

The incompatibility of quantum channels in general probabilistic theories *

Masataka Yamada[†] and Takayuki Miyadera[‡]

Department of Nuclear Engineering, Kyoto University, 6158540 Kyoto, Japan

In quantum theory, there exist sets of operations that cannot be performed simultaneously. These sets of operations are referred to as incompatible. While this definition of incompatibility extends to general probabilistic theories, the dependency of the set of compatible sets on the definition of composite systems has not been thoroughly investigated. In the context of quantum channels, compatibility is defined using the tensor product of Hilbert spaces, employing the usual composite system. However, in the context of general probabilistic theories, composite systems are not uniquely determined, and the set of states can range from min tensor to max tensor, forming various convex sets. In this paper, in addition to quantum compatibility using the usual composite system, we introduce min-tensor-compatibility using the min-tensor on the composite system of effect spaces and investigate their relationship using noisy identity channels on qubits. As a result, we found that the set of min-tensor-compatible channel pairs is strictly broader than the set of quantum-compatible channel pairs. Furthermore, we introduce the concept of almost quantum compatible channel pairs from an operational perspective. This concept corresponds to cases where the correlation functions appearing in the verification of compatibility can be realized through a channel and local reinterpretation of effects. We demonstrate that the set of all almost quantum compatible channel pairs is strictly narrower than the set of all min-tensor-compatible channel pairs.

I. INTRODOCUTION

In the realm of quantum theory, there exist pairs of operations that cannot be carried out simultaneously, a phenomenon termed incompatibility[1]. One of the most prominent examples is the uncertainty principle[2–5], which asserts that certain pairs of observables cannot be measured concurrently. This concept extends beyond observable measurements to encompass quantum channels as well[6, 7]; certain pairs of channels cannot be realized simultaneously, a principle exemplified by the no-cloning theorem[8, 9], which highlights the incompatibility of two identity channels.

While incompatibility serves to underscore the disparities between quantum and classical theories, its relevance extends to broader physical frameworks. Indeed, the no-cloning theorem holds in general probabilistic theories (GPTs) beyond classical theory[10], a fact elucidated within the context of incompatibility. Investigating these generalized frameworks holds promise for uncovering key characteristics of quantum theory.

This paper delves into the study of channel incompatibility, focusing particularly on the principles governing the construction of composite systems. In GPT, determining the composite system for a given pair of systems lacks a singular solution, leading to a multitude of potential composite systems beyond the conventional quantum framework[11–13]. The definition of generalized incompatibility inherently depends on how the composite system is constructed. Consequently, we inquire whether a pair of channels incompatible with the standard quantum composite system may exhibit compatibility within alternative composite systems.

More specifically, we demonstrate that pairs of noisy identity channels can be compatible within a min-tensored composite system despite being incompatible within the normal quantum composite system. This disparity prompts the introduction of new categories of compatible channels. Of particular interest is the exploration of whether this gap can be bridged by considering compatibility in a device-independent manner.

The paper is organized as follows: Section II begins with an exploration of preliminary concepts surrounding quantum incompatibility and properties of composite systems within general probabilistic theories. Within this context, we introduce the notion of min-tensor-compatibility, which is grounded in identifying composite systems that yield the smallest effect space.

Section III presents the primary findings. Initially, we contrast the normal quantum compatibility class with the min-tensor-compatibility class by analyzing a pair of noisy identity channels. Additionally, we introduce a distinct class of compatibility called almost quantum compatibility, motivated by operational considerations. This class is then compared with min-tensor-compatibility.

II. PRELIMINARIES

A. quantum incompatibility of channels

A quantum system is described by a Hilbert space. In the following, Hilbert spaces are assumed finite-dimensional. $\mathcal{L}(\mathcal{H})$ is the set of all linear (bounded) operators acting in a Hilbert space \mathcal{H} . $\mathcal{L}_+(\mathcal{H})$ is the set of all positive operators in $\mathcal{L}(\mathcal{H})$, which forms a positive cone in $\mathcal{L}_s(\mathcal{H}) := \{A \mid A \in \mathcal{L}(\mathcal{H}), A = A^*\}$, the set of all self-adjoint operators. The positive cone completely specifies the theory (system). The positive cone is used to introduce $\mathcal{E}(\mathcal{H}) := \mathcal{L}_+(\mathcal{H}) \cap (\mathbf{1} - \mathcal{L}_+(\mathcal{H})) = \{E \mid E \in \mathcal{L}_+(\mathcal{H}), E \leq \mathbf{1}\}$, the set of all effects. The state space $\mathcal{S}(\mathcal{H})$ is a subset of its dual as $\mathcal{S}(\mathcal{H}) := \{\rho \mid 0 \leq \langle \rho, E \rangle \leq 1 \text{ for all } E \in \mathcal{E}(\mathcal{H}), \langle \rho, \mathbf{1} \rangle = 1\}$, which can be identified with the set of all density operators through Hilbert-Schmidt inner product $\langle \rho, E \rangle = \text{tr}[\rho E]$. A physical state change is described by a map called a channel. A linear map $\Lambda : \mathcal{L}(\mathcal{K}) \rightarrow \mathcal{L}(\mathcal{H})$ is a channel if it is unit-preserving and completely positive. (In the following, we will mainly use the Heisenberg picture. A superscript $*$ refers to the Schrödinger picture.) The complete positivity means that a map $\Lambda \otimes id : \mathcal{L}(\mathcal{K}) \otimes \mathcal{L}(\mathbb{C}^d) \rightarrow \mathcal{L}(\mathcal{H}) \otimes \mathcal{L}(\mathbb{C}^d)$ is positive for all $d < \infty$.

In quantum theory, a composite system of two systems described by Hilbert spaces \mathcal{H}_1 and \mathcal{H}_2 is described by a tensored Hilbert space $\mathcal{H}_1 \otimes \mathcal{H}_2$. Thus we arrive at the following definitions of compatibility and incompatibility[1].

Definition 1. *Suppose that we have three quantum systems described by Hilbert spaces $\mathcal{H}_A, \mathcal{H}_B$ and \mathcal{H}_C . Channels $\Lambda_1 : \mathcal{L}(\mathcal{H}_B) \rightarrow \mathcal{L}(\mathcal{H}_A)$ and $\Lambda_2 : \mathcal{L}(\mathcal{H}_C) \rightarrow \mathcal{L}(\mathcal{H}_A)$ are **quantum compatible** if there exists a channel $\Lambda : \mathcal{L}(\mathcal{H}_B \otimes \mathcal{H}_C) \rightarrow \mathcal{L}(\mathcal{H}_A)$ satisfying $\Lambda(X \otimes \mathbf{1}) = \Lambda_1(X)$ and $\Lambda(\mathbf{1} \otimes Y) = \Lambda_2(Y)$ for all $X \in \mathcal{L}(\mathcal{H}_B)$ and $Y \in \mathcal{L}(\mathcal{H}_C)$. The channel Λ is called a **joint channel**. We call Λ_1 and Λ_2 **quantum incompatible** if they are not quantum compatible.*

Note that for compatible Λ_1 and Λ_2 their joint channel is not unique in general.

B. min-tensor-incompatibility of channels

In GPT, a composite system is not uniquely determined for a given pair of systems[11–13]. For a given pair of quantum systems described by \mathcal{H}_1 and \mathcal{H}_2 , the state space of a composite system is a convex subset \mathcal{S} of a set $\mathcal{S}(\mathcal{H}_1) \otimes_{max} \mathcal{S}(\mathcal{H}_2)$ defined by

$$\begin{aligned} & \mathcal{S}(\mathcal{H}_1) \otimes_{max} \mathcal{S}(\mathcal{H}_2) \\ & := \{\omega \mid \omega : \mathcal{L}(\mathcal{H}_1) \times \mathcal{L}(\mathcal{H}_2) \rightarrow \mathbb{C} \text{ bilinear map satisfying } 0 \leq \omega(E, F) \leq 1 \text{ for all } E \in \mathcal{E}(\mathcal{H}_1), F \in \mathcal{E}(\mathcal{H}_2), \text{ and } \omega(\mathbf{1}, \mathbf{1}) = 1\}. \end{aligned}$$

\mathcal{S} satisfies $\mathcal{S}(\mathcal{H}_1) \otimes_{min} \mathcal{S}(\mathcal{H}_2) \subset \mathcal{S} \subset \mathcal{S}(\mathcal{H}_1) \otimes_{max} \mathcal{S}(\mathcal{H}_2)$, where

$$\begin{aligned} & \mathcal{S}(\mathcal{H}_1) \otimes_{min} \mathcal{S}(\mathcal{H}_2) \\ & := \{\omega \mid \omega = \sum_n \lambda_n \sigma_n \otimes \eta_n, 0 \leq \lambda_n \leq 1, \sum_n \lambda_n = 1, \sigma_n \in \mathcal{S}(\mathcal{H}_1), \eta_n \in \mathcal{S}(\mathcal{H}_2)\}. \end{aligned}$$

Note that $\mathcal{S}(\mathcal{H}_1 \otimes \mathcal{H}_2)$ coincides with neither of $\mathcal{S}(\mathcal{H}_1) \otimes_{min} \mathcal{S}(\mathcal{H}_2)$ and $\mathcal{S}(\mathcal{H}_1) \otimes_{max} \mathcal{S}(\mathcal{H}_2)$. Thus we need another condition to specify the quantum composite system. Positive cones which generate effect spaces and thus their corresponding state spaces are denoted by $\mathcal{L}_+(\mathcal{H}) \otimes_{max} \mathcal{L}_+(\mathcal{H})$ for the state space $\mathcal{S}(\mathcal{H}_1) \otimes_{min} \mathcal{S}(\mathcal{H}_2)$ and $\mathcal{L}_+(\mathcal{H}) \otimes_{min} \mathcal{L}_+(\mathcal{H})$ for the state space $\mathcal{S}(\mathcal{H}_1) \otimes_{max} \mathcal{S}(\mathcal{H}_2)$. For state spaces $\mathcal{S}_1 \subset \mathcal{S}_2$, their corresponding positive cones \mathcal{P}_1 and \mathcal{P}_2 satisfy $\mathcal{P}_1 \supset \mathcal{P}_2$ in general. In particular, the concrete form of $\mathcal{L}_+(\mathcal{H}_1) \otimes_{min} \mathcal{L}_+(\mathcal{H}_2)$ is

$$\mathcal{L}_+(\mathcal{H}_1) \otimes_{min} \mathcal{L}_+(\mathcal{H}_2) = \{E \in \mathcal{L}_+(\mathcal{H}_1 \otimes \mathcal{H}_2) \mid E = \sum_n \lambda_n F_n \otimes G_n, \lambda_n \geq 0, F_n \in \mathcal{L}_+(\mathcal{H}_1), G_n \in \mathcal{L}_+(\mathcal{H}_2)\}.$$

For each composite system, it is natural to define its corresponding compatibility.

Definition 2. *Suppose that we have three quantum systems described by Hilbert spaces $\mathcal{H}_A, \mathcal{H}_B$ and \mathcal{H}_C . We consider a composite system of $\mathcal{L}_+(\mathcal{H}_B)$ and $\mathcal{L}_+(\mathcal{H}_C)$ defined by its positive cone \mathcal{P} . Channels $\Lambda_1 : \mathcal{L}(\mathcal{H}_B) \rightarrow \mathcal{L}(\mathcal{H}_A)$ and $\Lambda_2 : \mathcal{L}(\mathcal{H}_C) \rightarrow \mathcal{L}(\mathcal{H}_A)$ are **\mathcal{P} -compatible** if there exists a linear map $\Lambda : \mathcal{L}(\mathcal{H}_B \otimes \mathcal{H}_C) \rightarrow \mathcal{L}(\mathcal{H}_A)$ satisfying $\Lambda(\mathcal{P}) \subset \mathcal{L}_+(\mathcal{H}_A)$ and $\Lambda(X \otimes \mathbf{1}) = \Lambda_1(X)$ and $\Lambda(\mathbf{1} \otimes Y) = \Lambda_2(Y)$ for all $X \in \mathcal{L}(\mathcal{H}_B)$ and $Y \in \mathcal{L}(\mathcal{H}_C)$. The map Λ is called a **joint map**. We call Λ_1 and Λ_2 **\mathcal{P} -incompatible** if they are not \mathcal{P} -compatible. In particular, we call $\mathcal{L}(\mathcal{H}_B) \otimes_{min} \mathcal{L}(\mathcal{H}_C)$ -*(in)compatible* as **min-tensor-(in)compatible**.*

From the definition, it is trivial to see that for two composite systems specified by positive cones $\mathcal{P}_1 \subset \mathcal{P}_2$ a pair of \mathcal{P}_2 -compatible channels (Λ_1, Λ_2) is \mathcal{P}_1 -compatible. In particular, quantum compatible Λ_1 and Λ_2 are min-tensor-compatible.

III. MAIN RESULTS

A. quantum compatibility vs min-tensor-compatibility

In this section, we study the min-tensor-compatibility of two noisy identity channels to compare the min-tensor-compatibility and the quantum compatibility. We treat a family of noisy identity channels $\Lambda_\eta : \mathcal{L}(\mathbb{C}^2) \rightarrow \mathcal{L}(\mathbb{C}^2)$ ($0 \leq \eta \leq 1$) on a qubit defined by, for all $A \in \mathcal{L}(\mathbb{C}^2)$,

$$\Lambda_\eta(A) = \eta A + \frac{1-\eta}{2} \text{tr}[A].$$

The channel is a probabilistic mixture of the identity channel and the completely depolarized channel. The (quantum) no-cloning theorem represents the quantum incompatibility of Λ_1 and Λ_1 . It is known that Λ_{η_1} and Λ_{η_2} are quantum compatible if and only if the parameters η_1 and η_2 satisfy[14]

$$\eta_1^2 + \eta_2^2 + (1 - \eta_1 - \eta_2)^2 \leq 1. \quad (1)$$

On the other hand, the generalized no-cloning theorem[10] is applied to show Λ_1 and Λ_1 are min-tensor-incompatible. We find the following theorem for the min-tensor-compatibility.

Theorem 1. *A pair of noisy identity channels Λ_{η_1} and Λ_{η_2} is max-compatible if and only if*

$$\eta_1^2 + \eta_2^2 \leq 1. \quad (2)$$

In addition for η_1, η_2 satisfying $\eta_1^2 + \eta_2^2 = 1$, the joint map Λ is unique.

Proof. Let us assume that Λ_1 and Λ_2 are min-tensor-compatible and Λ is a joint map. For arbitrary normal vectors \mathbf{n} and \mathbf{m} in \mathbb{R}^3 , the joint map defines a POVM $\{\Lambda(\frac{1}{2}(\mathbf{1} \pm \mathbf{n} \cdot \boldsymbol{\sigma}) \otimes (\mathbf{1} \pm \mathbf{m} \cdot \boldsymbol{\sigma}))\}$. The POVM is a joint POVM of

$$\{\Lambda((\mathbf{1} \pm \mathbf{n} \cdot \boldsymbol{\sigma})/2 \otimes \mathbf{1})\} = \{\Lambda_{\eta_1}((\mathbf{1} \pm \mathbf{n} \cdot \boldsymbol{\sigma})/2)\} = \{(\mathbf{1} \pm \eta_1 \mathbf{n} \cdot \boldsymbol{\sigma})/2\}$$

and

$$\{\Lambda(\mathbf{1} \otimes (\mathbf{1} \pm \mathbf{m} \cdot \boldsymbol{\sigma})/2)\} = \{\Lambda_{\eta_2}((\mathbf{1} \pm \mathbf{m} \cdot \boldsymbol{\sigma})/2)\} = \{(\mathbf{1} \pm \eta_2 \mathbf{m} \cdot \boldsymbol{\sigma})/2\}$$

These unbiased qubit observables are jointly measurable if and only if $|\eta_1 \mathbf{n}|^2 + |\eta_2 \mathbf{m}|^2 \leq 1 + (\eta_1 \eta_2 (\mathbf{n} \cdot \mathbf{m}))^2$ holds[15]. Taking orthogonal \mathbf{n} and \mathbf{m} , we conclude

$$\eta_1^2 + \eta_2^2 \leq 1.$$

Now we show that Λ_{η_1} and Λ_{η_2} are max-compatible if η_1 and η_2 satisfy the above inequality. Let us first consider the case $\eta_1^2 + \eta_2^2 = 1$. We construct a joint map of Λ_{η_1} and Λ_{η_2} , which is also shown to be the unique joint map. We set an orthogonal basis $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ of \mathbb{R}^3 . A set $\{\xi_0, \xi_1, \xi_2, \xi_3, \xi_4\} := \{\mathbf{1}, \mathbf{e}_1 \cdot \boldsymbol{\sigma}, \mathbf{e}_2 \cdot \boldsymbol{\sigma}, \mathbf{e}_3 \cdot \boldsymbol{\sigma}\}$ forms a basis of $\mathcal{L}(\mathbb{C}^2)$. A linear map $\Lambda : \mathcal{L}(\mathbb{C}^2) \otimes \mathcal{L}(\mathbb{C}^2) \rightarrow \mathcal{L}(\mathbb{C}^2)$ is completely specified by coefficients $\{\Lambda_{\mu\nu}^\xi\}$ defined by

$$\Lambda(\xi_\mu \otimes \xi_\nu) = \sum_{\alpha=0}^3 \Lambda_{\mu\nu}^\alpha \xi_\alpha.$$

For the map Λ to be a joint map of Λ_{η_1} and Λ_{η_2} , the coefficients must satisfy for $i, j = 1, 2, 3$,

$$\begin{aligned} \Lambda_{i0}^\alpha &= \delta_{i\alpha} \eta_1 \\ \Lambda_{0j}^\alpha &= \delta_{j\alpha} \eta_2 \end{aligned}$$

and $\Lambda_{00}^\alpha = \delta_{0\alpha}$. For Λ to be a well-defined map from $\mathcal{L}_+(\mathbb{C}^2) \otimes_{\min} \mathcal{L}_+(\mathbb{C}^2)$ to $\mathcal{L}_+(\mathbb{C}^2)$, for all $i, j = 1, 2, 3$ the following inequality must hold:

$$\Lambda\left(\frac{1}{2}(\xi_0 \pm \xi_i) \otimes \frac{1}{2}(\xi_0 \pm \xi_j)\right) \geq 0.$$

That is,

$$\begin{aligned}
\mathbf{1} + \eta_1 \xi_i + \eta_2 \xi_j + \sum_{\alpha} \Lambda_{ij}^{\alpha} \xi_{\alpha} &\geq 0 \\
\mathbf{1} - \eta_1 \xi_i + \eta_2 \xi_j - \sum_{\alpha} \Lambda_{ij}^{\alpha} \xi_{\alpha} &\geq 0 \\
\mathbf{1} + \eta_1 \xi_i - \eta_2 \xi_j - \sum_{\alpha} \Lambda_{ij}^{\alpha} \xi_{\alpha} &\geq 0 \\
\mathbf{1} - \eta_1 \xi_i - \eta_2 \xi_j + \sum_{\alpha} \Lambda_{ij}^{\alpha} \xi_{\alpha} &\geq 0.
\end{aligned}$$

For $i = 1$ and $j = 2$, they give

$$\begin{aligned}
1 + \Lambda_{12}^0 &\geq \sqrt{(\eta_1 + \Lambda_{12}^1)^2 + (\eta_2 + \Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} = \sqrt{2(\Lambda_{12}^1 \eta_1 + \Lambda_{12}^2 \eta_2) + 1 + (\Lambda_{12}^1)^2 + (\Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} \\
1 - \Lambda_{12}^0 &\geq \sqrt{(\eta_1 + \Lambda_{12}^1)^2 + (\eta_2 - \Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} = \sqrt{2(\Lambda_{12}^1 \eta_1 - \Lambda_{12}^2 \eta_2) + 1 + (\Lambda_{12}^1)^2 + (\Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} \\
1 - \Lambda_{12}^0 &\geq \sqrt{(\eta_1 - \Lambda_{12}^1)^2 + (\eta_2 + \Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} = \sqrt{-2(\Lambda_{12}^1 \eta_1 - \Lambda_{12}^2 \eta_2) + 1 + (\Lambda_{12}^1)^2 + (\Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} \\
1 + \Lambda_{12}^0 &\geq \sqrt{(\eta_1 - \Lambda_{12}^1)^2 + (\eta_2 - \Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2} = \sqrt{-2(\Lambda_{12}^1 \eta_1 + \Lambda_{12}^2 \eta_2) + 1 + (\Lambda_{12}^1)^2 + (\Lambda_{12}^2)^2 + (\Lambda_{12}^3)^2}.
\end{aligned}$$

Let us first assume $\Lambda_{12}^0 > 0$. This contradicts with the second inequality in the case of $\Lambda_{12}^1 \eta_1 - \Lambda_{12}^2 \eta_2 \geq 0$ and with the third one in the case of $\Lambda_{12}^1 \eta_1 - \Lambda_{12}^2 \eta_2 < 0$. Therefore $\Lambda_{12}^0 > 0$ cannot be true. On the other hand, $\Lambda_{12}^0 < 0$ contradicts the first and the fourth inequalities in a similar way. Thus we conclude $\Lambda_{12}^0 = 0$ and $\Lambda_{12}^1 = \Lambda_{12}^2 = \Lambda_{12}^3 = 0$ for the above inequalities to hold. For any normalized \mathbf{e} and \mathbf{d} satisfying $\mathbf{e} \cdot \mathbf{d} = 0$, we can set an orthonormalized basis $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ so that $\mathbf{e}_1 = \mathbf{e}$ and $\mathbf{e}_2 = \mathbf{d}$. Thus we conclude for any $\mathbf{e} \cdot \mathbf{d} = 0$,

$$\Lambda(\mathbf{e} \cdot \boldsymbol{\sigma} \otimes \mathbf{d} \cdot \boldsymbol{\sigma}) = 0.$$

Let us examine $\Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{m} \cdot \boldsymbol{\sigma})$ for arbitrary normalized vectors \mathbf{n} and \mathbf{m} . As \mathbf{m} is written as $\mathbf{m} = (\mathbf{n} \cdot \mathbf{m})\mathbf{n} + (\mathbf{m} - (\mathbf{n} \cdot \mathbf{m})\mathbf{n})$ with $(\mathbf{m} - (\mathbf{n} \cdot \mathbf{m})\mathbf{n}) \cdot \mathbf{n} = 0$, we obtain

$$\Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{m} \cdot \boldsymbol{\sigma}) = (\mathbf{n} \cdot \mathbf{m})\Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{n} \cdot \boldsymbol{\sigma}).$$

Similarly it holds that $\Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{m} \cdot \boldsymbol{\sigma}) = (\mathbf{n} \cdot \mathbf{m})\Lambda(\mathbf{m} \cdot \boldsymbol{\sigma} \otimes \mathbf{m} \cdot \boldsymbol{\sigma})$. Therefore we find for any $\mathbf{n} \cdot \mathbf{m} \neq 0$,

$$\Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{n} \cdot \boldsymbol{\sigma}) = \Lambda(\mathbf{m} \cdot \boldsymbol{\sigma} \otimes \mathbf{m} \cdot \boldsymbol{\sigma}).$$

Thus $N := \Lambda(\mathbf{n} \cdot \boldsymbol{\sigma} \otimes \mathbf{n} \cdot \boldsymbol{\sigma})$ is independent of \mathbf{n} and is written as

$$N = a_0 \mathbf{1} + \mathbf{a} \cdot \boldsymbol{\sigma}$$

with $(a_0, \mathbf{a}) \in \mathbb{R}^4$. Now for Λ to be well-defined, it must hold that for arbitrary \mathbf{n}, \mathbf{m} ,

$$\Lambda\left(\frac{1}{2}(\mathbf{1} + \mathbf{n} \cdot \boldsymbol{\sigma}) \otimes \frac{1}{2}(\mathbf{1} + \mathbf{m} \cdot \boldsymbol{\sigma})\right) = \frac{1}{4}(\mathbf{1} + (\eta_1 \mathbf{n} + \eta_2 \mathbf{m}) \cdot \boldsymbol{\sigma} + (\mathbf{n} \cdot \mathbf{m})(a_0 \mathbf{1} + \mathbf{a} \cdot \boldsymbol{\sigma})) \geq 0.$$

We introduce a normalized vector $\mathbf{r} := \frac{\eta_1 \mathbf{n} + \eta_2 \mathbf{m}}{1 + 2(\mathbf{n} \cdot \mathbf{m})\eta_1 \eta_2}$ to rewrite the above quantity as

$$\begin{aligned}
\frac{1}{4}(\mathbf{1} + (\eta_1 \mathbf{n} + \eta_2 \mathbf{m}) \cdot \boldsymbol{\sigma} + (\mathbf{n} \cdot \mathbf{m})(a_0 \mathbf{1} + \mathbf{a} \cdot \boldsymbol{\sigma})) &= \frac{1}{4}(\mathbf{1} + (1 + 2\eta_1 \eta_2 (\mathbf{n} \cdot \mathbf{m}))\mathbf{r} \cdot \boldsymbol{\sigma} + (\mathbf{n} \cdot \mathbf{m})(a_0 \mathbf{1} + \mathbf{a} \cdot \boldsymbol{\sigma})) \\
&= \frac{1}{4}((1 + \mathbf{n} \cdot \mathbf{m} a_0)\mathbf{1} + (1 + 2(\mathbf{n} \cdot \mathbf{m})\eta_1 \eta_2)\mathbf{r} + (\mathbf{n} \cdot \mathbf{m})\mathbf{a}) \cdot \boldsymbol{\sigma} \geq 0.
\end{aligned}$$

Let us set \mathbf{n} and \mathbf{m} so that $\mathbf{r} \cdot \mathbf{a} = 0$. We obtain

$$1 + \mathbf{n} \cdot \mathbf{m} a_0 \geq \sqrt{(1 + 2(\mathbf{n} \cdot \mathbf{m})\eta_1 \eta_2)^2 + (\mathbf{n} \cdot \mathbf{m})^2 |\mathbf{a}|^2}.$$

Therefore it must hold that

$$1 + \mathbf{n} \cdot \mathbf{m} a_0 \geq 1 + 2\mathbf{n} \cdot \mathbf{m} \eta_1 \eta_2. \quad (3)$$

The vectors \mathbf{n} and \mathbf{m} can be taken arbitrarily as far as $\mathbf{n} \cdot \mathbf{m} \neq 0$ and $\mathbf{r} \cdot \mathbf{a} = 0$. The value $\mathbf{n} \cdot \mathbf{m}$ can take both positive and negative values as seen below. Let \mathbf{a}^\perp be a normalized vector orthogonal to \mathbf{a} . For $0 \leq \theta \leq \frac{\pi}{4}$, we set $\mathbf{n} = \cos \theta \mathbf{a}^\perp + \sin \theta \mathbf{a}$ and $\mathbf{m} = \cos(\theta - \frac{\pi}{4}) \mathbf{a}^\perp + \sin(\theta - \frac{\pi}{4}) \mathbf{a}$, which gives $\mathbf{n} \cdot \mathbf{m} = 1/\sqrt{2} > 0$. For given η_1, η_2 , there exists θ satisfying $\mathbf{r} = \mathbf{a}^\perp$. On the other hand, to obtain \mathbf{n} and \mathbf{m} realizing $\mathbf{n} \cdot \mathbf{m} < 0$, we set $\mathbf{n} = \cos \theta \mathbf{a}^\perp + \sin \theta \mathbf{a}$ and $\mathbf{m} = \cos(\theta - \frac{3\pi}{4}) \mathbf{a}^\perp + \sin(\theta - \frac{3\pi}{4}) \mathbf{a}$ for $0 \leq \theta \leq 3\pi/4$, which gives $\mathbf{n} \cdot \mathbf{m} = -1/\sqrt{2} < 0$. There exists θ satisfying $\mathbf{r} = \mathbf{a}^\perp$.

For $\mathbf{n} \cdot \mathbf{m} > 0$, the above inequality (3) gives $a_0 \geq 2\eta_1\eta_2$. On the other hand, for $\mathbf{n} \cdot \mathbf{m} < 0$, it gives $a_0 \leq 2\eta_1\eta_2$. Thus we conclude

$$a_0 = 2\eta_1\eta_2.$$

Next, let us set \mathbf{r} to be parallel with \mathbf{a} so that we can write \mathbf{a} as $\mathbf{a} = |\mathbf{a}|\mathbf{r}$. Then (3) shows

$$1 + 2\eta_1\eta_2(\mathbf{n} \cdot \mathbf{m}) \geq |1 + 2\eta_1\eta_2(\mathbf{n} \cdot \mathbf{m}) + |\mathbf{a}|(\mathbf{n} \cdot \mathbf{m})|.$$

It gives $|\mathbf{a}| = 0$. Thus we find $N = 2\eta_1\eta_2\mathbf{1}$ and conclude

$$\Lambda \left(\frac{1}{2}(\mathbf{1} + \mathbf{n} \cdot \boldsymbol{\sigma}) \otimes \frac{1}{2}(\mathbf{1} + \mathbf{m} \cdot \boldsymbol{\sigma}) \right) = \frac{1}{4}((1 + 2\eta_1\eta_2(\mathbf{n} \cdot \mathbf{m}))\mathbf{1} + (\eta_1\mathbf{n} + \eta_2\mathbf{m}) \cdot \boldsymbol{\sigma}).$$

This Λ is a map from $\mathcal{L}_+(\mathbb{C}^2) \otimes_{\min} \mathcal{L}_+(\mathbb{C}^2)$ to $\mathcal{L}_+(\mathbb{C}^2)$. Thus we proved that Λ_{η_1} and Λ_{η_2} are min-tensor-compatible for $\eta_1^2 + \eta_2^2 = 1$ and their joint map is uniquely determined.

For $\eta_1^2 + \eta_2^2 < 1$, we first consider Λ_{η_1} and $\Lambda_{\sqrt{1-\eta_1^2}}$ whose joint map is denoted by Λ . As $\eta_2 < \sqrt{1-\eta_1^2}$ holds, Λ_{η_2} can be written as $\Lambda_{\eta_2} = \Lambda_{\sqrt{1-\eta_1^2}} \circ \mathcal{E}$ with some channel \mathcal{E} . In fact, in general for $\eta'_2 < \eta'_1$,

$$\Lambda_{\eta'_2} = \Lambda_{\eta'_1} \circ \Lambda_{\eta'_2/\eta'_1}$$

holds. The map $\Lambda \circ (id \otimes \mathcal{E})$ is a joint map of Λ_{η_1} and Λ_{η_2} [13]. Thus Λ_{η_1} and Λ_{η_2} are min-tensor-compatible. \square

The above theorem shows that the set of all min-tensor-compatible pairs of channels is strictly larger than that of all quantum compatible pairs.

B. min-tensor-compatibility vs almost quantum compatibility

We introduced the notion of min-tensor-compatibility. Theorem 1 showed that there are pairs of min-tensor-compatible channels which are not quantum compatible. Joint maps of such pairs are not completely positive.

Let aside the incompatibility issue for the moment, we consider a map $\Phi : \mathcal{L}(\mathbb{C}^2 \otimes \mathbb{C}^2) \rightarrow \mathcal{L}(\mathbb{C}^2)$ defined by

$$\Phi(X) = \langle \varphi_- | (id \otimes T)(X) | \varphi_- \rangle \mathbf{1},$$

where $|\varphi_- \rangle$ is a singlet state defined by $|\varphi_- \rangle = \frac{1}{\sqrt{2}}(|01\rangle - |10\rangle)$ and T is a transpose map for z -basis. For $A \geq 0$ and $B \geq 0$, $\Phi(A \otimes B) = \langle \varphi_- | A \otimes T(B) | \varphi_- \rangle \mathbf{1} \geq 0$ holds as $T(B) \geq 0$. On the other hand, for $X = |\varphi_+ \rangle \langle \varphi_+ |$ with $|\varphi_+ \rangle := \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$, we obtain $\Phi(X) = -\mathbf{1}/2 < 0$. Thus Φ is not completely positive but is well-defined as a map from $\mathcal{L}_+(\mathbb{C}^2) \otimes_{\min} \mathcal{L}_+(\mathbb{C}^2)$ to $\mathcal{L}_+(\mathbb{C}^2)$. The map is unphysical as it is not completely positive. On the other hand, in the context of compatibility we are not interested in effects like $X = |\varphi_+ \rangle \langle \varphi_+ |$. Instead, quantities $P(A, B|\rho) := \text{tr}[\rho \Phi(A \otimes B)]$ for all $A, B \in \mathcal{L}_+(\mathbb{C}^2)$ and $\rho \in \mathcal{S}(\mathbb{C}^2)$ are all that we concern about in order to check if the map Φ is a joint map of some channels. Although Φ is not completely positive, the set of data $\{P(A, B|\rho) \mid 0 \leq A, B \leq \mathbf{1}\}$ is physically realizable by the following procedure. First we map a state $\rho \in \mathcal{S}(\mathbb{C}^2)$ to a state $\Psi^*(\rho)$ on the composite system by a channel Ψ defined by $\Psi(\cdot) := \langle \varphi_- | \cdot | \varphi_- \rangle \mathbf{1}$. ($\Psi^*(\rho) = |\varphi_- \rangle \langle \varphi_- |$ holds for all ρ .) Then we measure an effect $A \otimes T(B) \geq 0$ and read its outcome probability as that for $A \otimes B$. More concretely, an apparatus measuring $T(B)$ is constructed by changing its reference frame from $\{\mathbf{e}_x, \mathbf{e}_y, \mathbf{e}_z\}$ to $\{\mathbf{e}_x, -\mathbf{e}_y, \mathbf{e}_z\}$. Thus we may introduce yet another class of compatibility.

Definition 3. Consider a pair of channels $\Lambda_1 : \mathcal{L}(\mathcal{H}_1) \rightarrow \mathcal{L}(\mathcal{H}_0)$ and $\Lambda_2 : \mathcal{L}(\mathcal{H}_2) \rightarrow \mathcal{L}(\mathcal{H}_0)$. The pair is called **almost quantum compatible** if and only if it is min-tensor-compatible and there exists a joint map Λ written in a form

$$\Lambda = \Psi \circ (\Theta_1 \otimes \Theta_2),$$

where $\Psi : \mathcal{L}(\mathcal{H}_1 \otimes \mathcal{H}_2) \rightarrow \mathcal{L}(\mathcal{H}_0)$ is a channel, and $\Theta_1 : \mathcal{L}(\mathcal{H}_1) \rightarrow \mathcal{L}(\mathcal{H}_1)$ and $\Theta_2 : \mathcal{L}(\mathcal{H}_2) \rightarrow \mathcal{L}(\mathcal{H}_2)$ are positive maps.

By definition almost quantum compatible pairs of channels are min-tensor-compatible. We show the converse is not true. There are min-tensor-compatible pairs that are not almost quantum compatible.

Theorem 2. *Let Λ_η ($0 \leq \eta \leq 1$) be a noisy identity channel on a qubit. Λ_{η_1} and Λ_{η_2} are almost quantum compatible if and only if*

$$\eta_1^2 + \eta_2^2 + (1 - \eta_1 - \eta_2)^2 \leq 1. \quad (4)$$

Proof. If part is trivial as Λ_{η_1} and Λ_{η_2} satisfying inequality (4) are quantum compatible. Let us consider the only if part. Suppose that Λ_{η_1} and Λ_{η_2} are almost quantum compatible. We assume $\eta_1 + \eta_2 \geq 1$ and show that η_1 and η_2 satisfy (4). There exists a channel $\Psi : \mathcal{L}(\mathbb{C}^2 \otimes \mathbb{C}^2) \rightarrow \mathcal{L}(\mathbb{C}^2)$ and positive maps $\Theta_1, \Theta_2 : \mathcal{L}(\mathbb{C}^2) \rightarrow \mathcal{L}(\mathbb{C}^2)$ such that $\Lambda := \Psi \circ (\Theta_1 \otimes \Theta_2)$ is a joint map of Λ_{η_1} and Λ_{η_2} . We introduce an auxiliary qubit $\mathcal{K} = \mathbb{C}^2$ and consider a singlet state $|\varphi_{-}\rangle\langle\varphi_{-}| \in \mathcal{S}(\mathcal{K} \otimes \mathcal{H}_0) = \mathcal{S}(\mathbb{C}^2 \otimes \mathbb{C}^2)$. While $(id \otimes \Lambda)^*(|\varphi_{-}\rangle\langle\varphi_{-}|)$ may not be a quantum state, $\rho := (id \otimes \Psi)^*(|\varphi_{-}\rangle\langle\varphi_{-}|)$ is a quantum state on a composite system $\mathcal{K} \otimes \mathcal{H}_1 \otimes \mathcal{H}_2 = \mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$. We examine tripartite correlation functions with respect to the state ρ . We study Θ_1 to choose appropriate effects in considering the tripartite correlations. The map can be written with coefficients $v_i, A_{ij} \in \mathbb{R}^3$ ($i, j = 1, 2, 3$) as

$$\Theta_1(\mathbf{1}) = \mathbf{1}, \quad \Theta_1(\sigma_i) = v_i \mathbf{1} + \sum_{j=1}^3 A_{ij} \sigma_j.$$

Thus $\mathbf{a} = [a_1, a_2, a_3] \in \mathbb{R}^3$ satisfying $\mathbf{a} \cdot \mathbf{v} = 0$ with $\mathbf{v} = [v_1, v_2, v_3]$ gives

$$\Theta_1(\mathbf{a} \cdot \boldsymbol{\sigma}) = \sum_{i,j=1}^3 a_i A_{ij} \sigma_j.$$

That is $\Theta_1(\mathbf{a} \cdot \boldsymbol{\sigma})$ has no $\mathbf{1}$ component. We introduce a two-dimensional subspace $V_1 := \{\mathbf{a} \in \mathbb{R}^3 \mid \mathbf{a} \cdot \mathbf{v} = 0\}$. The above argument shows that $\Theta_1(\mathbf{a} \cdot \boldsymbol{\sigma})$ for any $\mathbf{a} \in V_1$ does not have $\mathbf{1}$ component. (V_1 is \mathbb{R}^3 in case $\mathbf{v} = 0$. The following argument holds also in this case.) By repeating the argument for Θ_2 , one can conclude that there is a two-dimensional subspace $V_2 \subset \mathbb{R}^3$ such that $\Theta_2(\mathbf{a} \cdot \boldsymbol{\sigma})$ has no $\mathbf{1}$ coefficient for $\mathbf{a} \in V_2$. We denote by $V = V_1 \cap V_2$, which satisfies $\dim V \geq 1$. Let us set an orthonormal basis $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ so that $\mathbf{e}_2 \in V$ and $\mathbf{e}_1 \in V_1$. We can write as, by using normalized vectors $\mathbf{p}, \mathbf{q}, \mathbf{r}, \mathbf{s} \in \mathbb{R}^3$ and $x_1, y_1, z'_2, z_2, y_2, \theta_1, \theta_2 \in \mathbb{R}$,

$$\begin{aligned} \Theta_1(\mathbf{e}_1 \cdot \boldsymbol{\sigma}) &= x_1 \mathbf{p} \cdot \boldsymbol{\sigma} \\ \Theta_1(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) &= y_1 (\sin \theta_1 \mathbf{p} + \cos \theta_1 \mathbf{q}) \cdot \boldsymbol{\sigma} \\ \Theta_2(\mathbf{e}_3 \cdot \boldsymbol{\sigma}) &= z'_2 \mathbf{1} + z_2 \mathbf{r} \cdot \boldsymbol{\sigma} \\ \Theta_2(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) &= y_2 (\sin \theta_2 \mathbf{r} + \cos \theta_2 \mathbf{s}) \cdot \boldsymbol{\sigma}, \end{aligned}$$

where $\mathbf{p} \cdot \mathbf{q} = 0$ and $\mathbf{r} \cdot \mathbf{s} = 0$. As Θ_1 is a unit-preserving positive map, $\Theta_1(\mathbf{1} - \mathbf{e}_1 \cdot \boldsymbol{\sigma}) = \mathbf{1} - x_1 \mathbf{p} \cdot \boldsymbol{\sigma} \geq 0$ holds and therefore $|x_1| \leq 1$ follows. Similarly, $|y_1|, |y_2| \leq 1$ holds. In addition, as $\Theta_1(\mathbf{1} - \mathbf{e}_3 \cdot \boldsymbol{\sigma}) = (1 - z'_2) \mathbf{1} - z_2 \mathbf{r} \cdot \boldsymbol{\sigma} \geq 0$, we have $1 - z'_2 \geq |z_2|$ and thus $0 \leq z'_2 \leq 1$ and $|z_2| \leq 1$. For later use, we choose \mathbf{q} so that $y_1 \cos \theta_1 \leq 0$ and \mathbf{s} so that $y_2 \cos \theta_2 \leq 0$. We need the following lemma on Clifford algebra.

Lemma 1. *Let $\{E_n\}_{n=1}^N$ be self-adjoint operators satisfying for any n, m ,*

$$E_n E_m + E_m E_n = 2\delta_{nm} \mathbf{1}.$$

For $\mathbf{x} \in \mathbb{R}^N$, we introduce $E(\mathbf{x}) := \sum_{n=1}^N x_n E_n$. For any state ρ , it holds that

$$|\text{tr}[\rho E(\mathbf{x})]| \leq |\mathbf{x}|.$$

In addition, it holds that

$$\sum_n \text{tr}[\rho E_n]^2 \leq 1.$$

The proof will be presented in Appendix A. We apply the Lemma to an anticommuting set $\{\mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \mathbf{p} \cdot \boldsymbol{\sigma} \otimes \mathbf{1}, \mathbf{e}_3 \cdot \boldsymbol{\sigma} \otimes \mathbf{1} \otimes \mathbf{r} \cdot \boldsymbol{\sigma}, \mathbf{1} \otimes \mathbf{q} \cdot \boldsymbol{\sigma} \otimes \mathbf{s} \cdot \boldsymbol{\sigma}\}$ to obtain

$$\text{tr}[\rho(\mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \mathbf{p} \cdot \boldsymbol{\sigma} \otimes \mathbf{1})]^2 + \text{tr}[\rho(\mathbf{e}_3 \cdot \boldsymbol{\sigma} \otimes \mathbf{1} \otimes \mathbf{r} \cdot \boldsymbol{\sigma})]^2 + \text{tr}[\rho(\mathbf{1} \otimes \mathbf{q} \cdot \boldsymbol{\sigma} \otimes \mathbf{s} \cdot \boldsymbol{\sigma})]^2 \leq 1. \quad (5)$$

The first term of the left-hand side of the above inequality is calculated as

$$\begin{aligned}
\text{tr}[\rho(\mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \mathbf{p} \cdot \boldsymbol{\sigma} \otimes \mathbf{1})]^2 &= \frac{1}{x_1^2} \text{tr}[\rho(\mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \Theta_1(\mathbf{e}_1 \cdot \boldsymbol{\sigma}) \otimes \mathbf{1})]^2 \\
&= \frac{1}{x_1^2} \langle \varphi_- | \mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \Psi(\Theta_1(\mathbf{e}_1 \cdot \boldsymbol{\sigma}) \otimes \Theta_2(\mathbf{1})) | \varphi_- \rangle^2 \\
&= \frac{1}{x_1^2} \langle \varphi_- | \mathbf{e}_1 \cdot \boldsymbol{\sigma} \otimes \Lambda_1(\mathbf{e}_1 \cdot \boldsymbol{\sigma}) | \varphi_- \rangle^2 = \frac{\eta_1^2}{x_1^2}.
\end{aligned} \tag{6}$$

The second term of the left-hand side of (5) is

$$\begin{aligned}
\text{tr}[\rho(\mathbf{e}_3 \cdot \boldsymbol{\sigma} \otimes \mathbf{1} \otimes \mathbf{r} \cdot \boldsymbol{\sigma})]^2 &= \frac{1}{z_2^2} \text{tr}[\rho(\mathbf{e}_3 \cdot \boldsymbol{\sigma} \otimes \mathbf{1} \otimes \Theta_2(\mathbf{e}_3 \cdot \boldsymbol{\sigma} - z_2' \mathbf{1}))]^2 \\
&= \frac{1}{z_2^2} \langle \varphi_- | \mathbf{e}_3 \cdot \boldsymbol{\sigma} \otimes \Lambda_2(\mathbf{e}_3 \cdot \boldsymbol{\sigma} - z_2' \mathbf{1}) | \varphi_- \rangle^2 = \frac{\eta_2^2}{z_2^2}.
\end{aligned} \tag{7}$$

Now we employ the following lemma to evaluate the third term of (5).

Lemma 2. *Let $\{p(a, b, c)\}_{a, b, c \in \{0, 1\}}$ be a probability distribution. We introduce the following quantities:*

$$\begin{aligned}
p_{12} &:= \sum_{abc} p(a, b, c) (-1)^{a \oplus b} \\
p_{23} &:= \sum_{abc} p(a, b, c) (-1)^{b \oplus c} \\
p_{13} &:= \sum_{abc} p(a, b, c) (-1)^{a \oplus c}.
\end{aligned}$$

They satisfy

$$p_{23} \geq p_{12} + p_{13} - 1.$$

The proof is found in Appendix B. This lemma claims that the second and the third random variables are strongly correlated if the correlation between the first and the second and that between the first and the third are strong. We examine

$$p(a, b, c) := \text{tr} \left[\rho \left(\frac{\mathbf{1} + (-1)^a \mathbf{e}_2 \cdot \boldsymbol{\sigma}}{2} \otimes \frac{\mathbf{1} + (-1)^b \mathbf{q} \cdot \boldsymbol{\sigma}}{2} \otimes \frac{\mathbf{1} + (-1)^c \mathbf{s} \cdot \boldsymbol{\sigma}}{2} \right) \right].$$

For this probability distribution, one can calculate to obtain

$$p_{12} = \text{tr}[\rho(\mathbf{e}_2 \cdot \boldsymbol{\sigma} \otimes \mathbf{q} \cdot \boldsymbol{\sigma} \otimes \mathbf{1})] = \langle \varphi_- | (\mathbf{e}_2 \cdot \boldsymbol{\sigma} \otimes \Psi(\mathbf{q} \cdot \boldsymbol{\sigma} \otimes \mathbf{1}) | \varphi_- \rangle$$

As it holds that

$$\mathbf{q} \cdot \boldsymbol{\sigma} = \frac{1}{y_1 \cos \theta_1} \Theta_1(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) - \tan \theta_1 \mathbf{p} \cdot \boldsymbol{\sigma} = \frac{1}{y_1 \cos \theta_1} \Theta_1(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) - \frac{\tan \theta_1}{x_1} \Theta_1(\mathbf{e}_1 \cdot \boldsymbol{\sigma}),$$

we obtain

$$\begin{aligned}
p_{12} &= \langle \varphi_- | \left(\mathbf{e}_2 \cdot \boldsymbol{\sigma} \otimes \Psi \left(\Theta_1 \left(\frac{\mathbf{e}_2 \cdot \boldsymbol{\sigma}}{y_1 \cos \theta_1} - \frac{\tan \theta_1 \mathbf{e}_1 \cdot \boldsymbol{\sigma}}{x_1} \right) \otimes \Theta_2(\mathbf{1}) \right) | \varphi_- \rangle \\
&= \langle \varphi_- | \left(\mathbf{e}_2 \cdot \boldsymbol{\sigma} \otimes \Lambda_1 \left(\frac{\mathbf{e}_2 \cdot \boldsymbol{\sigma}}{y_1 \cos \theta_1} - \frac{\tan \theta_1 \mathbf{e}_1 \cdot \boldsymbol{\sigma}}{x_1} \right) \right) | \varphi_- \rangle = -\frac{\eta_1}{y_1 \cos \theta_1}.
\end{aligned}$$

Similarly, as

$$\begin{aligned}
\mathbf{s} \cdot \boldsymbol{\sigma} &= \frac{1}{y_2 \cos \theta_2} \Theta_2(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) - \tan \theta_2 \mathbf{r} \cdot \boldsymbol{\sigma} \\
&= \frac{1}{y_2 \cos \theta_2} \Theta_2(\mathbf{e}_2 \cdot \boldsymbol{\sigma}) - \frac{\tan \theta_2}{z_2} \Theta_2(\mathbf{e}_3 \cdot \boldsymbol{\sigma} - z_2' \mathbf{1})
\end{aligned}$$

holds, we obtain

$$p_{13} = -\frac{\eta_2}{y_2 \cos \theta_2}.$$

The condition $0 \geq y_1 \cos \theta_1, y_2 \cos \theta_2 \geq -1$ gives $p_{12} \geq \eta_1$ and $p_{13} \geq \eta_2$. Applying Lemma 2, we obtain

$$p_{23} = \text{tr}[\rho(\mathbf{1} \otimes \mathbf{q} \cdot \boldsymbol{\sigma} \otimes \mathbf{s} \cdot \boldsymbol{\sigma})] \geq \eta_1 + \eta_2 - 1. \quad (8)$$

Combining (8), (6), (7) and (5), we find

$$\frac{\eta_1^2}{x_1^2} + \frac{\eta_2^2}{z_2^2} + (\eta_1 + \eta_2 - 1)^2 \leq 1.$$

As $|x_1|, |z_2| \leq 1$, we obtain the wanted inequality. \square

IV. DISCUSSIONS

In the expanded concept of compatibility, a pair of maps is termed compatible if a joint map exists. The presence of this joint map might vary depending on how we define a composite system. This paper addresses this issue through an examination of composite systems involving two qubits. Min-tensor-compatibility refers to compatibility within the context of the min-tensor product of effect spaces. We established the necessary and sufficient condition for a pair of noisy identity channels on qubits, denoted as Λ_{η_1} and Λ_{η_2} , to be min-tensor-compatible. These condition reveals the existence of min-tensor-compatible pairs of noisy identity channels that do not satisfy the criteria for quantum compatibility. This underscores that compatibility is contingent upon the approach to composite systems. This is distinct from the Tsirelson bound for the CHSH inequality, which yields an identical value for both normal quantum and min-tensored composite systems. Additionally, we introduced a novel concept, almost quantum compatibility, driven by operational perspectives. We derived the necessary and sufficient condition for a pair of noisy identity channels on a qubit to be almost quantum compatible, which aligns with those for quantum compatibility. In proving the condition, we investigated tripartite correlation functions of quantum states. While any bipartite correlations for quantum effects can be realized by quantum states[16], there exist tripartite correlations that cannot be replicated by any quantum states[17]. We introduced a new criterion in our proof to ascertain whether two given bipartite correlations can be extended to a tripartite quantum correlation.

There are still avenues for further exploration. Regarding the set of channel pairs, we demonstrated the inclusion:

$$\text{quantum compatible} \subseteq \text{almost quantum compatible} \subsetneq \text{min-tensor-compatible} .$$

Whether the sets of all quantum compatible pairs and all almost quantum compatible pairs coincide remains unknown. Additionally, from a device-independent perspective, we may introduce another class of compatibility allowing a channel Ψ to have a domain as $\mathcal{L}(\mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2})$ and positive maps Θ_j ($j = 1, 2$) to have codomains $\mathcal{L}(\mathbb{C}^{d_j})$ with $d_1, d_2 \geq 2$. Finally, the overarching goal is to develop a general theory unrestricted to qubits.

Appendix A: Proof of Lemma 1

Proof. Note that $E(\mathbf{x})^2 = |\mathbf{x}|^2 \mathbf{1}$ holds. Thus we obtain

$$|\mathrm{tr}[\rho E(\mathbf{x})]|^2 \leq \mathrm{tr}[\rho E(\mathbf{x})^2] = |\mathbf{x}|^2.$$

For any $\mathbf{x} \in \mathbb{R}^N$ with $|\mathbf{x}| = 1$ it holds that

$$\sum_n x_n \mathrm{tr}[\rho E_n] \leq 1.$$

Taking $x_n = \frac{\mathrm{tr}[\rho E_n]}{\sqrt{\sum_m \mathrm{tr}[\rho E_m]^2}}$, we obtain

$$\sum_n \mathrm{tr}[\rho E_n]^2 \leq 1.$$

□

Appendix B: Proof of Lemma 2

Proof. As $\sum_{c, a \oplus b = 0} p(a, b, c) + \sum_{c, a \oplus b = 1} p(a, b, c) = 1$,

$$p_{12} = 2 \sum_{c, a \oplus b = 0} p(a, b, c) - 1 = 2(p(0, 0, 0) + p(0, 0, 1) + p(1, 1, 0) + p(1, 1, 1)) - 1$$

holds. Similarly, we have

$$p_{13} = 2 \sum_{b, a \oplus c = 0} p(a, b, c) - 1 = 2(p(0, 0, 0) + p(0, 1, 0) + p(1, 0, 1) + p(1, 1, 1)) - 1.$$

Therefore we obtain

$$\begin{aligned} 1 + \frac{p_{12} + p_{13}}{2} &= 2(p(0, 0, 0) + p(1, 1, 1)) + p(1, 1, 0) + p(0, 0, 1) + p(0, 1, 0) + p(1, 0, 1) \\ &= 1 + p(0, 0, 0) + p(1, 1, 1) - p(0, 0, 1) - p(1, 0, 0) \leq 1 + p(0, 0, 0) + p(1, 1, 1). \end{aligned}$$

Thus

$$p_{23} = 2(p(0, 0, 0) + p(1, 0, 0) + p(0, 1, 1) + p(1, 1, 1)) - 1 \geq 2(p(0, 0, 0) + p(1, 1, 1)) - 1 \geq p_{12} + p_{13} - 1.$$

□
