(Dated: July 1st, 2024)

While hydrogen-rich materials have been demonstrated to exhibit high T_c superconductivity at high pressures, there is an ongoing search for ternary and quaternary hydrides that achieve such high critical temperatures at much lower pressures. First-principles searches are impeded by the computational complexity of solving the Eliashberg equations for large, complex crystal structures. Here, we adopt a simplified approach using electronic indicators previously established to be correlated with superconductivity in hydrides. This is used to study complex hydride structures, which are predicted to exhibit promisingly high critical temperatures for superconductivity. In particular, we propose three classes of hydrides inspired by the FCC RH₃ structures that exhibit strong hydrogen network connectivity, as defined through the electron localization function. The first class $[RH_{11}X_3Y]$ is based on a Pm3m structure showing moderately high T_c , where the T_c estimate from electronic properties is compared with direct Eliashberg calculations and found to be surprisingly accurate. The second class of structures $[(RH_{11})_2X_6YZ]$ improves on this with promisingly high density of states with dominant hydrogen character at the Fermi energy, typically enhancing T_c . The third class [(R¹H₁₁)(R²H₁₁)X₆YZ] improves the strong hydrogen network connectivity by introducing anisotropy in the hydrogen network through a specific doping pattern. These model structures and the design principles provide the enough flexibility to optimize both T_c and the structural stability of complex hydrides.

The synthesis of materials that superconduct at room temperature and atmospheric pressure has been a longstanding dream since the discovery of superconductivity [1]. The theoretical predictions of high T_c superconductivity in metallic hydrogen [2, 3] and its subsequent prediction in dense hydrogen-rich materials [4] have been realized experimentally [5–9] (see [10] for a review), alongside theoretical work. Notable in this regard are predictions of extremely high- T_c superconductivity in LaH₁₀ [11, 12] which were found to agree closely with experiment [5, 6], followed by later experiments on the YH_n system [7–9] and ternary hydrides [13–15]. Several more recent studies have proposed ternary or more complex hydrides as vehicles to lower the pressure needed for very high-temperature superconductivity [16–22].

Many such studies start with the highest T_c stoichiometric compounds and examine alloying effects that lower the pressure necessary to stabilize their structures. An alternative approach is to begin with hydrogen-rich MH₃ units that are already stable at ambient conditions and embed them in supercells designed to maximize T_c , as alluded to in Ref. [4] and explored in a recent computational study of [Al,Ga]H₃ alloys [22]. The FCC rare-earth trihydride (RH₃; R=Sc,Y,La-Lu) compounds have strong electron-phonon coupling (EPC) [23– 27] associated primarily with octahedrally coordinated hydrogen, as in palladium hydrides [28]. Notably, experiments on YH_3 indicate that the FCC phase can be metastabilized with doping [29, 30], ball milling [31], and quenching [32]. In FCC RH₃, doping the rare earth [33] and substituting nitrogen for octahedral hydrogen in LuH_3 [34, 35] have both been predicted to increase this electron-phonon coupling. Notably, evidence of superconductivity in near-ambient conditions has been reported for FCC LuH_{3-x}N_y [36, 37] with 0.8% N by weight. Other experiments indicate that the FCC phase of N-doped LuH_{3- δ} can be recovered to ambient conditions [38] and displays nearly-flat electronic bands just under the Fermi energy E_F[39]. Nearly-flat bands were first predicted in Fm3m Lu₈H₂₃N [40] which is predicted to be dynamically stable at 2 GPa when including nuclear quantum effects [41].

Inspired by the above work, we generalize the idea of doping the metal atom in RH₃ to include small amounts of doping of the octahedral hydrogen with Lewis bases [O,N,S,P]. As the space of possible quaternary structures and stoichiometries is huge, we use FCC RH_3 and the structural motif from our previous work [40] to design model structures with relatively few degrees of freedom. Specifically, we propose three model structures of increasing complexity that are engineered to have dominant hydrogen states at the E_F that emulate metallic hydrogen [4]. These structures are summarized in Fig. 1. When discussing specific examples, we use these structures as starting points and perform DFT variable-cell relaxations. We estimate T_c using a linear correlation observed between Eliashberg T_c and a quantity Φ based on electronic properties of the hydrogen sublattice in hydrides (see *Materials and Methods*). We also perform frozen phonon calculations near ambient pressures to examine the dynamical stability of selected structures.

FIG. 1: Three structures of increasing complexity that serve as model structures for quaternary (or even more complex) hydrides.

RESULTS

$Pm\overline{3}m RH_{11}X_{3}Y Structure$

We present first a simple model structure for quaternary hydrides, with the chemical formula RH₁₁X₃Y (Fig. 2). It is distinguished by a central RH_{11} unit with a typical electron localization function (ELF) and projected density of states (PDOS) illustrated using LuH_{11} as an example in Fig. 2(c,d) surrounded by an X_3Y 'cage'. In the RH₁₁X₃Y model structure, the hydrogens are placed in the positions they occupy in FCC RH₃, except for the 1a Wyckoff position which may be occupied by hydrogen or a Lewis base (N,P,O,S). The 3d Wyckoff positions are also kept unspecified, but the intent for these atoms is to stabilize the FCC lattice. Choices of X and Y are also intended to make the X_3Y cage inert such the chemical bonding of the central RH_{11} unit (and therefore its superconducting properties) is preserved. We explore the effects of filling the X and Y positions and hole doping in Fig. S5 (see SI), finding that the addition of trivalent X atoms typically leads to strong H bonding, bringing the hydrogen states far below E_F . Hole-doping and filling Y=O both result in hydrogen states dominating the $DOS(E_F)$, though not at the same magnitude as LuH_{11} [Fig. 2(d)]. These structures are simple enough to perform Eliashberg calculations for T_c , unlike the more complex structures discussed later. For the latter, estimate the critical temperature for hydride superconductors based on electronic indicators [42], which we refer to as T_c^{net} .

We first note that the networking-value T_c^{net} [(6)] was found to be within ±60 K of isotropic Eliashberg T_c^{Eli} calculations for 300 hydrides [42]. Calculations since then have verified its accuracy at predicting Eliashberg T_c s for CaH₆ (T_c^{Eli} : 236 K, T_c^{net} : 264 K) [43] and Lu₄H₁₁N (T_c^{Eli} : 100 K, T_c^{net} : 99 K) [44]. As a check on the T_c estimation process, we estimate (6) for Fm $\overline{3}$ m LuH₁₀ (see

FIG. 2: Proposed $RH_{11}X_3Y$ structure. (a) Structural parameters, (b) Visualization of the $RH_{11}X_3Y$ unit cell, (c) Example electron-localization-function (ELF) of LuH_{11} at an isovalue of 0.55, (d) PDOS of the example LuH_{11} showing metallic hydrogen states dominant at E_F .

Fig. S4) at 150 GPa (a = 4.91 Å) gives $T_c^{net} \approx 339$ K compared to the Eliashberg $T_c^{Eli} = 289$ K ($\lambda \approx 3.5$)for Fm3m LuH₁₀ at 175 GPa [44]. Additionally, our LuH₁₁ unit in Fig. 2 (a = 5.21 Å) is estimated to have a T_c^{net} of 266 K. Our hypothesis is that any structure with similar chemical tendencies as these FCC RH₁₁ units would have a T_c in a similar range. We note the similarity to the T_c range reported experimentally for Lu-H-N [37].

Lu₄H₁₁O Example

As a reference for structural, electronic and Eliashberg calculations, we choose the example $Pm\overline{3}m Lu_4H_{11}O$ (Fig. 3). The calculated DOS of the structure near E_F is dominated by hydrogen states $[DOS_H(E_F) \sim 0.5],$ meaning its predicted T_c should be higher than that of $Lu_4H_{11}N$ [44] [DOS_H(E_F) ~ 0.33]. This arises from the difference in ionic bonding strength of O compared to N. We find through the ELF that the $\phi_{net}^{crit} = 0.521$, with the networking value predicted $T_c^{net} = 130$ K. Pm $\overline{3}$ m $Lu_4H_{11}O$ features a nearly-flat electron band 0.36 eV below E_F (around X) [Fig. 3(c)] which is expected to contribute to the superconductivity due to the high energy of phonons around 12-15 THz (about 0.08 eV) and 35 THz (0.15 eV). We find increasing correlation effects via DFT+U ($U_d = 5.5$ on Lu) can induce Lifshitz transitions [Fig. 3(c)] indicating correlation effects could increase the EPC. Density functional perturbation theory calculations on a 4x4x4 q-point mesh indicate it is dynamically stable above 25 GPa. We used the EPW code [45] to interpolate the electron-phonon matrix elements using Wannier functions, with k/q meshes of 32^3 and 16^3 . The $\alpha^2 F(\omega)$ leads to a large integrated electron-phonon

FIG. 3: Electronic, structural, and superconducting properties of Pm3m Lu₄H₁₁O. (a) Visualization of the unit cell. (b) PDOS at 17 GPa with and without +U. (c) Band structures with and without +U. (d) $\alpha^2 F(\omega)$, integrated $\lambda(\omega)$, and integrated $\omega_{ln(\omega)}$ after convergence studies. (e) Quasiparticle density of states (QDOS) relative to the normal-state DOS.

coupling of $\lambda \approx 3$ [Fig. 3(d)] and $\omega_{log} \approx 5$ THz, with an Allen-Dynes T_c (see Eq. 1) of 90 K using $\mu = 0.10$ [46]. The Allen-Dynes T_c decreases to 50 K if not converged (e.g. using a coarser mesh and larger thermal broadening factor). The T_c has sizable contributions from the octahedral hydrogen modes below 5 THz and 12-15 THz, with a small contribution to ω_{log} from higher-frequency tetrahedral hydrogen modes at 35 THz.

We performed anisotropic Eliashberg calculations as implemented in the EPW software [47] and compute the quasiparticle DOS in the superconducting state at various temperatures, illustrating the gap closure around 125 K [Fig. 3(g)] which coincides with the T_c^{net} of 130 K predicted by (6). The sizable difference between the Allen-Dynes and Eliashberg T_c may reflect that the Allen-Dynes formula was created from fitting to alloys of conventional superconductors [46] with lower phonon frequencies, and so the high frequency modes here (15 THz and 35 THz) may not be appropriately captured in these fits. The phonon dispersion, superconducting properties, and effect of doping are further elucidated in the Supplementary Information.

Other $RH_{11}X_3$ Y Examples

Both LuH₁₁Ca₃O and CaH₁₁Y₃O have dominant $DOS_H(E_F)$ and end up having similar T_c^{net} despite the almost threefold difference in their total $DOS_{tot}(E_F)$ (Fig. S6, SI). We emphasize this is due to the observation that T_c is not correlated with the total $DOS(E_F)$ in hydrides, but the relative hydrogen contribution [42]. We also

As boron is known to attain an oxidation state as low as B^{5-} , we also explored Lu₄H₁₁B (Fig. S7, SI) and found an interesting flat band near E_F of Lu-d, H-s, and B-p character which remained under relaxation that would likely lead to an instability of some kind. We also found SiH₁₁Lu₃N to have a hybridized nearly-flat band near E_F (Fig. S22, SI) with $T_c^{net} = 90$ K. As their predicted T_c^{net} are below 200 K we did not further examine these examples. We confirm there is no DFT+U dependence for these results (the Fermi level properties do not change).

Selected examples discussed so far as well as the others we explore later are outlined in Table I, with some relative energies of formation computed in Table S1. The results establish that while the first model structure (Fig.

TABLE I: Table of selected materials, with the parent structure, computed electronic properties, and estimated^a T_c

^a The estimated T_c^{net} is rounded to the nearest 5 K with an error bound of ± 60 K [42].

2) can result in hydrogen-dominant states at E_F , the magnitude of the $DOS(E_F)$ is not comparable to that of the core RH_{11} structure; the $DOS_{H,rel}(E_F)$ ratio is not typically close to 1, which limits the achievable T_c^{net} (Eq. 6).

ties suggest a high estimated T_c in the 150-170 K range using (6). However, these examples are unrelaxed so we do not quantify their properties further.

$(CaH_{11})_2$ Sc₆NH Example

$\mathbf{Fm}\overline{3}\mathbf{m} \ (\mathbf{RH}_{11})_2 \mathbf{X}_6 \mathbf{YZ} \ \mathbf{Structure}$

Using T_c^{net} [(6)] as a guiding principle, we build on the simple $RH_{11}X_3Y$ structure (Fig. 2) and design a supercell to increase H_f and $DOS_H(E_F)$. The increased H_f requires less [O,N,S,P], and we hypothesize that high symmetry $Fm\overline{3}m$ structures inspired by our previous work [40, 41] will lead to large $DOS_H(E_F)$ by bringing tetrahedral hydrogen states to E_F . This leads to a supercell in which charge is redirected away from the X_3Y cage surrounding the RH_{11} unit [Fig. 4(a-b)]. We visualize and specify a model structure meeting these requirements in Fig. 4(c,d). The blue regions indicate the RH_{11} regions.

Our second model structure (Fig. 4) is designed to emulate the hydrogen-dominated band structure near E_F of the core RH_{11} units, with the appropriate choice of X,Y, and Z atoms. The chemical formula is $(RH_{11})_2X_6YZ$, where R is an atom in the 8c position, X is an atom stabilizing the FCC RH_{11} lattice in the 24e position with $x \approx 0.25$, and Y,Z in the 4a/4b positions ensure the X atoms are inert with respect to the RH_{11} lattice. The hydrogens occupy two 32f positions with $x \approx 0.875$ and $x \approx 0.625$ as well as the 24d positions. Figure S12 shows four examples without relaxing the structure from the parameters given in Fig. 4(d). Their electronic proper-

We start with an in-depth look at a particular example of the $(RH_{11})_2X_6YZ$ model structure. Choosing $R=Ca, X=Sc, Y=N, and Z=H, we have (CaH_{11})_2Sc_6NH,$ or $Sc_{0.75}Ca_{0.25}H_{2.875}N_{0.125}$. We focus on this example for a variety of reasons. In terms of stability, 25-33% Ca doping is predicted to decrease the pressure needed to stabilize cubic ScH_3 by over 10 GPa [33]. With respect to its potential for high- T_c superconductivity, CaH_6 has been shown to exhibit a T_c of 215 K [48] close to the original prediction [49] and possibly higher T_c with more hydrogen-rich compounds [50]. Additionally, doping CaH_6 with rare earths could achieve even higher T_c [51, 52]. Finally, these ingredients the following criteria: ScN is semiconducting, the Sc atoms will help stabilize the tetrahedral hydrogen in the CaH_{11} unit, and the large electonegativity of N is expected to weaken the ionic bonding of Sc atoms with tetrahedral hydrogen, bringing tetrahedral hydrogen states higher in energy to hybridize with the octahedral hydrogen.

electronic and phonon of The properties $(CaH_{11})_2Sc_6NH$ at 20 GPa are shown in Fig. 5. The PDOS/bandstructure shows multiple hydrogendominant van Hove singularities (vHs) near E_F , reminiscent of the flat bands in $Lu_8H_{23}N$ [40, 41]. We find $\phi_{net}^{crit} = 0.585$ and $T_c^{net} = 165$ K. Removing the 4b-H

or replacing the nitrogen with oxygen both result in T_c^{net} rising to 180 K (Fig. S15). The imaginary phonon frequencies at Γ indicate there may be a structural instability of the hydrogen sublattice.

To evaluate the likelihood of quantum effects stabilizing this structure against such an instability, we evaluate the anharmonicity of the potential energy surface (PES) associated with displacing the crystal along the corresponding dynamical matrix eigenvector (visualized in the inset). We define the number of hydrogen strongly displaced in the mode to be all hydrogen whose displaced distance is more than $D_{max}/6$, where D_{max} is the maximum distance a hydrogen is displaced. We see the maximum energy gain at 20 (30) GPa is 7 (2) meV/hydrogen at an average hydrogen displacement of 0.22 (0.15) Å. The double well PES becomes more harmonic with increased pressure, but the wells deepen as pressure is decreased, similar to $Lu_8H_{23}N$ [41]. Fig. S13 shows examples of ground state densities computed for anhar-

FIG. 5: Electronic density of states (a) and band structure (b) of $Sc_6Ca_2H_{23}N$ at 20 GPa, with several van Hove singularities near E_F circled, (c) Phonon density of states resolved by atomic projections of unique Wyckoff positions, (d) Potential energy surface (PES) of the mode with largest imaginary frequency at 20 and 30 GPa.

monic potentials; potentials can be surprisingly anharmonic while still favoring a centered wavefunction. These results indicate that nuclear quantum effects stabilize the structure against this instability at this or a slightly higher pressure. For pressure ranges where this distortion occurs, we find this distortion in fact could enhance T_c^{net} up to 220 K based on our calculations at 20 GPa (Fig. S2). For more information on this and related stoichiometries, see the Supplemental Information.

Other $(RH_{11})_2 X_6 YZ$ Examples

The electronic properties of twelve more examples are shown in Fig. S9. All twelve examples have hydrogen states dominant at E_F , which correlates with high T_c hydride superconductivity [42]. As H_f in (8) is nearly constant in these examples, the only remaining parameter to maximize T_c is ϕ_{iso}^{net} . Using this metric, we find the highest ϕ_{iso}^{net} values in the $(RH_{11})_2(Mg_6OH)$ systems, with a corresponding networking-value T_c^{net} of 200 K. For R=La the high ϕ_{iso}^{net} responsible for this is attributed to hydrogens tetrahedrally oriented with respect to Mg bending away from the oxygen atoms and forming a body-centered cubic hydrogen cage (Fig. S20), with H-H distance 1.964Å between cube edges and 1.692Å between the vertices and the central H atom. Such small H-H distances have also been observed in some intermetallic hydrides [53]. For R=Sc, the hydrogen cubic cage does not form, but the smaller lattice constant appears to make up for it in terms of high ϕ_{iso}^{net} values. Unfortunately, a stability analysis (see SI Section "Stability") indicates ([La,Sc]H₁₁)₂Mg₆OH are dynamically unstable. However, we note the ternary system (LuH₁₁)₂Lu₆HN was predicted to be dynamically stable at 2 GPa when considering quantum effects [41]. Clearly, fine-tuning of the stoichiometry can be a determining factor in each structure's dynamical stability.

We find that structures with dominant hydrogen states at E_F can be obtained by choosing X=Sc/Y/La/Lu, R = Li/Na/Mg/Ca/Sr/Al/Ga/In, Y = H/O/S/N/P, and Z = H or vacant (see SI). Swapping the role of the R and X atoms also results in hydrogen-dominant states at E_F (see SI), though dynamical and thermodynamic stability is in question.

The properties of a few $(RH_{11})_2X_6YZ$ examples are summarized in Table I. While T_c^{net} is generally higher for these examples the $RH_{11}X_3Y$ model structure, we find in $(CaH_{11})_2$ Sc₆NH that relaxation along instability pathways can in fact raise T_c^{net} through large increases in ϕ_{iso}^{net} (Fig. S2). A similar vibrational analysis on $(LuH_{11})_2$ Lu_6N also reveals a classical distortion [41], which coupled with fine-tuning of the doping level, raises T_c^{net} to 215 K. Based on these observations, we propose our last model structure, designed to increase ϕ_{iso}^{net} and therefore T_c^{net} .

$F\overline{4}3m (R^{1}H_{11})(R^{2}H_{11})X_{6}YZ$ Structure

This structure involves symmetry breaking of the 8c-R atoms of the previous model structure, captured with the formula $(R^1H_{11})(R^2H_{11})(X_6YZ)$, where X is a rare earth atom, and R^1 , R^2 are other electron-donating metal atoms (possibly the same as X). The Wyckoff positions are summarized in Fig. 1. The change in metal ion size enhances symmetry breaking of the 24d-H positions in the structure. Those hydrogen atoms are observed to shift to either R^1 or R^2 (typically whichever has more valence electrons). Fig. 1 shows the symmetry breaking hydrogens (red) as closer towards the 4d- R^2 atoms.

We use this generalization of the $Fm\overline{3}m (RH_{11})_2X_6YZ$ to simulate 12.5% doping of ternary $R_8H_{23}N$ structures, which involves choosing $X = R^2 = a$ rare earth, and R^1 a dopant atom.

Doping $R_8H_{23}N$

We begin with the interesting electronic structure of $Lu_8H_{23}N$ (A) [40] and investigate replacing Lu with Sc,Y. Cell relaxation was performed and the resulting PDOS and electronic properties are compared in Fig. S19 (see SI). U-values were chosen by performing DFT+U calculations on the rare earth nitrides and adjusting U_d to match the indirect band gaps to experiment [54]. For Y₈H₂₃N,

FIG. 6: Properties of (YLiH₂₂)(Y₆NH) (a = 10.1 Å) (a)
Electronic band structure and projected density of states, (b) Phonon density of states resolved by atomic projections of unique Wyckoff positions, (c) Potential energy surface (PES) of the mode with largest imaginary frequency at 1 GPa and 5 GPa.

while the flat hydrogen band is still present near E_F , the larger lattice constant results in a smaller ϕ_{iso}^{net} , lowering the estimated T_c^{net} . For $Sc_8H_{23}N$ the much smaller lattice constant leads to a higher ϕ_{iso}^{net} but the Sc_d orbitals hybridizing with the Fermi level leads to more charge screening of the negative nitrogen atoms. This brings hydrogen states below E_F and weakens the flatness of the hydrogen band.

Given that doping YH₃ assists in stabilizing the FCC phase [29, 55–57] and various studies indicate doping rare-earth hydrides yields high T_cs [33, 58, 59], we investigate the effects of substituting some R=[Sc,Y] atoms in $R_8H_{23}N$ with alkali and alkali earth atoms. In particular, we investigate Li, Na, and Mg doping in $Sc_8H_{23}N$, and Li, Mg, and Ca doping in $Y_8H_{23}N$. We start with the parent structure in Fig. 1(right) using X=Sc/Y,R¹=D (dopant), R^2 =Sc/Y, Y=H,Z=N, with the R¹ position occupied by either a dopant D=Li/Mg/Ca or Sc/Y for lower dopant concentrations.

$(YH_{11})(LiH_{11})Y_6HN Example$

A representative example of the F43m model structure [Fig. 1(right)] is $(YH_{11})(LiH_{11})Y_6HN$ (or $Y_{0.875}Li_{0.125}H_{2.875}N_{0.125}$), which has a lattice constant of 10.1 Å whose stoichiometry is similar to an experimentally stable cubic structure $Y_{0.9}Li_{0.1}H_{2.8}$ [30]. Figure 6 illustrates its electronic and vibrational properties via DFT and frozen phonon calculations [60]. As in previous examples, the $\text{DOS}_H(\mathbf{E}_F)$ is high and dominant [Fig. 6(a)], with contributions from all hydrogen, though the largest contribution is from the 4b-H. The band structure illustrates a propensity of vHs near \mathbf{E}_F , as well as flat band regions 0.3 eV below and 1.1 eV above \mathbf{E}_F [Fig. 6(b)]. As designed, the symmetry-broken octahedral hydrogen improve the connectivity of the hydrogen sublattice, increasing ϕ_{iso}^{net} to 0.6 (note our record of ϕ_{iso}^{net} for Y-based hydrides using the previous structure was 0.55; see Fig. S9). This increases \mathbf{T}_c^{net} to 185 K, which may be increased by pressure and further fine-tuning of the stoichiometry. We find electron doping can increase \mathbf{T}_c^{net} up to 220 K.

Since the zero pressure phonon calculation reveals imaginary modes [Fig. 6(c)], we perform an anharmonicity analysis as was done previously for $(CaH_{11})_2Sc_6NH$ (Fig. 5). Here we find another double well, which at 1 GPa is quite deep but becomes nearly flat at 5 GPa [Fig. 6(d)]. All frequencies are positive at 15 GPa, implying the high-symmetry F43m structure becomes dynamically stable in the 5-15 GPa range. The distortion expected to occur below 5 GPa features octahedral hydrogen bending towards tetrahedral hydrogen, which is expected to anisotropically change ϕ_{iso}^{net} . We find the distortion at 1 GPa to have a fairly negligible effect on the PDOS like in $(CaH_{11})_2Sc_6NH$, but the T_c^{net} drops to 145 K due to an undesirable anisotropy in ϕ_{net}^{crit} .

Various perturbations on $(YH_{11})(LiH_{11})Y_6HN$ also seem to yield high T_c^{net} . Removing the 4b-H yields F43m $Y_{0.875}Li_{0.125}H_{2.75}N_{0.125}$ with $T_c^{net} = 200$ K and a similar double well PES for the mode with largest imaginary frequency (Fig. S3). The primary difference from removing the 4b-H is the DOS is fairly flat around E_F , but an extremely flat hydrogen-based band exists 1 eV above E_F , corresponding to 'hydrogen-cage-like' nearlylocalized electronic states. Further changing one of the 4a-N to a hydrogen atom effectively electron-dopes the system, which also has a high T_c^{net} of 200 K after relaxation.

Other $(R^1H_{11})(R^2H_{11})X_6YZ$ Examples

 $(YH_{11})(CaH_{11})Y_6HN$ has a comparatively modest ϕ_{iso}^{net} of 0.56 and T_c^{net} of 180 K [Fig. S16]. We proceed with Sc-based examples, as the reduced lattice constant generally favors high ϕ_{iso}^{net} . Our remaining examples involve doping Sc₈H₂₃N to form F43m Sc₇[Li,Na,Mg]H₂₃N. The electronic and lattice parameters, and T_c estimates are shown in Table I with PDOS plots in the SI. Behavior similar to Li-doped Y₈H₂₃N occurs with H shifting towards the 4d-Sc Wyckoff positions. This change coupled with the smaller lattice constant of the FCC ScH₃ parent structure leads to large ϕ_{iso}^{net} due to the robust hydrogen network that forms around the 4d-Sc positions.

We summarize the properties of these examples in Table I. The T_c estimates of 185-230 K for these structures illustrate the power of combining both nitrogen and alkali metal dopants in this structure design, enabling heightened ϕ_{iso}^{net} . We mention we briefly investigated replacing N with S, and found F43m Sc₇MgH₂₃S is insulating but with a high $\phi_{iso}^{net} = 0.655$. Hole-doping, for example with further Mg (perhaps using Fm3m (MgH₁₁)₂Sc₆SH) would create a metal with hydrogen-dominant states.

Discussion

In the search for hydride superconductors with very high T_c , a complicating factor is the necessity to include quantum zero-point motion/energy and thermal effects. Without such effects, harmonic phonons with classical nuclei often overestimate structural instabilities for high \mathbf{T}_c hydrides [61, 62]. In fact, \mathbf{T}_c tends to be highest when the system is closest to structural transitions [63] (and where DFT methods can fail). Another complicating factor for first principles searches is that of metastability; it may prove sufficient for experimental purposes to produce a metastable superconductor (so long as its lifetime is measured in months or years), yet such structures would be discarded in many computational structure searches. We therefore take a different approach and design complex hydride structures with the intent of producing electronic properties that correlate with high T_c [42]. We use FCC RH₃ as the parent structure, as these structures have high EPC and can be stabilized at ambient pressures in a variety of ways [31–33, 38, 55].

We have proposed three successively more chemically complex model hydride structures with predicted T_c^{net} maximized by having hydrogen-dominant states at E_F and a strongly connected hydrogen sublattice. The three models exhibit increased flexibility for tuning stability and T_c relative to simple binary structures. Examples within each model structure are candidate high T_c superconductors that are potentially stable near ambient pressure and therefore deserve additional study.

Compounds based on the first and simplest model structure show moderate promise in producing ternary/quaternary hydride superconductors with T_c in the 100-150 K range and are potentially metastable near ambient pressures. We find $Pm\overline{3}m Lu_4H_{11}O$ has a lower formation energy than $LuH_3 + 3LuH_2 + H_2O$ by 0.128 eV/atom (Table S1). We also note YH₃ and Y₂O₃ are known to react to form cubic YH_xO_y under heating [64]. The second and third model structures of quaternary hydrides have enough flexibility to optimize parameters going into the T_c^{net} estimator, which we use to generate examples with upper estimated T_c^{net} s up to 220-230 K at near-ambient pressures when accounting for hydrogen distortions. While the examples discussed are not on the convex hull (Table S1), this does not discount their possible metastability. For example, diamond is also 0.14 eV/atom above its convex hull using data from Ref. [65].

The second model can produce compounds with high

 T_c^{net} stable at low pressures, as Lu₈H₂₃N (A) studied by us previously [40] was shown to be dynamically stable at 2 GPa when nuclear quantum effects are included [41]. Recently, N-doped FCC LuH₃ has been observed to be recoverable to ambient [38] using the techniques in Ref. [32]. Our Fm $\overline{3}$ m (CaH₁₁)₂ Sc₆NH example is expected to be dynamically stable above 20 GPa when nuclear quantum effects are included. As the double well is deepened (from i.e. lower pressure) the octahedral hydrogen are expected to distort from high symmetry positions which surprisingly increases T_c^{net} , with a pressure regime where spectroscopic signatures are broadened due to quantum ZPM. This interpretation on the structural dynamics is supported by high-pressure studies of ScH₃ [66].

Our third model structure involves complexity higher than quaternary systems. Nevertheless, we limit ourselves to the quaternary case by analyzing the doping of [Sc/Y]₈H₂₃N structures. The structure is designed to distort hydrogen to increase ϕ_{iso}^{net} with many possible dopants. Based on our calculations on cubic $Y_{0.875}Li_{0.125}H_{2.875-\delta}N_{0.125-\epsilon}$ structures, we predict T_c to have a maximum of 220 K \pm 60 K at a pressure between 5-15 GPa for optimal δ, ϵ . For synthesis we recommend leveraging the approaches used in Refs. [30, 32, 38]. At lower pressures, distortions away from the $F\overline{4}3m$ structure occur. It is difficult to predict what the effect on T_c is because the ϕ_{crit}^{net} parameter becomes very anisotropic; small four-center hydrogen bond net-works form for with $\phi_{crit}^{*,net} \equiv 0.8$ but extended hydrogen networks form across the entire cell at $\phi_{crit}^{net} = 0.5$. Such anisotropic behavior in large unit cells was not considered in the data for T_c^{net} [42], so the predicted T_c^{net} of 145 K for the distorted structure at 1 GPa could have a larger error bar than 60 K. Other examples of the $F\overline{4}3m$ model structure similarly illustrate that doping $R_8H_{23}N$ increases T_c^{net} by 30-50 K. As the highest predicted T_c^{net} comes from cubic (Mg,N)-doped ScH₃, we note Mg and Sc form cubic alloys [67] and in fact have been studied as hydrogen storage materials [68, 69]. Based on our results and previous studies [29, 33, 55], we find it likely that these doped $[Sc,Y]_8H_{23-\delta}[N,O]$ examples with extremely high predicted T_c are synthesizable and dynamically stable with compression.

We note again T_c^{net} only reproduces T_c from Eliashberg calculations within ± 60 K, so some examples presented may in fact have T_c exceeding 270 K. It is likely that the T_c for the structures presented here is large in a narrow pressure range, based on Eliashberg calculations on YH₃ [70] and experiments on N-doped LuH₃ [37, 71]. We remark that preliminary constrained DFT calculations indicate strong correlation effects may be present in these systems for the same reasons as presented in Ref. [72]; that is, DFT struggles to represent the nearneutral hydrogen atoms present in RH_{3- δ} and how its charge fluctuations impacts the electronic structure. A more thorough investigation of these effects is underway.

In summary, we present model structures based on doped supercells of FCC RH_3 to adopt their dynamical

stability properties at low pressures while tuning their electronic properties. These supercells have been engineered to have high T_c s with upper estimates of 220 ±60 K. We end by remarking that it is compelling that the highest predicted T_c using our methodology comes from (Mg,N)-doped ScH₃, which features both Ashcroft's proposal for hydrogen-dominant metallic alloys [4] and Feynman's guess that the highest temperature superconductor would be Sc-based [73].

MATERIALS AND METHODS

We use density functional theory (DFT) [74-76] and DFT+U [77, 78] first-principles electronic structure calculations to study the examples built using our proposed model structures (Fig. 1). The SSSP database [79] was used to vet pseudopotentials for convergence of the computed pressure, phonon frequencies, and formation energies. Each relaxed structure had remaining forces under 1e-5 Ry/Bohr, and energy differences were under 1e-5 Ry. We used wavefunction plane-wave cutoffs of 75 Ry for the structures and charge density cutoffs of 300 Ry, though we performed convergence tests with higher values (especially for Sc-based compounds) and found no differences. We generally used tight k-meshes corresponding to 0.13 \AA^{-1} , but did convergence tests with more k-points as needed. We used Quantum Espresso's default atomic projections for the PDOS calculations. The phonopy software [60] was used the compute phonon dispersions and generate the eigenvectors for atomic displacements.

The Allen-Dynes formula for T_c takes the form

$$T_c \approx f_1 f_2 \frac{\omega_{ln}}{1.20} \exp\left\{-1.04 \left(\frac{1+\lambda}{\lambda-\mu^*(1-0.62\lambda)}\right)\right\}$$
(1)
$$f_1 = \left[1 + \left(\frac{\lambda}{\Lambda_1}\right)^{3/2}\right]^{1/3} \qquad f_2 = 1 + \frac{\lambda^2}{\lambda^2 + \Lambda_2^2} \left(\frac{\overline{\omega}_2}{\omega_{ln}} - 1\right)$$
(2)

$$\Lambda_1 = 2.46(1+3.8\mu^*) \qquad \Lambda_2 = 1.82(1+6.3\mu^*)\frac{\overline{\omega}_2}{\omega_{ln}}$$
(3)

$$\omega_{ln} \equiv \exp\left(\frac{1}{\lambda} \int_0^\infty \frac{\alpha^2 f(\omega)}{\omega} \log(\omega) d\omega\right) \tag{4}$$

$$\overline{\omega}_2 \equiv \frac{\int_0^\infty \alpha^2 f(\omega)\omega d\omega}{\int_0^\infty \alpha^2 f(\omega)/\omega d\omega}$$
(5)

To study large amounts of stoichiometries in our model structures and try to maximize T_c , we take advantage of the established correlation between certain hydride electronic properties and the isotropic Eliashberg T_c [42], which yields a method to roughly estimate T_c . The T_c estimator takes the form

$$T_c^{net} \approx 750\Phi - 85 \quad \text{(Kelvin)} \tag{6}$$

$$\Phi \equiv \phi_{iso}^{net} \times H_f \times \sqrt[3]{\text{DOS}_{H,rel}(E_F)}$$
(7)

$$H_f \equiv \frac{\# \text{ of } H \text{ forming network}}{\# \text{ of atoms in unit cell}}$$
(8)

$$DOS_{H,rel}(E_F) \equiv \frac{DOS_H(E_F)}{DOS_{tot}(E_F)}$$
(9)

(10)

where ϕ_{iso}^{net} is the critical hydrogen networking isovalue [42] which roughly measures the bonding strength/connectivity of the hydrogen sublattice. It is determined by the isovalue in which the electron local-

ization function (ELF) of electrons centered on different hydrogen atoms begin to overlap. H_f is the fraction of hydrogen in the unit cell forming a network with overlapping ELF from different hydrogen, and $\text{DOS}_{H,rel}(E_F)$ is the relative contribution of hydrogen states to the density of states at E_F . T_c^{net} has been established to reproduce the computed isotropic Eliashberg T_c of hundreds of hydrides within ± 60 K [42], which we find acceptable to identify material candidates to look further into.
