# Two-phase rejective sampling

Shu Yang\* and Peng Ding<sup>†</sup>

#### Abstract

Rejective sampling improves design and estimation efficiency of single-phase sampling when auxiliary information in a finite population is available. When such auxiliary information is unavailable, we propose to use two-phase rejective sampling (TPRS), which involves measuring auxiliary variables for the sample of units in the first phase, followed by the implementation of rejective sampling for the outcome in the second phase. We explore the asymptotic design properties of double expansion and regression estimators under TPRS. We show that TPRS enhances the efficiency of the double expansion estimator, rendering it comparable to a regression estimator. We further refine the design to accommodate varying importance of covariates and extend it to multi-phase sampling.

Keywords: Covariate Adjustment; Design Property; Double Sampling; Multi-Phase Sampling

# 1 Introduction

Two-phase sampling, also known as double sampling, is a cost-effective method in large surveys, initially using auxiliary variables for broad measurement in the first phase, followed

<sup>&</sup>lt;sup>†</sup>Department of Statistics, University of California, Berkeley, California 94720, U.S.A. Email: pengding-pku@berkeley.edu

by targeted measurement of primary study variables in the second phase. Pioneered by Neyman (1938) and further developed by Cochran (2007) and Legg and Fuller (2009), two-phase sampling integrates auxiliary variables in both the design and analysis stages. In the design stage, stratified sampling is often used to leverage discrete auxiliary variables from the first phase to inform the selection of the second-phase sample. This strategy enhances the efficiency of estimators like weighted expansion estimators (Oh and Scheuren, 1983) over simple random sampling of the same size. In the analysis stage, auxiliary variables can be used to enhance the efficiency of estimation, for example, through regression estimators. Regression estimators work for both discrete and continuous variables, providing gains in efficiency over traditional approaches without auxiliary variables.

Regression estimators, however, have the practical drawback of having potential negative weights. Methods such as balanced sampling (Yates, 1946; Valliant et al., 2000; Deville and Tillé, 2004; Tillé and Favre, 2005) and rejective sampling (Fuller, 2009b) have been developed to mitigate the problem of negative weights associated with regression estimators. Yang et al. (2023) combined rejective sampling and rerandomization in experiments to enhance the external validity and internal validity. However, the existing design methods work for single-phase sampling and require the availability of auxiliary variable data for the entire population.

We introduce novel two-phase rejective sampling (TPRS) and explore its asymptotic design properties with commonly-used estimators, namely weighted expansion and regression estimators. TPRS allows for using both continuous and discrete auxiliary variables in the design stage, relaxing the requirement of observing auxiliary variables in the whole finite population typically associated with single-phase sampling. TPRS offers several practical benefits: it ensures a more representative sample of the target population, reduces the variance of the population mean estimator for covariates, prevents the selection of samples with extreme auxiliary variable values, and reduces the likelihood of negative weights in regression estimators. Additionally, TPRS enhances the efficiency of double-expansion estimators

across multiple outcomes to match the performance of regression estimators. This leads to a performance similar to regression estimators without the need of multiple model fitting for outcomes.

The paper proceeds as follows. Section 2 provides a review of existing design and analysis strategies of using auxiliary variables. Sections 3 and 4 propose TPRS with simple random sampling and general sampling, respectively. We further extend the application of TPRS to various scenarios, including sequential rejective sampling with different tiers of covariates and multi-phase sampling. Section 5 provides a summary of the extensions. Section 6 reports simulation results and an application that illustrates the finite-sample performance of TPRS. Section 7 concludes. We relegate all technical details and proofs to the supplementary material.

# 2 A review of design and analysis strategies of using auxiliary variables

Consider a finite population with a known size N. For each unit i,  $x_i$  is a p-dimensional auxiliary variable, and  $y_i$  is the study variable of interest. The finite population quantities  $\mathcal{F}_N = \{(x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)\}$  are fixed. For simplicity, we suppress the subscript N on  $\mathcal{F}$  if there is no ambiguity. The parameter of interest is the finite population mean of the study variable  $\bar{y}_0 = N^{-1} \sum_{i=1}^N y_i$ .

Two-phase sampling offers an efficient and economical method for conducting large-scale surveys. In this section, we review the existing methods for using auxiliary variables in twophase sampling to enhance estimation efficiency and identify areas needing new strategies.

# 2.1 Existing design strategy: two-phase stratified sampling

During the design stage, auxiliary variables are incorporated by selecting a second-phase sample through stratified sampling. Strata are based on first-phase variables, either directly from discrete variable categories or via discretization of continuous variables. We define  $x_i = (x_{1i}, \dots, x_{Hi})$  as the stratum indicator vector, where  $x_{hi} = 1$  if unit i is in stratum h, and  $x_{hi} = 0$  otherwise. Two-phase stratified sampling proceeds as follows:

- Step 1. From the population  $\mathcal{F}$ , select a first-phase sample  $\mathcal{A}$  of size  $n_{\mathrm{I}}$ . For  $i \in \mathcal{A}$ , record  $x_i$ . Define the sample size in each stratum h as  $m_h$  for  $h = 1, \ldots, H$ . The total first-phase sample size is  $n_{\mathrm{I}} = \sum_{h=1}^{H} m_h$ .
- Step 2. From each stratum h, randomly select  $r_h$  units, independently across strata, as the second-phase sample  $\mathcal{B}$ . For  $i \in \mathcal{B}$ , record  $y_i$ . The total second-phase sample size is  $n_{\text{II}} = \sum_{h=1}^{H} r_h$ .

In two-phase sampling, the double-expansion estimator ( $\pi^*$  estimator; Särndal et al., 2003) and the reweighted expansion estimator (REE; Oh and Scheuren, 1983, Kott and Stukel, 1997) are the canonical estimators for the population mean. The  $\pi^*$  estimator,

$$\hat{y}_{\pi^*} = \frac{1}{N} \sum_{i \in \mathcal{B}} \frac{y_i}{\pi_{\text{II}i}^*},$$

where  $\pi_{\text{II}i}^* = \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}$  with  $\pi_{\text{I}i} = P(i \in \mathcal{A})$  and  $\pi_{\text{II}i|\mathcal{A}} = P(i \in \mathcal{B} \mid i \in \mathcal{A})$ , adjusts individual observations by the product of their inclusion probabilities in both phases. We can also replace N in  $\hat{y}_{\pi^*}$  by  $\sum_{i \in \mathcal{B}} (\pi_{\text{II}i}^*)^{-1}$ , emulating the Hájek estimator. However, the combined probability  $\pi_{\text{II}i}^* = \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}$  is generally not the unconditional probability of a unit being in the phase-II sample  $P(i \in \mathcal{B}) = \sum_{\mathcal{A}} \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}P(\mathcal{A})$ , the average probability across all possible first-phase samples, unless  $\pi_{\text{II}i|\mathcal{A}}$  is invariant of the first-phase sample (Fuller, 2009a, Beaumont and Haziza, 2016). The REE,

$$\widehat{y}_{\text{REE}} = \frac{1}{N} \sum_{h=1}^{H} \left( \sum_{i \in \mathcal{A}} \frac{x_{hi}}{\pi_{\text{I}i}} \right) \frac{\sum_{i \in \mathcal{B}} (\pi_{\text{II}i}^*)^{-1} x_{hi} y_i}{\sum_{i \in \mathcal{B}} (\pi_{\text{II}i}^*)^{-1} x_{hi}},$$

recalculates the mean estimate for each stratum by a modified ratio estimator, where the stratum-specific mean of x is approximated based on phase-I data, while the coefficient is

derived from phase-II data. These estimators are often more efficient than the sample mean estimator under simple random sampling with the same size  $n_{\text{II}}$ .

#### 2.2 Existing analysis strategy: regression adjustment

Auxiliary variables can enhance estimation efficiency when used in the analysis stage of two-phase sampling, where they can be discrete, continuous, or a combination. In simple random sampling across both phases, we observe variable x in phase I and variables (x, y) in phase II. Then we can calculate the mean estimates  $\bar{x}_{\rm I} = n_{\rm I}^{-1} \sum_{i \in \mathcal{A}} x_i$  from phase I and  $(\bar{x}_{\rm II}, \bar{y}_{\rm II}) = n_{\rm II}^{-1} \sum_{i \in \mathcal{B}} (x_i, y_i)$  from phase II. The two-phase regression estimator is

$$\bar{y}_{\text{reg}} = \bar{y}_{\text{II}} - (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \hat{\beta}_{\text{II}},$$

where

$$\hat{\beta}_{\text{II}} = \left\{ \sum_{i \in \mathcal{B}} (x_i - \bar{x}_{\text{II}}) (x_i - \bar{x}_{\text{II}})^{\text{T}} \right\}^{-1} \sum_{i \in \mathcal{B}} (x_i - \bar{x}_{\text{II}}) (y_i - \bar{y}_{\text{II}})$$
(1)

is the regression coefficient based on the phase-II sample.

The regression estimator  $\bar{y}_{reg}$  can also be written as a weighted average of the secondphase outcomes, where the corresponding weights are called generalized regression estimation
weights. The regression estimator provides improved efficiency over  $\bar{y}_{II}$ , at least in large samples. However, issues like large numbers of x-variables or imbalance between  $\bar{x}_{II}$  and  $\bar{x}_{I}$  can
lead to extreme or negative weights and affect the performance of  $\bar{y}_{reg}$  in finite samples.

Researchers have explored various methods to mitigate the issue of negative weights associated with regression estimators, such as balanced sampling or rejective sampling, but these
approaches have mainly been studied in single-phase sampling (Yates, 1946; Valliant et al.,
2000; Deville and Tillé, 2004; Tillé and Favre, 2005; Fuller, 2009b).

Table 1 reviews the design and analysis strategies in multi-phase sampling for better efficiency, but currently it lacks strategies for integrating both continuous and discrete variables in the design stage. We will explore rejective sampling in multi-phase sampling to fill in the

Table 1: Design and analysis strategies in multi-phase sampling to improve estimation efficiency: rejective sampling is the main topic for our paper.

|              | Design stage       | Analysis stage        |
|--------------|--------------------|-----------------------|
| Discrete $x$ | stratification     | regression adjustment |
| General $x$  | rejective sampling | regression adjustment |

gap.

# 3 TPRS: two-phase rejective sampling

#### 3.1 Setup and notation

Throughout this paper, we use u and v to be generic notation for variables, which can be components of either x or y. Define  $E(\cdot \mid \mathcal{F})$ ,  $cov(\cdot \mid \mathcal{F})$ , and  $var(\cdot \mid \mathcal{F})$  as expectation, covariance, and variance under the sampling design. The finite population mean for  $u_i$  and covariance for  $u_i$  and  $v_i$  are

$$\bar{u}_0 = \frac{1}{N} \sum_{i=1}^{N} u_i, \quad V_{uv,0} = \cos(\bar{u}_{\rm I}, \bar{v}_{\rm I} \mid \mathcal{F}) = \frac{1}{N-1} \sum_{i=1}^{N} (u_i - \bar{u}_0)(v_i - \bar{v}_0)^{\rm T}.$$
 (2)

The phase-I sample mean for  $u_i$  and covariance for  $u_i$  and  $v_i$  are

$$\bar{u}_{\rm I} = \frac{1}{n_{\rm I}} \sum_{i \in \mathcal{A}} u_i, \quad V_{uv,\rm I} = \cos(\bar{u}_{\rm II}, \bar{v}_{\rm II} \mid \mathcal{A}, \mathcal{F}) = \frac{1}{n_{\rm I} - 1} \sum_{i \in \mathcal{A}} (u_i - \bar{u}_{\rm I})(v_i - \bar{v}_{\rm I})^{\mathrm{T}}.$$
 (3)

We assume  $V_{xx,0}$  and  $V_{xx,I}$  are positive definite. For a generic vector v, let  $v^{\otimes 2}$  denote  $vv^{\mathrm{T}}$ .

# 3.2 TPRS with simple random sampling

Rejective sampling aims for balanced phase-II sample selection by comparing the mean differences between phase-II and phase-I samples. We define TPRS with simple random sampling as follows.

**Definition 1 (TPRS with simple random sampling)** TPRS with simple random sampling consists of two steps:

Step 1. Select a phase-I sample A of size  $n_I$  by simple random sampling. For  $i \in A$ , record  $x_i$ .

Step 2. Select a phase-II sample  $\mathcal{B}$  of size  $n_{\text{II}} \leq n_{\text{I}}$  by simple random sampling from phase-I sample  $\mathcal{A}$ . Accept the phase-II sample if

$$Q_{\rm I} = (\bar{x}_{\rm II} - \bar{x}_{\rm I})^{\rm T} \left\{ (n_{\rm II}^{-1} - n_{\rm I}^{-1}) V_{xx,\rm I} \right\}^{-1} (\bar{x}_{\rm II} - \bar{x}_{\rm I}) < \gamma^2,$$

where  $\gamma^2 > 0$  is a pre-specified constant, and  $(n_{II}^{-1} - n_{I}^{-1})V_{xx,I}$  is the phase-II design variance of  $\bar{x}_{II} - \bar{x}_{I}$  given  $\mathcal{A}$ . For  $i \in \mathcal{B}$ , record  $y_i$ .

If  $Q_{\rm I}$  is below a specified threshold  $\gamma^2$ , the phase-II sample is considered balanced and accepted for further analysis, ensuring sample representativeness.

The sample mean estimator for the population mean  $\bar{y}_0$  is

$$\bar{y}_{\mathrm{II}} = n_{\mathrm{II}}^{-1} \sum_{i \in \mathcal{B}} y_i.$$

### 3.3 Large-sample design properties

We investigate the asymptotic design-based property of  $\bar{y}_{\text{II}}$  under TPRS in Definition 1. For asymptotic inference, we adopt the framework of Isaki and Fuller (1982), which establishes the asymptotic properties of estimators within a fixed sequence of populations and corresponding random samples. This involves a series of nested finite populations  $(\mathcal{F}_{N_1} \subset \mathcal{F}_{N_2} \subset \mathcal{F}_{N_3} \subset \cdots)$  and sequences of samples with increasing sample sizes  $(\mathcal{A}_{n_{\text{I},1}} \subset \mathcal{A}_{n_{\text{I},2}} \subset \mathcal{A}_{n_{\text{I},3}} \subset \cdots)$  and  $\mathcal{B}_{n_{\text{II},1}} \subset \mathcal{B}_{n_{\text{II},2}} \subset \mathcal{B}_{n_{\text{II},3}} \subset \cdots)$ . For simplicity, we will not explicitly mention the dependence of  $N_t$ ,  $n_{\text{I},t}$ , and  $n_{\text{II},t}$  on t, and refer to the asymptotic regime as the scenario where index t or N goes to infinity. Let  $O_P(1)$  the random variable that is bounded

in probability, and  $o_P(1)$  the random variable that converges to zero in probability as N increases, respectively. Let  $z_{\alpha}$  be the  $100\alpha$ th quantile of the standard normal distribution.

The linear projection of  $y_i$  onto  $x_i$  in the finite population  $\mathcal{F}$  is  $\bar{y}_0 + (x_i - \bar{x}_0)^T \beta_0$ , where

$$\beta_0 = \arg\min_{\beta} \sum_{i=1}^{N} \{ y_i - \bar{y}_0 - (x_i - \bar{x}_0)^{\mathrm{T}} \beta \}^2,$$

which equals

$$\beta_0 = \left\{ \sum_{i=1}^N (x_i - \bar{x}_0)^{\otimes 2} \right\}^{-1} \sum_{i=1}^N (x_i - \bar{x}_0)(y_i - \bar{y}_0) = V_{xx,0}^{-1} V_{xy,0}. \tag{4}$$

Assumption 1 Assume  $\mathcal{F}$  contains IID samples from a superpopulation of (x, y) with two conditions: (i) The sequence of  $\mathcal{F}$  has finite  $(4 + \delta)$  moments for some  $\delta > 0$ , implying  $E(|y|^{4+\delta}) < \infty$  and  $E(||x||^{4+\delta}) < \infty$  with respect to the superpopulation model; (ii)  $\lim_{N\to\infty} n_{\rm I}/N = f_{\rm I,0}$  a.s. and  $\lim_{N\to\infty} n_{\rm II}/n_{\rm I} = f_{\rm II,I}$  a.s. for some  $0 \le f_{\rm I,0} \le 1$  and  $0 \le f_{\rm II,I} \le 1$ .

Assumption 1(i) sets moment conditions for the superpopulation, which aids in applying central limit theorems. Chen and Rao (2007) studied sufficient moment conditions on the finite population that ensure the asymptotic normality of estimators in two-phase sampling. Assumption 1(i) implies that for any components u and v of x and y,

$$\lim_{N \to \infty} V_{uv,I} = \lim_{N \to \infty} V_{uv,0} = V_{uv} \text{ a.s.},$$
(5)

where  $V_{uv}$  is a constant vector or matrix. Assumption 1(ii) defines the sampling fractions  $f_{I,0}$  and  $f_{II,I}$  for the phase-I and phase-II samples, respectively. Sampling from a finite population or phase-I sample without replacement can introduce dependency among the individual samples. The sampling fractions serve to adjust for such dependency when calculating the asymptotic design variances and covariances.

Define the adjusted outcome as  $e_i = y_i - x_i^{\mathrm{T}} \beta_0$ . The error in the sample mean estimator

 $\bar{y}_{\rm II}$  of the population mean  $\bar{y}_0$  decomposes into three parts:

$$n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}_{0}) = n_{\text{II}}^{1/2}(\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}}\beta_{0} + n_{\text{II}}^{1/2}\{\bar{y}_{\text{II}} - \bar{y}_{\text{I}} - (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}}\beta_{0}\} + n_{\text{II}}^{1/2}(\bar{y}_{\text{I}} - \bar{y}_{0})$$

$$\equiv T_{1} + T_{2} + T_{3}. \tag{6}$$

In (6),  $T_1 = n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \beta_0$  and  $T_2 = n_{\text{II}}^{1/2} (\bar{e}_{\text{II}} - \bar{e}_{\text{I}})$  represent the errors of x and e in the phase-II sample conditional on the phase-I sample, respectively, and  $T_3 = n_{\text{II}}^{1/2} (\bar{y}_{\text{I}} - \bar{y}_{0})$  represents the error of y in the phase-I sample. The limiting distribution of  $(T_1, T_2, T_3)$  is given in the following lemma.

**Lemma 1** Suppose Assumption 1 holds. Under TPRS in Definition 1,  $(T_1, T_2, T_3)$  in the decomposition (6) has the following limiting distribution:

$$\begin{pmatrix}
T_{1} \\
T_{2} \\
T_{3}
\end{pmatrix} \middle| \mathcal{F} \to \mathcal{N} \left\{ \begin{pmatrix}
0 \\
0 \\
0
\end{pmatrix}, \begin{pmatrix}
(1 - f_{\text{II,I}}) V_{yx} V_{xx}^{-1} V_{xy}, & 0 & 0 \\
0 & (1 - f_{\text{II,I}}) V_{ee} & 0 \\
0 & 0 & f_{\text{II,I}} (1 - f_{\text{I,0}}) V_{yy}
\end{pmatrix} \right\},$$

a.s. for all sequences of finite populations, where  $V_{uv}$  is defined in (5), and  $f_{II,I}$  and  $f_{I,0}$  are defined in Assumption 1.

In TPRS, the distribution of the error  $n_{\rm II}^{1/2}(\bar{y}_{\rm II} - \bar{y}_0)$  equals  $n_{\rm II}^{1/2}(\bar{y}_{\rm II} - \bar{y}_0) \mid (Q_{\rm I} < \gamma^2)$  without rejective sampling. We use the normalized distance  $D_{\rm I} = \{(n_{\rm II}^{-1} - n_{\rm I}^{-1})V_{xx,\rm I}\}^{-1/2}(\bar{x}_{\rm II} - \bar{x}_{\rm I})$  for the phase-II sample to represent the acceptance criteria  $Q_{\rm I} < \gamma^2$  by  $D_{\rm I}^{\rm T}D_{\rm I} < \gamma^2$ . By Lemma 1,  $D_{\rm I} \to \mathcal{N}(0, I_p)$  and thus  $D_{\rm I}^{\rm T}D_{\rm I} \to \chi_p^2$  a.s.. We define the superpopulation squared correlation between x and y as  $R^2 = \{corr(x,y)\}^2 = V_{yx}V_{xx}^{-1}V_{xy}/V_{yy}$ . We show the limiting distribution of  $n_{\rm II}^{1/2}(\bar{y}_{\rm II} - \bar{y}_0)$  comprises three independent random components.

**Theorem 1** Suppose Assumption 1 holds. Under TPRS in Definition 1,  $\bar{y}_{II}$  follows the limiting distribution:

$$n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}_{0}) \mid (Q_{\text{I}} < \gamma^{2}) \rightarrow \{(1 - f_{\text{II},\text{I}})V_{yy}R^{2}\}^{1/2} L_{p,\gamma^{2}} + \{(1 - f_{\text{II},\text{I}})V_{yy}(1 - R^{2})\}^{1/2} Z_{1} + \{f_{\text{II},\text{I}}(1 - f_{\text{I},0})V_{yy}\}^{1/2} Z_{2}, \quad (7)$$

where

$$L_{p,\gamma^2} \sim \chi_{p,\gamma^2} \mathcal{S}\Gamma_p^{1/2},$$
 (8)

with  $\chi_{p,\gamma^2} \sim \chi_p^2 \mid (\chi_p^2 \leq \gamma^2)$ , S is a random sign,  $\Gamma_p \sim \text{Beta}\{1/2, (p-1)/2\}$ , and  $S\Gamma_p^{1/2}$  is the first coordinate of the uniform random vector over the (p-1)-dimensional unit sphere,  $Z_1$  and  $Z_2$  are standard normal variables, and  $(L_{p,\gamma^2}, Z_1, Z_2)$  are jointly independent.

The random variable  $L_{p,\gamma^2}$ , first introduced in Li et al. (2018) for rerandomization in causal inference, is also relevant here. Our context is more complex due to the uncertainty in phase-I estimators.

Denote  $v_{p,\gamma^2} = \text{var}(L_{p,\gamma^2})$ , which equals  $v_{p,\gamma^2} = P(\chi_{p+2}^2 \le \gamma^2)/P(\chi_p^2 \le \gamma^2)$  by (8) and is less than or equal to 1 (Morgan and Rubin, 2012, Li et al., 2018).

Corollary 1 Under Assumption 1 and TPRS in Definition 1, the asymptotic design variance of  $n_{\rm II}^{1/2}(\bar{y}_{\rm II}-\bar{y}_0)$  is

$$[(1 - f_{\text{II},\text{I}}) \{1 - (1 - v_{p,\gamma^2}) R^2\} + f_{\text{II},\text{I}} (1 - f_{\text{I},0})] V_{yy}.$$

The percentage reduction in asymptotic design variance compared with the standard two-phase simple random sampling is

$$\frac{1 - f_{\text{II,I}}}{1 - f_{\text{II,I}} f_{\text{L0}}} \left(1 - v_{p,\gamma^2}\right) R^2,\tag{9}$$

provided  $f_{\text{II},\text{I}}f_{\text{I},0} \neq 1$ . If  $f_{\text{II},\text{I}}f_{\text{I},0} = 1$ , indicating a census situation, this reduction is zero. Moreover,  $\bar{y}_{\text{II}}$  exhibits a narrower quantile range under TPRS in Definition 1 than under the standard two-phase simple random sampling.

From Theorem 1 and Corollary 1, we discuss the trade-off between variance and utility of the sample when selecting  $\gamma^2$ . A lower  $\gamma^2$  reduces the asymptotic variance of  $\bar{y}_{\rm II}$ , and in

particular,  $\{(1-f_{\text{II,I}})V_{yy}R^2\}^{1/2}L_{p,\gamma^2}$  can be eliminated from the asymptotic distribution (7) if  $\gamma$  approaches 0 (Wang and Li, 2022). In the limit with  $\gamma \to 0$ , the asymptotic distribution of  $\bar{y}_{\text{II}}$  under TPRS is similar to a sum of two normal random variables  $\{(1-f_{\text{II,I}})V_{yy}(1-R^2)\}^{1/2}Z_1 + \{f_{\text{II,I}}(1-f_{\text{I,0}})V_{yy}\}^{1/2}Z_2$ . However, it also lowers the acceptance rate for the phase-II sample and potentially limits randomness and observations in the tail of the x distribution, as discussed by Legg and Yu (2010). This reduces the utility of the sample for unplanned domain analysis, particularly those concerning aspects associated with the tail of the distribution of x.

Moreover, when  $R^2 = 0$ , indicating no correlation between auxiliary and study variables, the rejective procedure does not affect the limiting distribution for  $\bar{y}_{\text{II}}$ . Conversely, with  $R^2 = 1$ , the variance reduction for  $\bar{y}_{\text{II}}$  is maximized due to the strong correlation between auxiliary and study variables.

#### 3.4 Regression estimator

Design and analysis strategies can be integrated; Fuller (2009b) combined rejective sampling and regression adjustment in surveys, and Li and Ding (2020) combined rerandomization and regression adjustment in experiments. Under TPRS, a regression estimator is

$$\bar{y}_{\text{II,reg}} = \bar{y}_{\text{II}} - (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \hat{\beta}_{\text{II}}, \tag{10}$$

with  $\hat{\beta}_{\text{II}}$  specified earlier in (1). To derive the asymptotic distribution of  $\bar{y}_{\text{II},\text{reg}}$  in TPRS, we decompose it as follows

$$n_{\text{II}}^{1/2} (\bar{y}_{\text{II,reg}} - \bar{y}_0) = n_{\text{II}}^{1/2} (\bar{y}_{\text{II}} - \bar{y}_{\text{I}}) - n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \beta_0$$

$$-n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} (\hat{\beta}_{\text{II}} - \beta_0) + n_{\text{II}}^{1/2} (\bar{y}_{\text{I}} - \bar{y}_0)$$

$$= n_{\text{II}}^{1/2} (\bar{e}_{\text{II}} - \bar{e}_{\text{I}}) - n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} (\hat{\beta}_{\text{II}} - \beta_0) + n_{\text{II}}^{1/2} (\bar{y}_{\text{I}} - \bar{y}_0). \quad (11)$$

Here,  $n_{\rm II}^{1/2}(\bar{e}_{\rm II} - \bar{e}_{\rm I})$  represents the error of e in the phase-II sample conditional on the phase-I sample,  $n_{\rm II}^{1/2}(\bar{x}_{\rm II} - \bar{x}_{\rm I})^{\rm T}(\hat{\beta}_{\rm II} - \beta_0)$  is of order  $o_P(1)$ , and  $n_{\rm II}^{1/2}(\bar{y}_{\rm I} - \bar{y}_0)$  represents the error of y in the phase-I sample. The limiting distribution of  $\bar{y}_{\rm II,reg}$  is given in the following theorem.

**Theorem 2** Suppose Assumption 1 holds. Under TPRS in Definition 1, the regression estimator  $\bar{y}_{\text{II,reg}}$  in (10), has the following limiting distribution:

$$n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0) \mid \mathcal{F} \to \mathcal{N} \left\{ 0, f_{\rm II,I}(1 - f_{\rm I,0})V_{yy} + (1 - f_{\rm II,I})V_{ee} \right\},$$
 (12)

a.s., where  $V_{uv}$  is defined in (5),  $e = y - x^{T}\beta_{0}$ , and  $f_{II,I}$  and  $f_{I,0}$  are defined in Assumption 1.

Fuller (2009b) provided the consistency and asymptotic variance of the regression estimator under single phase rejective sampling, but did not include the asymptotic distribution results. The asymptotic distribution result in Theorem 2 complements Fuller (2009b)'s work, specifically by considering a census in phase I.

The limiting distribution of  $n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0) \mid \mathcal{F}$  in (12) under TPRS does not depend on  $\gamma^2$ , and as  $\gamma^2$  increases, it becomes equivalent to non-rejective sampling. This demonstrates the equivalence of the limiting distributions of  $\bar{y}_{\rm II,reg}$  with and without rejective sampling, aligning with Fuller (2009b), who found similar performance of regression estimators in single-phase samples regardless of rejective sampling.

Theorems 1 and 2 highlight the role of rejective sampling in estimation. When  $\gamma^2 \approx 0$ , the asymptotic design variance of the simple mean estimator  $\bar{y}_{\text{II}}$  is close to that of the two-phase regression estimator  $\bar{y}_{\text{II},\text{reg}}$ . That is, the simple mean estimator under rejective sampling performs similarly to the regression estimator.

If the two-phase regression estimator includes additional covariates (regressors) beyond the design covariates x, the results in Theorem 2 still apply by replacing x with the regressors, whether rejective sampling is used or not. Despite similar limiting properties with and without rejective sampling, Fuller (2009b) recommended rejective sampling for its practical

benefits. We can express the regression estimator as a weighted average of the  $y_i$ 's in the phase-II sample  $\bar{y}_{\text{II,reg}} = \sum_{i \in \mathcal{B}} \omega_i y_i$ , where

$$\omega_i = 1 + (\bar{x}_{\text{I}} - \bar{x}_{\text{II}})^{\text{T}} \left\{ \sum_{i \in \mathcal{B}} (x_i - \bar{x}_{\text{II}})^{\otimes 2} \right\}^{-1} (x_i - \bar{x}_{\text{II}})$$

are the weights. Without rejective sampling,  $\omega_i$  may be negative due to influential values of  $x_i$ , which can be a concern for survey statisticians. Rejective sampling reduces this chance, as demonstrated by simulation from Legg and Yu (2010) under single-phase sampling and further confirmed by our simulation under TPRS.

Moreover, rejective sampling improves phase-II sample representativeness, evidenced by a smaller asymptotic design variance of  $n_{\rm II}^{1/2}(\bar{x}_{\rm II} - \bar{x}_0)$  compared with designs without rejective sampling. Specially, under TPRS, the limit of the design covariance a.cov $\{n_{\rm II}^{1/2}(\bar{x}_{\rm II} - \bar{x}_0) \mid Q_{\rm I} < \gamma^2\} = \{(1 - f_{\rm II,I})v_{p,\gamma^2} + (f_{\rm II,I} - f_{\rm II,0})\}V_{xx}$  is always no larger than that without rejective sampling a.cov $\{n_{\rm II}^{1/2}(\bar{x}_{\rm II} - \bar{x}_0) \mid \mathcal{F}\} = (1 - f_{\rm II,0})V_{xx}$ .

#### 3.5 Inference: variance estimators and confidence intervals

To infer the population mean  $\bar{y}_0$  based on Theorems 1 and 2, we first estimate the asymptotic design variances and covariances. Let the estimator for  $V_{uv}$  be

$$\hat{V}_{uv} = \frac{1}{n_{\text{II}} - 1} \sum_{i \in \mathcal{B}} (u_i - \bar{u}_{\text{II}}) (v_i - \bar{v}_{\text{II}})^{\text{T}}.$$

**Proposition 1** Under Assumption 1,  $\hat{V}_{uv}$  is a consistent estimator of  $V_{uv}$  under both twophase simple random sampling and TPRS in Definition 1.

A consistent estimator for  $R^2$  is  $\hat{R}^2 = (\hat{V}_{yx}\hat{V}_{xx}^{-1}\hat{V}_{xy})/\hat{V}_{yy}$ . The variance estimator for  $\bar{y}_{II}$  under TPRS is

$$\frac{1}{n_{\rm II}} \left[ \left( 1 - \frac{n_{\rm II}}{n_{\rm I}} \right) \left\{ 1 - \left( 1 - v_{p,\gamma^2} \right) \hat{R}^2 \right\} + \frac{n_{\rm II}}{n_{\rm I}} \left( 1 - \frac{n_{\rm I}}{N} \right) \right] \hat{V}_{yy}.$$

Define  $\hat{e}_i = y_i - x_i^{\mathrm{T}} \hat{\beta}_{\mathrm{II}}$  for phase-II samples. Then, we can estimate  $V_{ee}$  by

$$\hat{V}_{ee} = \frac{1}{n_{\text{II}} - p - 1} \sum_{i \in \mathcal{B}} (\hat{e}_i - \bar{e}_{\text{II}})^2,$$

where  $n_{\rm II} - p - 1$  adjusts for degrees of freedom due to estimating  $\beta_0$ . Decompose  $V_{yy}$  into  $\beta_0^{\rm T} V_{xx} \beta_0 + V_{ee}$  and estimate it by  $\hat{V}_{yy} = \hat{\beta}_{\rm II}^{\rm T} \hat{V}_{xx} \hat{\beta}_{\rm II} + \hat{V}_{ee}$ . A consistent variance estimator for  $\bar{y}_{\rm II,reg}$  is

$$\hat{V}_{\text{reg}} = \frac{1}{n_{\text{II}}} \left\{ \frac{n_{\text{II}}}{n_{\text{I}}} \left( 1 - \frac{n_{\text{I}}}{N} \right) \hat{V}_{yy} + \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) \hat{V}_{ee} \right\}. \tag{13}$$

To construct the confidence interval, we define  $\nu_{\alpha}(R^2)$  as the 100 $\alpha$ th quantile of the distribution of

$$\left(1 - \frac{n_{\rm II}}{n_{\rm I}}\right)^{1/2} \left\{ RL_{p,\gamma^2} + \left(1 - R^2\right)^{1/2} Z_2 \right\} + \left\{ \frac{n_{\rm II}}{n_{\rm I}} \left(1 - \frac{n_{\rm I}}{N}\right) \right\}^{1/2} Z_3.$$

Because under TPRS,

$$P\left\{\nu_{\alpha/2}(\hat{R}^2)\hat{V}_{yy}^{1/2} \le n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}_0) \le \nu_{1-\alpha/2}(\hat{R}^2)\hat{V}_{yy}^{1/2}\right\} \to 1 - \alpha,$$

we can construct the asymptotic  $(1-\alpha)$  confidence interval of  $\bar{y}_0$  based on  $\bar{y}_{\rm II}$  as

$$\left(\bar{y}_{\rm II} - n_{\rm II}^{-1/2} \nu_{1-\alpha/2}(\hat{R}^2) \hat{V}_{yy}^{1/2}, \ \bar{y}_{\rm II} - n_{\rm II}^{-1/2} \nu_{\alpha/2}(\hat{R}^2) \hat{V}_{yy}^{1/2}\right).$$

Also, the asymptotic  $(1-\alpha)$  confidence interval of  $\bar{y}_0$  based on  $\bar{y}_{\rm II,reg}$  can be constructed as

$$\left(\bar{y}_{\mathrm{II,reg}} - n_{\mathrm{II}}^{-1/2} \hat{V}_{\mathrm{reg}}^{1/2} z_{1-\alpha/2}, \ \bar{y}_{\mathrm{II}} - n_{\mathrm{II}}^{-1/2} \hat{V}_{\mathrm{reg}}^{1/2} z_{\alpha/2}\right).$$

# 4 TPRS with general sampling

#### 4.1 Notation

We now consider two-phase sampling with general phase-I and II designs. Let  $\pi_{Ii}$  be the probability of including unit i in the phase-I sample  $\mathcal{A}$ , and let  $\pi_{IIi|\mathcal{A}}$  be the conditional probability of including unit i in the phase-II sample  $\mathcal{B}$  given that unit i is in the phase-I sample.

Define the finite population mean as  $\bar{u}_0 = N^{-1} \sum_{i=1}^{N} u_i$ . With slight abuse of the notation, define the phase-I estimator and the phase-II estimator as

$$\bar{u}_{\mathrm{I}} = \frac{1}{\sum_{i \in \mathcal{A}} \pi_{\mathrm{I}i}^{-1}} \sum_{i \in \mathcal{A}} \frac{u_i}{\pi_{\mathrm{I}i}},\tag{14}$$

and

$$\bar{u}_{\text{II}} = \frac{1}{\sum_{i \in \mathcal{B}} (\pi_{\text{II}i}^*)^{-1}} \sum_{i \in \mathcal{B}} \frac{u_i}{\pi_{\text{II}i}^*},\tag{15}$$

respectively. The phase-I estimator is a Hájek estimator for  $\bar{u}_0$ , while the phase-II estimator, known as the double expansion estimator (Kott and Stukel, 1997) or a  $\pi^*$  estimator (Särndal et al., 2003), is generally not a Hájek estimator for  $\bar{u}_0$  because  $\pi^*_{\text{II}i} = \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}$  is not the probability of i being selected for phase II in general as we discussed in Section 2.1.

To calculate the design variances for (14) and (15), we require positive second-order inclusion probabilities. The probabilities,  $\pi_{\text{I}ij} = P(i, j \in \mathcal{A} \mid \mathcal{F})$  and  $\pi_{\text{II}ij|\mathcal{A}} = P(i, j \in \mathcal{B} \mid i, j \in \mathcal{A})$ , determine the likelihood or the conditional likelihood of pairs of units being included in phase-I and phase-II samples, respectively.

Under suitable regularity conditions on sampling (with details in Section 4.2), the sums  $\sum_{i\in\mathcal{A}} \pi_{\mathrm{I}i}^{-1}$  and  $\sum_{i\in\mathcal{B}} (\pi_{\mathrm{II}i}^*)^{-1}$  are design consistent for the population size N. Using Taylor expansion and ignoring small order terms, the design covariance of  $\bar{u}_{\mathrm{I}}$  and  $\bar{v}_{\mathrm{I}}$  is

$$V_{uv,\mathcal{F}} = \operatorname{cov}(\bar{u}_{I}, \bar{v}_{I} \mid \mathcal{F}) = \frac{1}{N^{2}} \sum_{i=1}^{N} \sum_{j=1}^{N} \frac{\pi_{Iij} - \pi_{Ii}\pi_{Ij}}{\pi_{Ii}\pi_{Ij}} (u_{i} - \bar{u}_{0})(v_{j} - \bar{v}_{0})^{\mathrm{T}},$$
(16)

and the conditional design covariance of  $\bar{u}_{\rm II}$  and  $\bar{v}_{\rm II}$  given the phase-I sample is

$$V_{uv,I} = \operatorname{cov}\left(\bar{u}_{II}, \bar{v}_{II} \mid \mathcal{A}, \mathcal{F}\right) = \frac{1}{N^2} \sum_{i \in \mathcal{A}} \sum_{j \in \mathcal{A}} \frac{\pi_{IIij|\mathcal{A}} - \pi_{IIi|\mathcal{A}} \pi_{IIj|\mathcal{A}}}{\pi_{IIi}^* \pi_{IIj}^*} (u_i - \bar{u}_I)(v_j - \bar{v}_I)^{\mathrm{T}}.$$
(17)

We assume that  $V_{xx,0}$  and  $V_{xx,I}$  are positive definite for all phase-I samples.

#### 4.2 TPRS with general sampling

We define TPRS with general sampling designs as follows.

**Definition 2 (TPRS with general sampling)** TPRS with general sampling consists of two steps:

- Step 1. Select a phase-I sample A of size  $n_I$  by a general  $\pi$  sampling with the inclusion probability  $\pi_{Ii}$ . For  $i \in A$ , record  $x_i$ .
- Step 2. Treat the phase-I sample A as the population and select a phase-II sample B of size  $n_{\text{II}}$  by a general  $\pi$  sampling with the conditional inclusion probability  $\pi_{\text{II}i|A}$ . Accept the phase-II sample if

$$Q_{\rm I} = (\bar{x}_{\rm II} - \bar{x}_{\rm I})^{\rm T} V_{xx,\rm I}^{-1} (\bar{x}_{\rm II} - \bar{x}_{\rm I}) < \gamma^2,$$

where  $\gamma^2 > 0$  is a pre-specified constant, and  $V_{xx,I}$  is the design variance of  $\bar{x}_{II} - \bar{x}_{I}$  given  $\mathcal{A}$ , given by (17) with u and v being x. For  $i \in \mathcal{B}$ , record  $y_i$ .

For the population mean  $\bar{y}_0$ , the  $\pi^*$  estimator is

$$\bar{y}_{\text{II}} = \frac{1}{\sum_{i \in \mathcal{B}} (\pi_{\text{II}i}^*)^{-1}} \sum_{i \in \mathcal{B}} \frac{y_i}{\pi_{\text{II}i}^*},\tag{18}$$

recalling that  $\pi_{\text{II}i}^* = \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}$ . We focus on the  $\pi^*$  estimator for simplicity because the REE is more natural for two-phase stratified sampling. Below we will show that integrating the  $\pi^*$  estimator with TPRS suffices to attain favorable design properties.

#### 4.3 Large-sample design properties

To understand the limiting properties of  $\bar{y}_{\text{II}}$ , we follow the asymptotic framework in Section 3 and specify the following regularity conditions for TPRS in Definition 2.

Assumption 2 Assumption 1(i) and (ii) hold. (iii) The phase-I estimator (14) satisfies

$$\operatorname{var}(\hat{u}_{\mathrm{I}} \mid \mathcal{F})^{-1/2}(\hat{u}_{\mathrm{I}} - \bar{u}_{0}) \mid \mathcal{F} \to \mathcal{N}(0, 1) \text{ a.s.},$$

and  $var(n_{\rm I}^{1/2}\hat{u}_{\rm I} \mid \mathcal{F}) = O_P(1);$ 

(iv) The sequence of phase-I selection probabilities are bounded by  $K_{I,L} < n_I^{-1} N \pi_{Ii} < K_{I,U}$  for all i, for some positive  $K_{I,L} > 0$  and  $K_{I,U} > 0$ , and the design weighted sums of moments coverage to constants,

$$\lim_{N \to \infty} \sum_{i \in A} \pi_{\mathrm{I}i}^{-1}(1, x_i^{\mathrm{T}}, y_i, y_i^2)^{\mathrm{T}}(1, x_i^{\mathrm{T}}, y_i, y_i^2) = M_{\mathrm{I}} \text{ a.s.},$$

where  $M_{\rm I}$  is a matrix of constants.

(v) The phase-II estimator (14) satisfies

$$var(\hat{u}_{II} \mid \mathcal{A}, \mathcal{F})^{-1}(\hat{u}_{II} - \bar{u}_{I}) \mid \mathcal{A}, \mathcal{F} \rightarrow \mathcal{N}(0, 1) \text{ a.s.},$$

and  $\operatorname{var}(n_{\operatorname{II}}^{1/2}\hat{u}_{\operatorname{II}} \mid \mathcal{A}, \mathcal{F}) = O_P(1);$ 

(vi) The sequence of phase-II selection probabilities are bounded by  $K_{II,L} < n_{II}^{-1} n_I \pi_{IIi|\mathcal{A}} < K_{II,U}$  for all i, for some positive  $K_{II,L} > 0$  and  $K_{II,U} > 0$ , and the design weighted sums of

moments coverage to constants,

$$\lim_{N \to \infty} \sum_{i \in \mathcal{B}} \pi_{\text{II}i|\mathcal{A}}^{-1}(1, x_i^{\text{T}}, y_i, y_i^2)^{\text{T}}(1, x_i^{\text{T}}, y_i, y_i^2) = M_{\text{II}} \text{ a.s.},$$

where  $M_{\rm II}$  is a matrix of constants.

(vii) The design covariance between the differences in x and e in phases I and II is negligible:  $cov(\bar{x}_{II} - \bar{x}_{I}, \bar{e}_{II} - \bar{e}_{I} \mid \mathcal{A}, \mathcal{F}) = o_{P}(n_{II}^{-1}).$ 

These conditions in Assumption 2 are standard for sample moments and sampling designs (Fuller, 2009a, Theorem 3.3.1). They ensure the general applicability of the phase-I and phase-II estimators across various designs (Chapter 3, Fuller, 2009a). For instance, Assumption 2(vii) holds under two-phase simple random sampling and stratified sampling. Below, we provide a heuristic explanation. Let  $r_i = y_i - x_i^{\mathrm{T}} \hat{\beta}_{\mathrm{I}}$  be the residual based on the phase-I regression had the study variables been measured in the phase-I sample, where  $\hat{\beta}_{\mathrm{I}} = \{\sum_{i \in \mathcal{A}} \pi_{\mathrm{I}i}^{-1} (x_i - \bar{x}_{\mathrm{I}})^{\otimes 2}\}^{-1} \sum_{i \in \mathcal{A}} \pi_{\mathrm{I}i}^{-1} (x_i - \bar{x}_{\mathrm{I}}) (y_i - \bar{y}_{\mathrm{I}})$  is the phase-I regression coefficient. Then, we have  $\operatorname{cov}(\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}}, \bar{r}_{\mathrm{II}} - \bar{r}_{\mathrm{I}} \mid \mathcal{A}, \mathcal{F}) = 0$ . Recall that  $e_i = y_i - x_i^{\mathrm{T}} \beta_0$ , which can be written as  $e_i = r_i + x_i^{\mathrm{T}} (\hat{\beta}_{\mathrm{I}} - \beta_0)$ . Thus, we have

$$cov(\bar{x}_{II} - \bar{x}_{I}, \bar{e}_{II} - \bar{e}_{I} \mid \mathcal{A}, \mathcal{F}) = cov(\bar{x}_{II} - \bar{x}_{I}, \bar{e}_{II} - \bar{e}_{I} \mid \mathcal{A}, \mathcal{F})$$

$$= cov(\bar{x}_{II} - \bar{x}_{I}, \bar{r}_{II} - \bar{r}_{I} \mid \mathcal{A}, \mathcal{F})$$

$$+ cov\{\bar{x}_{II} - \bar{x}_{I}, (\bar{x}_{II} - \bar{x}_{I})^{\mathrm{T}}(\hat{\beta}_{I} - \beta_{0}) \mid \mathcal{A}, \mathcal{F}\}$$

$$= var(\bar{x}_{II} - \bar{x}_{I} \mid \mathcal{A}, \mathcal{F})(\hat{\beta}_{I} - \beta_{0}). \tag{19}$$

Because  $\operatorname{var}(\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}} \mid \mathcal{A}, \mathcal{F}) = O_{P}(n_{\mathrm{II}}^{-1})$  a.s., where the probability distribution in  $O_{P}$  is induced by phase-II sampling given  $(\mathcal{A}, \mathcal{F})$ , and  $\hat{\beta}_{\mathrm{I}} - \beta_{0} = O_{P}(n_{\mathrm{I}}^{-1})$ , where the probability distribution in  $O_{P}$  is induced by phase-I sampling, the quantity in (19) is of order  $o_{P}(n_{\mathrm{II}}^{-1})$ .

Following the decomposition in (6), we decompose  $n_{\rm II}^{1/2}(\bar{y}_{\rm II}-\bar{y}_0)$  into three components

$$n_{\rm II}^{1/2} \left( \bar{y}_{\rm II} - \bar{y}_0 \right) = T_1 + T_2 + T_3, \tag{20}$$

where  $T_1 = n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \beta_0$ ,  $T_2 = n_{\text{II}}^{1/2} (\bar{e}_{\text{II}} - \bar{e}_{\text{I}})$ , and  $T_3 = n_{\text{II}}^{1/2} (\bar{y}_{\text{I}} - \bar{y}_{0})$  with the general  $\pi$  estimators for  $\bar{u}_{\text{I}}$  and  $\bar{u}_{\text{II}}$  defined in (14) and (15), respectively. The limiting distribution of  $(T_1, T_2, T_3)$  is given in the following lemma.

**Lemma 2** Suppose Assumption 2 holds. Under TPRS in Definition 2, the joint distribution of  $(T_1, T_2, T_3)$  in the decomposition (20) has the following limiting distribution:

$$\begin{pmatrix}
T_1 \\
T_2 \\
T_3
\end{pmatrix} \middle| \mathcal{F} \to \mathcal{N} \left\{ \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} V_1, & 0 & 0 \\ 0 & V_2 & 0 \\ 0 & 0 & V_3 \end{pmatrix} \right\},$$

a.s. for all sequences of finite populations, where

$$V_1 = \lim_{N \to \infty} n_{\text{II}} \beta_0^{\text{T}} E(V_{xx,\text{I}} \mid \mathcal{F}) \beta_0, \qquad (21)$$

$$V_2 = \lim_{N \to \infty} n_{\text{II}} E\left(V_{ee,\text{I}} \mid \mathcal{F}\right), \tag{22}$$

$$V_3 = \lim_{N \to \infty} n_{\text{II}} V_{yy,0}. \tag{23}$$

By construction, the distribution of  $n_{\rm II}^{1/2}(\bar{y}_{\rm II}-\bar{y}_0)$  under TPRS in Definition 2 is equivalent to the distribution of  $n_{\rm II}^{1/2}(\bar{y}_{\rm II}-\bar{y}_0)\mid (Q_{\rm I}<\gamma^2)$  without rejective sampling. To study the asymptotic design property, we define  $D_{\rm I}=(n_{\rm II}V_{xx,\rm I})^{-1/2}n_{\rm II}^{1/2}(\bar{x}_{\rm II}-\bar{x}_{\rm I})$ . Then,  $Q_{\rm I}$  is expressed as  $D_{\rm I}^{\rm T}D_{\rm I}$ , with  $D_{\rm I}\to\mathcal{N}(0,I_p)$  and thus  $D_{\rm I}^{\rm T}D_{\rm I}\to\chi_p^2$  a.s..

**Theorem 3** Suppose Assumption 2 holds. Under TPRS in Definition 2,

$$n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}_0) \mid (Q_{\text{I}} < \gamma^2) \to V_1^{1/2} L_{p,\gamma^2} + V_2^{1/2} Z_1 + V_3^{1/2} Z_2,$$
 (24)

where  $V_1$ ,  $V_2$ , and  $V_3$  are defined in (21)–(23),  $Z_1$  and  $Z_2$  are standard normal variables, and

 $(L_{p,\gamma^2}, Z_1, Z_2)$  are jointly independent.

The results of TPRS with general sampling are similar to those of TPRS with simple random sampling, hence inheriting all the benefits, including reduced variance and quantile range and enhanced representativeness, as detailed in Section 3.

#### 4.4 Regression estimator

Integrating the design and analysis strategies, the two-phase regression estimator for  $\bar{y}_0$  is

$$\bar{y}_{\mathrm{II,reg}} = \bar{y}_{\mathrm{II}} - (\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}})^{\mathrm{T}} \hat{\beta}_{\mathrm{II}},$$

where

$$\hat{\beta}_{\text{II}} = \left\{ \sum_{i \in \mathcal{B}} \frac{\left(x_i - \bar{x}_{\text{II}}\right)^{\otimes 2}}{\pi_{\text{II}i}^*} \right\}^{-1} \sum_{i \in \mathcal{B}} \frac{\left(x_i - \bar{x}_{\text{II}}\right)\left(y_i - \bar{y}_{\text{II}}\right)}{\pi_{\text{II}i}^*}$$

is the regression coefficient based on the phase-II sample.

**Theorem 4** Suppose Assumption 2 holds. Under TPRS in Definition 2,

$$n_{\mathrm{II}}^{1/2}(\bar{y}_{\mathrm{II,reg}} - \bar{y}_{0}) \mid \mathcal{F} \to \mathcal{N}\left(0, V_{\mathrm{II,reg}}\right),$$

a.s. for all sequences of finite populations, where

$$V_{\text{II,reg}} = \lim_{N \to \infty} n_{\text{II}} \left\{ V_{yy,0} + E \left( V_{ee,\text{I}} \mid \mathcal{F} \right) \right\}$$

with  $V_{yy,0}$  and  $V_{ee,I}$  defined in (16) and (17), respectively.

Theorem 4 indicates that the advantages of TPRS are also applicable to the regression estimator in a general setup.

Remark 1 Estevao and Särndal (2010) proposed using auxiliary variables in the analysis stage through two-stage calibration in two-phase sampling. They noted that, with the generalized least squares distance in calibration, the calibration estimator matches the two-phase

regression estimator. Deville and Särndal (1992) demonstrated that calibration estimators are asymptotically equivalent across various distance metrics. Based on this, we hypothesize that calibration estimators in two-phase sampling, with or without rejective sampling, share similar limiting distributions. The practical advantage of rejective sampling is to yield a more representative sample by design.

#### 4.5 Inference: variance estimators and confidence intervals

We estimate the asymptotic design variances of  $\bar{y}_{\text{II}}$  and  $\bar{y}_{\text{II,reg}}$  in general TPRS. For  $\bar{y}_{\text{II}}$ , the variance is estimated by  $n_{\text{II}}^{-1}(\hat{V}_1 v_{p,\gamma^2} + \hat{V}_2 + \hat{V}_3)$ , where

$$\hat{V}_{1} = n_{\text{II}} \hat{\beta}_{\text{II}}^{\text{T}} V_{xx,\text{I}} \hat{\beta}_{\text{II}},$$

$$\hat{V}_{2} = \frac{n_{\text{II}}}{N^{2}} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}} \pi_{\text{II}j|\mathcal{A}}}{\pi_{\text{II}i}^{*} \pi_{\text{II}j}^{*}} \frac{(\hat{e}_{i} - \hat{e}_{\text{II}})(\hat{e}_{j} - \hat{e}_{\text{II}})^{\text{T}}}{\pi_{\text{II}ij|\mathcal{A}}},$$

$$m_{\text{II}} = \pi_{\text{II}} = \pi_{\text{II}} \pi_{\text{II}ij} (u_{\text{I}} - \bar{u}_{\text{II}})^{\text{T}}$$

$$m_{\text{II}} = \pi_{\text{II}} \pi_{\text{II}ij|\mathcal{A}} (u_{\text{I}} - \bar{u}_{\text{II}})^{\text{T}}$$
(25)

$$\hat{V}_{3} = \frac{n_{\text{II}}}{N^{2}} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{\text{I}ij} - \pi_{\text{I}i}\pi_{\text{I}j}}{\pi_{\text{I}i}\pi_{\text{I}j}} \frac{(y_{i} - \bar{y}_{\text{II}})(y_{j} - \bar{y}_{\text{II}})^{\text{T}}}{\pi_{\text{I}ij}\pi_{\text{II}ij}|\mathcal{A}},$$
(26)

and  $\hat{e}_i = y_i - x_i^{\mathrm{T}} \hat{\beta}_{\mathrm{II}}$  and  $\hat{e}_{\mathrm{II}}$  are (18) with  $y_i$  being  $\hat{e}_i$ . For  $\bar{y}_{\mathrm{II},\mathrm{reg}}$ , the variance is estimated by  $n_{\mathrm{II}}^{-1}(\hat{V}_2 + \hat{V}_3)$ .

Remark 2 Regarding variance estimation in two-phase sampling, two points are noteworthy. First, obtaining the joint inclusion probabilities  $\pi_{\text{I}ij}$  and  $\pi_{\text{II}ij}|_{\mathcal{A}}$  may be difficult in practice, and approximations may be needed. For example, Haziza and Beaumont (2005) and Beaumont et al. (2015) considered a simplified variance estimator which does not require the information on  $\pi_{\text{II}ij}|_{\mathcal{A}}$  and specified conditions under which the bias of the variance estimator is negligible.

Second, while Horvitz-Thompson-type variance estimators (25) and (26) are standard, they can be unstable and negative in unequal probability sampling. An alternative is the

Sen-Yates-Grundy-type (Sen, 1953, Yates and Grundy, 1953) variance estimators

$$\hat{V}_{2,SYG} = -\frac{1}{2} \frac{n_{II}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{IIij|\mathcal{A}} - \pi_{IIij|\mathcal{A}}}{\pi_{IIij|\mathcal{A}}} \left( \frac{\hat{e}_i - \hat{e}_{II}}{\pi_{IIi}^*} - \frac{\hat{e}_j - \hat{e}_{II}}{\pi_{IIj}^*} \right)^{\otimes 2}, \quad (27)$$

$$\hat{V}_{3,SYG} = -\frac{1}{2} \frac{n_{II}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \left( \pi_{Iij} - \pi_{Ii} \pi_{Ij} \right) \left( \frac{y_i - \bar{y}_{II}}{\pi_{Ii}} - \frac{y_j - \bar{y}_{II}}{\pi_{Ij}} \right)^{\otimes 2}.$$
(28)

These estimators are asymptotically equivalent to  $\hat{V}_2$  and  $\hat{V}_3$  with additional mean zero terms but are more stable and non-negative for various sampling designs with fixed sample sizes (Hidiroglou et al., 2009).

To construct confidence intervals, we define  $\nu_{\alpha}(V_1, V_2, V_3)$  as the  $100\alpha$ th quantile of the distribution of  $V_1^{1/2}L_{p,\gamma^2} + V_2^{1/2}Z_1 + V_3^{1/2}Z_2$ . Because under TPRS,

$$P\left\{\nu_{\alpha/2}(\hat{V}_1, \hat{V}_2, \hat{V}_3) \le n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}_0) \le \nu_{1-\alpha/2}(\hat{V}_1, \hat{V}_2, \hat{V}_3)\right\} \to 1 - \alpha,$$

the asymptotic  $(1-\alpha)$  confidence interval for  $\bar{y}_0$  based on  $\bar{y}_{\rm II}$  can be constructed as

$$\left(\bar{y}_{\rm II} - n_{\rm II}^{-1/2} \nu_{1-\alpha/2}(\hat{V}_1, \hat{V}_2, \hat{V}_3), \ \bar{y}_{\rm II} - n_{\rm II}^{-1/2} \nu_{\alpha/2}(\hat{V}_1, \hat{V}_2, \hat{V}_3)\right).$$

Also, the asymptotic  $(1-\alpha)$  confidence interval for  $\bar{y}_0$  based on  $\bar{y}_{\rm II,reg}$  can be constructed as

$$\left(\bar{y}_{\rm II,reg} - n_{\rm II}^{-1/2} \left(\hat{V}_2 + \hat{V}_3\right)^{1/2} z_{1-\alpha/2}, \ \bar{y}_{\rm II,reg} - n_{\rm II}^{-1/2} \left(\hat{V}_2 + \hat{V}_3\right)^{1/2} z_{\alpha/2}\right).$$

# 5 Extensions

When covariates have varying importance, applying different thresholds for different covariates in rejective sampling can be more effective. Legg and Yu (2010) explored two approaches for this: weighted rejective sampling and sequential rejective sampling, with the former also studied by Lu et al. (2023) and the latter by Morgan and Rubin (2015) and Li et al. (2018)

in rerandomization in experiments. We further develop sequential rejective sampling in twophase sampling in Section S1 of the supplementary material and demonstrate that it provides better balance control for each specific covariate compared with weighted rejective sampling.

As a natural extension, we introduce multi-phase rejective sampling and establish asymptotic design properties of the double expansion estimator and the regression estimator in Section S2 of the supplementary material. As a special case, if phase I is a census, the three-phase rejective sampling becomes equivalent to TPRS with rejective sampling in both phases.

In both sequential and multi-phase rejective sampling methods, we employ block-wise Gram-Schmidt orthogonalization on tiers or phases of covariates. This strategy ensures a clear distinction between various sets of covariates, categorizing them according to their level of importance or their availability across different phases.

# 6 Empirical studies

We evaluate the finite-sample performance of rejective sampling through simulations. We first apply the TPRS with simple random sampling in Section 6.1. We then apply the three-phase rejective sampling based on an actual study in Section 6.2 to showcase the effectiveness of multiple phases.

# 6.1 TPRS with simple random sampling

Consider the finite population with bivariate data  $\{(x_i, y_i) : i = 1, ..., N = 10^5\}$ , where  $x_i \sim 0.5^{1/2}(\chi_1^2 - 1)$  and  $y_i = 1 + \beta x_i + e_i$  with  $e_i \sim \mathcal{N}(0, 1)$  and  $\beta \in \{0.5, 1, 2\}$ . This setup yields  $R^2 = \beta^2/(\beta^2 + 1)$  values of  $\{0.2, 0.5, 0.8\}$ .

We implement two-phase simple random sampling with phase-I and phase-II sample sizes of  $n_{\rm I} = 5,000$  and  $n_{\rm II} = 200$ , respectively, and the corresponding TPRS with various  $\gamma^2 \in \{0.01, 0.05, 0.1\}$ . We compare the mean estimators  $\bar{y}_{\rm II}$  and  $\bar{y}_{\rm II,reg}$  in both sampling

Figure 1: Comparison of the simple mean estimator and the regression estimator under two-phase simple random sampling and rejective sampling with  $R^2 \in \{0.2, 0.5, 0.8\}$ 

scenarios.

We summarize the results in Figures 1 and 2 and Tables 2 and 3. In all scenarios,  $\bar{y}_{\rm II}$  with rejective sampling improves the efficiency of  $\bar{y}_{\rm II}$  without rejective sampling with the percentage of variance reduction increases with  $R^2$  and decreases with  $\gamma^2$ , which is cohesive with our theoretical results in Theorem 1 and Corollary 1. Table 3 presents the theoretical values of percentage of variance reduction (9) under the simulation setup. The results in Table 2 are consistent with that in Table 3. The performance of  $\bar{y}_{\rm II}$  with rejective sampling is close to that of  $\bar{y}_{\rm II,reg}$ , and the results for  $\bar{y}_{\rm II,reg}$  in both rejective and non-rejective samples are similar, aligning with our theoretical results in Theorem 2. Moreover, the regression weights in  $\bar{y}_{\rm II,reg}$  can be negative for 30 simulated datasets under two-phase non-rejective sampling; however, the regression weights are always positive with rejective sampling in this simulation setting. This demonstrates the practical value of rejective sampling. Additionally, our variance estimators and confidence intervals, based on the asymptotic variance formula, prove accurate in both variance estimation and coverage rates, as evidenced in Table 3 and Figure 2.

Table 2: Simulation results based on 1,000 Monte Carlo samples: bias ( $\times 10^{-2}$ ), variance ( $\times 10^{-3}$ ), mean variance estimator ( $\times 10^{-3}$ ), percentage of variance reduction of the estimator under rejective sample compared to the corresponding estimator under two phase sample random sampling, variance estimate ( $\times 10^{-3}$ ) and coverage rate for 95% confidence intervals calculated based on the asymptotic variance formula.  $R^2 = \beta^2/(\beta^2 + 1) \in \{0.2, 0.5, 0.8\}$ .

# 6.2 Three-phase sampling based on the Academic Performance Index data

To demonstrate the practical relevance, we use the Academic Performance Index (API) data. The full population data consist of 6, 194 observations for all California schools with at least 100 students based on standardized testing of students. We use the API in 2000 as the study variable y, the API in 1999 as the auxiliary variable x, and the percentage of English Language Learners, the percentage of students eligible for subsidized meals, the percentage of students for whole this is the first year at the school as additional auxiliary variable z in both the design and analysis stages. The parameter of interest is the population mean of the API in 2000.

We employed three-phase sampling designs. We select a phase-I sample  $\mathcal{A}$  of size  $n_{\rm I}=2000$  by simple random sampling. For  $i\in\mathcal{A}$ , we observe  $x_i$ . We select a phase-II sample  $\mathcal{B}$  of size  $n_{\rm II}$  by Poisson sampling with  $\pi_{\rm IIi}=p_{\rm IIi}E(n_{\rm II})$ , where  $E(n_{\rm II})$  is the expected sample size of the phase-II sample,  $p_{\rm IIi}\propto x_i$  and  $\sum_{i\in\mathcal{A}}p_{\rm IIi}=1$ . For  $i\in\mathcal{B}$ , we observe  $z_i$  and calculate  $a_i=z_i-\bar{z}_{\rm II}-(x_i-\bar{x}_{\rm II})^{\rm T}\hat{\beta}_{zx,\rm II}$ . We select a phase-III sample  $\mathcal{C}$  by Poisson sampling

with  $\pi_{\text{III}i} = p_{\text{III}i}E(n_{\text{III}})$ , where  $E(n_{\text{III}})$  is the expected sample size of the phase-III sample,  $p_{\text{III}i}$  is proportional to the summation of components in  $z_i$  and  $\sum_{i \in \mathcal{B}} p_{\text{III}i} = 1$ . For  $i \in \mathcal{C}$ , we observe  $y_i$ . We consider the above three-phase sampling without rejective sampling and with rejective sampling described in Section S2.2. We consider the impact of the number of phases, phase sample sizes  $E(n_{\text{II}})$  and  $E(n_{\text{III}})$ , constraints  $\gamma_1^2$  and  $\gamma_2^2$ . For comparison, we also consider two-phase sampling designs. In a two-phase sampling, we assume that the outcome is measured for the phase-II samples. This may be more costly than the three-phase sampling.

Simulation results, summarized in Figures 3 and 4, show that phase-II estimators are more efficient due to more information collection, but phase-III designs might provide greater cost-effectiveness. For instance, phase-II rejective regression estimators with an average sample size of  $n_{\rm II}=500$  had a variance of 5.4, compared with phase-III estimators with a smaller average sample size of  $n_{\rm III}=100$  but a higher variance of 15.9. This implies that multiple phases can achieve desired variances with smaller samples. The efficiency of rejective regression estimators improves with tighter constraints  $\gamma_1^2$  and  $\gamma_2^2$ , especially  $\gamma_2^2$ . Increasing the phase-II sample size showed minimal impact on the efficiency of phase-III estimator. The coverage rates of the confidence intervals align well with the nominal level, confirming our results on the asymptotic distributions.

Table 4 shows that rejective sampling enhances the representativeness of covariates and regression weights compared with non-rejective sampling. This was determined by calculating the average  $\bar{z}_{\rm III}$  from phase-III samples, both with and without rejective sampling, across 5,000 Monte Carlo simulations. The results indicated significantly lower empirical variance for all covariates with rejective sampling. Additionally, tighter constraints  $\gamma_1^2$  and  $\gamma_2^2$  further improve covariate representativeness. Moreover, the absence of rejective sampling increases the likelihood of negative regression weights.

### 7 Discussion

We focused on a scalar outcome, and extending these findings to a vector outcome is straightforward. Our current approach to constructing variance estimators and confidence intervals relies on asymptotic distributions. In survey contexts, replication variance estimation is often used. Fuller et al. (2017) have recently innovated a bootstrap variance estimation method for single-phase rejective sampling. The development of a replication variance estimation methodology for multi-phase rejective sampling will be addressed in a separate paper.

# Supplementary material for "Two-phase rejective sampling"

Section S1 describes sequential rejective sampling with tiers of covariates. Section S2 presents multi-phase rejective sampling. Section S3 provides all proofs.

# S1 Sequential rejective sampling with tiers of covariates

Decompose covariate x into K tiers of varying importance, denoted by  $(x[1], \ldots, x[K])$ , each x[k] having dimension p[k]. Let  $x[\overline{k}] = (x[1], \ldots, x[k])$ . It is convenient to apply the blockwise Gram–Schmidt orthogonalization to the covariates: construct  $g = (g[1], \ldots, g[K])$  from g[1] = x[1], and

$$g[k] = x[k] - V_{x[k]x[\overline{k-1}],\mathbf{I}} \left( V_{x[\overline{k-1}]x[\overline{k-1}],\mathbf{I}} \right)^{-1} x[\overline{k-1}]$$

for k = 2, ..., K. We assume  $\operatorname{cov}(\bar{g}_{\text{II}}[k], \bar{g}_{\text{II}}[l] \mid \mathcal{A}) = o_P(n_{\text{II}}^{-1})$  a.s. for  $k \neq l$  under suitable regularity conditions. See the discussion of Assumption 2(vii) in the main paper. For each tier k, we can impose a threshold  $\omega_k^{-1}\gamma^2$ , where  $\gamma^2$  is a positive constant and  $\omega_k$  is the weight for tier k, with higher  $\omega_k$  indicating a stricter threshold.

We define two-phase sequential rejective sampling (TPSRS) as follows.

**Definition S1 (TPSRS with general sampling)** TPSRS with general sampling consists of two steps:

- Step 1. Select a phase-I sample A of size  $n_I$  by a general  $\pi$  sampling with the inclusion probability  $\pi_{Ii}$ . For  $i \in A$ , record  $x_i$ .
- Step 2. Treat the phase-I sample A as the population and select a phase-II sample B of size  $n_{II}$  by a general  $\pi$  sampling with the conditional inclusion probability  $\pi_{IIi|A}$  given unit i is in the phase-I sample. Accept the phase-II sample if

$$Q_{\rm I}[k] = (\bar{g}_{\rm II}[k] - \bar{g}_{\rm I}[k])^{\rm T} V_{g[k]g[k],{\rm I}}^{-1}(\bar{g}_{\rm II}[k] - \bar{g}_{\rm I}[k]) < \omega_k^{-1} \gamma^2, \ (1 \le k \le K), \tag{S1}$$

done sequentially from tier 1 to K. For  $i \in \mathcal{B}$ , record  $y_i$ .

Remark S3 In a weighted rejective sampling, we accept the phase-II sample if

$$\sum_{k=1}^{K} \omega_k Q_{\mathrm{I}}[k] < K\gamma^2, \tag{S2}$$

where the  $\omega_k$ 's may be different from the ones in the sequential rejective sampling as in (S1).

Sequential rejective sampling, unlike weighted rejective sampling, ensures balance across all tiers, as it requires each tier to individually meet its threshold. Weighted rejective sampling is less stringent, allowing some tiers to be poorly balanced if others are well balanced. The limiting distributions of  $\bar{y}_{II}$  and  $\bar{y}_{II,reg}$  under weighted rejective sampling (S2) are more challenging to characterize (Lu et al., 2023).

To study the limiting properties of  $\bar{y}_{\text{II}}$ , let  $\beta_{gy}$  be the probability limit of  $V_{gg,\text{I}}^{-1}V_{gy,\text{I}}$ . By the Gram–Schmidt orthogonalization,  $V_{gg,\text{I}}$  is a diagonal matrix with the kth block diagonal component  $V_{g[k]g[k],\text{I}}$ . We decompose  $\beta_{gy}$  as  $\beta_{gy} = (\beta_{g[1]y}, \dots, \beta_{g[K]y})$  with  $\beta_{g[k]y}$  being the probability of  $V_{g[k]g[k],\text{I}}^{-1}V_{g[k]y,\text{I}}$ . The decomposition of  $\bar{y}_{\text{II}} - \bar{y}_{0}$  then becomes

$$\begin{split} \bar{y}_{\text{II}} - \bar{y}_{0} &= (\bar{g}_{\text{II}} - \bar{g}_{\text{I}})^{\text{\tiny T}} \beta_{gy} + \{\bar{y}_{\text{II}} - \bar{y}_{\text{I}} - (\bar{g}_{\text{II}} - \bar{g}_{\text{I}})^{\text{\tiny T}} \beta_{gy}\} + \bar{y}_{\text{I}} - \bar{y}_{0} \\ &= \sum_{k=1}^{K} (\bar{g}_{\text{II}}[k] - \bar{g}_{\text{I}}[k])^{\text{\tiny T}} \beta_{g[k]y} + \{\bar{y}_{\text{II}} - \bar{y}_{\text{I}} - (\bar{g}_{\text{II}} - \bar{g}_{\text{I}})^{\text{\tiny T}} \beta_{gy}\} + \bar{y}_{\text{I}} - \bar{y}_{0}. \end{split}$$

Let  $D_{\mathrm{I}}[k] = V_{g[k]g[k],\mathrm{I}}^{-1/2}(\bar{g}_{\mathrm{II}}[k] - \bar{g}_{\mathrm{I}}[k])$ , then  $D_{\mathrm{I}}[k] \to \mathcal{N}(0,I_{p[k]})$ . For any  $k \neq l$ ,  $\bar{g}_{\mathrm{II}}[k] - \bar{g}_{\mathrm{I}}[k]$  and  $\bar{g}_{\mathrm{II}}[l] - \bar{g}_{\mathrm{I}}[l]$  are asymptotically independent given  $\mathcal{A}$  a.s.. Therefore,

$$\sum_{k=1}^{K} (\bar{g}_{\text{II}}[k] - \bar{g}_{\text{I}}[k])^{\text{T}} \beta_{g[k]y} \mid (D_{\text{I}}^{\text{T}}[k]D_{\text{I}}[k] < \omega_k^{-1} \gamma^2 : 1 \le k \le K)$$

has the same limiting distribution of

$$\sum_{k=1}^{K} (\bar{g}_{\text{II}}[k] - \bar{g}_{\text{I}}[k])^{\text{T}} \beta_{g[k]y} \mid (D_{\text{I}}^{\text{T}}[k] D_{\text{I}}[k] < \omega_k^{-1} \gamma^2).$$

Theorem S5 below describes the limiting distributions of  $\bar{y}_{\text{II}}$  and  $\bar{y}_{\text{II},\text{reg}}$  under TPSRS with general sampling.

**Theorem S5** Suppose Assumption 2 holds. Under TPSRS in Definition S1,

$$n_{\text{II}}^{1/2}(\bar{y}_{\text{II}} - \bar{y}) \mid \left(D_{\text{I}}^{\text{T}}[k]D_{\text{I}}[k] < \omega_{k}^{-1}\gamma^{2} : 1 \leq k \leq K\right) \rightarrow \sum_{k=1}^{K} V_{1}^{1/2}[k]L_{p[k],\omega_{k}^{-1}\gamma^{2}} + V_{2}^{1/2}Z_{1} + V_{3}^{1/2}Z_{2}, \tag{S3}$$

where  $V_1[k] = \lim_{n_{\text{II}} \to \infty} n_{\text{II}} \beta_{g[k]y}^{\text{T}} E(V_{g[k]g[k],\text{I}} \mid \mathcal{F}) \beta_{g[k]y}$ ,  $V_2$  and  $V_3$  are defined in (22) and (23), respectively,  $Z_1$  and  $Z_2$  are independent standard normal variables, and  $(L_{p[k],\omega_k^{-1}\gamma^2}, Z_1, Z_2)$  are jointly independent. Moreover,

$$n_{\mathrm{II}}^{1/2}(\bar{y}_{\mathrm{II,reg}} - \bar{y}_0) \mid (D_{\mathrm{I}}^{\mathrm{T}}[k]D_{\mathrm{I}}[k] < \omega_k^{-1}\gamma^2 : 1 \le k \le K) \to V_2^{1/2}Z_1 + V_3^{1/2}Z_2.$$

# S2 Multi-phase rejective sampling

#### S2.1 Notation

We extend our theory to multi-phase rejective sampling. To simplify the presentation, we discuss three-phase sampling below. Let  $\pi_{\text{I}i}$ ,  $\pi_{\text{II}i|\mathcal{A}}$ , and  $\pi_{\text{III}i|\mathcal{B}}$  represent the probabilities of a unit being included in the phase-I, phase-II, and phase-III samples, with each phase indexed by  $\mathcal{A}$ ,  $\mathcal{B}$  and  $\mathcal{C}$ , respectively. The combined probability for phase-III is  $\pi_{\text{III}i}^* = \pi_{\text{I}i}\pi_{\text{II}i|\mathcal{A}}\pi_{\text{III}i|\mathcal{B}}$ . For the finite population mean  $\bar{u}_0$ , the phase-I, phase-II, and phase-III estimators are

(14), (15), and

$$\bar{u}_{\text{III}} = \frac{1}{\sum_{i \in \mathcal{C}} (\pi_{\text{III}i}^*)^{-1}} \sum_{i \in \mathcal{C}} \frac{u_i}{\pi_{\text{III}i}^*},\tag{S4}$$

respectively. The design variance for the phase-III estimator involves conditional secondorder inclusion probabilities  $\pi_{\text{III}ij|\mathcal{B}}$ . By Taylor expansion and ignoring the small order terms, the design covariance of  $\bar{u}_{\text{III}\pi}$  and  $\bar{v}_{\text{III}\pi}$  given the phase-II sample is

$$V_{uv,\text{II}} = \text{cov}\left(\bar{u}_{\text{III}\pi}, \bar{v}_{\text{III}\pi} \mid \mathcal{B}, \mathcal{A}, \mathcal{F}\right) = \frac{1}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{\text{III}ij|\mathcal{B}} - \pi_{\text{III}i|\mathcal{B}}\pi_{\text{III}j|\mathcal{B}}}{\pi_{\text{III}i}^* \pi_{\text{III}j}^*} (u_i - \bar{u}_{\text{II}})(v_j - \bar{v}_{\text{II}})^{\text{T}}.$$
(S5)

#### S2.2 Three-phase rejective sampling

We define a three-phase rejective sampling method with  $p_1$ -dimensional phase-I covariate x and  $p_2$ -dimensional phase-II covariate z as follows.

Definition S2 (Three-phase rejective sampling with general sampling) Three-phase rejective sampling with general sampling consists of three steps:

Step 1. Select a phase-I sample A by a general  $\pi$  sampling with the inclusion probability  $\pi_{Ii}$ . For  $i \in A$ , record  $x_i$ .

Step 2. Select a phase-II sample  $\mathcal{B}$  by a general  $\pi$  sampling with the conditional inclusion probability  $\pi_{\text{II}i|\mathcal{A}}$  given unit i is in the phase-I sample. Accept the phase-II sample if

$$Q_{x,I} = (\bar{x}_{II} - \bar{x}_{I})^{\mathrm{T}} V_{xx,I}^{-1} (\bar{x}_{II} - \bar{x}_{I}) < \gamma_{1}^{2},$$

where  $\gamma_1^2 > 0$ , and  $V_{xx,I}$  is the positive definite design variance of  $\bar{x}_{II} - \bar{x}_{I}$  given the phase-I sample. For  $i \in \mathcal{B}$ , record  $z_i$ . It is convenient to apply the Gram-Schmidt orthogonalization to  $z_i$ , and construct a phase-II covariate  $a_i = z_i - \bar{z}_{II} - (x_i - \bar{x}_{II})^T \hat{\beta}_{zx,II}$ , where

$$\hat{\beta}_{zx,\text{II}} = \left\{ \sum_{i \in \mathcal{B}} \frac{(x_i - \bar{x}_{\text{II}})^{\otimes 2}}{\pi_{\text{II}i}^*} \right\}^{-1} \sum_{i \in \mathcal{B}} \frac{(x_i - \bar{x}_{\text{II}})(z_i - \bar{z}_{\text{II}})^{\text{T}}}{\pi_{\text{II}i}^*}.$$
 (S6)

Let  $c = (x^T, a^T)^T$  represent the combined vector of phase-II covariates, where a can be seen as the part of z that is both correlated with y and orthogonal to x, representing the additional information beyond what is available from phase I.

Step 3. Select a phase-III rejective sample C by a general  $\pi$  sampling with the conditional inclusion probability  $\pi_{\text{III}i|\mathcal{B}}$  given unit i is in the phase-III sample. Accept the phase-III sample if

$$Q_{c,\text{II}} = (\bar{c}_{\text{III}} - \bar{c}_{\text{II}})^{\text{T}} V_{cc,\text{II}}^{-1} (\bar{c}_{\text{III}} - \bar{c}_{\text{II}}) < \gamma_2^2,$$

where  $\gamma_2^2 > 0$ , and  $V_{cc,II}$  is the positive definite design variance of  $\bar{c}_{III} - \bar{c}_{II}$  given the phase-II sample. For  $i \in \mathcal{C}$ , record  $y_i$ .

In Step 3, balance can be directly controlled on  $(x^{\mathrm{T}}, z^{\mathrm{T}})^{\mathrm{T}}$  instead of c, because  $\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}}$  is a linear transformation of  $\bar{x}_{\mathrm{III}} - \bar{x}_{\mathrm{II}}$  and  $\bar{z}_{\mathrm{III}} - \bar{z}_{\mathrm{II}}$  given  $\hat{\beta}_{zx,\mathrm{II}}$  and the Mahalanobis distance is invariant to linear transformations.

For the population mean  $\bar{y}_0$ , the  $\pi^*$  estimator based on the phase-III rejective sample is

$$\bar{y}_{\text{III}} = \frac{1}{\sum_{i \in \mathcal{C}} (\pi_{\text{III}i}^*)^{-1}} \sum_{i \in \mathcal{C}} \frac{y_i}{\pi_{\text{III}i}^*}.$$

To derive the asymptotic properties of  $\bar{y}_{\text{III}}$ , we specify the following regularity condition.

**Assumption S1** The phase-III estimator (S4) satisfies

$$\operatorname{var}(\hat{u}_{\mathrm{III}} \mid \mathcal{B}, \mathcal{A}, \mathcal{F})^{-1}(\hat{u}_{\mathrm{III}} - \bar{u}_{\mathrm{II}}) \mid \mathcal{B}, \mathcal{A}, \mathcal{F} \to \mathcal{N}(0, 1) \text{ a.s.},$$

and  $\operatorname{var}(n_{\operatorname{III}}^{1/2}\hat{u}_{\operatorname{III}} \mid \mathcal{B}, \mathcal{A}, \mathcal{F}) = O_P(1)$ .

The sequence of phase-II selection probabilities are bounded by  $K_{\rm III,L} < n_{\rm III}^{-1} n_{\rm II} \pi_{\rm IIIi} < K_{\rm III,U}$  for all i, for some positive  $K_{\rm III,L} > 0$  and  $K_{\rm III,U} > 0$ . Assume that the design is such that

$$\lim_{N \to \infty} \sum_{i \in \mathcal{C}} \pi_{\text{III}i}^{-1}(1, c_i^{\text{\tiny T}}, y_i, y_i^2)^{\text{\tiny T}}(1, c_i^{\text{\tiny T}}, y_i, y_i^2) = M_{\text{III}} \text{ a.s.},$$

where  $M_{\rm III}$  is a matrix of constants. Moreover,  $\operatorname{cov}(\bar{c}_{\rm III} - \bar{c}_{\rm II}, \bar{e}_{\rm III} - \bar{e}_{\rm II} \mid \mathcal{B}, \mathcal{A}, \mathcal{F}) = o_P(n_{\rm III}^{-1})$ .

**Theorem S6** Suppose Assumptions 2 and S1 hold. Under three-phase rejective sampling in

Definition S2,

$$n_{\text{III}}^{1/2} (\bar{y}_{\text{III}} - \bar{y}_0) \mid (Q_{z,\text{I}} < \gamma_1^2, Q_{c,\text{II}} < \gamma_2^2)$$

$$\rightarrow V_{\text{III},1}^{1/2} L_{p_1 + p_2, \gamma_2^2} + V_{\text{III},2}^{1/2} Z_1 + V_{\text{III},3}^{1/2} L_{p_1, \gamma_1^2} + V_{\text{III},4}^{1/2} Z_2 + V_{\text{III},5}^{1/2} Z_3, \quad (S7)$$

where

$$V_{\text{III},1} = \lim_{N \to \infty} n_{\text{III}} \beta_{yc,0}^{\text{T}} E\left(V_{cc,\text{II}} \mid \mathcal{F}\right) \beta_{yc,0}, \qquad V_{\text{III},2} = \lim_{N \to \infty} n_{\text{III}} E\left(V_{e_{yc}e_{yc},\text{II}} \mid \mathcal{F}\right),$$

$$V_{\text{III},3} = \lim_{N \to \infty} n_{\text{III}} \beta_{yx,0}^{\text{T}} E(V_{xx,\text{I}} \mid \mathcal{F}) \beta_{yx,0}, \qquad V_{\text{III},4} = \lim_{N \to \infty} n_{\text{III}} E\left(V_{e_{yx}e_{yx},\text{I}} \mid \mathcal{F}\right),$$

$$V_{\text{III},5} = \lim_{N \to \infty} n_{\text{III}} V_{yy,0}, \qquad e_{uv} = u - v^{\text{T}} \beta_{uv,0}, \qquad (S8)$$

 $Z_1$ ,  $Z_2$ , and  $Z_3$  are standard normal variables, and  $(Z_1, Z_2, Z_3, L_{p_1, \gamma_1^2}, L_{p_1+p_2, \gamma_2^2})$  are jointly independent.

# S2.3 Regression estimator

Integrating the design and analysis strategies, the three-phase regression estimator of  $\bar{y}_0$  is

$$\bar{y}_{\text{III,reg}} = \bar{y}_{\text{III}} + \begin{pmatrix} \bar{x}_{\text{I}} - \bar{x}_{\text{III}} \\ \bar{a}_{\text{II}} - \bar{a}_{\text{III}} \end{pmatrix}^{\text{T}} \hat{\beta}_{yc,\text{III}}, \tag{S9}$$

where  $\bar{a}_{\text{II}} = 0$  by our construction of  $a_i$ , and

$$\hat{\beta}_{yc,\text{III}} = \left\{ \sum_{i \in \mathcal{C}} \frac{(c_i - \bar{c}_{\text{III}}) (c_i - \bar{c}_{\text{III}})^{\text{T}}}{\pi_{\text{III}i}^*} \right\}^{-1} \sum_{i \in \mathcal{C}} \frac{(c_i - \bar{c}_{\text{III}}) (y_i - \bar{y}_{\text{III}})}{\pi_{\text{III}i}^*}.$$
 (S10)

The regression estimator exhibits the same asymptotic behavior, irrespective of the use of rejective sampling.

**Theorem S7** Under Assumptions 2 and S1, under three-phase rejective sampling in Definition S2,

$$n_{\text{III}}^{1/2}(\bar{y}_{\text{III,reg}} - \bar{y}_0) \mid \mathcal{F} \to \mathcal{N}\left(0, V_{\text{III,reg}}\right),$$

a.s. for all sequences of finite populations, where

$$V_{\text{III,reg}} = \lim_{N \to \infty} n_{\text{III}} \left\{ V_{yy,0} + E \left( V_{e_{yx}e_{yx},\text{I}} \mid \mathcal{F} \right) + E \left( V_{e_{yc}e_{yc},\text{II}} \mid \mathcal{F} \right) \right\},\,$$

and  $V_{uv,0}$ ,  $V_{uv,I}$  and  $V_{uv,II}$  are defined in (16), (17) and (S5), respectively.

Thus, the limiting distribution of  $n_{\text{III}}^{1/2}(\bar{y}_{\text{III,reg}} - \bar{y}_0)$  remains unchanged with or without rejective procedure. Combining the results from Theorems S6 and S7 suggests that utilizing auxiliary variables in both the design stage (via rejective sampling) and analysis stage (via regression) can improve estimation efficiency.

# S2.4 Inference: variance estimators and confidence intervals

We derive the asymptotic design variance formula. Let  $\hat{\beta}_{uv,\text{III}}$  be (S10) with  $y_i$  and  $c_i$  being  $u_i$  and  $v_i$ ,  $\hat{e}_{uv,i} = u_i - v_i^{\text{T}} \hat{\beta}_{uv,\text{III}}$ , and  $\hat{e}_{uv,\text{III}}$  be (S4) with  $u_i$  being  $\hat{e}_{uv,i}$ . We estimate  $V_{yy,0}$ ,  $V_{e_{yx}e_{yx},\text{I}}$  and  $V_{e_{yc}e_{yc},\text{II}}$  by

$$\hat{V}_{yy,0} = \frac{1}{N^2} \sum_{i \in \mathcal{A}_{\text{III}}} \sum_{j \in \mathcal{A}_{\text{III}}} \frac{\pi_{\text{I}ij} - \pi_{\text{I}i}\pi_{\text{I}j}}{\pi_{\text{I}i}\pi_{\text{I}j}} \frac{(y_i - \bar{y}_{\text{III}})(y_j - \bar{y}_{\text{III}})^{\text{T}}}{\pi_{\text{I}ij}\pi_{\text{II}ij}|\mathcal{A}},$$

$$\hat{V}_{e_{yx}e_{yx},\text{I}} = \frac{1}{N^2} \sum_{i \in \mathcal{A}_{\text{III}}} \sum_{j \in \mathcal{A}_{\text{III}}} \frac{\pi_{\text{II}ij}|\mathcal{A} - \pi_{\text{II}i}|\mathcal{A}}{\pi_{\text{II}i}^*\pi_{\text{II}j}^*} \frac{(\hat{e}_{yx,i} - \hat{e}_{yx,\text{III}})(\hat{e}_{yx,j} - \hat{e}_{yx,\text{III}})^{\text{T}}}{\pi_{\text{II}ij}|\mathcal{A}},$$

$$\hat{V}_{e_{yc}e_{yc},\text{II}} = \frac{1}{N^2} \sum_{i \in \mathcal{A}_{\text{III}}} \sum_{j \in \mathcal{A}_{\text{III}}} \frac{\pi_{\text{III}ij}|\mathcal{B} - \pi_{\text{III}i}|\mathcal{B}}{\pi_{\text{III}i}|\mathcal{B}} \frac{(\hat{e}_{yc,i} - \hat{e}_{yc,\text{III}})(\hat{e}_{yc,j} - \hat{e}_{yc,\text{III}})^{\text{T}}}{\pi_{\text{III}ij}|\mathcal{B}},$$

respectively. Then, the variance estimator for  $\bar{y}_{\text{III}}$  is

$$\hat{V}_{\text{III}} = \left(\hat{\beta}_{yc,\text{III}}^{\text{T}} V_{cc,\text{II}} \hat{\beta}_{yc,\text{III}}\right) v_{p_1 + p_2, \gamma_2^2} + \left(\hat{\beta}_{yx,\text{III}}^{\text{T}} V_{xx,\text{I}} \hat{\beta}_{yx,\text{III}}\right) v_{p_1, \gamma_1^2} + \hat{V}_{e_{yc}e_{yc},\text{II}} + \hat{V}_{e_{yx}e_{yx},\text{I}} + \hat{V}_{yy,0}.$$

The variance estimator for  $\bar{y}_{\text{III,reg}}$  is  $\hat{V}_{\text{III,reg}} = \hat{V}_{yy,0} + \hat{V}_{e_{yx}e_{yx},\text{I}} + \hat{V}_{e_{yc}e_{yc},\text{II}}$ .

To construct confidence intervals, we define  $\nu_{\alpha}(V_{\text{III},1}, \dots, V_{\text{III},5})$  as the  $100\alpha$ th quantile of the distribution of  $V_{\text{III},1}^{1/2}L_{p_1+p_2,\gamma_2^2} + V_{\text{III},2}^{1/2}Z_1 + V_{\text{III},3}^{1/2}L_{p_1,\gamma_1^2} + V_{\text{III},4}^{1/2}Z_2 + V_{\text{III},5}^{1/2}Z_3$ . Because under three-phase rejective sampling,

$$P\left\{\nu_{\alpha/2}(\hat{V}_{\text{III},1},\cdots,\hat{V}_{\text{III},5}) \leq n_{\text{III}}^{1/2}(\bar{y}_{\text{III}} - \bar{y}_0) \leq \nu_{1-\alpha/2}(\hat{V}_{\text{III},1},\cdots,\hat{V}_{\text{III},5})\right\} \to 1 - \alpha,$$

we can construct the asymptotic  $(1-\alpha)$  confidence interval for  $\bar{y}_0$  based on  $\bar{y}_{\rm III}$  as

$$\left(\bar{y}_{\text{III}} - n_{\text{III}}^{-1/2} \nu_{1-\alpha/2}(\hat{V}_{\text{III},1}, \cdots, \hat{V}_{\text{III},5}), \ \bar{y}_{\text{III}} - n_{\text{III}}^{-1/2} \nu_{\alpha/2}(\hat{V}_{\text{III},1}, \cdots, \hat{V}_{\text{III},5})\right).$$

Also, the asymptotic  $(1-\alpha)$  confidence interval of  $\bar{y}_0$  based on  $\bar{y}_{\rm II,reg}$  can be constructed as

$$\left(\bar{y}_{\rm III,reg} - \hat{V}_{\rm III,reg}^{1/2} z_{1-\alpha/2}, \ \bar{y}_{\rm III} - \hat{V}_{\rm III,reg}^{1/2} z_{\alpha/2}\right)$$
.

# S3 Proofs

#### S3.1 Useful lemmas

We state some useful lemmas for two-phase simple random sampling.

**Lemma S1**  $E(\bar{u}_{II} \mid \mathcal{A}, \mathcal{F}) = \bar{u}_{I}$  and  $E(\bar{u}_{I} \mid \mathcal{F}) = \bar{u}_{0}$ .

**Lemma S2** 
$$cov(\bar{u}_{II}, \bar{v}_{II} \mid \mathcal{A}, \mathcal{F}) = (n_{II}^{-1} - n_{I}^{-1}) V_{uv,I} \text{ and } cov(\bar{u}_{I}, \bar{v}_{I} \mid \mathcal{F}) = (n_{I}^{-1} - N^{-1}) V_{uv,0}.$$

Lemma S3 
$$E(V_{uv,II} \mid \mathcal{A}, \mathcal{F}) = V_{uv,I}$$
 and  $E(V_{uv,I} \mid \mathcal{F}) = V_{uv,0}$ .

Lemmas S2 and S3 are standard textbook results (e.g., Fuller, 2009a); therefore, we omit their proofs.

For a sequence of finite populations, the variability of the estimators comes from the sampling design. In the following proofs for the asymptotic design properties, the asymptotic design variance and covariance (the limits of the design variance and covariances), denoted by a.var and a.cov, respectively, are relevant.

# S3.2 Proof of Lemma 1

Recall the following definitions  $T_1 = n_{\text{II}}^{1/2} (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \beta_0$ ,  $T_2 = n_{\text{II}}^{1/2} \{\bar{y}_{\text{II}} - \bar{y}_{\text{I}} - (\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}} \beta_0\}$ , and  $T_3 = n_{\text{II}}^{1/2} (\bar{y}_{\text{I}} - \bar{y}_0)$ . The asymptotic normality follows by Assumption 1; see, e.g., Chapter 1 in Fuller (2009a).

Because  $\mathcal{B}$  is a simple random sample from  $\mathcal{A}$ , and  $\mathcal{A}$  is a simple random sample from  $\mathcal{F}$ , by Lemma S1, we have

$$E(T_1 \mid \mathcal{A}, \mathcal{F}) = 0, \ E(T_2 \mid \mathcal{A}, \mathcal{F}) = 0, \ E(T_3 \mid \mathcal{F}) = 0,$$
 (S11)

and therefore  $E(T_k \mid \mathcal{F}) = 0$ , for k = 1, 2, 3.

We then show the asymptotic variance formulas. First, the asymptotic design variance of  $T_1$  given  $\mathcal{F}$  is

a.var
$$(T_1 \mid \mathcal{F}_N) \equiv \lim_{N \to \infty} \text{var}(T_1 \mid \mathcal{F})$$
  

$$= \lim_{N \to \infty} \left[ \text{var} \left\{ E(T_1 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} + E \left\{ \text{var}(T_1 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left[ 0 + E \left\{ \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) \beta_0^{\text{T}} V_{xx,\text{I}} \beta_0 \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) \beta_0^{\text{T}} V_{xx,0} \beta_0$$

$$= \lim_{N \to \infty} \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) V_{yx,0} V_{xx,0}^{-1} V_{xy,0}$$

$$= (1 - f_{\text{II},\text{I}}) \sigma_{yx} \sigma_{xx}^{-1} \sigma_{xy}, \text{ a.s.,}$$

where the second equality follows by (S11) and Lemma S2, and the third equality follows by Lemma S3. Second, by writing  $T_2 = n_{\text{II}}^{1/2}(\bar{e}_{\text{II}} - \bar{e}_{\text{I}}) + o_P(1)$ , the asymptotic design variance

of  $T_2$  given  $\mathcal{F}$  is

a.var
$$(T_2 \mid \mathcal{F}) \equiv \lim_{N \to \infty} \text{var}(T_2 \mid \mathcal{F})$$

$$= \lim_{N \to \infty} \left[ \text{var} \left\{ E(T_2 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} + E \left\{ \text{var}(T_2 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left[ 0 + E \left\{ \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) V_{ee,\text{I}} \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) V_{ee,0}$$

$$= (1 - f_{\text{II},\text{I}}) \sigma_{ee}, \text{ a.s.,}$$

where the second equality follows by (S11) and Lemma S2, and the third equality follows by Lemma S3. Third, the asymptotic design variance of  $T_3$  given  $\mathcal{F}$  is a.var $(T_3 \mid \mathcal{F}) \equiv \lim_{N\to\infty} \text{var}(T_3 \mid \mathcal{F}) = \lim_{N\to\infty} (n_{\text{II}}/n_{\text{I}} - n_{\text{II}}/N) V_{yy,0} = f_{\text{II},\text{I}}(1 - f_{\text{I},0}) \sigma_{yy}$ , a.s..

Finally, we show that all covariances of cross terms are zero asymptotically. We have

a.cov
$$(T_{1}, T_{2} \mid \mathcal{A}, \mathcal{F}) \equiv \lim_{N \to \infty} \text{cov}(T_{1}, T_{2} \mid \mathcal{A}, \mathcal{F})$$

$$= \lim_{N \to \infty} n_{\text{II}} \beta_{0}^{\text{T}} \text{cov}(\bar{x}_{\text{II}} - \bar{x}_{\text{I}}, \bar{y}_{\text{II}} - \bar{y}_{\text{I}} \mid \mathcal{A}, \mathcal{F})$$

$$- \lim_{N \to \infty} n_{\text{II}} \beta_{0}^{\text{T}} \text{cov}(\bar{x}_{\text{II}} - \bar{x}_{\text{I}}, \bar{x}_{\text{II}} - \bar{x}_{\text{I}} \mid \mathcal{A}, \mathcal{F}) \beta_{0}$$

$$= \lim_{N \to \infty} \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) (\beta_{0}^{\text{T}} V_{xy,\text{I}} - \beta_{0}^{\text{T}} V_{xx,\text{I}} \beta_{0})$$

$$= \lim_{N \to \infty} \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) (V_{yx,0} V_{xx,0}^{-1} V_{xy,\text{I}} - V_{yx,0} V_{xx,0}^{-1} V_{xx,\text{I}} V_{xx,0}^{-1} V_{xy,0})$$

$$= (1 - f_{\text{II},\text{I}}) (\sigma_{yx} \sigma_{xx}^{-1} \sigma_{xy} - \sigma_{yx} \sigma_{xx} \sigma_{xx}^{-1} \sigma_{xx} \sigma_{xy}) = 0, \text{ a.s.,} \quad (S12)$$

where the second equality follows by Lemma S3. Because conditional on  $\mathcal{A}$  and  $\mathcal{F}$ ,  $T_3$  is a constant, we then have

$$a.cov(T_k, T_3 \mid A, \mathcal{F}) = 0, \ k = 1, 2.$$
 (S13)

Combining (S11)–(S13), we have

$$a.cov(T_j, T_k \mid \mathcal{F}) \equiv \lim_{N \to \infty} cov(T_j, T_k \mid \mathcal{F})$$

$$= \lim_{N \to \infty} E\{ \operatorname{cov}(T_j, T_k \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \}$$

$$+ \lim_{N \to \infty} \operatorname{cov}\{ E(T_j \mid \mathcal{A}, \mathcal{F}), E(T_k \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \}$$

$$= 0, \ (j \neq k \in \{1, 2, 3\}), \text{ a.s..}$$

Combining all results, we complete the proof.

# S3.3 Proof of Theorem 2

To express (11) further, by the moment condition in Assumption 1, we have  $n_{\text{II}}^{1/2}(\bar{x}_{\text{II}} - \bar{x}_{\text{I}}) = O_P(1)$ ,

$$\hat{\beta}_{\text{II}} - \beta_{0} = \left\{ \sum_{i \in \mathcal{B}} (x_{i} - \bar{x}_{\text{II}}) (x_{i} - \bar{x}_{\text{II}})^{\text{T}} \right\}^{-1} \sum_{i \in \mathcal{B}} (x_{i} - \bar{x}_{\text{II}}) \left\{ y_{i} - \bar{y}_{\text{II}} - (x_{i} - \bar{x}_{\text{II}})^{\text{T}} \beta_{0} \right\}$$

$$= \left\{ n_{\text{II}}^{-1} \sum_{i \in \mathcal{B}} (x_{i} - \bar{x}_{\text{II}}) (x_{i} - \bar{x}_{\text{II}})^{\text{T}} \right\}^{-1} n_{\text{II}}^{-1} \sum_{i \in \mathcal{B}} (x_{i} - \bar{x}_{\text{II}}) (e_{i} - \bar{e}_{\text{II}})$$

$$= O_{P}(n_{\text{II}}^{-1/2}),$$

and therefore  $n_{\text{II}}^{1/2}(\bar{x}_{\text{II}} - \bar{x}_{\text{I}})^{\text{T}}(\hat{\beta}_{\text{II}} - \beta_0) = O_P(1)O_P(n_{\text{II}}^{-1/2}) = O_P(n_{\text{II}}^{-1/2}) = o_P(1)$ . We then express (11) as

$$n_{\rm II}^{1/2} \left( \bar{y}_{\rm II,reg} - \bar{y}_0 \right) = n_{\rm II}^{1/2} \left( \bar{e}_{\rm II} - \bar{e}_{\rm I} \right) + n_{\rm II}^{1/2} \left( \bar{y}_{\rm I} - \bar{y}_0 \right) + o_P(1). \tag{S14}$$

Under TPRS in Definition 1, based on (S14), the design variance  $\operatorname{var}\{n_{\text{II}}^{1/2}(\bar{y}_{\text{II,reg}}-\bar{y}_0)\mid \mathcal{F}\}$  is approximately

$$n_{\text{II}} \text{var} \left( \bar{y}_{\text{I}} - \bar{y}_{0} \mid \mathcal{F} \right) + n_{\text{II}} E \left\{ \text{var} (\bar{e}_{\text{II}} \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\}$$

$$= n_{\text{II}} \left( \frac{1}{n_{\text{I}}} - \frac{1}{N} \right) V_{yy,0} + E \left\{ \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) V_{ee,\text{I}} \mid \mathcal{F} \right\}$$

$$= n_{\text{II}} \left( \frac{1}{n_{\text{I}}} - \frac{1}{N} \right) V_{yy,0} + \left( 1 - \frac{n_{\text{II}}}{n_{\text{I}}} \right) V_{ee,0}$$

$$\rightarrow f_{\text{II,I}} \left( 1 - f_{\text{I,0}} \right) \sigma_{yy} + \left( 1 - f_{\text{II,I}} \right) \sigma_{ee}, \text{ a.s.},$$

where the second equality follows by Lemma S3.

Under TPRS in Definition 1,  $n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0)$  is equivalent to  $n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0) \mid (Q_{\rm I} < \gamma^2)$  without rejective sampling. Similar to (S12), we can show that  $\bar{e}_{\rm II} - \bar{e}_{\rm I}$  and  $Q_{\rm I}$  are asymptotically independent. Moreover, we can show that  $\bar{y}_{\rm I} - \bar{y}_0$  and  $Q_{\rm I}$  are asymptotically independent. Based on (S14),  $n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0)$  and  $Q_{\rm I}$  are asymptotically independent. As a result,  $n_{\rm II}^{1/2}(\bar{y}_{\rm II,reg} - \bar{y}_0)$  has the same distribution under two-phase sampling with and without rejective sampling.

#### S3.4 Proof of Proposition 1

We follow the similar augment in Li and Ding (2018). Under TPRS in Definition 1,  $\bar{u}_{\rm II} \rightarrow E(u)$  a.s., and

$$\hat{V}_{uv} = \frac{1}{n_{\text{II}} - 1} \sum_{i \in \mathcal{B}} (u_i - \bar{u}_{\text{II}})(v_i - \bar{v}_{\text{II}}) 
= \frac{1}{n_{\text{II}} - 1} \sum_{i \in \mathcal{B}} \{u_i - E(u)\} \{v_i - E(v)\} - \frac{n_{\text{II}}}{n_{\text{II}} - 1} \{\bar{u}_{\text{II}} - E(u)\} \{\bar{v}_{\text{II}} - E(v)\} 
\rightarrow V_{uv}, \text{ a.s.,}$$

where the last line follows from Assumption 1. Next, we have

$$E\left\{(\hat{V}_{uv} - V_{uv})^{2}\right\}$$

$$= \left(\frac{n_{\text{II}}}{n_{\text{II}} - 1}\right)^{2} \text{var} \left[\frac{1}{n_{\text{II}}} \sum_{i \in \mathcal{B}} \{u_{i} - E(u)\}\{v_{i} - E(v)\} - \{\bar{u}_{\text{II}} - E(u)\}\{\bar{v}_{\text{II}} - E(v)\}\right]$$

$$= \left(\frac{n_{\text{II}}}{n_{\text{II}} - 1}\right)^{2} \text{var} \left[\frac{1}{n_{\text{II}}} \sum_{i \in \mathcal{B}} \{u_{i} - E(u)\}\{v_{i} - E(v)\}\right]$$

$$+ \text{var} \left[\{\bar{u}_{\text{II}} - E(u)\}\{\bar{v}_{\text{II}} - E(v)\}\right]. \tag{S15}$$

To further evaluate (S15), we have

$$\operatorname{var}\left[\frac{1}{n_{\Pi}}\sum_{i\in\mathcal{B}}\{u_{i}-E(u)\}\{v_{i}-E(v)\}\right] = \left(\frac{1}{n_{\Pi}}\right)^{2}E\left(\sum_{i\in\mathcal{B}}\left[\{u_{i}-E(u)\}\{v_{i}-E(v)\}\right]^{2}\right) \\ - \frac{1}{n_{\Pi}}\sum_{j\in\mathcal{B}}\{u_{j}-E(u)\}\{v_{j}-E(v)\}\right]^{2}\right) \\ \leq \left(\frac{1}{n_{\Pi}}\right)^{2}E\left[\sum_{i\in\mathcal{B}}\{u_{i}-E(u)\}^{2}\{v_{i}-E(v)\}^{2}\right] \\ \leq \frac{1}{n_{\Pi}}E\left[\frac{1}{n_{\Pi}}\sum_{i\in\mathcal{B}}\{u_{i}-E(u)\}^{4}+\frac{1}{n_{\Pi}}\sum_{i\in\mathcal{B}}\{v_{i}-E(v)\}^{4}\right] \\ = \frac{1}{n_{\Pi}}E\left[\{u-E(u)\}^{4}\right]+\frac{1}{n_{\Pi}}E\left[\{v-E(v)\}^{4}\right]$$

and

$$\operatorname{var} \left[ \{ \bar{u}_{\text{II}} - E(u) \} \{ \bar{v}_{\text{II}} - E(v) \} \right] \leq E \left[ \{ \bar{u}_{\text{II}} - E(u) \}^2 \{ \bar{v}_{\text{II}} - E(v) \}^2 \right] \\
\leq E \left[ \{ \bar{u}_{\text{II}} - E(u) \}^4 + \{ \bar{v}_{\text{II}} - E(v) \}^4 \right] \\
= \frac{1}{n_{\text{II}}} E \left[ \{ u - E(u) \}^4 \right] + \frac{1}{n_{\text{II}}} E \left[ \{ v - E(v) \}^4 \right].$$

Therefore, under Assumption 1,

$$E\left\{ (\hat{V}_{uv} - V_{uv})^2 \right\} \le \frac{2}{n_{\text{II}}} E\left[ \left\{ u - E(u) \right\}^4 \right] + \frac{2}{n_{\text{II}}} E\left[ \left\{ v - E(v) \right\}^4 \right] \to 0.$$
 (S16)

By the law of total probability, we have

$$E\left\{ (\hat{V}_{uv} - V_{uv})^{2} \right\} = E\left\{ (\hat{V}_{uv} - V_{uv})^{2} \mid Q_{I} < \gamma^{2} \right\} P(Q_{I} < \gamma^{2})$$

$$+ E\left\{ (\hat{V}_{uv} - V_{uv})^{2} \mid Q_{I} \ge \gamma^{2} \right\} P(Q_{I} \ge \gamma^{2})$$

$$\ge E\left\{ (\hat{V}_{uv} - V_{uv})^{2} \mid Q_{I} < \gamma^{2} \right\} P(Q_{I} < \gamma^{2}).$$

Combining with (S16),

$$E\left\{ (\hat{V}_{uv} - V_{uv})^2 \mid Q_{\rm I} < \gamma^2 \right\} \le \{ P(Q_{\rm I} < \gamma^2) \}^{-1} E\left\{ (\hat{V}_{uv} - V_{uv})^2 \right\} = o(1).$$

Therefore,  $\hat{V}_{uv} = V_{uv} + o_P(1)$ , which completes the proof.

# S3.5 Proof of Lemma 2

By the constructions of phase I and II samples and estimators, we have

$$E(T_1 \mid \mathcal{A}, \mathcal{F}) = 0, \ E(T_2 \mid \mathcal{A}, \mathcal{F}) = 0, \ E(T_3 \mid \mathcal{F}) = 0,$$
 (S17)

and therefore  $E(T_k \mid \mathcal{F}) = 0$ , for k = 1, 2, 3.

We then show the asymptotic variance formulas. First, the asymptotic design variance of  $T_1$  given  $\mathcal{F}$  is

a.var
$$(T_1 \mid \mathcal{F}) \equiv \lim_{N \to \infty} \text{var}(T_1 \mid \mathcal{F})$$
  

$$= \lim_{N \to \infty} \left[ \text{var} \left\{ E(T_1 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} + E \left\{ \text{var}(T_1 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left[ 0 + E \left\{ \frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{A}} \sum_{j \in \mathcal{A}} \frac{\pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}} \pi_{\text{II}j|\mathcal{A}}}{\pi_i^* \pi_j^*} (y_i - \bar{y}_0) (y_j - \bar{y}_0) \mid \mathcal{F} \right\} \right]$$

$$= V_1, \text{ a.s..}$$

Second, the asymptotic design variance of  $T_2$  given  $\mathcal{F}$  is

a.var
$$(T_2 \mid \mathcal{F}) \equiv \lim_{N \to \infty} \operatorname{var}(T_2 \mid \mathcal{F})$$
  

$$= \lim_{N \to \infty} \left[ \operatorname{var} \left\{ E(T_2 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} + E \left\{ \operatorname{var}(T_2 \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left[ 0 + E \left\{ \frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{A}} \sum_{j \in \mathcal{A}} \frac{\pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}} \pi_{\text{II}j|\mathcal{A}}}{\pi_i^* \pi_j^*} (e_i - \bar{e}_0)(e_j - \bar{e}_0) \mid \mathcal{F} \right\} \right]$$

$$= V_2, \text{ a.s..}$$

Third, the asymptotic design variance of  $T_3$  given  $\mathcal{F}$  is

a.var
$$(T_3 \mid \mathcal{F}) \equiv \lim_{N \to \infty} \text{var}(T_3 \mid \mathcal{F})$$
  

$$= \lim_{N \to \infty} \left\{ \frac{n_{\text{II}}}{N^2} \sum_{i=1}^{N} \sum_{j=1}^{N} \frac{\pi_{\text{I}ij} - \pi_{\text{I}i} \pi_{\text{I}j}}{\pi_{\text{I}i} \pi_{\text{I}j}} (y_i - \bar{y}_0) (y_j - \bar{y}_0) \right\}$$

$$= V_3, \text{ a.s.}.$$

Note that  $V_1$ ,  $V_2$  and  $V_3$  are finite, guaranteed by Assumption 2.

Finally, we show that all covariances of cross terms are zero asymptotically. By Assumption 2(vii), a.cov $(T_1, T_2 \mid \mathcal{F}) = 0$  a.s.. Because conditional on  $\mathcal{A}$ ,  $T_3$  is a constant, we then have

$$a.cov(T_k, T_3 \mid A, \mathcal{F}) = 0, \ k = 1, 2.$$
 (S18)

Combining (S17)–(S18), we have

$$a.cov(T_j, T_k \mid \mathcal{F}) \equiv \lim_{N \to \infty} cov(T_j, T_k \mid \mathcal{F})$$

$$= \lim_{N \to \infty} E\{cov(T_j, T_k \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F}\}$$

$$+ \lim_{N \to \infty} cov\{E(T_j \mid \mathcal{A}, \mathcal{F}), E(T_k \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F}\}$$

$$= 0, (j \neq k \in \{1, 2, 3\}), \text{ a.s..}$$

Combining all results completes the proof.

#### S3.6 Proof of Theorem 4

To derive the asymptotic design property of the two-phase regression estimator, we use the following decomposition:

$$\bar{y}_{\text{II,reg}} - \bar{y}_0 = \bar{y}_{\text{II}} - \bar{y}_{\text{I}} + (\bar{x}_{\text{I}} - \bar{x}_{\text{II}})^{\text{T}} \beta_0 + (\bar{x}_{\text{I}} - \bar{x}_{\text{II}})^{\text{T}} (\hat{\beta}_{\text{II}} - \beta_0) + \bar{y}_{\text{I}} - \bar{y}_0$$

$$= \bar{e}_{\text{II}} - \bar{e}_{\text{I}} + \bar{y}_{\text{I}} - \bar{y}_0 + O_P(n_{\text{II}}^{-1}),$$

where the second equality follows by  $(\bar{x}_{\rm I} - \bar{x}_{\rm II})^{\rm T}(\hat{\beta}_{\rm II} - \beta_0) = O_P(n_{\rm II}^{-1})$  due to  $\bar{x}_{\rm I} - \bar{x}_{\rm II} = O_P(n_{\rm II}^{-1/2})$  and  $\hat{\beta}_{\rm II} - \beta_0 = O_P(n_{\rm II}^{-1/2})$ .

Therefore, the asymptotic design variance of  $\bar{y}_{\rm II,reg}$  is

a.var 
$$\left\{ n_{\text{II}}^{1/2} (\bar{y}_{\text{II,reg}} - \bar{y}_{0}) \mid \mathcal{F} \right\} \equiv \lim_{N \to \infty} \text{var} \left\{ n_{\text{II}}^{1/2} (\bar{y}_{\text{II,reg}} - \bar{y}_{0}) \mid \mathcal{F} \right\}$$

$$= \lim_{N \to \infty} \left[ \text{var} (n_{\text{II}}^{1/2} \bar{y}_{\text{I}} \mid \mathcal{F}) + E \left\{ \text{var} (n_{\text{II}}^{1/2} \bar{e}_{\text{II}} \mid \mathcal{A}, \mathcal{F}) \mid \mathcal{F}_{N} \right\} \right]$$

$$= \lim_{N \to \infty} \left[ \frac{n_{\text{II}}}{N^{2}} \sum_{i=1}^{N} \sum_{j=1}^{N} \frac{\pi_{\text{I}ij} - \pi_{\text{I}i} \pi_{\text{I}j}}{\pi_{\text{I}i} \pi_{\text{I}j}} (y_{i} - \bar{y}_{0}) (y_{j} - \bar{y}_{0}) \right]$$

$$+ E \left\{ \frac{n_{\text{II}}}{N^{2}} \sum_{i \in \mathcal{A}} \sum_{j \in \mathcal{A}} \frac{\pi_{\text{II}ij} |\mathcal{A} - \pi_{\text{II}i} |\mathcal{A} \pi_{\text{II}j} |\mathcal{A}}{\pi_{i}^{*} \pi_{j}^{*}} (e_{i} - \bar{e}_{0}) (e_{j} - \bar{e}_{0}) \mid \mathcal{F} \right\} \right]$$

$$= \lim_{N \to \infty} \left\{ n_{\text{II}} V_{yy,0} + E \left( n_{\text{II}} V_{ee,\text{I}} \mid \mathcal{F} \right) \right\}.$$

#### S3.7 Proof of Remark 2

For the phase-I and phase-II sample sizes, we have

$$\sum_{j=1}^{N} I(j \in \mathcal{A}) = n_{\mathrm{I}}, \tag{S19}$$

$$\sum_{j \in \mathcal{A}} I(j \in \mathcal{B}) = n_{\text{II}}. \tag{S20}$$

By taking the expectation of (S19), we obtain

$$\sum_{i=1}^{N} \pi_{\mathbf{I}j} = n_{\mathbf{I}},\tag{S21}$$

By taking the conditional expectation of (S20) given A, we obtain

$$\sum_{j \in \mathcal{A}} \pi_{\text{II}j|\mathcal{A}} = n_{\text{II}}.$$
 (S22)

Multiplying (S19) by  $I(i \in \mathcal{A})$  and multiplying (S20) by  $I(i \in \mathcal{B})$ , we obtain

$$\sum_{j=1}^{N} I(j \in \mathcal{A})I(i \in \mathcal{A}) = n_{\mathbf{I}}I(i \in \mathcal{A}), \tag{S23}$$

$$\sum_{i \in \mathcal{A}} I(j \in \mathcal{B}) I(i \in \mathcal{B}) = n_{\text{II}} I(i \in \mathcal{B}). \tag{S24}$$

By taking the expectation of (S23), we obtain

$$\sum_{i=1}^{N} \pi_{Iij} = n_{I} \pi_{Ii}, \tag{S25}$$

By taking the conditional expectation of (S24) given  $\mathcal{A}$ , we obtain

$$\sum_{j \in \mathcal{A}} \pi_{\Pi i j | \mathcal{A}} = n_{\Pi} \pi_{\Pi i | \mathcal{A}}. \tag{S26}$$

We now write

$$\hat{V}_{2,\text{SYG}} = -\frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}}\pi_{\text{II}j|\mathcal{A}}}{\pi_{\text{II}ij|\mathcal{A}}} \left(\frac{\hat{e}_i - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^*}\right)^{\otimes 2} 
+ \frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \frac{\pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}}\pi_{\text{II}j|\mathcal{A}}}{\pi_{\text{II}ij|\mathcal{A}}} \left(\frac{\hat{e}_i - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^*}\right) \left(\frac{\hat{e}_j - \hat{e}_{\text{II}}}{\pi_{\text{II}j}^*}\right)^{\text{T}} 
= T_{2,\text{SYG}} + \hat{V}_2.$$

Moreover,

$$E\left(T_{2,\text{SYG}} \mid \mathcal{A}, \mathcal{F}\right) = -\frac{n_{\text{II}}}{N^{2}} E\left\{ \sum_{i \in \mathcal{A}} \sum_{j \in \mathcal{A}} \left( \pi_{\text{II}ij|\mathcal{A}} - \pi_{\text{II}i|\mathcal{A}} \pi_{\text{II}j|\mathcal{A}} \right) \left( \frac{\hat{e}_{i} - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^{*}} \right)^{\otimes 2} \mid \mathcal{A}, \mathcal{F} \right\}$$

$$= -\frac{n_{\text{II}}}{N^{2}} E\left\{ \sum_{i \in \mathcal{A}} \left( \sum_{j \in \mathcal{A}} \pi_{\text{II}ij|\mathcal{A}} \right) \left( \frac{\hat{e}_{i} - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^{*}} \right)^{\otimes 2} \mid \mathcal{A}, \mathcal{F} \right\}$$

$$+ \frac{n_{\text{II}}}{N^{2}} E\left\{ \sum_{i \in \mathcal{A}} \pi_{\text{II}i|\mathcal{A}} \left( \sum_{j \in \mathcal{A}} \pi_{\text{II}j|\mathcal{A}} \right) \left( \frac{\hat{e}_{i} - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^{*}} \right)^{\otimes 2} \mid \mathcal{A}, \mathcal{F} \right\}$$

$$= -\frac{n_{\text{II}}}{N^2} E \left\{ \sum_{i \in \mathcal{A}} \left( n_{\text{II}} \pi_{\text{II}i|\mathcal{A}} \right) \left( \frac{\hat{e}_i - \hat{e}_{\text{II}}}{\pi_{\text{II}i}^*} \right)^{\otimes 2} \mid \mathcal{A}, \mathcal{F} \right\}$$
 (S27)

$$+\frac{n_{\text{II}}}{N^2}E\left\{\sum_{i\in\mathcal{A}}\pi_{\text{II}i|\mathcal{A}}n_{\text{II}}\left(\frac{\hat{e}_i-\hat{e}_{\text{II}}}{\pi_{\text{II}i}^*}\right)^{\otimes 2}\mid\mathcal{A},\mathcal{F}\right\}$$

$$= 0. \tag{S28}$$

where (S27) follows by (S26), and (S28) follows by (S22). Therefore,  $\hat{V}_{2,SYG}$  is asymptotically equivalent to  $\hat{V}_2$  adding a mean zero term.

We also write

$$\hat{V}_{3,\text{SYG}} = -\frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \left( \frac{\pi_{\text{I}ij} - \pi_{\text{I}i}\pi_{\text{I}j}}{\pi_{\text{I}ij}\pi_{\text{II}ij}|\mathcal{A}} \right) \left( \frac{y_i - \bar{y}_{\text{II}}}{\pi_{\text{I}i}} \right)^{\otimes 2} 
+ \frac{n_{\text{II}}}{N^2} \sum_{i \in \mathcal{B}} \sum_{j \in \mathcal{B}} \left( \frac{\pi_{\text{I}ij} - \pi_{\text{I}i}\pi_{\text{I}j}}{\pi_{\text{I}ij}\pi_{\text{II}ij}|\mathcal{A}} \right) \left( \frac{y_i - \bar{y}_{\text{II}}}{\pi_{\text{I}i}} \right) \left( \frac{y_j - \bar{y}_{\text{II}}}{\pi_{\text{I}j}} \right)^{\text{T}} 
= T_{3,\text{SYG}} + \hat{V}_3.$$

Moreover,

$$E(T_{3,SYG}) = -\frac{n_{II}}{N^{2}} E\left\{ \sum_{i=1}^{N} \left( \sum_{j=1}^{N} \pi_{Iij} \right) \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} - \left( \sum_{j=1}^{N} \pi_{Ij} \right) \sum_{i=1}^{N} \pi_{Ii} \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} \right\}$$

$$= -\frac{n_{II}}{N^{2}} E\left\{ \sum_{i=1}^{N} \left( \sum_{j=1}^{N} \pi_{Iij} \right) \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} - \left( \sum_{j=1}^{N} \pi_{Ij} \right) \sum_{i=1}^{N} \pi_{Ii} \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} \right\}$$

$$= -\frac{n_{II}}{N^{2}} E\left\{ \sum_{i=1}^{N} n_{I} \pi_{Ii} \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} - n_{I} \sum_{i=1}^{N} \pi_{Ii} \left( \frac{y_{i} - \bar{y}_{II}}{\pi_{Ii}} \right)^{\otimes 2} \right\}$$

$$= 0. \tag{S29}$$

where (S29) follows by (S21) and (S25). Therefore,  $\hat{V}_{3,SYG}$  is asymptotically equivalent to  $\hat{V}_3$  adding a mean zero term.

# S3.8 Proof Theorem S6

We use the following decomposition:

$$\begin{split} n_{\mathrm{III}}^{1/2} \left( \bar{y}_{\mathrm{III}} - \bar{y}_{0} \right) &= n_{\mathrm{III}}^{1/2} (\bar{y}_{\mathrm{III}} - \bar{y}_{\mathrm{II}}) + n_{\mathrm{III}}^{1/2} (\bar{y}_{\mathrm{II}} - \bar{y}_{\mathrm{I}}) + n_{\mathrm{III}}^{1/2} (\bar{y}_{\mathrm{I}} - \bar{y}_{0}) \\ &= n_{\mathrm{III}}^{1/2} (\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}}) \beta_{yc,0} + n_{\mathrm{III}}^{1/2} \left\{ \bar{y}_{\mathrm{III}} - \bar{y}_{\mathrm{II}} - (\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}}) \beta_{yc,0} \right\} \\ &+ n_{\mathrm{III}}^{1/2} (\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}}) \beta_{yx,0} + n_{\mathrm{III}}^{1/2} \left\{ \bar{y}_{\mathrm{II}} - \bar{y}_{\mathrm{I}} - (\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}}) \beta_{yx,0} \right\} \\ &+ n_{\mathrm{III}}^{1/2} (\bar{y}_{\mathrm{I}} - \bar{y}_{0}) \\ &= n_{\mathrm{III}}^{1/2} (\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}}) \beta_{yc,0} + n_{\mathrm{III}}^{1/2} (\bar{e}_{yc,\mathrm{III}} - \bar{e}_{yc,\mathrm{II}}) \\ &+ n_{\mathrm{III}}^{1/2} (\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}}) \beta_{yx,0} + n_{\mathrm{III}}^{1/2} (\bar{e}_{yx,\mathrm{II}} - \bar{e}_{yx,\mathrm{I}}) \\ &+ n_{\mathrm{III}}^{1/2} (\bar{y}_{\mathrm{I}} - \bar{y}_{0}). \end{split}$$

We have  $D_{x,I} = V_{xx,I}^{-1/2}(\bar{x}_{II} - \bar{x}_{I}) \to \mathcal{N}(0, I_{p_1})$  and  $D_{c,II} = V_{cc,II}^{-1/2}(\bar{c}_{III} - \bar{c}_{II}) \to \mathcal{N}(0, I_{p_1+p_2})$ . Therefore, we have

$$\begin{split} &n_{\mathrm{III}}^{1/2}\left(\bar{y}_{\mathrm{III}} - \bar{y}_{0}\right) \mid \left(Q_{x,\mathrm{I}} < \gamma_{1}^{2}, Q_{c,\mathrm{II}} < \gamma_{2}^{2}\right) \\ &= n_{\mathrm{III}}^{1/2}(\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}})\beta_{yc,0} \mid \left(Q_{x,\mathrm{I}} < \gamma_{1}^{2}, Q_{c,\mathrm{II}} < \gamma_{2}^{2}\right) + n_{\mathrm{III}}^{1/2}\left(\bar{e}_{yc,\mathrm{III}} - \bar{e}_{yc,\mathrm{II}}\right) \\ &+ n_{\mathrm{III}}^{1/2}(\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}})\beta_{yx,0} \mid \left(Q_{x,\mathrm{I}} < \gamma_{1}^{2}, Q_{c,\mathrm{II}} < \gamma_{2}^{2}\right) + n_{\mathrm{III}}^{1/2}\left(\bar{e}_{yx,\mathrm{II}} - \bar{e}_{yx,\mathrm{I}}\right) \\ &+ n_{\mathrm{III}}^{1/2}(\bar{y}_{\mathrm{I}} - \bar{y}_{0}) \\ &= n_{\mathrm{III}}^{1/2}(\bar{c}_{\mathrm{III}} - \bar{c}_{\mathrm{II}})\beta_{yc,0} \mid \left(Q_{c,\mathrm{II}} < \gamma_{2}^{2}\right) + n_{\mathrm{III}}^{1/2}\left(\bar{e}_{yc,\mathrm{III}} - \bar{e}_{yc,\mathrm{II}}\right) \\ &+ n_{\mathrm{III}}^{1/2}(\bar{x}_{\mathrm{II}} - \bar{x}_{\mathrm{I}})\beta_{yx,0} \mid \left(Q_{x,\mathrm{I}} < \gamma_{2}^{2}\right) + n_{\mathrm{III}}^{1/2}\left(\bar{e}_{yx,\mathrm{II}} - \bar{e}_{yx,\mathrm{I}}\right) \\ &+ n_{\mathrm{III}}^{1/2}(\bar{y}_{\mathrm{I}} - \bar{y}_{0}) \\ &\rightarrow V_{\mathrm{III},1}^{1/2}D_{c,\mathrm{II}} \mid \left(D_{c,\mathrm{II}}^{\mathrm{T}}D_{c,\mathrm{II}} < \gamma_{2}^{2}\right) + V_{\mathrm{III},2}^{1/2}Z_{1} + V_{\mathrm{III},3}^{1/2}D_{x,\mathrm{I}} \mid \left(D_{x,\mathrm{I}}^{\mathrm{T}}D_{x,\mathrm{I}} < \gamma_{1}^{2}\right) + V_{\mathrm{III},5}^{1/2}Z_{3} \\ &\rightarrow V_{\mathrm{III},1}^{1/2}L_{p_{\mathrm{I}}+p_{\mathrm{II}},\gamma_{\mathrm{S}}}^{2} + V_{\mathrm{III},2}^{1/2}Z_{1} + V_{\mathrm{III},3}^{1/2}L_{p_{\mathrm{I}},\gamma_{\mathrm{S}}^{2}} + V_{\mathrm{III},5}^{1/2}Z_{3}. \end{split}$$

#### S3.9 Proof of Theorem S7

To derive the asymptotic design properties of the three-phase regression estimator, we use the following facts:

$$E\left(\bar{y}_{\text{III,reg}} \mid \mathcal{B}, \mathcal{A}, \mathcal{F}\right) = \bar{y}_{\text{II,reg}} + O_P(n_{\text{III}}^{-1}),$$

where the probability distribution in  $O_P$  is due to phase-III random sampling given  $(\mathcal{B}, \mathcal{A}, \mathcal{F})$ ,  $\bar{y}_{\text{II,reg}} = \bar{y}_{\text{II}} + (\bar{x}_{\text{I}} - \bar{x}_{\text{II}})^{\text{T}} \hat{\beta}_{yx,\text{II}}$ , and  $\hat{\beta}_{yx,\text{II}}$  is defined as (S6) with z and x being y and x, and

$$E(\bar{y}_{\mathrm{II,reg}} \mid \mathcal{A}, \mathcal{F}) = \bar{y}_{\mathrm{I}} + O_{P}(n_{\mathrm{II}}^{-1}),$$

the probability distribution in  $O_P$  is due to phase-II random sampling given  $(\mathcal{A}, \mathcal{F})$ . Therefore, we use the following decomposition:

$$\begin{split} \bar{y}_{\rm III,reg} - \bar{y}_0 &= \bar{y}_{\rm III,reg} - \bar{y}_{\rm II,reg} + \bar{y}_{\rm II,reg} - \bar{y}_{\rm I} + \bar{y}_{\rm I} - \bar{y}_0 \\ &= \left\{ \bar{y}_{\rm III} + \begin{pmatrix} \bar{x}_{\rm I} - \bar{x}_{\rm III} \\ -\bar{a}_{\rm III} \end{pmatrix}^{\rm T} \hat{\beta}_{yc,\rm III} \right\} - \left\{ \bar{y}_{\rm II} + (\bar{x}_{\rm I} - \bar{x}_{\rm II})^{\rm T} \hat{\beta}_{yx,\rm II} \right\} \\ &+ \left\{ \bar{y}_{\rm II} - \bar{y}_{\rm I} + (\bar{x}_{\rm I} - \bar{x}_{\rm II})^{\rm T} \hat{\beta}_{yx,\rm II} \right\} + \bar{y}_{\rm I} - \bar{y}_0 \\ &= (\bar{e}_{yc,\rm III} - \bar{e}_{yc,\rm II}) + (\bar{e}_{yx,\rm II} - \bar{e}_{yx,\rm I}) + \bar{y}_{\rm I} - \bar{y}_0 + O_P(n_{\rm III}^{-1}). \end{split}$$

By repeated application of conditional expectation arguments, the asymptotic design variance of  $\bar{y}_{\text{III,reg}}$  is

$$\operatorname{a.var}\left\{n_{\operatorname{III}}^{1/2}(\bar{y}_{\operatorname{III,reg}} - \bar{y}_{0}) \mid \mathcal{F}\right\} = \lim_{N \to \infty} \left\{n_{\operatorname{III}}V_{yy,0} + E\left(n_{\operatorname{III}}V_{e_{yx}e_{yx},\operatorname{I}} \mid \mathcal{F}\right) + E\left(n_{\operatorname{III}}V_{e_{yc}e_{yc},\operatorname{II}} \mid \mathcal{F}\right)\right\}.$$

Then, under Assumptions 2 and S1, we establish the result in Theorem S7.
