{split} ||\rho - \sigma||_{1} &= ||\frac{P}{\operatorname{Tr} P} - \frac{P}{d} - \frac{P^{\perp}}{d}||_{1} \\ &= \alpha ||P||_{1} + \frac{1}{d} ||P^{\perp}||_{1}, \\ &= \alpha \operatorname{Tr} P + \frac{1}{d} \operatorname{Tr} P^{\perp}, \end{split}$$
(S14)

where $\alpha := \left|\frac{1}{\operatorname{Tr} P} - \frac{1}{d}\right|$. On the other hand, since Φ is unital and $\Phi(P) = Q$, we get

$$\begin{split} |\Phi(\rho) - \Phi(\sigma)||_{1} &= ||\frac{\Phi(P)}{\operatorname{Tr} P} - \frac{1}{d}||_{1} \\ &= ||\frac{Q}{\operatorname{Tr} P} - \frac{Q}{d} - \frac{Q^{\perp}}{d}||_{1} \\ &= \alpha \operatorname{Tr} Q + \frac{1}{d} \operatorname{Tr} Q^{\perp} \\ &= \alpha \operatorname{Tr} P + \frac{1}{d} \operatorname{Tr} P^{\perp}, \end{split}$$
(S15)

where we used the fact that $\operatorname{Tr} P^{\perp} = \operatorname{Tr} Q^{\perp}$ since $\operatorname{Tr} P = \operatorname{Tr} Q$. Hence, from (SIII B) and (SIII B) we have

$$||\Phi(\rho) - \Phi(\sigma)||_1 = ||\rho - \sigma||_1$$

and hence the quantum channel Φ is not scrambling. This concludes the proof.

One might wonder whether the converse of the above proposition is true. The following example shows that this is not the case.

Example SIII.8. Let $\Phi : \mathbb{M}_4(\mathbb{C}) \to \mathbb{M}_4(\mathbb{C})$ be a unital quantum channel defined as follows:

$$\forall X \in \mathbb{M}_4(\mathbb{C}): \quad \Phi(X) = 1/2 \begin{bmatrix} X_{11} + X_{22} & 0 & 0 & 0 \\ 0 & X_{22} + X_{33} & 0 & 0 \\ 0 & 0 & X_{33} + X_{44} & 0 \\ 0 & 0 & 0 & X_{44} + X_{11} \end{bmatrix}.$$

It is easy to see that Φ is fully irreducible, since it sends any projection to a positive semi-definite matrix of rank strictly larger than the rank of the input projection. However,

$$\Phi(|1\rangle\!\langle 1|) = \frac{1}{2}(|1\rangle\!\langle 1| + |4\rangle\!\langle 4|) \quad \text{and} \quad \Phi(|3\rangle\!\langle 3|) = \frac{1}{2}(|2\rangle\!\langle 2| + |3\rangle\!\langle 3|).$$

Hence, $\operatorname{Tr}(\Phi(|1\rangle\langle 1|)\Phi(|3\rangle\langle 3|)) = 0$ and it follows that Φ is not scrambling (see Theorem SI.11).

The following corollary provides the main result of the subsection.

Corollary SIII.9. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be a unital quantum channel and suppose that Φ is scrambling. Then Φ^{d-1} is strictly positive. Consequently, for any primitive unital channel Φ , we get $c(\Phi) \leq w(\Phi) \leq (d-1)c(\Phi)$.

Proof. It is known that a fully irreducible unital channel is strictly rank increasing, i.e., for any singular positive semi-definite $A \in \mathbb{M}_d(\mathbb{C})$: Rank $(\Phi(A)) > \text{Rank}(A)$ (see [22, Theorem 3.7]).

Now, since Φ is scrambling, the previous result shows that Φ is fully irreducible, and hence also strictly rank increasing. Thus, starting from any rank one projection P, it requires at most d-1 iterations of Φ to send P to an invertible matrix. This concludes the proof.

Remark: The above corollary provides an upper bound on the number of iterations for a scrambling channel that are needed to guarantee that it becomes strictly positive. This upper bound depends solely on the dimension d of the underlying space. It is natural to ask whether this bound can be improved. Note that from the definition of scrambling it follows that if Φ is scrambling, then $\Phi^* \circ \Phi$ is strictly positive. So for self-adjoint scrambling channels, it holds that Φ^2 is strictly positive. This raises the following question: Could it be true that for any scrambling channel Φ , Φ^2 is strictly positive? However, this is not true, as shown below by an explicit example of a classical channel, defined by the column stochastic matrix, A:

$$A = \begin{pmatrix} 1/3 & 1/3 & 0 & 0 & 1/3 \\ 0 & 1/3 & 1/3 & 0 & 1/3 \\ 1/3 & 0 & 1/3 & 1/3 & 0 \\ 0 & 1/3 & 0 & 1/3 & 1/3 \\ 1/3 & 0 & 1/3 & 0 & 1/3 \end{pmatrix}$$

A is clearly scrambling but A^2 is not strictly positive.

C. Linear bounds on indices for channels with extra structure

If the mixing channel Φ is unital and its operator system S_{Φ} is such that S_{Φ^n} is an algebra for all $n \in \mathbb{N}$, we can provide better bounds on its scrambling indices.

In order to state and prove our main result, we need the following lemma.

Lemma SIII.10. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be a unital channel, and let \mathcal{M}_{Φ^k} denote the multiplicative domain of Φ^k for each $k \in \mathbb{N}$, and let $\mathcal{M}_{\Phi^{\infty}} = \bigcap_{k>1} \mathcal{M}_{\Phi^k}$ be the stabilized multiplicative domain as introduced in Section SIB.

1. The stabilized multiplicative domain can be described as follows

$$\mathcal{M}_{\Phi^{\infty}} = \operatorname{alg}\{A \in \mathbb{M}_d(\mathbb{C}) : \Phi(A) = \lambda A; |\lambda| = 1\}.$$

- 2. It holds that for all $k \geq 1$, $\mathcal{M}_{\Phi^k} = [S_{\Phi^k}]'$.
- 3. If Φ is primitive, then $\mathcal{M}_{\Phi^{\infty}} = \mathbb{C}1$, i.e., the trivial algebra with only scalars. Furthermore, the containments in the following chain of subalgebras are proper:

$$\mathcal{M}_{\Phi} \supsetneq \mathcal{M}_{\Phi^2} \supsetneq \cdots \mathcal{M}_{\Phi^n} \supsetneq \cdots \supsetneq \mathbb{C}\mathbb{1}.$$

Proof. The proofs of the first statement above can be found in [36]. To prove the second assertion, recall from Section SIB that for a unital channel Φ ,

$$\mathcal{M}_{\Phi} = \operatorname{Fix}_{(\Phi^* \circ \Phi)} = S'_{\Phi},$$

and this relation holds for every Φ^k , $k \in \mathbb{N}$.

Here we prove the last statement. If Φ is unital and primitive, then $\mathbb{1}$ is its only peripheral eigenoperator, and hence (1) shows that $\mathcal{M}_{\Phi^{\infty}} = \mathbb{C}\mathbb{1}$. In fact, having $\mathcal{M}_{\Phi^{\infty}} = \mathbb{C}\mathbb{1}$ can be an alternative characterization of primitivity for unital channels (see Corollary 3.5 in [36]).

To prove the containment of the subalgebras is proper we analyze the behaviour of multiplicative domain under composition of two channels. From [36, Lemma 2.3], it holds that

$$\mathcal{M}_{\Phi^k} = \{a \in \mathcal{M}_{\Phi^{(k-1)}} | \Phi^{(k-1)}(a) \in \mathcal{M}_{\Phi}\} = \{a \in \mathcal{M}_{\Phi} | \Phi(a) \in \mathcal{M}_{\Phi^{(k-1)}}\}.$$

Hence, $\mathcal{M}_{\Phi^{(k+1)}} \subseteq \mathcal{M}_{\Phi^k}$, for all $k \in \mathbb{N}$ and if $x \in \mathcal{M}_{\Phi^k}$, then $\Phi(x) \in \mathcal{M}_{\Phi^{(k-1)}}$.

Now suppose $\mathcal{M}_{\Phi^k} = \mathcal{M}_{\Phi^{(k-1)}}$, for some $k \geq 2$. From the above observation, we know that $x \in \mathcal{M}_{\Phi^k} \implies \Phi(x) \in \mathcal{M}_{\Phi^{(k-1)}} = \mathcal{M}_{\Phi^k}$. Since $\mathcal{M}_{\Phi^k} \subseteq \mathcal{M}_{\Phi}$, it follows that $x \in \mathcal{M}_{\Phi^k} \implies x \in \mathcal{M}_{\Phi}$ and $\Phi(x) \in \mathcal{M}_{\Phi^k} \implies x \in \mathcal{M}_{\Phi^{(k+1)}}$. So $\mathcal{M}_{\Phi^k} = \mathcal{M}_{\Phi^{(k+1)}}$. Since by primitivity we know $\mathcal{M}_{\Phi^n} = \mathbb{C}1$, for large n, it must be the case that $\mathcal{M}_{\Phi^{(k+1)}} \subset \mathcal{M}_{\Phi^k}$, unless the latter set is just the trivial algebra.

Let us also note another lemma, which is obtained by combining Propositions SI.12 and SI.13

Lemma SIII.11. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be a channel such that S_{Φ} is an algebra. Then,

$$C_{0E}^{(1)}(\Phi) = 0 \iff C_0^{(1)}(\Phi) = 0 \iff [S_{\Phi}]' = \mathbb{C}\mathbb{1}.$$

Proof. The second equivalence is contained in Proposition SI.13. The (\Longrightarrow) implication in the first equivalence is trivial to show. Thus, it suffices to prove that $[S_{\Phi}]' = \mathbb{C}\mathbb{1} \implies C_{0E}^{(1)}(\Phi) = 0$. So, assume that $[S_{\Phi}]' = \mathbb{C}\mathbb{1}$ and note that since S_{Φ} is an algebra, the double commutant theorem shows that $S_{\Phi} = [S_{\Phi}]'' = \mathbb{M}_d(\mathbb{C})$. The result then follows from Proposition SI.12.

We can now state and prove our main result.

Proposition SIII.12. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be a primitive unital quantum channel such that the associated operator systems S_{Φ^n} are C^* -algebras for all $n \in \mathbb{N}$. Then,

$$q(\Phi) \leq d-2$$
 and $c(\Phi) = c_E(\Phi) \leq 2(d-1)$

Proof. Note that for any channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, we have an increasing chain of subspaces $S_{\Phi} \subseteq S_{\Phi^2} \subseteq \cdots \subseteq S_{\Phi^n} \subseteq \cdots$, which yields a decreasing chain of commutants $[S_{\Phi}]' \supseteq [S_{\Phi^2}]' \supseteq \cdots \supseteq [S_{\Phi^n}]' \supseteq \cdots$. Note that the commutants $[S_{\Phi^n}]'$ are unital C*-subalgebras of $\mathbb{M}_d(\mathbb{C})$ for all $n \in \mathbb{N}$ and by Lemma SIII.10, we have $[S_{\Phi^n}]' = \mathcal{M}_{\Phi^n}$. Since Φ is primitive, $\exists n \in \mathbb{N}$ such that $[S_{\Phi^n}]' = \mathbb{C}1$. So the above chain of C*-algebras stabilizes at some n:

$$[S_{\Phi}]' \supseteq [S_{\Phi^2}]' \supseteq \cdots \supseteq [S_{\Phi^n}]' = \mathbb{C}\mathbb{1}.$$
(S16)

Since S_{Φ^n} are algebras for all $n \in \mathbb{N}$, we can use the necessary and sufficient conditions given in Proposition SI.13 and Lemma SIII.11 for the zero-error capacities to vanish. Firstly, note that Lemma SIII.11 immediately tells us that $c(\Phi) = c_E(\Phi)$. Also note that if $[S_{\Phi}]' = \mathbb{M}_d(\mathbb{C})$, then by the double-commutant theorem, $S_{\Phi} = [S_{\Phi}]'' = \mathbb{C}\mathbb{1}$. It follows that the Choi rank of Φ is 1, which means that the channel is just a unitary conjugation. Such a channel can not be primitive, contradicting our hypothesis. Thus, we can assume that $[S_{\Phi}]'$ is a proper subalgebra of $\mathbb{M}_d(\mathbb{C})$.

Now, if $[S_{\Phi}]'$ is trivial to begin with, then Lemma SIII.11 shows that $C_0^{(1)}(\Phi) = 0$. In this case, $c(\Phi) = 1 \leq 2(d-1)$. Hence, we can assume that $[S_{\Phi}]'$ is a proper non-trivial subalgebra of $\mathbb{M}_d(\mathbb{C})$. From Lemma SIII.10, we know that each containment in Eq. (SIII C) is proper. It is known that such a chain of decreasing unital C*-subalgebras can have length at most 2(d-1) [52, Lemma 5 and Theorem 3.6]. Thus $c(\Phi) \leq 2(d-1)$.

For the other bound, note that if $[S_{\Phi}]'$ is abelian to begin with, then $Q_0^{(1)}(\Phi) = 0$ and $q(\Phi) = 1 \le (d-2)$ (for $d \ge 2$), see Proposition SI.13. So, we can assume that $[S_{\Phi}]'$ is non-abelian. Now, in order to descend down the chain of commutants in Eq. (SIII C) all the way to C1, in the worst case, there are *d*-many steps required from the full diagonal algebra to stabilize to the trivial algebra. Hence, it requires at most 2(d-1) - d = (d-2) steps to go from a non-abelian to an abelian algebra, proving that $q(\Phi) \le d-2$.

We now provide an example of a channel for which the operator system fulfils the requirements of the above proposition.

Example SIII.13. We construct a primitive unital channel $\Phi : \mathbb{M}_3(\mathbb{C}) \to \mathbb{M}_3(\mathbb{C})$ for which S_{Φ}, S_{Φ^2} , and S_{Φ^3} are all algebras, $q(\Phi) = 1$, and $c(\Phi) = c_E(\Phi) = 3$. This is the example given after Theorem 3.9 in [52], giving the maximum length of the chain in Eq. (SIII C) when the starting algebra is a maximal abelian subalgebra (MASA).

The channel is defined by its Kraus operators $\{K_i\}_{i=1}^3 \subseteq M_3(\mathbb{C})$, which are given below:

$$K_1 = \frac{1}{\sqrt{2}} \begin{bmatrix} 0 & 0 & 1\\ 0 & 0 & 1\\ 0 & 0 & 0 \end{bmatrix}, K_2 = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 & 0\\ -1 & 0 & 0\\ 0 & 0 & 0 \end{bmatrix}, K_3 = \begin{bmatrix} 0 & 0 & 0\\ 0 & 0 & 0\\ 0 & 1 & 0 \end{bmatrix}.$$

One can check that $S_{\Phi} = \left\{ \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix} \mid a, b, c \in \mathbb{C} \right\}$. This is the full diagonal algebra. It is not hard to see that

 $S_{\Phi^2} = \left\{ \begin{bmatrix} a & 0 & b \\ 0 & c & 0 \\ d & 0 & e \end{bmatrix} \mid a, b, c, d, e \in \mathbb{C} \right\} \simeq \mathbb{M}_2(\mathbb{C}) \oplus \mathbb{M}_1(\mathbb{C}), \text{ where } \mathbb{M}_1(\mathbb{C}) \text{ is just the scalar algebra. Hence } S_{\Phi^2} \text{ is also an } \mathbb{M}_2(\mathbb{C}) \oplus \mathbb{M}_2(\mathbb{C}) \oplus \mathbb{M}_2(\mathbb{C}) \oplus \mathbb{M}_2(\mathbb{C}) = \mathbb{M}_2(\mathbb{C}) \oplus \mathbb{M}$

algebra. And finally, $S_{\Phi^3} = \mathbb{M}_3(\mathbb{C})$. Thus, we obtain the chain

$$S_{\Phi} \subset S_{\Phi^2} \subset S_{\Phi^3} = \mathbb{M}_3(\mathbb{C}).$$

Since $S_{\Phi^3} = \mathbb{M}_3(\mathbb{C})$, it follows that $[S_{\Phi^3}]' = \mathcal{M}_{\Phi^3} = \mathbb{C}\mathbb{1}$ and hence Φ is primitive (see [36, Corollary 3.5]). Furthermore, since $[S_{\Phi^2}]' \simeq \mathbb{C}\mathbb{1}_2 \oplus \mathbb{M}_1(\mathbb{C})$ is not trivial, it is clear from Lemma SIII.11 that $c(\Phi) = c_E(\Phi) = 3$. Finally, since S_{Φ} is the full diagonal algebra, $[S_{\Phi}]' = S_{\Phi}$ is also abelian and Proposition SI.13 shows that $q(\Phi) = 1$.

The example given above is a special case (d = 3) for a more general construction given in [52, Theorem 3.9], where the decreasing chain of multiplicative domains have been created to provide the multiplicative index of the channel to be d. We think in the general case, the operator systems are also algebras and one can get $c(\Phi) = d$, but we leave it as a future avenue to explore.

D. Diagonal unitary covariant channels

In this section, we study the scrambling times and Wielandt indices of a special class of quantum channels that are covariant under the action of the diagonal unitary group. These channels were introduced and extensively studied in [53]. Here, we only recall some basic results. Note that we call $A \in \mathbb{M}_d(\mathbb{C})$ column stochastic if it is entrywise non-negative and for all $i, \sum_i A_{ji} = 1$. Furthermore, \mathcal{DU}_d denotes the set of all diagonal unitary matrices in $\mathbb{M}_d(\mathbb{C})$.

Theorem SIII.14. For a channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the following are equivalent:

- $\forall X \in \mathbb{M}_d(\mathbb{C}), \forall U \in \mathcal{DU}_d : \Phi(UXU^*) = U\Phi(X)U^*.$
- $\exists A, B \in \mathbb{M}_d(\mathbb{C})$ with A column stochastic and B positive semi-definite such that

$$\forall X \in \mathbb{M}_d(\mathbb{C}): \quad \Phi(X) = \sum_{i,j} A_{ij} X_{jj} |i\rangle\langle i| + \sum_{i \neq j} B_{ij} X_{ij} |i\rangle\langle j| =: \Phi_{A,B}(X).$$

A channel $\Phi = \Phi_{A,B}$ as above is called conjugate diagonal unitary covariant (CDUC).

Theorem SIII.15. For a channel $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$, the following are equivalent:

- $\forall X \in \mathbb{M}_d(\mathbb{C}), \forall U \in \mathcal{DU}_d : \Phi(UXU^*) = U^*\Phi(X)U.$
- $\exists A, C \in \mathbb{M}_d(\mathbb{C})$ with A column stochastic, $C = C^*$, and $A_{ij}A_{ji} \ge |C_{ij}|^2 \quad \forall i, j$, such that

$$\forall X \in \mathbb{M}_d(\mathbb{C}): \quad \Phi(X) = \sum_{i,j} A_{ij} X_{jj} |i\rangle\langle i| + \sum_{i \neq j} C_{ij} X_{ji} |i\rangle\langle j| =: \Phi_{A,C}(X).$$

A channel $\Phi = \Phi_{A,C}$ as above is called diagonal unitary covariant (DUC).

For the class of (C)DUC channels, we will show that the properties of strict positivity, scrambling, mixing, and primitivity are all equivalent to the corresponding properties of the classical stochastic matrix A. Let us first introduce the definitions of these properties for a stochastic matrix.

Definition SIII.16. A column stochastic matrix $A \in \mathbb{M}_d(\mathbb{C})$ is said to be

- strictly positive if $A_{ij} > 0 \ \forall i, j$.
- scrambling if $\forall i, j, \exists k \text{ such that } A_{ki}A_{kj} > 0.$
- mixing if $\lambda = 1$ is a simple eigenvalue of A and A has no other peripheral eigenvalues.
- primitive if it is mixing and its unique invariant vector has full support.

Remark SIII.17. For a stochastic matrix, the spectral properties of mixing/primitivity can be verified by analyzing the connectivity of the directed graph associated with the matrix [34, Section 2.3].

Note that if one uses classical channels of the form $\Phi_A := \Phi_{A,\text{diag}A}$, the quantum definitions of strict positivity, scrambling, mixing, and primitivity that were introduced in the previous sections all reduce to the classical definitions introduced above. Let us also observe that in the classical case, Theorem SII.1 and Corollary SIII.5 reduce to the following results.

Theorem SIII.18. For a column stochastic $A \in \mathbb{M}_d(\mathbb{C})$, the following are equivalent

- A is mixing.
- $\exists k \in \mathbb{N}$ such that A^k is scrambling.

Theorem SIII.19. For a column stochastic $A \in \mathbb{M}_d(\mathbb{C})$, the following are equivalent

- A is primitive.
- $\exists k \in \mathbb{N}$ such that A^k is strictly positive.

We are now ready to prove some of our main results in this section.

Theorem SIII.20. The following equivalences hold for DUC and CDUC channels.

- A CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is strictly positive $\iff A$ is strictly positive.
- A DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is strictly positive $\iff A$ is strictly positive.

Proof. Clearly, if $\Phi_{A,B}$ or $\Phi_{A,C}$ is strictly positive, we can restrict to diagonal input states to conclude that A is also strictly positive. Conversely, let A be strictly positive. Let us first deal with the CDUC case. It suffices to show that $\Phi_{A,B}(\psi)$ is invertible for all pure states $\psi \in \mathbb{S}_d(\mathbb{C})$. If $\psi = |\psi\rangle\langle\psi| = |i\rangle\langle i|$ for some $i = 0, 1, \ldots, d-1$, invertibility of $\Phi_{A,B}(\psi)$ follows easily from strict positivity of A. Otherwise, there exist distinct $k \neq l$ such that $\psi_k \neq 0, \psi_l \neq 0$. Note that ψ_i denotes the i^{th} entry of the column vector $|\psi\rangle \in \mathbb{C}^d$. In this case, for an arbitrary $|\varphi\rangle \in \mathbb{C}^d$ we can write

$$\operatorname{Tr}\left[\Phi_{A,B}(\psi)(\varphi)\right] = \sum_{i} \left(\sum_{n} A_{in} |\psi_{n}|^{2}\right) |\varphi_{i}|^{2} + \sum_{i \neq j} B_{ij} \psi_{i} \overline{\psi_{j}\varphi_{i}} \varphi_{j}$$
$$= \sum_{i \neq n} A_{in} |\psi_{n}|^{2} |\varphi_{i}|^{2} + \sum_{i} A_{ii} |\varphi_{i}|^{2} |\psi_{i}|^{2} + \sum_{i \neq j} B_{ij} \psi_{i} \overline{\psi_{j}\varphi_{i}} \varphi_{j}$$
$$= \sum_{i \neq n} A_{in} |\psi_{n}|^{2} |\varphi_{i}|^{2} + \left\langle \overline{\psi} \odot \varphi \right| B \left| \overline{\psi} \odot \varphi \right\rangle.$$

Here, \odot denotes the entrywise product of vectors and since *B* is positive semi-definite, the second term above is always non-negative. Moreover, the first term is positive for all $|\varphi\rangle \notin \text{span}\{|k\rangle\}$. For $|\varphi\rangle = |k\rangle$, the first term is again positive since $\psi_l \neq 0$ and $l \neq k$. Thus, $\text{Tr} \left[\Phi_{A,B}(\psi)(\varphi)\right] > 0$ for all $|\psi\rangle, |\varphi\rangle \in \mathbb{C}^d$, which proves that $\Phi_{A,B}(\psi)$ is invertible for all pure $\psi \in \mathbb{S}_d(\mathbb{C})$.

In the DUC case, we proceed similarly. It suffices to show that $\Phi_{A,C}(\psi)$ is invertible for all pure states $\psi \in S_d(\mathbb{C})$, when A is strictly positive. If $|\psi\rangle = |i\rangle$ for some $i \in \{0, \ldots, d-1\}$, invertibility of $\Phi_{A,C}(\psi)$ follows easily from strict positivity of A. Otherwise, there exist distinct $k \neq l$ such that $\psi_k \neq 0, \psi_l \neq 0$. In this case, for an arbitrary $|\varphi\rangle \in \mathbb{C}^d$ we can write

$$\operatorname{Tr}\left[\Phi_{A,C}(\psi)\varphi\right] = \sum_{i} \left(\sum_{n} A_{in} |\psi_{n}|^{2}\right) |\varphi_{i}|^{2} + \sum_{i \neq j} C_{ij} \overline{\psi_{i}} \psi_{j} \overline{\varphi_{i}} \varphi_{j}$$
$$= \sum_{i} A_{ii} |\psi_{i}|^{2} |\varphi_{i}|^{2} + \sum_{i \neq j} \left(A_{ij} |\varphi_{i}|^{2} |\psi_{j}|^{2} + C_{ij} \overline{\psi_{i}} \psi_{j} \overline{\varphi_{i}} \varphi_{j}\right)$$
$$= \sum_{i} A_{ii} |\psi_{i}|^{2} |\varphi_{i}|^{2} + \sum_{i < j} \left(\psi_{j} \overline{\varphi_{i}} \ \psi_{i} \overline{\varphi_{j}}\right) \left(A_{ij} \ C_{ij} \ A_{ji}\right) \left(\overline{\psi_{j}} \varphi_{i} \right)$$

Note that all the terms inside the sum above are non-negative. Moreover, the first sum is positive for all $|\varphi\rangle$ with either $\varphi_k \neq 0$ or $\varphi_l \neq 0$. If both $\varphi_k = 0$ and $\varphi_l = 0$ (i.e. $|\varphi\rangle \perp \text{span}\{|k\rangle, |l\rangle\}$, we can choose $p \neq k, l$ such that $\varphi_p \neq 0$. Then, the k, p block in the second sum above is positive, since

$$\begin{pmatrix} 0 & \psi_k \overline{\varphi_p} \end{pmatrix} \begin{pmatrix} A_{kp} & C_{kp} \\ C_{pk} & A_{pk} \end{pmatrix} \begin{pmatrix} 0 \\ \overline{\psi_k} \varphi_p \end{pmatrix} = A_{pk} |\psi_k|^2 |\varphi_p|^2 > 0.$$

Thus, $\operatorname{Tr}\left[\Phi_{A,C}(\psi)(\varphi)\right] > 0$ for all $|\psi\rangle, |\varphi\rangle \in \mathbb{C}^d$, which proves the desired result.

Theorem SIII.21. The following equivalences hold for DUC and CDUC channels.

- A CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is scrambling if and only if A is scrambling.
- A DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is scrambling if and only if A is scrambling.

Proof. In both the CDUC and the DUC case, our aim would be to appropriately decompose the function $f(\psi, \varphi) = \text{Tr} \left[\Phi(\psi) \Phi(\varphi) \right]$ (for pure states $\psi, \varphi \in \mathbb{S}_d(\mathbb{C})$) into non-negative parts so as to obtain the desired result. Let us tackle

the CDUC case first. Here, we have

$$\begin{split} f_{A,B}(\psi,\varphi) &= \operatorname{Tr}\left[\Phi_{A,B}(\psi)\Phi_{A,B}(\varphi)\right] \\ &= \sum_{i,j=1}^{d} \Phi_{A,B}(\psi)_{ij}\overline{\Phi_{A,B}(\varphi)_{ij}} \\ &= \sum_{i} \left(\sum_{k} A_{ik} |\psi_{k}|^{2}\right) \left(\sum_{l} A_{il} |\varphi_{l}|^{2}\right) + \sum_{i\neq j} |B_{ij}|^{2} \psi_{i} \overline{\psi_{j}\varphi_{i}}\varphi_{j} \\ &= \sum_{i} \sum_{k\neq l} A_{ik} A_{il} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i,k} A_{ik}^{2} |\psi_{k}|^{2} |\varphi_{k}|^{2} + \sum_{i\neq j} |B_{ij}|^{2} \psi_{i} \overline{\psi_{j}\varphi_{i}}\varphi_{j} \\ &= \sum_{k\neq l} (A^{\top}A)_{kl} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i\neq k} A_{ik}^{2} |\psi_{k}|^{2} |\varphi_{k}|^{2} + \sum_{i} A_{ii}^{2} |\psi_{i}|^{2} |\varphi_{i}|^{2} + \sum_{i\neq j} |B_{ij}|^{2} \psi_{i} \overline{\psi_{j}\varphi_{i}}\varphi_{j} \\ &= \sum_{k\neq l} (A^{\top}A)_{kl} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i\neq k} A_{ik}^{2} |\psi_{k}|^{2} |\varphi_{k}|^{2} + \left\langle \overline{\psi} \odot \varphi \right| B \odot \overline{B} \left| \overline{\psi} \odot \varphi \right\rangle \end{split}$$

Notice that since A is entrywise non-negative and B is positive semi-definite, all three terms above are non-negative. Now, assume that $\Phi_{A,B}$ is scrambling, so that $f_{A,B}(\psi,\varphi) > 0$ for all pure states ψ,φ . Then, we can choose $|\psi\rangle = |k\rangle$ and $|\varphi\rangle = |l\rangle$ for $k \neq l$, so that

$$f_{A,B}(\psi,\varphi) = (A^{\top}A)_{kl} > 0 \implies A \text{ is scrambling.}$$

Conversely, if A is scrambling, i.e., $(A^{\top}A)_{kl} > 0$ for all $k \neq l$, then for any two orthogonal pure states $\psi \perp \varphi$, by identifying indices $k \neq l$ such that $\psi_k \neq 0$ and $\varphi_l \neq 0$, we get

$$f_{A,B}(\psi,\varphi) \ge (A^{\top}A)_{kl}|\psi_k|^2|\varphi_l|^2 > 0 \implies \Phi_{A,B}$$
 is scrambling

Now, for a DUC channel $\Phi_{A,C}$, we can follow the same steps as above to obtain

$$\begin{split} f_{A,C}(\psi,\varphi) &= \operatorname{Tr} \left[\Phi_{A,C}(\psi) \Phi_{A,C}(\varphi) \right] \\ &= \sum_{i,j=1}^{d} \Phi_{A,C}(\psi)_{ij} \overline{\Phi_{A,C}(\varphi)_{ij}} \\ &= \sum_{i} \left(\sum_{k} A_{ik} |\psi_{k}|^{2} \right) \left(\sum_{l} A_{il} |\varphi_{l}|^{2} \right) + \sum_{i \neq j} |C_{ij}|^{2} \overline{\psi_{i}} \psi_{j} \varphi_{i} \overline{\varphi_{j}} \\ &= \sum_{i} \sum_{k \neq l} A_{ik} A_{il} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i,k} A_{ik}^{2} |\psi_{k}|^{2} |\varphi_{k}|^{2} + \sum_{i \neq j} |C_{ij}|^{2} \overline{\psi_{i}} \psi_{j} \varphi_{i} \overline{\varphi_{j}} \\ &= \sum_{k \neq l} (A^{\top} A)_{kl} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i} A_{ii}^{2} |\psi_{i}|^{2} |\varphi_{i}|^{2} + \sum_{i \neq j} A_{ij}^{2} |\psi_{j}|^{2} |\varphi_{j}|^{2} + \sum_{i \neq j} |C_{ij}|^{2} \overline{\psi_{i}} \psi_{j} \varphi_{i} \overline{\varphi_{j}} \\ &= \sum_{k \neq l} (A^{\top} A)_{kl} |\psi_{k}|^{2} |\varphi_{l}|^{2} + \sum_{i} A_{ii}^{2} |\psi_{i}|^{2} |\varphi_{i}|^{2} + \sum_{i < j} \left(\psi_{j} \overline{\varphi_{j}} \ \psi_{i} \overline{\varphi_{i}} \right) \left(\frac{A_{ij}^{2}}{|C_{ij}|^{2}} \ A_{ji}^{2} \right) \left(\frac{\overline{\psi_{j}} \varphi_{j}}{\overline{\psi_{i}} \varphi_{j}} \right) \end{split}$$

As before, since $\Phi_{A,C}$ is a channel, the constraints on A, C force all three sums above to be non-negative. The remaining argument is an exact replica of the one used in the CDUC case.

Theorem SIII.22. The following equivalences hold for DUC and CDUC channels.

- A CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is primitive if and only if A is primitive.
- A DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is primitive if and only if A is primitive.

Proof. We only tackle the CDUC case here. Using Corollary SIII.5 and Theorems SIII.19, SIII.20, we obtain

 $\Phi_{A,B} \text{ is primitive } \iff \exists k \in \mathbb{N} \text{ such that } \Phi_{A,B}^k = \Phi_{A^k,f(B)} \text{ is strictly positive} \\ \iff \exists k \in \mathbb{N} \text{ such that } A^k \text{ is strictly positive } \iff A \text{ is primitive.}$

Note that above, $f(B) = B^{\odot k} + \text{diag}(A^k - A^{\odot k})$. This follows from the composition rule:

$$\Phi_{A_1,B_1} \circ \Phi_{A_2,B_2} = \Phi_{A_1A_2,B_1 \odot B_2 + \operatorname{diag}(A_1A_2 - A_1 \odot A_2)}.$$

Note that \odot here denotes the entrywise (or Hadamard) product of matrices.

Theorem SIII.23. The following equivalences hold for DUC and CDUC channels.

- A CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is mixing if and only if A is mixing.
- A DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ is mixing if and only if A is mixing.

Proof. We only tackle the CDUC case here. Using Theorems SII.1, SIII.18 and SIII.21, we obtain

 $\Phi_{A,B} \text{ is mixing } \iff \exists k \in \mathbb{N} \text{ such that } \Phi^k_{A,B} = \Phi_{A^k,f(B)} \text{ is scrambling}$ $\iff \exists k \in \mathbb{N} \text{ such that } A^k \text{ is scrambling } \iff A \text{ is mixing.}$

We now shift our focus to the scrambling times and Wielandt indices of (C)DUC channels. We will borrow results from the classical literature to provide optimal upper bounds on these indices for (C)DUC channels. Let us first define these indices for stochastic matrices.

Definition SIII.24. For a mixing (resp. primitive) stochastic matrix $A \in M_d(\mathbb{C})$, we define

 $c(A) := \min\{n : A^n \text{ is scrambling}\}$ resp. $w(A) := \min\{n : A^n \text{ is strictly positive}\}$

We call c(A) the time of A and w(A) the Wielandt index [54] of A. Optimal bounds are known for these indices, which are stated below. The following stochastic matrix (in appropriate dimension d) serves to prove the optimality of these bounds:

$$A_d := \begin{pmatrix} 0 & 1/2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1/2 & 0 & 0 & 0 & 0 \end{pmatrix}$$
(S17)

Theorem SIII.25. [55] For any primitive stochastic matrix $A \in M_d(\mathbb{C})$:

$$w(A) \le d^2 - 2d + 2.$$

Moreover, $w(A_d) = d^2 - 2d + 2$.

Theorem SIII.26. [50, 51] For any mixing stochastic matrix $A \in M_d(\mathbb{C})$:

$$c(A) \le \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil$$

Moreover, $c(A_d) = \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil$.

Clearly, from Theorems SIII.20-SIII.23 and SIII.25, SIII.26, the corollaries given below follow immediately.

Corollary SIII.27. Let $A \in \mathbb{M}_d(\mathbb{C})$ be a mixing stochastic matrix. Then, for any CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ and any DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$,

$$c(\Phi_{A,B}) = c(\Phi_{A,C}) = c(A) \le d^2 - 2d + 2d$$

Equality is achieved above for $A = A_d$ (see Eq. (SIII D)).

Corollary SIII.28. Let $A \in \mathbb{M}_d(\mathbb{C})$ be a primitive stochastic matrix. Then, for any CDUC channel $\Phi_{A,B} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ and any DUC channel $\Phi_{A,C} : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$,

$$w(\Phi_{A,B}) = w(\Phi_{A,C}) = w(A) \le \left\lceil \frac{d^2 - 2d + 2}{2} \right\rceil$$

Equality is achieved above for $A = A_d$ (see Eq. (SIII D)).

Е. Trade-off relation

In this short section, we connect the one-shot zero-error capacities of a channel with that of its complementary channel. Recall that for any channel $\Phi: \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ with linearly independent Kraus representation

$$\Phi(X) = \sum_{i=1}^{n} K_i X K_i^*,$$

there is a complementary channel $\Phi^C : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_n(\mathbb{C})$ defined by

$$\Phi^C(X) = \sum_{i,j} \operatorname{Tr}(K_i^* K_j X) E_{i,j},$$

where $\{E_{i,j}\}$ are the matrix units of $\mathbb{M}_n(\mathbb{C})$. Note that if Φ^{C^*} denotes the adjoint of the channel Φ^C , then

$$\operatorname{Tr}(K_i^* K_j X) = \operatorname{Tr}\left(E_{j,i} \Phi^C(X)\right) = \operatorname{Tr}\left(\Phi^{C^*}(E_{i,j}^*)X\right),$$

for all $X \in \mathbb{M}_d(\mathbb{C})$ and $1 \leq i, j \leq n$. Thus, it follows that $\Phi^{C^*}(E_{i,j}) = K_i^* K_i$ and hence we get the operator system of Φ as the image of Φ^{C^*} , that is,

$$S_{\Phi} = \operatorname{span}\{K_i^* K_j : 1 \le i, j \le n\} = \operatorname{range}(\Phi^{C^*}).$$

In the following proposition we provide a relation between the one-shot zero-error quantum capacity of Φ to the one-shot zero-error classical capacity of its complementary channel Φ^C .

Proposition SIII.29. Let $\Phi : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_d(\mathbb{C})$ be a quantum channel and let $\Phi^C : \mathbb{M}_d(\mathbb{C}) \to \mathbb{M}_n(\mathbb{C})$ be its complementary channel. Then, it holds that

$$2^{C_0^{(1)}(\Phi^C)} + 2^{Q_0^{(1)}(\Phi)} \le d + 1.$$

Proof. The basic idea of the proof is the complementary relation between the error correcting subspaces of a channel and the private subspaces of its complementary channel (see [56, 57]).

Let $S \subseteq \mathbb{C}^d$ be the largest subspace in which Φ can be recovered, i.e., $Q_0^{(1)}(\Phi) = \log \dim S$. More precisely, S is the largest subspace where Φ admits a channel \mathcal{R} such that $\mathcal{R} \circ \Phi(\rho) = \rho$, for all $\rho \in \mathcal{D}(S)$. Then, it follows that $\Phi^{C}(\rho_{1}) = \Phi^{C}(\rho_{2})$ for all $\rho_{1}, \rho_{2} \in \mathcal{D}(S)$. Indeed, from the Knill-Laflamme condition ([18]) for error correction, it holds that

$$P_S K_i^* K_j P_S = \lambda_{i,j} P_S,$$

where P_S is the projection onto S, $\{K_i\}_i$ are the Kraus operator of Φ , and $\lambda_{i,j} \in \mathbb{C}$. Note that any $\rho \in \mathcal{D}(S)$ satisfies $\rho = P_S \rho P_S$. Thus, we obtain for any $\rho \in \mathcal{D}(S)$

$$\Phi^C(\rho) = \sum_{i,j} \operatorname{Tr}(K_i^* K_j P_S \rho P_S) E_{i,j} = \sum_{i,j} \operatorname{Tr}(P_S K_i^* K_j P_S \rho) E_{i,j} = \sum_{i,j} \lambda_{i,j} \operatorname{Tr}(P_S \rho) E_{i,j}.$$

Let $A = (\lambda_{i,j})$. Note that A is a positive semi-definite matrix. This follows from writing $B = (K_1 P_S, \dots, K_d P_S)$ as a row matrix, and noting that $B^*B = (\lambda_{i,j}P_S)$. Thus, Φ^C takes the form

$$\Phi^C(\rho) = \operatorname{Tr}(\rho)A$$

on $\mathcal{D}(S)$. Therefore, in any zero-error encoding $\{|\psi_i\rangle\}_{i=1}^p$ of classical messages $\{1, 2, \ldots, p\}$ to be sent through Φ^C , there can only be at most one code state from S, which means that $p \leq (d - \dim S) + 1$. Optimizing over all zero-error classical encodings gives us the required bound:

$$2^{C_0^{(1)}(\Phi^C)} + 2^{Q_0^{(1)}(\Phi)} \le d + 1.$$
