The ability of quantum computers to directly manipulate and analyze quantum states stored in quantum memory allows them to learn about aspects of our physical world that would otherwise be invisible given a modest number of measurements. Here we investigate a new learning resource which could be available to quantum computers in the future – measurements on the unknown state accompanied by its complex conjugate  $\rho \otimes \rho^*$ . For a certain shadow tomography task, we surprisingly find that measurements on only copies of  $\rho \otimes \rho^*$  can be exponentially more powerful than measurements on  $\rho^{\otimes K}$ , even for large K. This expands the class of provable exponential advantages using only a constant overhead quantum memory, or minimal quantum memory, and we provide a number of examples where the state  $\rho^*$  is naturally available in both computational and physical applications. In addition, we precisely quantify the power of classical shadows on single copies under a generalized Clifford ensemble and give a class of quantities that can be efficiently learned. The learning task we study in both the single copy and quantum memory settings is physically natural and corresponds to real-space observables with a limit of bosonic modes, where it achieves an exponential improvement in detecting certain signals under a noisy background. We quantify a new and powerful resource in quantum learning, and we believe the advantage may find applications in improving quantum simulation, learning from quantum sensors, and uncovering new physical phenomena.

### I. INTRODUCTION

Efficiently extracting information from quantum states is a central task in quantum information science. It is crucial in physical experiments and will be critical in simulations run on future quantum computers. Often learning the details of an entire quantum state is not required, but rather we would like to extract the expectation values of a set of interesting observables.

Naively, measurements of many properties of quantum states are constrained by the uncertainty principle for non-commuting operators. Additionally, tomographic techniques for exactly learning a quantum state up to a stringent standard like worst case observable error (or trace distance) are known to scale exponentially in the number of qubits or polynomially in the size of the Hilbert space [\[1,](#page-5-0) [2\]](#page-5-1). Surprisingly however, the development of shadow tomography techniques demonstrated that one can learn a set of expectation values of even non-commuting observables with high probability with a shockingly small number of samples, scaling only polylogarithmically in the number of observables [\[3–](#page-5-2)[6\]](#page-5-3). While powerful, the general schemes suffer from two large caveats: they are computationally inefficient, and they require immense quantum memories, sometimes millions of times the size of the original state, to enable huge entangled measurements. Classical shadows [\[7\]](#page-5-4) were developed to circumvent both of these limitations – it is computationally efficient, and requires only single-copy measurements for a wide class of useful observables. However, classical shadows place limitations on the sets of observables that are available, for example some schemes are only able to learn observables which are either local or low rank.

It is now known that many of the limitations of classical shadows performed only on single copies at a time are fundamental. For general quantum states, certain collections of observables can only be learned with a logarithmic number of samples by exploiting entangled measurements across multiple copies of a state [\[8–](#page-5-5)[10\]](#page-5-6). This was shown to be true even for some of the simplest large sets of observables, namely Pauli operators on  $n$  qubits. Phrased a different way, the ability to make entangled measurements on copies of a quantum state can grant exponentially more power in learning tasks. Since such schemes require a quantum memory to store simultaneous copies of an unknown state and this type of advantage cannot be overcome even by an arbitrary amount of classical computation when samples are limited, this constitutes a promising future application of quantum computers. It was demonstrated experimentally in Ref. [\[10\]](#page-5-6) that the advantage persists even for small numbers of qubits and in the presence of noise. Importantly, Ref. [\[10\]](#page-5-6) showed that exponential advantages are available using only 2 copies at a time of the state in quantum memory, or an example of a minimal quantum memory for which the number of copies required is independent of the learning task. This demonstrated the existence of learning tasks for which extremely limited quantum resources could provide huge advantages, in contrast to the need of general shadow tomography to have memories that could be millions of times larger than the system of interest even when tasked with estimating observables to a precision of only  $10^{-3}$ .

In this work, we explore a novel resource for learning which is able to grant exponential advantages using only a minimal quantum memory (space for only 2 copies) – the ability to make joint measurements on

FIG. 1: A cartoon of the techniques and novel resources in this work. Here we quantify the advantage endowed by minimal quantum memories containing  $\rho \otimes \rho^*$  in learning about natural properties of quantum states coming from quantum sensors or digital quantum simulations. (Left) The resources  $\rho$  and  $\rho^*$  are available from both

computational sources such as a known quantum circuit or natural sources like certain quantum sensor setups. (Right) This resource provides an exponential advantage in queries and computation for some learning tasks when only a minimal quantum memory (or constant number of copies) is available, as in most devices in the foreseeable future. Without  $\rho^*$ , one needs either a large quantum memory or exponentially many samples. Several applications of this technique are introduced and we believe this will motivate the development of further applications of minimal quantum memories.

an unknown quantum state with its complex conjugate, denoted  $\rho \otimes \rho^*$ . We give a learning task that can be achieved with low sample complexity using measurements on  $\rho \otimes \rho^*$ . In contrast, without access to  $\rho^*$ , the same learning task requires exponentially more measurements, unless the size of the quantum memory is allowed to expand to practically unrealistic sizes as a function of the learning task. While it is known that quantum memory access to  $\rho$  and  $\rho^*$  provide an efficient means to sample in the Heisenberg-Weyl basis, accomplishing a similar learning task to one discussed here [\[11](#page-5-7)[–13\]](#page-5-8), to the knowledge of the authors a quantum memory size lower bound without access to  $\rho^*$  has not been shown previously. Although the operation of complex conjugation to an unknown state  $\rho^*$  is not physical and cannot be implemented efficiently, in Appendix [D](#page-16-0) we highlight a wide class of cases where the complex conjugate state is available and discuss potential limitations. We prove a lower bound showing that that copies of  $\rho^*$  and  $\rho$  without quantum memory are also insufficient for the learning task.

Previous schemes using minimal quantum memory have only been able to resolve the magnitude of the observable [\[10,](#page-5-6) [14\]](#page-5-9) requiring a quantum memory scaling polynomially in precision to determine the sign. The question of whether it is possible to determine both the magnitude and sign using a minimal quantum memory is resolved in Ref. [\[15\]](#page-5-10) and we introduce a specialization here for the specific class of operators we are interested in.

Our exponential separation holds for a natural and

physically motivated set of observables. The setting is a d-dimensional Hilbert space that discretizes position and momentum space with a natural limit of a continuous bosonic mode, and the operators we learn if we take the infinite dimensional limit are the bosonic displacement operators [\[16\]](#page-5-11). These operators more naturally correspond to real-space arrays of quantum sensors. Recent developments in reconfigurable atom arrays [\[17\]](#page-5-12) may provide a fruitful test bed for applications in a sensing context for example, especially given their wide bandwidth and sensitivity in other applications [\[18–](#page-5-13)[22\]](#page-5-14). In addition to the learning algorithm using  $\rho \otimes \rho^*$ , we develop a version of classical shadows tailored to the d-dimensional bosonic setting. It uses a uniform distribution over the generalized d-dimensional Clifford group to make singlecopy measurements with good predictive power. Despite the more limited power of single copies, we identify a wide class of quantities that are efficiently learnable.

The core technique of our learning algorithm using  $\rho \otimes \rho^*$  relies on using extensions via tensor products to create commutativity among displacement operators with Pauli operators as a special case. One may wonder if this technique can be applied to a broader class of operators than displacement operators, and we partly resolve this question in the negative by showing commutativity via tensor extension naturally corresponds to a definition of the Heisenberg-Weyl group with a relationship to uniqueness via the Stone-von Neumann theorem.

Finally, we highlight two potential applications of our work. The first is to learn efficiently from the output of quantum simulations run on quantum computers. Given

a quantum algorithm and the explicit quantum circuit that prepares a state of interest  $\rho$ , one can easily complexconjugate the gates of the quantum circuit to prepare the complex conjugate state  $\rho^*$ . Then incurring a factor of two overhead in the size of the quantum computer, one can perform entangled measurements on  $\rho \otimes \rho^*$  to realize this exponential advantage. The second realm of applications lies in learning from quantum data collected by quantum sensors, such arrays that have been proposed for long baseline interferometry [\[23–](#page-6-0)[26\]](#page-6-1). The operators we consider are naturally related to regular arrays of quantum sensors arranged in real-space, and we provide examples where  $\rho^*$  can be obtained in Appendix D4. In this setting, our technique represents a specialized form of mixedness testing [\[27\]](#page-6-2), where it allows exponentially improved signal to noise ratios in determining if a signal is present in high background noise settings for certain classes of states. Potential applications and natural sources of  $\rho^*$  are discussed in Appendix [D.](#page-16-0) We hope these results motivate the discovery of additional applications of minimal quantum memories equipped with complex conjugate resources.

### II. NECESSITY AND POWER OF CONJUGATE QUANTUM STATES

Here we provide some background on the operators and states that we aim to learn, and then state our main theorems showing the exponential power of access to the complex conjugate resource in a minimal quantum memory. Shifts in discrete position and momentum space are given by the d-dimensional clock and shift operators, Z and X, which are generalizations of the qubit Pauli operators to d dimensions.

$$
X = \begin{pmatrix} 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 \end{pmatrix}, \tag{1}
$$

$$
Z = \begin{pmatrix} 0 & \omega & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \omega^{d-1} \end{pmatrix}, \tag{2}
$$

where  $\omega := e^{i2\pi/d}$ . The operators map naturally to a 1D discrete line in real space, and can be interchanged via the d-dimensional quantum Fourier transform. Combined position and momentum shifts may be lumped together into displacement operators  $D_{q,p}$ , defined briefly as

$$
D_{q,p} = e^{i\pi qp/d} X^q Z^p \tag{3}
$$

and in more detail in Appendix [A.](#page-7-0)

Definition 1. The displacement amplitudes of a ddimensional state ρ are

$$
y_{q,p} = \text{Tr}\left(D_{q,p}\rho\right) \tag{4}
$$

The displacement operators may be used to form a basis for quantum states, and there are  $d^2$  displacement amplitudes. The central task we consider in this paper is to estimate all  $y_{q,p}$  to precision  $\varepsilon$  given copies of an unknown quantum state  $\rho$ .

<span id="page-2-1"></span>Task 1. (Informal) Given access to a quantum state  $\rho$ , estimate all the displacement amplitudes  $\{y_{q,p}\}\$  to precision  $\varepsilon$  with high probability.

Our first result is a sample complexity lower bound showing the minimal size of a conventional quantum memory required to efficiently perform this task without access to the resource  $\rho^*$ . We assume we can measure K copies  $\rho^{\otimes K}$  at a time, possibly in entangled bases, but allow no access to  $\rho^*$ .

<span id="page-2-2"></span>Theorem 1. Let d be the dimension of the Hilbert space. Assume d is prime. Any protocol which learns the magnitudes of all displacement amplitudes to precision  $\varepsilon$  with probability 2/3 by measuring copies of  $\rho^{\otimes K}$ ston  $\varepsilon$  with probability  $2/3$  by measuring copies of  $\rho^{0.5}$ <br>for  $K \leq 1/(12\varepsilon)$  requires  $\Omega(\sqrt{d}/(K^2\varepsilon^2))$  measurements.

The full proof of this is given in Appendix [G 2.](#page-26-0) Using a quantum memory with  $\rho^{\otimes K}$ , performing the learning task whilst consuming a number of copies scaling only as  $polylog(d)$  is impossible, even if K grows as large as  $1/(12\varepsilon)$ . Hence it is impossible to efficiently perform the task with a minimal quantum memory.

This negative result may lead one to conclude that quantum memories are not as powerful as one might hope for physical learning tasks, but there is a resolution to this challenge which reveals an interesting subtlety in the power of quantum computing in analyzing quantum data. While a quantum memory containing K states  $\rho^{\otimes K}$  is insufficient, measurements on the state  $\rho \otimes \rho^*$  are able to learn the displacement amplitudes of  $\rho$  up to a sign. Not only does the learning algorithm using  $\rho \otimes \rho^*$  have logarithmic sample complexity, but the algorithm is very simple and computationally efficient. Note that we use the term "up to a sign" to convey that because these are unitary but not always Hermitian operators, they are complex valued and we are able to learn some, but not all, phase information about that value with this procedure. With the detailed proof and algorithm given in Appendix [B,](#page-9-0) we show

<span id="page-2-0"></span>Theorem 2. There is an algorithm which can learn all displacement amplitudes up to a possible minus sign, with precision  $\varepsilon$ , using  $\mathcal{O}(\log d/\varepsilon^4)$  samples. The algorithm makes measurements only on copies of  $\rho \otimes \rho^*$  contained in a minimal quantum memory. Moreover, the algorithm is computationally efficient.

When viewed together, these theorems highlight the exponential advantage of using  $\rho^*$  as a resource in learn-ing tasks. Indeed as we show in Appendix [D 1,](#page-16-1)  $\rho^*$  is quite a powerful resource in other contexts, and may not be available for totally general unknown states. This naturally leads one to wonder whether the state  $\rho^*$  has this

power in the single copy setting, but indeed lower bounds rule this out and show that entangled measurements are also a necessary component of the learning algorithm in Theorem [2.](#page-2-0) Our following theorem articulates this more precisely.

<span id="page-3-2"></span>Theorem 3. Let d be the dimension of the Hilbert space. Any single-copy protocol which learns the magnitudes of all displacement amplitudes to precision  $\varepsilon$  with probability 2/3 requires a number of copies scaling as  $\Omega(d/\varepsilon^2)$ . This holds even if the protocol has access to single-copy measurements of both  $\rho$  and  $\rho^*$ .

With the detailed proof given in Appendix [G 1,](#page-24-0) this result reiterates the conclusion that entangled measurements using quantum memories have dramatically more power than those that can process only a single copy at a time, and indeed that  $\rho^*$  inside a minimal quantum memory is a powerful and novel resource.

The algorithm to learn the displacement amplitudes up to a sign uses a technique where one attaches a second system and constructs a mutually commuting set of operators on the joint system which contain information about the original non-commuting operators on the single system. This trick was used previously to develop a shadow tomography algorithm for Pauli operators in [\[14\]](#page-5-9). Given the success of this technique, it is natural to wonder what other types of measurement and systems this could be applied to more generally. In Appendix [E,](#page-21-0) we give evidence that the ability to use this trick is unique to displacement operators which arise from representations of the Heisenberg groups. The qubit Pauli operators are a special case, and our work provides arguably the maximal generalization. We can show the following theorem using an idea reminiscent of the Stone-von Neumann theorem.

<span id="page-3-0"></span>**Theorem 4.** Let  $U, V$  be unitaries of finite order  $d$  on some Hilbert space  $H$ . Suppose U and V do not commute, but we can attach a second Hilbert space  $\mathcal{H}'$  with unitaries U, V such that U⊗U and V⊗V commute. Then there is some unitary transformation of  $H$  mapping  $U, V$ to a direct sum of displacement operators.

Theorem [4](#page-3-0) suggests that to go beyond these classes of observables with efficient shadow tomography, we must search for new quantum learning primitives.

### III. RESOLVING THE SIGNS

So far the tasks discussed have only pertained to learning expectation values up to a sign. Previous work has shown that learning the magnitudes of Pauli operators was possible with a minimal quantum memory, but determining the signs required a large quantum memory with task dependent size [\[14\]](#page-5-9) leaving the question of an efficient, minimal memory protocol open. The signs of these operators clearly contain useful information, and hence one may ask if it is possible to efficiently measure

the signs in an information theoretic and computationally efficient sense using only measurements on  $\rho \otimes \rho^*$ as well. This question is resolved by techniques developed in Ref. [\[15\]](#page-5-10); we introduce a specialization here for the specific class of operators we are interested in, with detailed algorithms in Appendix [C.](#page-13-0)

<span id="page-3-1"></span>Theorem 5. There is an algorithm which can learn all  $d^2$  displacement amplitudes (including their sign) using  $\mathcal{O}(\log d/\varepsilon^4)$  samples. The algorithm makes measurements only on copies of  $\rho \otimes \rho^*$ . The runtime of the algo*rithm is*  $\text{poly}(d, \varepsilon^{-1})$ .

The algorithm in Theorem [5](#page-3-1) relies on two key ideas [\[15\]](#page-5-10): one is to use a hypothesis state to 'shift the origin' of a subsequent magnitude measurement, and the other is to use matrix multiplicative weights [\[4,](#page-5-15) [28\]](#page-6-3) as a subroutine to efficiently determine the hypothesis state.

# IV. APPLICATION 1: QUANTUM DATA FROM QUANTUM COMPUTATION

As a first application, we consider cases where an explicit quantum circuit is known for a state we wish to study. When conducting a physical experiment, we are often preparing some natural quantum state and subsequently performing measurements. In quantum simulation, we aim to design quantum algorithms that simulate Nature, so that the quantum algorithm prepares the physical quantum state of interest. One may wonder, is there any advantage to having a quantum algorithm which prepares state  $\rho$ , rather than accessing copies of  $\rho$ through an experimental setup? In particular, are there natural learning tasks where performing quantum simulation gives a big benefit?

Task [1](#page-2-1) answers this question in the affirmative. While other polynomial advantages to having access to the source code are known [\[29\]](#page-6-4), the learning task here demonstrates an exponential advantage over black box access. In general experimental setups, it can sometimes be unclear how to access the complex conjugate  $\rho^*$  of the state of interest  $\rho$ . We detail this difficulty in Appendix [D 1](#page-16-1) and discuss some natural cases where it is accessible in Appendix [D](#page-16-0) more broadly. However, if we have a quantum algorithm which prepares  $\rho$  we can easily access  $\rho^*$ on our quantum computer – we simply complex conjugate the quantum algorithm itself.

More concretely, suppose unitary U prepares state  $\rho$ via  $\rho = \text{Tr}_{\bar{S}}(U|0...0\rangle\langle0...0|U^{\dagger}),$  and we have an efficient quantum circuit for  $U$ . Then by complex conjugating every gate in the circuit we can implement unitary  $U^*$ , which will prepare state  $\rho^*$  via  $\rho^*$  =  $\text{Tr}_{\bar{S}}\left(U^*|0...0\rangle\langle0...0|U^T\right).$ 

Theorems [1](#page-2-2) and [2](#page-2-0) then exhibit an exponential cost saving for Task [1](#page-2-1) from having white-box access to a quantum algorithm which prepares a quantum state of interest  $\rho$ .

### V. APPLICATION 2: QUANTUM DATA FROM NATURE

As a second category of applications, we consider unknown quantum states collected from nature. For example, these states could be gathered via quantum sensors or transduced from other quantum systems. The ability to learn about unknown states  $\rho$  with exponentially fewer samples using a minimal quantum memory with only  $K = 2$  prompted experimental demonstrations of this idea showing they were robust even with noisy operations today [\[10\]](#page-5-6). Despite these promising results, connecting these advantages to existing quantum sensor states today has been challenging, as many quantum sensors today are single qubit, ensembles of single qubits, stretched single qubits like GHZ states, or cavity modes [\[24\]](#page-6-5).

In contrast to the collection of qubit case, the operators considered in d-dimensions here connect naturally with quantum sensor arrays in regular spatial arrangements with connections to applications like very long baseline interferometry enabled by quantum communication [\[23\]](#page-6-0). We detail some of these connections in Appendix [D 4,](#page-18-0) and given examples of setups where access to the complex conjugate state  $\rho^*$  may be available either exactly or approximately. The displacement operators are a natural description of discrete position and momentum for realspace arrays, especially in a quantum regime where few excitations are expected and background thermal noise is high.

For these scenarios, we argue that one way to view the results here is as a specialized form of mixedness testing, where for a natural class of signals, exponentially fewer samples are require to detect the presence of the signal when combined with a sea of background noise. For applications like detection of radio signals as in NMR, it is common for an infinite temperature background to be quite strong, and this may find applications in that area. These results provide an additional setting for which exponential advantage in signal detection is possible with quantum memory, outside of the existing hierarchies of conventional quantum memory [\[27\]](#page-6-2).

# VI. GENERALIZED CLIFFORD SHADOWS

Given the current difficulty of going beyond minimal quantum memories, one may wonder about the information that can be gleaned from single copies in this ddimensional setting. One of the most effective methods for consuming single copies in the case of qubit operators is classical shadows. Here we develop a version suitable for the d-level quantum system, by considering the classical shadows associated with random generalized Clifford circuits. The group  $\text{Cl}_d$  of generalized Cliffords in d dimensions is the normaliser of the Heisenberg-Weyl group. In [\[30\]](#page-6-6) they analyze a related construction in the continuous-variable setting.

<span id="page-4-0"></span>**Theorem 6.** Let d be prime, and let  $\{|j\rangle : j \in \mathbb{Z}_d\}$  be the computational basis for  $\mathbb{C}^d$ . For any unknown state  $\rho$  in  $\mathbb{C}^d$ , any subset of the quantities  $\{ \langle i | U^{\dagger} \rho U | j \rangle : i, j \in$  $\mathbb{Z}_d, i \neq j, U \in \mathrm{Cl}_d$  can be estimated with high probability to within additive error  $\varepsilon$  using at most  $\mathcal{O}(\log(d)/\varepsilon^2)$ single-copy measurements of  $\rho$ . Moreover, the measurements can be done up front, independent of  $U, i, j,$  and the classical postprocessing to compute estimates is efficient.

In other words, we can efficiently measure the transition elements of  $\rho$  with respect to any and all stabiliser bases, i.e.,  $\{U|j\rangle : j \in \mathbb{Z}_d\}$  for all  $U \in \mathrm{Cl}_d$ , using a number of copies that scales only logarithmically with d.  $\mathrm{Cl}_d$  includes, for example, the quantum Fourier transform over d dimensions. In Appendix [H,](#page-30-0) we prove Theorem [6](#page-4-0) and analyse at a general level the classical shadows corresponding to the uniform distribution over  $\mathrm{Cl}_d$ , by evaluating k-fold twirl channels for  $\mathrm{Cl}_d$  for k up to 3. In particular, we derive an explicit expression for the variance of estimates for  $tr(O_\theta)$ , for an arbitrary operator  $O$  (Theorem [31\)](#page-40-0). Interestingly, like the classical shadows associated with n-qubit Clifford circuits, this variance depends on the Hilbert-Schmidt norm of O, but it also has a further dependence on the overlaps of O with displacement operators in a particular way (that is somewhat reminiscent of the variance for matchgate shadows in Ref. [\[31\]](#page-6-7)). Because of this additional dependence, the variance is not small for all low-rank observables; for instance, it scales linearly with d when  $O = |j\rangle\langle j|$ , which is why we only consider off-diagonal elements  $\langle i|U^{\dagger}\rho U|j\rangle$ with  $i \neq j$  in Theorem [6.](#page-4-0)

It can also be shown using Theorem [31](#page-40-0) that the variance for measuring displacement operators is  $\Omega(d)$ . This implies that learning all displacement amplitudes using this particular classical shadows procedure may require  $\Omega(d/\varepsilon^2)$  copies of  $\rho$ , which is consistent with our lower bound result in Theorem [3.](#page-3-2)

### VII. CONCLUSIONS AND OUTLOOK

Exponential advantages in learning about physical systems made possible by quantum memories and quantum control represent a new opportunity for early quantum computers. These techniques will find use in the readout stage of quantum simulations run on quantum computers and provide the exciting prospect of learning from quantum sensors with unprecedented efficiency. While there remain many practical challenges in the implementation of this full quantum data pipeline and the full extent of applications of this technology remain unknown, there has been much recent progress.

In this work we investigated a new resource for learning – the ability to perform measurements on  $\rho \otimes \rho^*$ . We showed that for a natural set of operators, these measurements can provide exponential savings in sample complexity while using only a minimal quantum memory. Moreover, the setting of our learning task is closer

to quantum sensors people imagine constructing, providing a more natural design path towards advantage in real applications. We also resolved the question of whether a minimal quantum memory is sufficient to learn the signs of operators as well as just their magnitudes, and investigated a new form of classical shadows native to the d-dimensional setting.

We argued that the particular technique based on commutation achieved by simple tensor products that has been prominent in achieving learning advantages with quantum control is uniquely satisfied by the displacement operators we consider here. This raises the question of if

# <span id="page-7-0"></span>Appendix A: Background

### 1. Displacement operators

Given a d-dimensional quantum system  $\mathbb{C}^d$  with basis  $\{|0\rangle, \ldots, |d-1\rangle\}$ , we define the operators X and Z by

$$
X : |j\rangle \mapsto |j+1\rangle \tag{A1}
$$

$$
Z:|j\rangle \mapsto \omega^j|j\rangle. \tag{A2}
$$

Here and throughout, the addition inside the ket is modulo  $d$ , and

<span id="page-7-7"></span>
$$
\omega := e^{i2\pi/d}.\tag{A3}
$$

The matrix representations of X and Z are

$$
X = \begin{pmatrix} 0 & 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & 0 \end{pmatrix},
$$
(A4)  

$$
Z = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ 0 & \omega & 0 & \dots & 0 \\ 0 & 0 & \omega^2 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \omega^{d-1} \end{pmatrix}
$$

 $X, Z$  are traceless and unitary but not Hermitian in general.  $X$  is a *shift* rotation, generated by the discrete momentum operator, and Z is a phase rotation, generated by the discrete position operator. For  $d = 2$ , X and Z coincide with the usual Pauli matrices, and in this case they are in fact Hermitian.  $X, Z$  obey the commutation relation

$$
ZX = \omega XZ
$$
  
\n
$$
\implies Z^p X^q = \omega^{qp} X^q Z^p
$$
\n(A6)

Define the *displacement operator*  $D_{q,p}$  by

<span id="page-7-6"></span><span id="page-7-4"></span>
$$
D_{q,p} = e^{i\pi qp/d} X^q Z^p \tag{A7}
$$

 $D_{q,p}$  acts on basis vectors by

<span id="page-7-5"></span>
$$
D_{q,p}:|j\rangle \to e^{i\pi(q+2j)p/d}|j+q\rangle \tag{A8}
$$

<span id="page-7-3"></span> $D_{q,p}$  is a unitary which can be interpreted as shifting by the vector  $(q, p)$  in discrete position-momentum phase space. Proposition 7. The displacement operators have properties

$$
D_{q,p}^{-1} = D_{q,p}^{\dagger} = D_{-q,-p} \tag{A9}
$$

$$
D_{q,p}^* = D_{q,-p} \tag{A10}
$$

$$
D_{q,p}^T = D_{-q,p} \tag{A11}
$$

$$
D_{q',p'}D_{q,p} = e^{i2\pi(qp'-q'p)/d} D_{q,p}D_{q',p'}
$$
\n(A12)

$$
D_{q,p}^k = D_{kq,kp} \tag{A13}
$$

<span id="page-7-1"></span>**Proposition 8.**  $\{D_{q,p}\}$  form a basis of the  $(d \times d)$ -dimensional space of operators on  $\mathbb{C}^d$ . Moreover, they are orthogonal in the Hilbert-Schmidt inner product.

<span id="page-7-2"></span>
$$
\operatorname{Tr}\left(D_{q,p}^{\dagger}D_{q',p'}\right) = d \cdot \delta_{q,q'} \delta_{p,p'} \tag{A14}
$$

Proposition [8](#page-7-1) lets us decompose any d-dimensional density matrix  $\rho$  as

$$
\rho = \frac{1}{d} \sum_{q,p} \text{Tr} \left( D_{q,p} \rho \right) D_{q,p}^{\dagger} \tag{A15}
$$

This can be viewed as the d-dimensional analog of the Bloch vector representation

$$
\rho = \frac{1}{d} \left( 1 + \sum_{(q,p)\neq(0,0)} y_{q,p} D_{q,p}^{\dagger} \right) , \quad y_{q,p} = \text{Tr} \left( D_{q,p} \rho \right)
$$
\n(A16)

# 2. Bosonic limit  $d \to \infty$

For an overview of continuous bosonic modes, see [\[16\]](#page-5-11).

As d increases, the d-dimensional system described above forms an increasingly good discrete approximation to an infinite-dimensional continuous bosonic mode. To formalize this, let's set

$$
x = \sqrt{\frac{\pi}{d}}(q, p) \tag{A17}
$$

x lives on a lattice with spacing  $\sim 1/$ √ d and size  $\sim$ √ d with periodic boundary conditions. As d goes to infinity,  $x$ becomes a continuous phase space variable in the plane.

For the quantum harmonic oscillator with frequency  $\omega$  and mass m, the characteristic length and momentum scales For the quantum harmonic oscillator with frequency  $\omega$  and mass m, the characteristic length and momentum scales are  $\sqrt{\hbar/m\omega}$  and  $\sqrt{\hbar m\omega}$  respectively. Thus if we can measure the position to precision  $\delta$ , this i the particle on a discrete lattice with

$$
d \sim \frac{\hbar}{m\omega\delta^2} \tag{A18}
$$

The analog of Proposition [8](#page-7-1) in the continuous limit is

$$
\operatorname{Tr} D_x D_{x'} = \pi \delta^2 (x - x')
$$
\n(A19)

which leads to the infinite-dimensional Bloch representation

$$
\rho = \frac{1}{\pi} \int [d^2 x] y_x D_x^{\dagger} \quad , \quad y_x = \text{Tr} \left( D_x \rho \right) \tag{A20}
$$

 $D_x$  represents a shift in phase plane by x. The commutation relation Equation [A12](#page-7-2) becomes

$$
D_{x'}D_x = e^{i2x^T Jx'} D_x D_{x'}
$$
\n(A21)

where  $J$  is the *symplectic form*, defined by

$$
J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} . \tag{A22}
$$

If we have  $n$  bosonic modes, the phase space variable becomes

$$
\vec{x} = (\vec{q}, \vec{p}) = (q_1, \dots, q_n, p_1, \dots, p_n)
$$
\n(A23)

# 3. Gaussian operations

Gaussian unitaries can be defined in three equivalent ways:

- They are the *normalizer* of the Heisenberg-Weyl group. That is, they conjugate displacement operators to themselves.
- They are symplectic transformations of phase space. (See Equation [A25.](#page-9-1))

• They are generated by Hamiltonians quadratic in position and momentum operators.

A matrix  $S \in \mathbb{R}^{2n \times 2n}$  is symplectic if

$$
SJS^{T} = J , J = \begin{pmatrix} 0 & I_{n} \\ -I_{n} & 0 \end{pmatrix}
$$
 (A24)

J is the symplectic form. Denote the set of symplectic matrices  $Sp(2n)$ .

For every symplectic  $S \in Sp(2n)$ , there is a corresponding Gaussian unitary  $U_S$  on n bosonic modes. This acts on the position and momentum operators via

<span id="page-9-1"></span>
$$
U_S^{\dagger} \vec{x} U_S = S \vec{x} \tag{A25}
$$

The adjoint action of a Gaussian unitary on the displacement operators is

$$
U_S^{\dagger} D(\vec{x}) U_S = D(S^{-1}\vec{x}) \tag{A26}
$$

Note that for a single mode, the symplectic condition  $SJS^T = J$  simply becomes det  $S = 1$ . Gaussian unitaries are the infinite-dimensional version of Clifford operations.

### <span id="page-9-0"></span>Appendix B: Learning displacement amplitudes

**Definition 2.** The displacement amplitudes of a d-dimensional state  $\rho$  are

$$
y_{q,p} = \text{Tr}\left(D_{q,p}\rho\right) \tag{B1}
$$

Note however that the coefficients  $y_{q,p}$  are now *complex* in general, since  $D_{q,p}$  are not always Hermitian. The Hermiticity of  $\rho$  is reflected in the relation

$$
y_{q,p}^* = y_{-q,-p} \tag{B2}
$$

Given copies of a d-dimensional state and its conjugate  $\rho \otimes \rho^*$ , the first phase of our learning algorithm will aim to learn the displacement amplitudes  $\{\pm y_{q,p}\}$  up to a sign  $\pm$ . The second phase will use entangled measurements across a few more copies to resolve the signs.

### 1. Estimating displacement amplitudes up to a sign

Using commutation relation Equation [A12,](#page-7-2) it can be checked that the following operators mutually commute when acting on two systems  $\mathbb{C}^d \otimes \mathbb{C}^d$ .

<span id="page-9-3"></span><span id="page-9-2"></span>
$$
\{D_{q,p}\otimes D_{-q,p}\}\tag{B3}
$$

This suggests that we can measure two systems in the joint eigenbasis of these operators. If we placed  $\rho \otimes \rho^*$  in the two systems for some d-dimensional state  $\rho$ , we would have

$$
\operatorname{Tr}\left((D_{q,p}\otimes D_{-q,p})(\rho\otimes\rho^*)\right) = \operatorname{Tr}\left(D_{q,p}\rho\right)\operatorname{Tr}\left(D_{q,p}^T\rho^*\right)
$$
\n
$$
= \operatorname{Tr}\left(D_{q,p}\rho\right)^2 = y_{q,p}^2
$$
\n(B4)

Here we used Proposition [7.](#page-7-3)

We now construct the desired eigenbasis. It will form a d-dimensional generalization of the Bell basis on 2 qubits. Define

$$
|\Phi_{0,0}\rangle = \frac{1}{\sqrt{d}} \sum_{j} |j\rangle| - j\rangle
$$
 (B5)

<span id="page-9-4"></span>
$$
|\Phi_{a,b}\rangle = (X^a Z^b \otimes 1)|\Phi_{0,0}\rangle
$$
  
=  $\frac{1}{\sqrt{d}} \sum_j e^{i2\pi bj/d} |j+a\rangle| - j\rangle$  (B6)

<span id="page-10-1"></span>
$$
(D_{q,p} \otimes D_{-q,p})|\Phi_{a,b}\rangle = e^{i2\pi(a_p - bq)/d}|\Phi_{a,b}\rangle.
$$
\n(B7)

We provide more intuition for the simultaneous diagonalisability of the  $D_{q,p} \otimes D_{-q,p}$  and their common eigenbasis  $|\Phi_{a,b}\rangle$  in Appendix [F.](#page-22-0)

# <span id="page-10-0"></span>Algorithm 1 Learning displacement amplitudes up to a sign.

Input:

- A list of M displacement indices  $S \in \mathbb{Z}_d^2$ ,  $|S| = M$ .
- Precision  $\varepsilon$ .
- N copies of  $\rho \otimes \rho^*$ , where  $\rho$  is an unknown quantum state in d dimensions.

**Output:** For each  $(q, p) \in \mathcal{S}$ , either output  $\hat{u}_{q,p} = 0$  or some  $\hat{u}_{q,p}$  with  $|\hat{u}_{q,p}| \geq \frac{\sqrt{2}}{\sqrt{3}}\varepsilon$ . If  $\hat{u}_{q,p} = 0$ , we are guaranteed  $|y_{q,p}| \leq \varepsilon$ . If  $|\hat{u}_{q,p}| \ge \frac{\sqrt{2}}{\sqrt{3}}\varepsilon$ , we are guaranteed  $|\pm \hat{u}_{q,p} - y_{q,p}| \le \frac{\sqrt{2}}{2\sqrt{3}}\varepsilon$  for one of the choices of sign  $\pm$ .

# Algorithm:

- 1. Measure each copy of  $\rho \otimes \rho^*$  in the basis  $\{\phi_{a,b}\}\$ , receiving outcomes  $\{(a^{(k)},b^{(k)})\}_{k=1}^N$ .
- 2. Now given  $(q, p) \in \mathcal{S}$ , compute

$$
\hat{v}_{q,p} = \frac{1}{N} \sum_{k=1}^{N} \exp\left(i2\pi (a^{(k)}p - b^{(k)}q)/d\right).
$$
 (B8)

- 3. If  $|\hat{v}_{q,p}| \leq \frac{2}{3} \varepsilon^2$ , output  $\hat{u}_{q,p} = 0$ .
- 4. Else output  $\hat{u}_{q,p} = \sqrt{\hat{v}_{q,p}}$ , choosing the primary square root without loss of generality.

<span id="page-10-3"></span>**Theorem 9.** Algorithm [1](#page-10-0) succeeds with high probability using  $N = \mathcal{O}(\log M/\varepsilon^4)$  copies of  $\rho \otimes \rho^*$ .

*Proof.* Suppose we measure  $\rho \otimes \rho^*$  in the basis  $\{\ket{\Phi_{a,b}}\}$ , and get the distribution  $(a, b) \sim \mathcal{P}$ . From Equations [B4](#page-9-2) and [B7,](#page-10-1) we can construct an estimator for  $y_{q,p}^2$ .

$$
J_{q,p}^{2} = \text{Tr} ((D_{q,p} \otimes D_{-q,p})(\rho \otimes \rho^{*}))
$$
  
\n
$$
= \mathbb{E}_{(a,b)\sim\mathcal{P}} \text{ Tr} ((D_{q,p} \otimes D_{-q,p})|\Phi_{a,b}\rangle \langle \Phi_{a,b}|)
$$
  
\n
$$
= \mathbb{E}_{(a,b)\sim\mathcal{P}} \exp (i2\pi(ap - bq)/d)
$$
 (B9)

Applying Hoeffding's inequality in the complex plane tells us that with  $N = \mathcal{O}(\log M/\varepsilon^4)$  copies,

<span id="page-10-2"></span>
$$
\left|\hat{v}_{q,p} - y_{q,p}^2\right| \le \frac{1}{3}\varepsilon^2\tag{B10}
$$

for any M displacement operators  $D_{q,p}$  with high probability.

y

**Case 1:**  $|\hat{v}_{q,p}| \leq \frac{2}{3}\varepsilon^2$ . Then with high probability

$$
|y_{q,p}^2| \le |\hat{v}_{q,p}| + |\hat{v}_{q,p} - y_{q,p}^2| \le \frac{2}{3}\varepsilon^2 + \frac{1}{3}\varepsilon^2 = \varepsilon^2 \implies |y_{q,p}| \le \varepsilon
$$
\n(B11)

and the estimate  $\hat{u}_{q,p} = 0$  satisfies  $|\hat{u}_{q,p} - y_{q,p}| \leq \varepsilon$ .

**Case 2:**  $|\hat{v}_{q,p}| > \frac{2}{3} \varepsilon^2$ . Then  $|\hat{u}_{q,p}| > \frac{\sqrt{2}}{\sqrt{2}}$  $\frac{\sqrt{2}}{2}$  $\frac{2}{3}\varepsilon$ . Negating  $\hat{u}_{q,p}$  if necessary, suppose we choose the correct hemisphere for  $\hat{u}_{q,p}$ . This guarantees that

$$
|\hat{u}_{q,p} + y_{q,p}| \ge |\hat{u}_{q,p}| > \frac{\sqrt{2}}{\sqrt{3}}\varepsilon
$$
\n(B12)

Now

$$
\frac{1}{3}\varepsilon^2 \ge |\hat{v}_{q,p} - y_{q,p}^2| \tag{B13}
$$

12

 $\Box$ 

$$
= |\hat{u}_{q,p}^2 - y_{q,p}^2| = |\hat{u}_{q,p} + y_{q,p}| \cdot |\hat{u}_{q,p} - y_{q,p}|
$$
\n(B14)

$$
\geq \frac{\sqrt{2}}{\sqrt{3}} \varepsilon \cdot |\hat{u}_{q,p} - y_{q,p}| \tag{B15}
$$

$$
\implies |\hat{u}_{q,p} - y_{q,p}| \le \frac{\sqrt{2}}{2\sqrt{3}}\varepsilon
$$
\n(B16)

finishing the proof.

# 2. Implementing the measurements

**Proposition 10.** If we encode the d-dimensional system in  $\mathcal{O}(\log d)$  qubits on a quantum computer, then we can measure in the basis  $\{|\Phi_{a,b}\rangle\}$  in time poly log d.

Proof. The quantum Fourier transform  $W$  in  $d$  dimensions is the map

$$
W: |b\rangle \to \frac{1}{\sqrt{d}} \sum_{j} e^{-i2\pi bj/d} |j\rangle \tag{B17}
$$

with matrix representation

$$
W = \frac{1}{\sqrt{d}} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega^{-1} & \omega^{-2} & \dots & \omega^{-(d-1)} \\ 1 & \omega^{-2} & \omega^{-4} & \dots & \omega^{-2(d-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega^{-(d-1)} & \omega^{-2(d-1)} & \dots & \omega^{-(d-1)^2} \end{pmatrix}
$$
(B18)

 $W$  is a unitary. In relation to  $X, Z$ , it has the properties

$$
WXW^{\dagger} = Z \tag{B19}
$$

$$
WZW^{\dagger} = X^{\dagger} \tag{B20}
$$

If we encode the d-dimensional system in  $\mathcal{O}(\log d)$  qubits, then W can be implemented in time poly log d.

Define the *controlled shift* operator  $CX$  on two  $d$ -dimensional systems to act by

$$
CX:|j\rangle|l\rangle \rightarrow |j+l\rangle|l\rangle \tag{B21}
$$

W and CX together can be used to transform the standard product basis on two d-dimensional systems to the entangled  $\{|\Phi_{a,b}\rangle\}$  basis.

$$
(CX)^{-1} \cdot (\mathbb{1} \otimes W) \cdot |a\rangle |b\rangle = |\Phi_{a,b}\rangle \tag{B22}
$$

This lets us implement a measurement in the basis  $\{|\Phi_{a,b}\rangle\}$  by first inverting this transformation and then measuring in the standard product basis.  $\Box$ 

(a) Transforming between bases

(b) Algorithm [1](#page-10-0)

FIG. 2

### 3. n subsystems

Suppose now we have n d-dimensional subsystems, with Hilbert space  $(\mathbb{C}^d)^{\otimes n}$ . We can promote  $q, p, a, b$  to vectors  $\vec{q}, \vec{p}, \vec{a}, \vec{b} \in \mathbb{Z}_d^n$  and define

$$
D_{\vec{q},\vec{p}} = D_{q_1,p_1} \otimes \cdots \otimes D_{q_n,p_n} \tag{B23}
$$

$$
|\Phi_{\vec{a},\vec{b}}\rangle = |\Phi_{a_1,b_1}\rangle \otimes \cdots \otimes |\Phi_{a_n,b_n}\rangle
$$
\n(B24)

All statements in Proposition [7](#page-7-3) hold with  $q, p$  replaced with the vectors  $\vec{q}, \vec{p}$ . In the commutation relation Equation [A12,](#page-7-2) the products  $qp', q'p$  are to be replaced with dot products  $\vec{q} \cdot \vec{p'}, \vec{q'} \cdot \vec{p}$ .

Following Proposition [8,](#page-7-1)  $\{D_{\vec{q}, \vec{p}}\}$  form a basis of the  $(d^n \times d^n)$ -dimensional space of operators on  $(\mathbb{C}^d)^{\otimes n}$ , orthogonal in the Hilbert-Schmidt inner product.

$$
\operatorname{Tr}\left(D_{\vec{q},\vec{p}}D_{\vec{q'},\vec{p'}}\right) = d \cdot \delta_{q_1,q'_1} \delta_{p_1,p'_1} \dots \delta_{q_n,q'_n} \delta_{p_n,p'_n}
$$
\n(B25)

We have the Bloch vector decomposition

$$
\rho = \frac{1}{d^n} \left( \mathbb{1} + \sum_{\vec{q}, \vec{p}} y_{\vec{q}, \vec{p}} D_{\vec{q}, \vec{p}}^{\dagger} \right) , \quad y_{\vec{q}, \vec{p}} = \text{Tr} \left( D(\vec{q}, \vec{p}) \rho \right)
$$
(B26)

The analog of Equation [B9](#page-10-2) is

$$
y_{\vec{q},\vec{p}}^2 = \mathbb{E}_{(\vec{a},\vec{b})} \exp\left(i2\pi(\vec{a}\cdot\vec{p}-\vec{b}\cdot\vec{q})/d\right)
$$
(B27)

Theorem 11. The natural generalization of Algorithm [1](#page-10-0) to n qudits has the same guarantee as in Theorem [9](#page-10-3), and likewise the measurements can be implemented in time poly log d.

### 4. Learning algorithm in infinite dimensions

<span id="page-12-0"></span>Using Gaussian unitaries, we can phrase Algorithm [1](#page-10-0) in the infinite-dimensional setting. Step 1 of Algorithm [1](#page-10-0) is to measure  $\rho \otimes \rho^*$  in the generalized Bell basis  $\{|\Phi_{a,b}\rangle\}$ . This is achieved by applying a controlled shift Gaussian operation, followed by homodyne measurements along certain quadratures. Let the position and momentum variables of the first and second register be  $q_1, p_1, q_2, p_2$ .

FIG. 3: Algorithm [1](#page-10-0) in infinite dimensions

On two modes, the controlled shift corresponds to the Gaussian unitary

$$
CX = \exp i p_1 q_2 \tag{B28}
$$

It has symplectic matrix

$$
CX = U_S \quad , \quad S = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{B29}
$$

In the Heisenberg picture, the procedure shown in Figure [3](#page-12-0) transforms the variables  $q_1, p_2$  to the observables

$$
a = q_1 + q_2 \quad , \quad b = -p_1 + p_2 \tag{B30}
$$

We finish the procedure by measuring the first register in the  $q$  quadrature, and the second register in the  $p$ quadrature. Note measuring in the  $p$  quadrature is equivalent to doing a quantum Fourier transform, or phase shift, before measuring in the  $q$  quadrature.

Define

$$
\alpha = (a, b) \tag{B31}
$$

The estimator for the learning algorithm has a nice expression in terms of the symplectic product. The analogue of Equation [B9](#page-10-2) is

$$
y_x^2 = \mathbb{E}_\alpha \exp(i2\alpha^T Jx) \tag{B32}
$$

An example of a class of states where the displacement amplitudes are non-trivial are the GKP codestates. These are the states stabilized by two displacement operators  $D_x$  and  $D_{x'}$  for some x and x' satisfying  $x^T J x' = \pi$ .

### <span id="page-13-0"></span>Appendix C: Determining signs

### 1. Determining signs of displacement operators

Here we describe a method to resolve the signs  $\pm$  with an additional  $\mathcal{O}(\log M/\varepsilon^4)$  copies of  $\rho$ . The method only consumes a single copy of  $\rho$  at a time. The ideas in this section are taken from a different work, currently in preparation [\[15\]](#page-5-10).

The intuition behind the algorithm is that the ability to measure |x| and  $|x + \varepsilon|$  should determine x; that is, we have estimated the magnitude with a shifted origin. The algorithm's strategy is to find a hypothesis quantum state  $\tilde{\rho}$  which it can use to shift the origin of the magnitude measurements. In order to find  $\tilde{\rho}$ , we will use Algorithm [3](#page-15-0) in Section C<sub>2</sub> below, which in turn relies on results from [\[4,](#page-5-15) [28\]](#page-6-3).

<span id="page-13-1"></span>Algorithm 2 Determining the signs of displacement amplitudes.

Input:

- A list of M displacement indices  $S \in \mathbb{Z}_d^2$ ,  $|S| = M$ .
- Precision  $\varepsilon$ .
- $\mathcal{O}((\log d + \log M)/\varepsilon^4)$  copies of unknown state  $\rho$ .
- The output of Algorithm [1](#page-10-0) for S and  $\rho$  and precision  $\varepsilon/2$ .

**Output:** For each  $(q, p) \in \mathcal{S}$  such that  $\hat{u}_{q, p} \neq 0$ , output a sign  $\hat{r}_{q, p}$  so that  $|\hat{r}_{q, p} \hat{u}_{q, p} - y_{q, p}| \leq \varepsilon$ .  $(\hat{u}_{q, p}$  is the output of Algorithm [1.](#page-10-0))

# Algorithm:

- 1. Denote  $\mathcal{T} = \{(q, p) : \hat{u}_{q, p} \neq 0\}$ . We must output a sign  $\hat{r}_{q, p}$  for each  $(q, p) \in \mathcal{T}$ .
- 2. Using Algorithm [3,](#page-15-0) find a classical description of a density matrix  $\tilde{\rho}$  satisfying

$$
|\operatorname{Tr}(D_{q,p}\tilde{\rho}) - s_{q,p}\hat{u}_{q,p}| \le \frac{\sqrt{2}}{2\sqrt{3}}\varepsilon \quad \forall (q,p) \in \mathcal{T}
$$
\n(C1)

for some choices of signs  $s_{q,p} \in \{+1,-1\}$ . This requires  $\mathcal{O}(\log d/\varepsilon^4)$  single-copy measurements of  $\rho$ . Using the classical description of  $\tilde{\rho}$ , we are able to manufacture copies of its complex conjugate state  $\tilde{\rho}^*$  on our quantum computer.

- 3. Measure  $N = \mathcal{O}(\log M/\varepsilon^4)$  copies of  $\rho \otimes \tilde{\rho}^*$  in the basis  $\{|\Phi_{a,b}\rangle\}$ , receiving outcomes  $\{(a^{(k)},b^{(k)})\}_{k=1}^N$ .
- 4. Now given  $(q, p) \in \mathcal{T}$ , compute

$$
\hat{v}_{q,p} = \frac{1}{N} \sum_{k=1}^{N} \exp\left(i2\pi (a^{(k)}p - b^{(k)}q)/d\right).
$$
 (C2)

5. Output

$$
\hat{r}_{q,p} = \begin{cases}\n+ s_{q,p} & \left| \arg \left( \hat{v}_{q,p} \right) - 2 \arg \left( \hat{u}_{q,p} \right) \right| \le \pi/2 \\
-s_{q,p} & \left| \arg \left( \hat{v}_{q,p} \right) - 2 \arg \left( \hat{u}_{q,p} \right) \right| > \pi/2\n\end{cases}\n\tag{C3}
$$

**Remark 1.** The runtime of Algorithm [2](#page-13-1) is polynomial in the dimension d of the Hilbert space and in  $\varepsilon^{-1}$ .

*Proof.* Denote  $\tilde{y}_{q,p} = \text{Tr} (D_{q,p}\tilde{\rho})$ . By design,  $|\tilde{y}_{q,p} - s_{q,p}\hat{u}_{q,p}| \leq \frac{\sqrt{2}}{2\sqrt{2}}$  $\frac{\sqrt{2}}{2\sqrt{3}}\varepsilon \ \forall (q,p) \in \mathcal{T}$ . Recall that  $|\hat{u}_{q,p}| \geq \frac{\sqrt{2}}{\sqrt{3}}$  $\frac{\sqrt{2}}{2}$  $\frac{2}{3}\varepsilon \ \forall (q,p) \in \mathcal{T}.$ This means that

$$
|\arg(\tilde{y}_{q,p}) - \arg(s_{q,p}\hat{u}_{q,p})| \le \pi/6 \ \forall (q,p) \in \mathcal{T}
$$
\n
$$
(C4)
$$

Recall that  $|y_{q,p} - r_{q,p}\hat{u}_{q,p}| \leq \frac{\sqrt{2}}{2\sqrt{q}}$  $\frac{\sqrt{2}}{2\sqrt{3}}\varepsilon \ \forall (q,p) \in \mathcal{T}$  for one of the choices of sign  $r_{q,p} \in \{+1,-1\}$ . It is also the case that

$$
|\arg(y_{q,p}) - \arg(r_{q,p}\hat{u}_{q,p})| \le \pi/6 \,\forall (q,p) \in \mathcal{T}
$$
\n(C5)

If we guessed correctly with  $\tilde{\rho}$  and  $s_{q,p} = r_{q,p}$ , then

$$
s_{q,p} = r_{q,p} \implies |\arg(y_{q,p}) + \arg(\tilde{y}_{q,p}) - 2\arg(u_{q,p})| \le \pi/3
$$
 (C6)

On other other hand, if we guessed incorrectly and  $s_{q,p} = -r_{q,p}$ , then

$$
s_{q,p} = -r_{q,p} \implies |\arg(y_{q,p}) + \arg(\tilde{y}_{q,p}) - 2\arg(u_{q,p})| \ge 2\pi/3
$$
 (C7)

Thus to determine  $r_{q,p}$ , it is sufficient to estimate  $\arg(y_{q,p}) + \arg(\tilde{y}_{q,p}) = \arg(y_{q,p}\tilde{y}_{q,p})$ .

Now consider the product  $y_{q,p}\tilde{y}_{q,p}$  for  $(q, p) \in \mathcal{T}$ . By triangle inequalities,

$$
|y_{q,p}\tilde{y}_{q,p}| = |y_{q,p}| \cdot |\tilde{y}_{q,p}| \tag{C8}
$$

$$
\geq (|\hat{u}_{q,p}| - |y_{q,p} - r_{q,p}\hat{u}_{q,p}|) \cdot (|\hat{u}_{q,p}| - |\tilde{y}_{q,p} - s_{q,p}u_{q,p}|) \tag{C9}
$$

$$
\geq \left(\frac{\sqrt{2}}{\sqrt{3}}\varepsilon - \frac{\sqrt{2}}{2\sqrt{3}}\varepsilon\right)^2 = \frac{1}{6}\varepsilon^2\tag{C10}
$$

Suppose that in Step 3 we measure  $\rho \otimes \tilde{\rho}^*$  in the basis  $\{|\Phi_{a,b}\rangle\}$ , and get the distribution  $(a,b) \sim \mathcal{P}$ . This gives an unbiased estimator of  $y_{q,p}\tilde{y}_{q,p}$ .

$$
y_{q,p}\tilde{y}_{q,p} = \text{Tr}(D_{q,p}\rho)\text{Tr}(D_{q,p}\tilde{\rho})
$$
  
\n
$$
= \text{Tr}(D_{q,p}\rho)\text{Tr}(D_{-q,p}\tilde{\rho}^*)
$$
  
\n
$$
= \text{Tr}((D_{q,p} \otimes D_{-q,p})(\rho \otimes \tilde{\rho}^*))
$$
  
\n
$$
= \mathbb{E}_{(a,b)\sim\mathcal{P}} \text{Tr}((D_{q,p} \otimes D_{-q,p})|\Phi_{a,b}\rangle\langle\Phi_{a,b}|)
$$
  
\n
$$
= \mathbb{E}_{(a,b)\sim\mathcal{P}} \exp(i2\pi(ap - bq)/d)
$$
 (C11)

On the second line used Equation [A11.](#page-7-4) On the fourth line, we decohered in the simultaneous eigenbasis of the operators  $\{D_{q,p} \otimes D_{-q,p}\}$ , as in Algorithm [1.](#page-10-0) In the final line, we used Equation [B7.](#page-10-1)

Applying Hoeffding's inequality in the complex plane tells us that with  $N = \mathcal{O}(\log M/\varepsilon^4)$  copies,

$$
\left|\hat{v}_{q,p} - y_{q,p}\tilde{y}_{q,p}\right| < \frac{1}{12}\varepsilon^2\tag{C12}
$$

for any M displacement operators  $D_{q,p}$  with high probability. Since  $|y_{q,p}\tilde{y}_{q,p}| \geq \varepsilon^2/6$  for all  $(q,p) \in \mathcal{T}$ , this guarantees

$$
|\arg(\hat{v}_{q,p}) - \arg(y_{q,p}\tilde{y}_{q,p})| < \pi/6 \,\forall (q,p) \in \mathcal{T}
$$
\n(C13)

and thus

$$
s_{q,p} = r_{q,p} \implies |\arg(\hat{v}_{q,p}) - 2\arg(\hat{u}_{q,p})|
$$
\n
$$
(C14)
$$

$$
\leq |\arg\left(y_{q,p}\tilde{y}_{q,p}\right) - 2\arg\left(\hat{u}_{q,p}\right)| + |\arg\left(\hat{v}_{q,p}\right) - \arg\left(y_{q,p}\tilde{y}_{q,p}\right)|\tag{C15}
$$

$$
\langle \pi/3 + \pi/6 = \pi/2 \tag{C16}
$$

$$
s_{q,p} = -r_{q,p} \implies |\arg(\hat{v}_{q,p}) - 2\arg(\hat{u}_{q,p})|
$$
\n
$$
\sum |\arg(\hat{v}_{q,p}) - 2\arg(\hat{u}_{q,p})|
$$
\n
$$
\sum |\arg(\hat{v}_{q,p}) - 2\arg(\hat{u}_{q,p})|
$$
\n
$$
\sum |\arg(\hat{v}_{q,p}) - 2\arg(\hat{u}_{q,p})|
$$
\n(C18)

$$
\geq |\arg(y_{q,p}y_{q,p}) - 2\arg(u_{q,p})| - |\arg(v_{q,p}) - \arg(y_{q,p}y_{q,p})|
$$
\n
$$
(C18)
$$

$$
> 2\pi/3 - \pi/6 = \pi/2
$$
\n(C19)

 $\Box$ 

<span id="page-15-0"></span>Algorithm 3 Finding hypothesis state.

# Input:

- A stream of observables  $(E_1, E_2, ...)$  on Hilbert space of dimension d.
- $\mathcal{O}(\log d/\varepsilon^4)$  copies of unknown state  $\rho$ .
- Estimates  $\{\hat{u}_j\}$  satisfying  $|r_j\hat{u}_j \text{Tr}(E_j\rho)| \leq \varepsilon/2$  for some choices of signs  $r_j \in \{+1, -1\}$ .

**Output:** A classical description of a density matrix  $\tilde{\rho}$  satisfying

<span id="page-15-1"></span>
$$
|\operatorname{Tr}(E_j\tilde{\rho}) - s_j\hat{u}_j| \le \varepsilon \,\forall j \tag{C20}
$$

for some choices of signs  $s_j \in \{+1, -1\}.$ 

# Algorithm:

- 1. Set  $T := \lceil 16 \log d/\varepsilon^2 \rceil$  and  $\beta := \sqrt{\log d/T}$ .
- 2. Initialize  $\omega^{(0)} = \mathbb{1}/d$  and  $t = 0$ .
- 3. For each  $j$ ,

Compute 
$$
\tilde{y}_j^{(t)} = \text{Tr}(E_j \omega^{(t)})
$$
.  
\nIf  $|\tilde{y}_j^{(t)} - \hat{u}_j| \ge \varepsilon$  and  $|\tilde{y}_j^{(t)} - \hat{u}_j| \ge \varepsilon$ , declare ERROR and do:  
\nMeasure  $\mathcal{O}(1/\varepsilon^2)$  copies of  $\rho$  to measure the sign  $r_j \in \{+1, -1\}$  with high probability.

Set

$$
M^{(t)} = \frac{1}{2|\tilde{y}_j - r_j \hat{u}_j|} ((\tilde{y}_j^* - r_j \hat{u}_j^*) E_j + (\tilde{y}_j - r_j \hat{u}_j) E_j^{\dagger}).
$$
\n(C21)

Set

$$
\omega^{(t+1)} := \frac{\exp\left(-\beta \sum_{\tau=1}^{t} M^{(\tau)}\right)}{\text{Tr}\left(\exp\left(-\beta \sum_{\tau=1}^{t} M^{(\tau)}\right)\right)}
$$
(C22)

 $t \leftarrow t + 1.$ 4. Output  $\tilde{\rho} = \omega^{(t)}$ .

<span id="page-15-2"></span>**Remark 2.** The runtime of Algorithm [3](#page-15-0) is polynomial in the dimension d of the Hilbert space and in  $\varepsilon^{-1}$ . Proposition 13. ([\[28\]](#page-6-3) Theorem 3.1) The choice

$$
\omega^{(t+1)} := \frac{\exp\left(-\beta \sum_{\tau=1}^{t} M^{(\tau)}\right)}{\text{Tr}\left(\exp\left(-\beta \sum_{\tau=1}^{t} M^{(\tau)}\right)\right)}
$$
(C23)

satisfies

$$
\sum_{t=1}^{T} \text{Tr}\left(M^{(t)}\omega^{(t)}\right) - \lambda_{\min}\left(\sum_{t=1}^{T} M^{(t)}\right) \leq \beta \sum_{t=1}^{T} \text{Tr}\left((M^{(t)})^2 \omega^{(t)}\right) + \frac{n}{\beta} \tag{C24}
$$

Proof. Omitted.

The choice of  $\omega^{(t)}$  in Proposition [13](#page-15-2) is known as the *matrix multiplicative weights* algorithm, and the left hand side is often referred to as the *regret*. If the matrices are normalized as  $||M^{(t)}||_{op} \leq 1$ , we can write the regret bound as

$$
\sum_{t=1}^{T} \text{Tr}\left(M^{(t)}\rho^{(t)}\right) \le \lambda_{\min}\left(\sum_{t=1}^{T} M^{(t)}\right) + \beta T + \frac{n}{\beta} \tag{C25}
$$

A common choice is  $\beta = \sqrt{n/T}$ . In this case we get the bound

$$
\sum_{t=1}^{T} \text{Tr}\left(M^{(t)}\rho^{(t)}\right) \le \lambda_{\min}\left(\sum_{t=1}^{T} M^{(t)}\right) + 2\sqrt{n}T\tag{C26}
$$

**Theorem 14.** ([\[4\]](#page-5-15) Theorem 1, adapted) Algorithm [3](#page-15-0) makes at most  $T = \lceil 16 \log d/\varepsilon^2 \rceil$  errors, regardless of the number of observables  $(E_1, E_2, \dots)$  presented.

*Proof.* Let error number t occur on  $E_{j^{(t)}}$ . View T as unknown, but nevertheless insist on the relation  $\beta = \sqrt{n/T}$ . By the regret bound in Proposition [13,](#page-15-2) we have

$$
\sum_{t=1}^{T} \text{Re}\left(\frac{\tilde{y}_{j^{(t)}}^{*} - r_{j^{(t)}}\hat{u}_{j^{(t)}}^{*}}{\left|\tilde{y}_{j^{(t)}} - r_{j^{(t)}}\hat{u}_{j^{(t)}}\right|}\tilde{y}_{j^{(t)}}\right) \tag{C27}
$$

$$
\leq \lambda_{\min} \left( \sum_{t=1}^{T} \frac{\tilde{y}_{j^{(t)}}^{*} - r_{j^{(t)}} \hat{u}_{j^{(t)}}^{*}}{2|\tilde{y}_{j^{(t)}} - r_{j^{(t)}} \hat{u}_{j^{(t)}}|} E_{j^{(t)}} + \text{h.c.} \right) + 2\sqrt{n}T
$$
\n(C28)

$$
\leq \sum_{t=1}^{T} \text{Re}\left(\frac{\tilde{y}_{j^{(t)}}^{*} - r_{j^{(t)}} \hat{u}_{j^{(t)}}^{*}}{|\tilde{y}_{j^{(t)}} - r_{j^{(t)}} \hat{u}_{j^{(t)}}|} \text{Tr}\left(E_{j^{(t)}}\rho\right)\right) + 2\sqrt{n}T\tag{C29}
$$

To get the last equation, we substituted in the particular quantum state  $\rho$ . Rewriting, we get

<span id="page-16-2"></span>
$$
\sum_{t=1}^{T} \text{Re}\left(\frac{\tilde{y}_{j^{(t)}}^{*} - r_{j^{(t)}}\hat{u}_{j^{(t)}}^{*}}{\left|\tilde{y}_{j^{(t)}} - r_{j^{(t)}}\hat{u}_{j^{(t)}}\right|}\left(\tilde{y}_{j^{(t)}} - \text{Tr}\left(E_{j^{(t)}}\rho\right)\right)\right) \leq 2\sqrt{nT}
$$
\n(C30)

Now since  $E_{j^{(t)}}$  was an error, we have  $|\tilde{y}_{j^{(t)}} - r_{j^{(t)}}\hat{u}_{j^{(t)}}| \ge \varepsilon$ . But also  $|r_j\hat{u}_j - \text{Tr}(E_j\rho)| \le \varepsilon/2$ . From these, we can deduce the following

$$
|\arg\left(\tilde{y}_{j^{(t)}} - r_{j^{(t)}}\hat{u}_{j^{(t)}}\right) - \arg\left(\tilde{y}_{j^{(t)}} - \text{Tr}\left(E_{j^{(t)}}\rho\right)\right)| \le \pi/6 \tag{C31}
$$

$$
\implies (\tilde{y}_{j^{(t)}}^* - r_{j^{(t)}}\hat{u}_{j^{(t)}}^*)(\tilde{y}_{j^{(t)}} - \text{Tr}(E_{j^{(t)}}\rho)) \ge (1 - 1/\sqrt{2}) \cdot |\tilde{y}_{j^{(t)}} - r_{j^{(t)}}\hat{u}_{j^{(t)}}| \cdot |\tilde{y}_{j^{(t)}} - \text{Tr}(E_{j^{(t)}}\rho)| \tag{C32}
$$

$$
\left|\tilde{y}_{j^{(t)}} - \text{Tr}\left(E_{j^{(t)}}\rho\right)\right| \ge \frac{\varepsilon}{2} \tag{C33}
$$

Equations [C30](#page-16-2) and [C32](#page-16-3) lets us deduce

$$
\sum_{t=1}^{T} \left| \text{Tr} \left( E_{j^{(t)}} \omega^{(t)} \right) - \text{Tr} \left( E_{j^{(t)}} \rho \right) \right| \leq 2\sqrt{n}T \tag{C34}
$$

and finally Equation [C33](#page-16-4) gives

$$
T \cdot \frac{\varepsilon}{2} \le 2\sqrt{n}T\tag{C35}
$$

$$
\implies T \le \frac{16n}{\varepsilon^2} \tag{C36}
$$

<span id="page-16-4"></span><span id="page-16-3"></span> $\Box$ 

# <span id="page-16-0"></span>Appendix D: Natural States

A key question is where one may encounter pairs of states  $\rho$  and  $\rho^*$ . Here we discuss potential sources of  $\rho$  and  $\rho^*$  and some of the challenges and opportunities in different application spaces. In addition to general systems, we highlight how they relate to types of quantum sensors that have been proposed for different applications. A key element of this connection is the conceptual connection to the generalized operators we focus on in this text and the exponential overhead in connecting standard Pauli operators to these more natural choices.

# <span id="page-16-1"></span>1. The power of  $\rho^*$  and hardness of producing  $\rho^*$  from copies of  $\rho$

The operation of complex conjugation of the entries of a density matrix  $\rho$ , denoted here by  $\rho^*$  is not strictly a physical operation, in part, due to its basis dependence. As physics should not depend on the basis one represents a problem in, this makes it clear the operation is unphysical. While this basis dependence does not prevent it from

being a useful operation, this non-physicality suggests that it may be difficult in general to produce  $\rho^*$  from only copies of an unknown  $\rho$ , and that there is no efficient quantum operation for the general task. Here we briefly review existing arguments why this is the case from a computational perspective.

Two input models of interest from the computational perspective are when one has access to copies of the state  $\rho$  with no additional information about the state, and when one has blackbox access to a unitary U that prepares a general  $\rho$  without access to the source code, or description of the quantum circuit that produces U. Considering first the input model where one may receive copies of  $\rho$  for unit cost, it was shown in the proof of Theorem 1 of Ref. [\[32\]](#page-6-8), that any quantum algorithm that can locate the random all-real-entry state among a collection of generally random that any quantum algorithm that can locate the random all-real-entry state among a collection of generally random states requires  $\Omega(2^{n/2}) = \Omega(\sqrt{d})$  copies of  $\rho$  where n is the number of qubits in the constituent state produce copies of  $\rho^*$  from a polynomial number of copies of  $\rho$ , this would allow one to check whether a vector was all real to precision  $\epsilon$  in time  $O(c(n)/\epsilon^2)$ , where  $c(n)$  is the theoretical polynomial cost of complex conjugation on the unknown state  $\rho$ , and allow solution of the real-vector search problem in a time that is only linear in the number of vectors on top of this. This is in clear contradiction to the proven lower bound of Ref. [\[32\]](#page-6-8) and hence polynomial-time conjugation is not possible in the totally general case given only copies of an unknown  $\rho$ .

In the case of having black box access to U that prepares  $\rho$  from a reference state, but not its source code, it was shown in Ref. [\[33\]](#page-6-9) that the optimal procedure to act the complex conjugated unitary map  $U^*$  is given by  $d-1$  calls to the unitary black box U, where d is the dimension of the unitary. A procedure for producing  $\rho^*$  for any given reference state that maps to  $\rho$  would be equivalent to implementing  $U^*$ , and hence a procedure that can do this in less than  $d-1=2^n-1$  calls to U for a qubit system with n qubits would be in violation of the lower bound. As a result, for the most general unknown  $\rho$ , it is inefficient to produce  $\rho^*$  with either blackbox access to copies of  $\rho$  or a unitary that prepares  $\rho$  from a particular reference state. In spite of this general limitation, there are many useful cases for which production of  $\rho^*$  is efficient, a subset of which we review in subsequent sections.

# 2. Naturally real density matrices

As a starting point, a wide class of useful states for which  $\rho$  and  $\rho^*$  are available, is the somewhat trivial case of a totally real density matrix, where naturally  $\rho = \rho^*$ . While this makes the creation and use of  $\rho^*$  something of a formality, it helps to highlight the cases where these techniques are applicable in practice.

Consider, for example, any real Hamiltonian  $H$ . Real Hamiltonians encompass essentially all of chemistry without magnetic fields  $[34]$ , all XZ-type spin Hamiltonians, and many real-space Hamiltonians built from spatially local pieces without magnetic fields. One central object of study for these systems is the density matrix at thermal equilibrium for some temperature  $T = 1/\beta$ , or the Gibbs state, which is given by

$$
\rho_{\beta} = \exp(\beta H)/\mathcal{Z}
$$
 (D1)

where  $\mathcal Z$  is a real-valued normalization constant. As the Hamiltonian is real-valued, the Gibbs state is clearly also manifestly real by properties of the exponential function. Much effort has been devoted to the creation of these states on quantum computers [\[35–](#page-6-11)[37\]](#page-6-12), which is often quite expensive. Hence efficient use of these resources can be quite important in both theory and practice. This raises the question of when the displacement operators may be the subject of interest in physical systems, and a natural choice is real space systems, i.e.

$$
H = -\sum_{j} \nabla_j^2 / m_j + V(x_1, ..., x_n).
$$
 (D2)

where  $x_i$  is a real-valued coordinate and the kinetic energy operator  $-\sum_j \nabla_j^2/m_j$  is taken with respect to a Euclidean geometry along each of the coordinates  $x_i$ . This choice of a Euclidean geometry is what marks the displacement operators as the most relevant, as now  $X$  will correspond naturally to evolution under the kinetic energy and  $Z$ will correspond naturally to evolution under the potential term  $V(x_1,...x_n)$ . While implementing this on a quantum computer requires an appropriate discretization step that respects the geometry of the original model, these types of discretization are not uncommon in first quantized simulations of chemistry, which are among some of the most efficient for very large systems on a quantum computer [\[38\]](#page-6-13). Indeed, first quantized dynamics are so efficient, that performing them exactly on a quantum computer can be more efficient than comparable mean-field dynamics on a classical computer, and efficient classical shadows methods have been developed in this setting for understanding chemistry in the context of real-space bases [\[39\]](#page-6-14).

Another class of real-valued density matrices are those composed of mixtures of eigenstates of real-valued Hamiltonians, superpositions of degenerate eigenstates with real-valued relative phases, their time evolutions, and mixtures therein. This is because a real-valued Hamiltonian can always be expressed in a real-valued eigenbasis. Even under

$$
\rho = \sum_{j} p_j |E_j\rangle\langle E_j| \tag{D3}
$$

$$
\partial_t \rho = i[H, \rho] = iE_j \rho - i\rho E_j = 0. \tag{D4}
$$

This is important to note, as particular eigenstates, often low energy, are the specific subject of study in many quantum simulation experiments. Gibbs states are a special case of this more general property, and both play a central role in many areas of chemistry and physics. Hence for these studies we always expect to have access to  $\rho$  and  $\rho^*$  through the trivial relation  $\rho = \rho^*$ , and any benefits from the techniques in this work apply naturally to all of these systems.

### 3. Time evolution from a real-valued initial state

A key application of interest in quantum computing is quantum simulation of quantum systems. The state generated by the time evolution of a physical system can be quite complex and contain interesting physics one wishes to study. In these cases, even time-independent evolution can be quite interesting and challenging to simulate on a classical computer. While at a glance this model may seem to be equivalent to having the source code for a quantum evolution, casting it as a physical time evolution allows one to consider schemes for approximate time reversal as an alternative to exact access to source code as has been proposed in applications to NMR and quantum learning [\[40\]](#page-6-15).

In the absence of magnetic fields or other time reversal symmetry breaking terms, it is always possible to choose a basis such that the eigenstates are real-valued. In such a case, any initial state that is real-valued can be evolved under the real Hamiltonian  $H$  as

$$
|\psi(t)\rangle = \exp(-iHt)|\psi(0)\rangle.
$$
 (D5)

In such a case, we often have a prescription for either evolving backwards in time  $t \to -t$  or equivalently flipping the signs in the Hamiltonian  $H \to -H$  such that

$$
|\psi(-t)\rangle = \exp(iHt)|\psi(0)\rangle = |\psi(t)\rangle^*.
$$
 (D6)

Hence for any time-reversal symmetric Hamiltonian, the ability to reverse time is equivalent to creating the complex conjugate state  $\rho^*$ , and copies may be produced as needed when the ability to create the initial state and perform the reverse time evolution is available upon demand.

### <span id="page-18-0"></span>4. Sensor arrays

Another broad class of quantum sensors naturally related to the displacement operators are quantum sensor arrays, with a specific emphasis on low intensities. Arrays of sensors in this regime have been discussed for enabling very long baseline optical interferometry for dramatically improved resolution in astronomical imaging [\[23,](#page-6-0) [25,](#page-6-16) [26\]](#page-6-1). These sensor arrays are sometimes proposed to be composed of neutral atoms that are tunable across a wide range of frequencies from MHz to THz [\[18](#page-5-13)[–22,](#page-5-14) [41\]](#page-6-17) as well as optical single photons [\[42\]](#page-6-18), and recent progress in tunable neutral atom arrays may open up other applications with such setups [\[17\]](#page-5-12). Here we will introduce and explore this category of source in the context of conjugate quantum memory.

In the low intensity regime, incoming light is essentially a weak coherent state, but with an average photon number much less than 1. This means the probability of two-photon and higher events is quite small, and we may assume there is a single incident photon to consider at all locations of the array. To build intuition, we consider a simplified but reasonable situation physical situation where we obtain  $\rho$  and  $\rho^*$ .

Consider an array of sensors with two accessible levels and an incoming photon with wavevector k coming from a fixed source that repeatedly generates identical photons at some fixed time interval. This array may be distributed in essentially any configuration, but the simplest and most applicable to the displacement operator setup is a Euclidean 1D array of sensors with a fixed length  $L$  and number of equally spaced sensors  $n^x$ . Current atomic traps allow neutral atoms to be prepared in high fidelity identical states with long-memory times [\[17\]](#page-5-12), and as such as an initial simplifying assumption, we take the detuning with respect to the incident photon to be uniform and the decoherence to be negligible. Moreover, we consider a spatial extent of light much larger than any array under consideration such that any position dependence of the absorption amplitude is approximately uniform as in Ref. [\[23\]](#page-6-0).

Fourier analysis on the uniform grid provides us some insight on the resolution and limitations of measurements we would take. In particular, the resolution of the wavevector  $\Delta k$  is determined by the reciprocal of the physical length of the array itself, that is

$$
\Delta k = \frac{1}{L} \tag{D7}
$$

which is directly related to imaging resolution in interferometry, and the origin of the desire to create very-long baseline interferometers enabled by quantum technology [\[23\]](#page-6-0). In addition, the maximum observable (unaliased) wavevector is determined by the Nyquist-Shannon sampling theorem [\[43\]](#page-6-19) derived in this case from the number of points in the interval, or

$$
|k| < \frac{1}{2\Delta x} = \frac{L}{2n_x}.\tag{D8}
$$

For the case of a weak interaction, one may increase the number of absorbers to match complete absorption, or alternatively post-select results on the case that at least 1 photon is present in any complete setup and have the state

$$
|\psi\rangle \propto \sum_{x=1}^{n^x - 1} e^{-2\pi i (kx)/L} |x\rangle \tag{D9}
$$

where  $|x\rangle$  is the state with the x'th absorber excited and the rest 0 and the associated pure state density matrix is  $\rho = |\psi\rangle \langle \psi|.$ 

This simple example provides a platform to understand the conceptual merit of working directly with displacement operators as opposed to qubit Pauli operators. A general application area we are interested in is the use of quantum computers to do minimal processing directly on quantum states (with or without quantum memory). As such one might expect an (imperfect) transduction and encoding step into  $O(\lceil \log n^x \rceil)$  logical qubits for compactness. The step of encoding the above W-like state and manipulations on the bit representation can be done via tools like unary iteration without significant overhead. Once in this encoding, the effective memory time and number of processing operations without concern about memory or imperfect gate fidelity extends greatly. It is also possible at that juncture to choose between something like measuring Pauli operators on tensor products  $\log n_x$  qubits, or directly measuring the displacement operators living in dimension  $n_x$ .

If we consider the cases where our natural operations are measurements of k−local operators (in the qubit or qudit sense), the local qubit operators on the above state have a somewhat unnatural representation. A Z measurement on the first qubit would correspond to occupation in the left or right half of the line, whereas a Z measurement on the last qubit would indicate occupation on evenly or oddly labeled sites within the lattice. For the Z-like displacement operators, one may measure all the qubits transversally and infer the positional value for the operator  $D_{0,1} = Z_{n_x}$ . This draws a stark contrast with the X local qubit operators and the X-like displacement operators, such as  $D_{1,0} = X_{n_x}$ .

In contrast, any local X measurement (obtained via local Hadamard transformations) on select qubits would yield a result in a local momentum basis that reflects the geometry of a hypercube rather than a Euclidean line. These two coincide only for the unique common ground state of the two operators that is of uniform phase. Indeed perhaps the biggest conceptual difference between the qubit and qudit pictures of the same line is the mismatch in the geometry implied by the qubit  $X$  operators reflecting an implied hypercube geometry and the displacement operators  $D_{1,0} = X_{n_x}$  reflecting a Euclidean geometry. If it were, in general possible to infer the result of measurements in the qudit picture after a QFT reading only transversal measurements after a Hadamard transversal operation efficiently, this would replace the need for many QFT's found in phase estimation algorithms, for example.

The above state is naturally an eigenstate of the displacement operator  $D_{1,0} = X_{n^x}$  and its measurement yields up to  $\log n^x$  bits of precision the very physical interpretation as the photon's wavevector along the x spatial coordinate. In contrast, measuring the local qubit  $X$  operators yields a mixture of corresponding eigenstates that cannot be efficiently reassembled into the wavevector precisely without a number of measurements scaling like  $n_x$  in the worst case.

So far we have not invoked the advantage of using quantum memory and  $\rho^*$  for these states, but merely motivated the importance and naturalness of displacement operators in this context. To see how  $\rho^*$  is available in this simplified system where we assume identical photons are received at regular intervals, consider building a second copy of the sensor array inside a mirrored cavity with a known change in the pathlength of the incoming photon along the array axis b, such that the positions of the new detectors are shifted by the value b. Using two mirrors, we may reflect the wavevector k about the array axis from  $k \to -k$  yielding

$$
|\psi'\rangle \propto \sum_{x=1}^{n^x - 1} e^{2\pi i (k(x - b))/L} |x\rangle = e^{-2\pi i kb/L} \sum_{x=1}^{n^x - 1} e^{2\pi i (kx)/L} |x\rangle = e^{-2\pi i kb} |\psi\rangle^*.
$$
 (D10)

In this case, we are able to obtain the complex conjugate state somewhat easily while picking up only a global phase. While the assumptions that led to this were idealized in several ways, for more realistic cases it may be possible to use a similar procedure to build an approximation of the state that still allows one to retain advantage.

Assuming we build the conjugate state or an approximation of it, we now turn to the utility of the state in the sensor array context. A common problem in sensor arrays, especially those tuned to low energy excitations like radio waves in thermal environments is a heavy amount of background thermal noise. For example in the case of NMR, the background noise is often modeled as a nearly infinite temperature, or a totally mixed state. For the most general type of signal when  $\varepsilon \ll 1$ , determining if any signal is present is equivalent to the mixedness testing problem, which can require a number of samples scaling like the dimension of the space in the worst case even with access to many copies at once [\[27\]](#page-6-2). One way of viewing the advantage from the measurements in this scenario is a specialized form of mixedness testing, which permits distinguishing a sensor state from the maximally mixed state with an efficient number of samples, but only over a specialized class of states.

The natural questions are then what types of sensor state can we distinguish from noise using the conjugate memory resource, and how natural are they in physical systems? The states we prove explicit lower bounds for while being sample efficient to distinguish from the maximally mixed state with conjugate memory are of the form

$$
\rho = \rho_{qp} = \frac{1}{d} \left( 1 + r \varepsilon E_{q,p} \right). \tag{D11}
$$

By extension, we can also sample efficiently distinguish randomly states of the form

$$
\rho = \frac{1}{d} \left( \mathbb{1} + \sum_{q,p} \alpha_{qp} E_{q,p} \right) \tag{D12}
$$

from the maximally mixed state so long as we sample according to the maximum magnitude of  $\alpha_{pq}$ , and we conjecture similar lower bounds apply for single copies considering the first case as a special case of the second so long as  $\varepsilon \ll 1$ and the number of such operators is relatively small.

To gain intuition, consider first the operator  $D_{0,1} = Z$ . The corresponding state  $\rho_{qp}$  on a 1D sensor array is a mixed state in the position basis, with probabilities of detection at each site given by  $(1 + r\varepsilon \cos(2\pi x/L))/d$ . Similarly, if we consider  $D_{0,2} = Z^2$ , we have site populations  $(1 + r\varepsilon \cos(2\pi x/L))^2/d$  and more generally  $D_{0,q}$  gives site populations  $(1 + r\varepsilon \cos(2\pi x/L))^q/d$ . Generalizing this to the flexible sum above but still only in the position basis, we see we can have site populations given by trigonometric polynomials. Hence it can distinguish very general population distribution patterns, like a Gaussian distribution with heavy background noise, from the totally random mixed state, but efficiency gain will be determined by the shape of the function. By symmetry, the same is true of momentum space distributions. However, there cannot be an advantage for states guaranteed to be probabilistic mixtures of only position or momentum eigenstates as efficient sampling within the two bases separately is possible, there must be non-trivial coherence in the states that manifests as a randomly oriented basis with  $p, q \in [0, n_x - 1]$ . A combination of these can be a quite general expression of a physical state, like an incoherent distribution of Gaussian wavepackets on a real-space grid with heavy background noise.

As one makes more general population distributions, one has to consider when the technique remains sample efficient and a gap to single copy techniques persist. We leave precise derivations of these parameter regimes as future work, but in the  $\varepsilon \ll 1$  regime the techniques can be viewed as an exponential improvement in signal to noise ratios per sample and an exponential improvement in the detection of any signal at all in analogy to specialized mixedness testing. Multi-copy mixedness testing has also been considered to form a hierarchy for different numbers of copies as well [\[27\]](#page-6-2). In the  $\varepsilon \approx 1$  regime, the question of advantage may be harder, as potentially one can construct a nearly pure state where other sample efficient techniques like classical shadows may apply. We leave this interesting more general construction as an open question in applications of the techniques here.

# 5. Access to  $U^*$  via access to  $U^{\dagger}$  on high temperature states

Related to the above case of Gibbs states, another interesting model where one can access  $U^*$  is when one has access to  $U^{\dagger}$ . We note that access only to  $U^{\dagger}$  does not generally permit efficient access to  $U^*$ , but here we examine a special case. The maximally entangled state produced by a simple Bell basis change

$$
|\Psi\rangle = \frac{1}{\sqrt{2^n}} \sum_{i=0}^{2^n - 1} |i\rangle |i\rangle \tag{D13}
$$

is the so-called thermofield double of an infinite temperature system on  $n$  qubits. For this state, the following identity is known to be true for any operators  $V, W$ 

$$
(V \otimes W)|\Psi\rangle = (VW^T \otimes I)|\Psi\rangle \tag{D14}
$$

where  $W^T$  is the transpose of W. Hence by choosing  $V = I$  and  $W = U^{\dagger}$ , which physically means accessing  $U^{\dagger}$  once on only one of the registers and doing nothing on the other after preparing the entangled state, we have implemented

$$
U^* \otimes I|\Psi\rangle \tag{D15}
$$

which is equivalent to the action of  $U^*$  on the infinite temperature state when the second register is traced out or ignored. On its own, this does nothing of note due to the infinite temperature state being invariant under unitary transformations, but if the application of  $U^{\dagger}$  is controlled on ancilla qubits, it can be used to project into the basis with its conjugate basis, as well as other more general tasks. As a special case, if a single ancilla qubit is prepared in the  $|+\rangle$  state, this is related to the one-clean qubit model of computation, also known as DQC1 [\[44\]](#page-6-20). This at least contains DQC1 and we believe there may be interesting applications within this resource context.

While restricted compared to general polynomial time quantum computation, the DQC1 model is known to have various applications including NMR structure prediction in chemistry [\[45\]](#page-6-21), but we are not aware of the explicit use of  $U^*$  as a resource within this model to date. Finally we note that the application of U to two-parts of the above Bell state, followed by Bell measurements, has been used to efficiently distinguish between a random real and general random unitary matrix, which is closely related to the identities discussed here [\[8–](#page-5-5)[10\]](#page-5-6).

### <span id="page-21-0"></span>Appendix E: Commutation properties of Heisenberg group

Almost all of the techniques to make practical use of minimal quantum memories so far take advantage of a trick to make non-commuting operators into commuting ones that offer partial information about the original operators. Here we will show that the displacement operators we consider in this paper are the most general class of operators for which this trick works, and hence one must go beyond this method to learn about other classes of operators with a minimal quantum memory.

Recall that Algorithm [1](#page-10-0) to learn the displacement amplitudes up to a sign relied on the crucial property that the following set of operators commute on two registers:

$$
\{D_{q,p}\otimes D_{-q,p}\}\tag{E1}
$$

This was because braiding two displacement operators picks up a complex phase:

<span id="page-21-1"></span>
$$
D_{q',p'} D_{q,p} = e^{i2\pi (qp'-q'p)/d} D_{q,p} D_{q',p'}
$$
\n(E2)

and the second register picks up the conjugate phase:

<span id="page-21-2"></span>
$$
D_{-q',p'}D_{-q,p} = e^{-i2\pi(qp'-q'p)/d}D_{-q,p}D_{-q',p'}
$$
\n(E3)

so that they cancel and

$$
(D_{q,p} \otimes D_{-q,p})(D_{q',p'} \otimes D_{-q',p'}) = (D_{q',p'} \otimes D_{-q',p'})(D_{q,p} \otimes D_{-q,p})
$$
(E4)

Information about the state could be extracted from simultaneously measuring these commuting operators, since

$$
\operatorname{Tr}\left((D_{q,p}\otimes D_{-q,p})(\rho\otimes\rho^*)\right)=\operatorname{Tr}\left(D_{q,p}\rho\right)^2\tag{E5}
$$

We now ask the question: how generally can this method be used? The following theorem gives evidence that the technique cannot be applied more broadly than the setting of displacement operators.

**Theorem 15.** Let  $U, V$  be unitaries of finite order d on some Hilbert space  $H$ . Suppose  $U$  and  $V$  do not commute, but we can attach a second Hilbert space  $\mathcal{H}'$  with unitaries  $\tilde{U}, \tilde{V}$  such that  $U \otimes \tilde{U}$  and  $V \otimes \tilde{V}$  commute. Then there is some unitary transformation of  $H$  mapping  $U, V$  to a direct sum of displacement operators.

*Proof.* By assumption,  $U$  and  $V$  do not commute, so

$$
UVU^{-1}V^{-1} \neq \mathbb{1}
$$
\n(E6)

but  $U \otimes \tilde{U}$  and  $V \otimes \tilde{V}$  commute, so

$$
(UVU^{-1}V^{-1}) \otimes (\tilde{U}\tilde{V}\tilde{U}^{-1}\tilde{V}^{-1}) = \mathbb{1}.
$$
 (E7)

Only scalars can pass through tensor factors, so we must have

$$
UVU^{-1}V^{-1} = \omega \mathbb{1}
$$
\n(E8)

for some phase  $\omega \neq 1$ . Now using that  $V^d = \mathbb{1}$ ,

$$
\omega^{d} 1 \mathbb{I} = (\omega V)^{d} = (UVU^{-1})^{d} = UV^{d}U^{-1} = 1 \tag{E9}
$$

$$
\implies \omega^d = 1. \tag{E10}
$$

Overall, we can write

$$
UVU^{-1}V^{-1} = \omega \mathbb{1} \quad , \quad U^{d} = V^{d} = (\omega \mathbb{1})^{d} = \mathbb{1}
$$
 (E11)

The discrete Heisenberg group  $H(\mathbb{Z}_d)$  has presentation

$$
H(\mathbb{Z}_d) = \{x, z, w : xzx^{-1}z^{-1} = w, \ x^d = z^d = w^d = 1, \ wx = xw, \ wz = zw\}
$$
(E12)

Thus  $\{U, V, \omega\mathbb{1}\}\$  generate a representation of  $H(\mathbb{Z}_d)$ .

To complete the proof, we invoke the representation theory of  $H(\mathbb{Z}_d)$ . The irreducible representations (irreps) of  $H(\mathbb{Z}_d)$  are classified in [\[46\]](#page-6-22) using character theory. They are indexed by three integers  $(\gamma, \alpha, \beta) \in \mathbb{Z}_d \times \mathbb{Z}_h \times \mathbb{Z}_h$  where  $h := \gcd(\gamma, d)$ . The dimension of irrep $(\gamma, \alpha, \beta)$  is  $d' = d/h$ . Define the clock and shift operators in d' dimensions as usual

$$
X := \begin{pmatrix} 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 \end{pmatrix}, \qquad Z := \begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & \omega & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \omega^{d-1} \end{pmatrix}, \tag{E13}
$$

and  $\omega := e^{2\pi i/d'}$ . Then we can write irrep $(\gamma, \alpha, \beta)$  as

$$
irrep(\gamma, \alpha, \beta) : H(\mathbb{Z}_d) \to GL(d')
$$
 (E14)

$$
w \to \omega^{\gamma} \tag{E15}
$$

$$
x \to X^{\alpha} \tag{E16}
$$

$$
z \to Z^{\beta} \tag{E17}
$$

As we can see, all of the irreducible representations consist of displacement operators in some basis, thus decomposing our  $H(\mathbb{Z}_d)$ -representation generated by  $\{U, V, \omega\mathbb{I}\}\$  into a direct sum over its irreducible components completes the proof. □

The representation theory of the discrete Heisenberg group  $H(\mathbb{Z}_d)$  is reminiscent of that of the continuous Heisenberg group  $H(\mathbb{R})$ , where the Stone-von Neumann theorem tells us that there is a unique representation up to unitary equivalence [\[47\]](#page-6-23).

### <span id="page-22-0"></span>Appendix F: Simultaneous diagonalisability from Pauli braiding

So far, we have justified that  $D_{q,p} \otimes D_{-q,p} = D_{q,p} \otimes D_{q,p}^T$  simply through explicit verification (see e.g., Eqs. [\(E2\)](#page-21-1) and [\(E3\)](#page-21-2), and we exhibited a simultaneous eigenbasis, whose eigenvalues can also be found through explicit calculation (Eq. [\(B7\)](#page-10-1)). Similarly, the operators  $D_{q,p} \otimes D_{q,-p} = D_{q,p} \otimes D_{q,p}^*$  also mutually commute. In this section, we aim to provide more foundation for these commutation relations and their associated eigenvalue-eigenvector equations, by showing that the simultaneously diagonalisability of  $D_{q,p} \otimes D_{q,p}^*$  is in fact equivalent to the well-known property that Paulis leave other Paulis fixed under conjugation, up to a global phase, i.e., for any two Paulis  $P$  and  $Q$ ,

<span id="page-22-1"></span>
$$
PQP^{\dagger} = \alpha Q \tag{F1}
$$

for some phase α. This equivalence is given by a simple linear algebra maneuver known as operator-vector correspondence, which will moreover allow us to directly obtain the simultaneous eigenbasis and the corresponding eigenvalues.

Fixing a computational basis  $\{|i\rangle\}$ , operator-vector correspondence is given by the linear "vectorisation" map vec defined by

$$
\text{vec}(|i\rangle\langle j|) = |i\rangle \otimes |j\rangle.
$$

It follows from linearity that for arbitrary states  $|\psi\rangle$  and  $|\varphi\rangle$ , we have

$$
\text{vec}(|\psi\rangle\langle\varphi|)=|\psi\rangle\otimes|\varphi\rangle^* = |\psi\rangle(\langle\varphi|)^T,
$$

where the complex conjugate and transpose are taken with respect to the chosen computational basis. In particular,

$$
\operatorname{vec}(P|i\rangle\langle j|P^{\dagger}) = P|i\rangle(\langle j|P^{\dagger})^T = P|i\rangle \otimes P^*|j\rangle.
$$

Thus, when we conjugate some operator by P, under operator-vector correspondence the  $P^{\dagger}$  on one side gets transposed and becomes a  $P^*$ . So writing  $Q = \sum_{i,j \in \mathbb{Z}_d} Q_{ij} |i\rangle\langle j|$  in terms of basis elements and applying vec to both sides of the Pauli braiding equation Eq. [\(F1\)](#page-22-1), we obtain

$$
\sum_{i,j\in\mathbb{Z}_d} Q_{ij} P|i\rangle \otimes P^*|j\rangle = \alpha \sum_{i,j\in\mathbb{Z}_d} Q_{ij}|i\rangle \otimes |j\rangle,
$$

i.e.,

<span id="page-23-0"></span>
$$
(P \otimes P^*)\text{vec}(Q) = \alpha \text{vec}(Q). \tag{F2}
$$

Therefore, Eq. [\(F1\)](#page-22-1) is equivalent to the statement that  $vec(Q)$  is an eigenvector of  $P \otimes P^*$ , with eigenvalue  $\alpha$ . This holds for all Paulis P and Q, and since the vec $(Q)$  form an orthogonal basis of states (from the fact that Paulis comprise a Hilbert-Schmidt orthogonal basis for operators), the  $P \otimes P^*$  are simultaneously diagonalisable.

The explicit version of Eq. [\(F1\)](#page-22-1) is

<span id="page-23-1"></span>
$$
D_{q,p}D_{a,b}D_{q,p}^{\dagger} = \omega^{ap-qb}D_{a,b}
$$
\n(F3)

(from Eq.  $(A12)$ ), and we have

$$
D_{a,b} = \omega^{ab/2} \sum_{j \in \mathbb{Z}_d} \omega^{jb} |j + a\rangle\langle j|
$$

(from Eq. [\(A8\)](#page-7-5)). Hence, using Eq. [\(F2\)](#page-23-0), which becomes  $(D_{q,p} \otimes D_{q,p}^*)\text{vec}(D_{a,b}) = \omega^{ap-qb}\text{vec}(D_{a,b})$  with these substitutions, we immediately see that the simultaneous eigenbasis for  $\{D_{q,p} \otimes D_{q,p}^*\}$  consists of the vectorisations of the Paulis  $D_{a,b}$ ,

$$
\text{vec}(D_{a,b}) \propto \sum_{j \in \mathbb{Z}_d} \omega^{jb} |j+a\rangle |j\rangle \tag{F4}
$$

for  $a, b \in \mathbb{Z}_d$ , and the corresponding eigenvalues of  $D_{q,p}$  are  $\omega^{ap-qb}$ .

In representation-theoretic terms, the simultaneous diagonalisability of  $D_{q,p} \otimes D_{q,p}^*$  is also equivalent to the statement that the representation  $U \mapsto U \otimes U^*$  of the Heisenberg group consists solely of 1-dimensional irreps. However, it is nontrivial to directly build the irreps of this representation from  $U$  and  $U^*$ . Here, we are instead using operator-vector correspondence to relate the  $U \mapsto U \otimes U^*$  representation to the adjoint representation  $U \mapsto U(\cdot)U^{\dagger}$ , because the latter is well-known to consist of 1-dimensional irreps (Eq. [\(F1\)](#page-22-1)).

To get the analogous result for  $D_{q,p} \otimes D_{q,p}^T$ , we use the fact that  $SD_{q,p}S = D_{-q,-p} = D_{q,p}^{\dagger}$ , where  $S \coloneqq \sum_{j \in \mathbb{Z}_d} |-j\rangle\langle j|.$ Then, Eq. [\(F3\)](#page-23-1) can be written  $D_{q,p}D_{a,b}SD_{q,p}S = \omega^{ap-qb}D_{a,b}$ , or  $D_{q,p}D_{a,b}SD_{q,p} = \omega^{ap-qb}D_{a,b}S$ , which vectorises to

$$
(D_{q,p} \otimes D_{q,p}^T) \text{vec}(D_{a,b}S) = \omega^{ap-qb} D_{a,b} \text{vec}(D_{a,b}S).
$$

Thus, the simultaneous eigenbasis of  $D_{q,p} \otimes D_{q,p}^T$  is given by

$$
\text{vec}(D_{a,b}S) \propto \sum_{j\in\mathbb{Z}_d} \omega^{jb} |j+a\rangle| - j\rangle,
$$

which are precisely the  $|\Phi_{a,b}\rangle$  states defined in Eqs. [\(B5\)](#page-9-3) and [\(B6\)](#page-9-4), and the corresponding eigenvalues of  $D_{q,p}$  are  $\omega^{ap-qb}$  as claimed in Eq. [\(B7\)](#page-10-1).

### Appendix G: Sample complexity lower bounds

The aim of this section is to show that the use of entangled measurements across  $\rho \otimes \rho^*$  are essential to our learning task. Any strategy which uses only single-copy measurements on  $\rho$  and  $\rho^*$ , even an adaptive one, necessarily requires exponentially many copies. On the other hand, any strategy which uses only  $\rho$ , and does not have access to  $\rho^*$ , must necessarily make entangled measurements across  $\Omega(1/\varepsilon)$  copies at a time.

The proofs will follow the techniques introduced in [\[8,](#page-5-5) [27\]](#page-6-2). Here we briefly state two lemmas adapted from [\[8\]](#page-5-5) which will be useful to us.

<span id="page-24-3"></span>Lemma 16. ([\[8\]](#page-5-5) Lemma 4.8) When we only consider the classical outcome of the POVM measurement and neglect the post-measurement quantum state, then any POVM can be simulated by a rank-1 POVM with some postprocessing. A rank-1 POVM is defined by  $\{w_s, |\psi_s\rangle\}$  where  $w_s > 0$  and

$$
\sum_{s} w_s |\psi_s\rangle\langle\psi_s| = \mathbb{1}
$$
 (G1)

The outcomes probabilities are

$$
\mathbb{P}_{\rho}(s) = w_s \langle \psi_s | \rho | \psi_s \rangle \tag{G2}
$$

This lemma lets us consider only rank-1 POVMs without loss of generality.

<span id="page-24-6"></span>**Lemma 17.** ([\[8\]](#page-5-5) Lemma 5.4) Suppose we have a many vs one distinguishing task

- (YES)  $\rho = \rho_x$  for some random x and some family of states  $\{\rho_x\}$ .
- (NO)  $\rho = \frac{1}{d} \mathbb{1}$  maximally mixed.

If all outcomes l of a protocol satisfy

<span id="page-24-5"></span>
$$
\frac{\mathbb{E}_x \mathbb{P}_{\rho_x}(l)}{\mathbb{P}_{1/d}(l)} \ge 1 - \delta \tag{G3}
$$

then the probability of success is at most  $(1 + \delta)/2$ . Note that the outcome l refers to the entire history of many measurements, which are possibly adaptive.

We will also use a set of operators defined in [\[48\]](#page-6-24). These are given by

<span id="page-24-8"></span>
$$
E_{q,p} = \chi D_{q,p} + \chi^* D_{-q,-p} \quad , \quad \chi = \frac{1+i}{2} \tag{G4}
$$

and are known as displacement observables.

Proposition 18. [\[48\]](#page-6-24) The displacement observables are Hermitian and have properties

$$
E_{q,p}^* = E_{q,p}^T = E_{-q,p} \tag{G5}
$$

<span id="page-24-7"></span><span id="page-24-4"></span>
$$
||E_{q,p}||_{\text{op}} \le \sqrt{2}
$$
\n(G6)

$$
\text{Tr}\left(E_{q,p}E_{q',p'}\right) = d \cdot \delta_{q,q'}\delta_{p,p'}\tag{G7}
$$

# <span id="page-24-0"></span>1. Single copies of  $\rho$  and  $\rho^*$

<span id="page-24-2"></span>**Theorem 19.** Let d be the dimension of the Hilbert space. Any single-copy protocol which learns  $\text{Tr}(D_{q,p}\rho)$  to precision  $\varepsilon$  for all  $(q, p) \in \mathbb{Z}_d^2$  with probability  $2/3$  requires  $\Omega(d/\varepsilon^2)$  copies. This holds even if the protocol has access to single-copy measurements of both  $\rho$  and  $\rho^*$ .

This will follow from Proposition [20,](#page-24-1) which concerns a certain distinguishing task.

<span id="page-24-1"></span>Proposition 20. Let d be the dimension of the Hilbert space. Consider the task of distinguishing between the following two scenarios:

• (YES)  $\rho = \rho_{q,p,r} = \frac{1}{d}(\mathbb{1} + r \varepsilon E_{q,p})$  for some uniformly random  $(q, p) \in \mathbb{Z}_d^2 \setminus \{(0, 0)\}$  and some uniformly random sign  $r \in \{\pm 1\}$ . (We assume  $0 < \varepsilon < 1$ .)

 $\Box$ 

• (NO)  $\rho = \frac{1}{d} \mathbb{1}$  maximally mixed.

Any single-copy protocol requires  $\Omega(d/\varepsilon^2)$  copies in order to succeed with probability 2/3. This holds even if the protocol has access to single-copy measurements of both  $\rho$  and  $\rho^*$ .

Proof. of Theorem [19](#page-24-2) using Proposition [20.](#page-24-1) Suppose protocol A is able to learn  $|\text{Tr}(D_{q,p}\rho)|$  to precision  $\varepsilon$  for all Froot. Of Theorem 19 assig Froposition [20](#page-24-1). Suppose protocol A is able to learn |  $\Pi(\mathcal{D}_{q,p}p)$  to precision  $\varepsilon$  for all  $(q,p) \in \mathbb{Z}_{d}^{2} \setminus \{(0,0)\}$  with probability 2/3. Consider the task in Proposition 20 with  $\varepsilon$ argue that  $\mathcal A$  is able to succeed at this task with probability 2/3.

$$
\operatorname{Tr}\left(D_{q,p}\rho_{q,p,r}\right) = \frac{3\sqrt{2}r\varepsilon}{d}\operatorname{Tr}\left(D_{q,p}E_{q,p}\right)
$$
\n(G8)

$$
= \begin{cases} 3\sqrt{2}r\varepsilon & d \text{ even, } q = p = d/2\\ 3\sqrt{2}\chi^*r\varepsilon & \text{otherwise} \end{cases}
$$
(G9)

$$
\implies |\operatorname{Tr}(D_{q,p}\rho_{q,p,r})| \ge 3\varepsilon \tag{G10}
$$

using Proposition [8.](#page-7-1) Thus A can distinguish any  $\rho_{q,p,r}$  from the maximally mixed state, which has

$$
\operatorname{Tr}\left(D_{q,p}\frac{\mathbb{1}}{d}\right) = 0 \,\forall q, p \tag{G11}
$$

In this case, Proposition [20](#page-24-1) gives us a sample complexity lower bound of  $\Omega(d/\varepsilon^2)$ .

Proof. of Proposition [20.](#page-24-1) Suppose single-copy protocol A uses T copies of  $\rho$  or  $\rho^*$ , and at step t applies the rank-1 POVM  $\{w_s^t, |\psi_s^t\rangle\}_s$ . By Lemma [16,](#page-24-3) this is without loss of generality. Note the slight abuse of notation, since the POVM of later steps are allowed to depend on the outcomes of earlier measurements. Suppose the outcome of the measurements are  $l = (s_1, \ldots, s_T)$ . We have

$$
\mathbb{P}_{\rho}(l) = \prod_{t=1}^{T} w_{s_t}^t \langle \psi_{s_t}^t | \rho^t | \psi_{s_t}^t \rangle \tag{G12}
$$

where  $\rho^t$  is either  $\rho$  or  $\rho^*$  for each t. Note that

$$
\rho_{q,p,r}^* = \frac{1}{d} \left( \mathbb{1} + r \varepsilon E_{-q,p} \right) \tag{G13}
$$

using Equation [G5.](#page-24-4) Let

$$
\gamma_t = \begin{cases} +1 & \rho^t = \rho \\ -1 & \rho^t = \rho^* \end{cases}
$$
 (G14)

The aim is to establish an inequality like Equation [G3,](#page-24-5) so that we can invoke Lemma [17](#page-24-6)

$$
\frac{\mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_{r}\mathbb{P}_{\rho_{q,p,r}}(l)}{\mathbb{P}_{1/d}(l)} = \mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_{r}\prod_{t=1}^{T} \frac{w_{s_t}^{t} + r\varepsilon w_{s_t}^{t}\langle \psi_{s_t}^{t}|E_{\gamma_t q,p}|\psi_{s_t}^{t}\rangle}{w_{s_t}^{t}}
$$
(G15)

$$
= \mathbb{E}_{(q,p)\neq(0,0)} \mathbb{E}_r \exp\Big(\sum_{t=1}^T \log\big(1 + r\varepsilon \langle \psi_{s_t}^t | E_{\gamma_t q,p} | \psi_{s_t}^t \rangle \big) \Big) \tag{G16}
$$

<span id="page-25-0"></span>
$$
\geq \exp\left(\sum_{t=1}^{T} \mathbb{E}_{(q,p)\neq(0,0)} \mathbb{E}_r \log\left(1 + r\varepsilon \langle \psi^t_{s_t} | E_{\gamma_t q,p} | \psi^t_{s_t} \rangle \right)\right) \tag{G17}
$$

$$
= \exp\Big(\sum_{t=1}^{T} \frac{1}{2} \mathbb{E}_{(q,p)\neq(0,0)} \log\big(1 - \varepsilon^2 \langle \psi_{s_t}^t | E_{\gamma_t q, p} | \psi_{s_t}^t \rangle^2 \big) \Big) \tag{G18}
$$

<span id="page-26-2"></span><span id="page-26-1"></span>27

$$
\geq \exp\left(-\sum_{t=1}^{T} \varepsilon^2 \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi^t_{s_t} | E_{\gamma_t q,p} | \psi^t_{s_t} \rangle^2\right) \tag{G19}
$$

$$
\geq \exp(-T\varepsilon^2 \Gamma) \tag{G20}
$$

$$
\geq 1 - T\varepsilon^2 \Gamma \tag{G21}
$$

where

$$
\Gamma = \sup_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi | E_{\pm q,p} | \psi \rangle^2
$$
\n(G22)

In Equation [G17](#page-25-0) we used Jensen's inequality. In Equation [G19](#page-26-1) we used  $\log 1 - x \ge -2x \,\forall x \in [0, 0.79]$ , which is valid as long as  $\varepsilon \leq 0.62$  by Equation [G6.](#page-24-7)

It remains to upper bound Γ. At this point, it is clear that we can drop the  $\pm$  coming from the use of the conjugate state, since it is averaged over all  $q, p$ . We can express  $\Gamma$  as

$$
\Gamma = \sup_{|\psi\rangle} \langle \psi | \langle \psi | \mathbb{E}_{(q,p)\neq(0,0)} (E_{q,p} \otimes E_{q,p}) | \psi \rangle | \psi \rangle \tag{G23}
$$

It can be checked using Equation [G4](#page-24-8) that

$$
E_{q,p} \otimes E_{q,p} + E_{-q,-p} \otimes E_{-q,-p} = D_{q,p} \otimes D_{-q,-p} + D_{-q,-p} \otimes D_{q,p}
$$
(G24)

and thus we can write

$$
\mathbb{E}_{(q,p)\neq(0,0)}(E_{q,p}\otimes E_{q,p})=\mathbb{E}_{(q,p)\neq(0,0)}(D_{q,p}\otimes D_{-q,-p})
$$
\n(G25)

It can be checked that

$$
\sum_{q,p} (D_{q,p} \otimes D_{-q,-p}) = d \cdot \text{SWAP}
$$
 (G26)

and so

$$
\mathbb{E}_{(q,p)\neq(0,0)}(D_{q,p}\otimes D_{-q,-p})=\frac{d}{d^2-1}\cdot\text{SWAP}-\frac{1}{d^2-1}\cdot\mathbb{1}
$$
\n(G27)

Putting this all together, we get

$$
\Gamma = \frac{1}{d^2 - 1} \sup_{|\psi\rangle} \langle \psi | \langle \psi | (d \cdot \text{SWAP} - 1) | \psi \rangle | \psi \rangle = \frac{d - 1}{d^2 - 1} = \frac{1}{d + 1}
$$
\n(G28)

Returning to Equation [G21,](#page-26-2) we have

$$
\frac{\mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_r \mathbb{P}_{\rho_{q,p,r}}(l)}{\mathbb{P}_{1/d}(l)} \geq 1 - \frac{T\varepsilon^2}{d+1}
$$
\n(G29)

By Lemma [17,](#page-24-6) our single-copy protocol A succeeds with probability at most  $(1 + T\epsilon^2/(d+1))/2$ . This completes the proof of Proposition [20:](#page-24-1) to succeed with probability 2/3, A requires  $T = \Omega(d/\varepsilon^2)$ .  $\Box$ 

# <span id="page-26-0"></span>2. Entangled measurements without  $\rho^*$

<span id="page-26-4"></span>Theorem 21. Let d be the dimension of the Hilbert space. Assume d is prime. Any protocol which learns  $|\operatorname{Tr}(D_{q,p}\rho)|$  to precision  $\varepsilon$  for all  $(q,p) \in \mathbb{Z}_d^2$  with probability 2/3 by measuring copies of  $\rho^{\otimes K}$  for  $K \leq 1/(12\varepsilon)$  $r_1 \text{ in } (\nu_{q,p}\rho) \mid w \text{ }$  precision  $\varepsilon$  for an  $(q,$ <br>requires  $\Omega(\sqrt{d}/(K^2\varepsilon^2))$  measurements.

This will follow from Proposition [22.](#page-26-3) The proof of Proposition [22](#page-26-3) is similar to Appendix D of [\[27\]](#page-6-2).

<span id="page-26-3"></span>Proposition 22. Let d be the dimension of the Hilbert space. Assume d is prime. Consider the task of distinguishing between the following two scenarios:

- (YES)  $\rho = \rho_{q,p,r} = \frac{1}{d}(\mathbb{1} + r \varepsilon E_{q,p})$  for some uniformly random  $(q, p) \in \mathbb{Z}_d^2 \setminus \{(0, 0)\}$  and some uniformly random sign  $r \in \{\pm 1\}$ . (We assume  $0 < \varepsilon < 1$ .)
- (NO)  $\rho = \frac{1}{d} \mathbb{1}$  maximally mixed.

Any protocol succeeding with probability 2/3 which measures copies of  $\rho^{\otimes K}$  for  $K \leq 1/(2\sqrt{2}\varepsilon)$  requires  $\Omega(\sqrt{d}/(K^2\varepsilon^2))$ measurements.

Proof. of Theorem [21](#page-26-4) using Proposition [22.](#page-26-3) Suppose protocol A is able to learn  $\left| \text{Tr} (D_{q,p} \rho) \right|$  to precision  $\varepsilon$  for all Froot. Of Theorem 21 using Froposition [22](#page-26-3). Suppose protocol A is able to learn |  $\Pi(\mathcal{D}_{q,p}p)$  to precision  $\varepsilon$  for all  $(q,p) \in \mathbb{Z}_{d}^{2} \setminus \{(0,0)\}$  with probability 2/3. Consider the task in Proposition 22 with  $\varepsilon$ argue that  $\mathcal A$  is able to succeed at this task with probability 2/3.

$$
\operatorname{Tr}\left(D_{q,p}\rho_{q,p,r}\right) = \frac{3\sqrt{2}r\varepsilon}{d}\operatorname{Tr}\left(D_{q,p}E_{q,p}\right)
$$
\n(G30)

$$
= \begin{cases} 3\sqrt{2}r\varepsilon & d \text{ even}, q = p = d/2\\ 3\sqrt{2}\chi^*r\varepsilon & \text{otherwise} \end{cases}
$$
(G31)

$$
\implies |\operatorname{Tr}(D_{q,p}\rho_{q,p,r})| \ge 3\varepsilon \tag{G32}
$$

using Proposition [8.](#page-7-1) Thus A can distinguish any  $\rho_{q,p,r}$  from the maximally mixed state, which has

$$
\operatorname{Tr}\left(D_{q,p}\frac{\mathbb{1}}{d}\right) = 0 \,\forall q, p \tag{G33}
$$

 $\sqrt{2} \cdot (3\sqrt{2}\varepsilon) = 1/(12\varepsilon)$ In this case, Proposition [22](#page-26-3) says that A requires either entangled measurements across at least  $1/2$ In this case, Proposition 22 says that A requires either<br>copies of  $\rho$  at a time, or  $\Omega(\sqrt{d}/(K^2 \varepsilon^2))$  total copies.  $\Box$ 

*Proof. of Proposition [22.](#page-26-3)* Suppose protocol A measures K copies of  $\rho$  at a time, where  $K \leq 1/(2\sqrt{2}\varepsilon)$ . At step t, A applies the rank-1 POVM  $\{w_s^t, |\psi_s^t\rangle\}_s$ , where t goes from 1 up to T. By Lemma [16,](#page-24-3) this is without loss of generality. Note the slight abuse of notation, since the POVM of later steps are allowed to depend on the outcomes of earlier measurements. Suppose the outcome of the measurements are  $l = (s_1, \ldots, s_T)$ . We have

$$
\mathbb{P}_{\rho}(l) = \prod_{t=1}^{T} w_{s_t}^t \langle \psi_{s_t}^t | \rho^{\otimes K} | \psi_{s_t}^t \rangle \tag{G34}
$$

The aim is to establish an inequality like Equation [G3,](#page-24-5) so that we can invoke Lemma [17](#page-24-6)

$$
\frac{\mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_r \mathbb{P}_{\rho_{q,p,r}}(l)}{\mathbb{P}_{1/d}(l)} = \mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_r \prod_{t=1}^T \langle \psi_{s_t}^t | \left(1 + r \varepsilon E_{q,p}\right)^{\otimes K} |\psi_{s_t}^t \rangle \tag{G35}
$$

$$
= \mathbb{E}_{(q,p)\neq(0,0)} \mathbb{E}_r \prod_{t=1}^T F_{q,p,r}^t
$$
\n(G36)

<span id="page-27-0"></span>
$$
= \mathbb{E}_{(q,p)\neq(0,0)} \mathbb{E}_r \exp\left(\sum_{t=1}^T \log F_{q,p,r}^t\right)
$$
(G37)

$$
\geq \exp\left(\sum_{t=1}^{T} \mathbb{E}_{(q,p)\neq(0,0)} \mathbb{E}_r \log F_{q,p,r}^t\right) \tag{G38}
$$

$$
= \exp\left(\sum_{t=1}^{T} \frac{1}{2} \mathbb{E}_{(q,p)\neq(0,0)} \log \left(F_{q,p,+1}^t \cdot F_{q,p,-1}^t\right)\right)
$$
(G39)

$$
= \exp\left(\sum_{t=1}^{T} \frac{1}{2} \mathbb{E}_{(q,p)\neq(0,0)} \log\left(1 - G_{q,p}^t\right)\right)
$$
(G40)

<span id="page-28-1"></span><span id="page-28-0"></span>29

$$
\geq \exp\left(\sum_{t=1}^{T} \frac{1}{2} \mathbb{E}_{(q,p)\neq(0,0)} \log\left(1 - \max(0, G_{q,p}^t)\right)\right) \tag{G41}
$$

$$
\geq \exp\left(-\sum_{t=1}^{T} \mathbb{E}_{(q,p)\neq(0,0)} \max(0, G_{q,p}^t)\right) \tag{G42}
$$

$$
\geq 1 - \sum_{t=1}^{T} \mathbb{E}_{(q,p)\neq(0,0)} \max(0, G_{q,p}^t)
$$
\n(G43)

where

$$
F_{q,p,r}^t := \langle \psi_{s_t}^t | \left( \mathbb{1} + r \varepsilon E_{q,p} \right)^{\otimes K} | \psi_{s_t}^t \rangle \tag{G44}
$$

$$
G_{q,p}^t := 1 - F_{q,p,+1}^t \cdot F_{q,p,-1}^t \tag{G45}
$$

In Equation [G38](#page-27-0) we used Jensen's inequality. In Equation [G42](#page-28-0) we used  $\log 1 - x \ge -2x \,\forall x \in [0, 0.79]$ , which is valid in Equation G38 we used Jensen's inequality. In Equation G42 we used  $\log 1 - x \ge$ <br>as long as  $G_{q,p}^t \leq 0.79$ . This is guaranteed by the assumption  $K \leq 1/(2\sqrt{2}\varepsilon)$ , since

$$
F_{q,p,r}^t = \langle \psi | (I + r \varepsilon E_{q,p})^{\otimes K} | \psi \rangle \tag{G46}
$$

$$
\geq (1 - \varepsilon \sqrt{2})^K \tag{G47}
$$

$$
\geq 1 - \sqrt{2}K\varepsilon \qquad \text{(provided } \varepsilon \leq 1/\sqrt{2}\text{)}\tag{G48}
$$

$$
\geq 1/2 \qquad \text{for the choice of } K,\tag{G49}
$$

so

$$
G_{q,p}^{t} = 1 - F_{q,p,+1}^{t} \cdot F_{q,p,-1}^{t} \le 3/4
$$
\n(G50)

We would like to upper bound  $\mathbb{E}_{(q,p)\neq(0,0)}$  max $(0, G_{q,p}^t)$ . Let's calculate

$$
G_{q,p}^{t} = 1 - \langle \psi_{s_t}^{t} | \left( 1 + \varepsilon E_{q,p} \right)^{\otimes K} | \psi_{s_t}^{t} \rangle \langle \psi_{s_t}^{t} | \left( 1 - \varepsilon E_{q,p} \right)^{\otimes K} | \psi_{s_t}^{t} \rangle \tag{G51}
$$

$$
=1-\sum_{S,S'\subset[K]}(-1)^{|S'|\varepsilon|S|+|S'|}\langle\psi^t_{s_t}|E_{q,p}^{\otimes S}|\psi^t_{s_t}\rangle\langle\psi^t_{s_t}|E_{q,p}^{\otimes S'}|\psi^t_{s_t}\rangle\tag{G52}
$$

$$
=1-\langle \psi_{s_t}^t | (1+H_{q,p}^0) | \psi_{s_t}^t \rangle^2 + \langle \psi_{s_t}^t | H_{q,p}^1 | \psi_{s_t}^t \rangle^2 \tag{G53}
$$

$$
= -2\langle \psi_{s_t}^t | H_{q,p}^0 | \psi_{s_t}^t \rangle - \langle \psi_{s_t}^t | H_{q,p}^0 | \psi_{s_t}^t \rangle^2 + \langle \psi_{s_t}^t | H_{q,p}^1 | \psi_{s_t}^t \rangle^2 \tag{G54}
$$

$$
\leq -2\langle \psi_{s_t}^t | H_{q,p}^0 | \psi_{s_t}^t \rangle + \langle \psi_{s_t}^t | H_{q,p}^1 | \psi_{s_t}^t \rangle^2
$$
\n(G55)

$$
\implies \mathbb{E}_{(q,p)\neq(0,0)} \max(0, G_{q,p}^t) \leq 2 \max_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} |\langle \psi | H_{q,p}^0 | \psi \rangle| + \max_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi | H_{q,p}^1 | \psi \rangle^2 \tag{G56}
$$

$$
\leq 2\sqrt{\Gamma^0} + \Gamma^1 \tag{G57}
$$

where

$$
H_{q,p}^0 = \sum_{S \subset [K], |S| \text{even}, S \neq \emptyset} \varepsilon^{|S|} E_{q,p}^{\otimes S} \tag{G58}
$$

$$
H_{q,p}^1 = \sum_{S \subset [K], |S| \text{odd}} \varepsilon^{|S|} E_{q,p}^{\otimes S} \tag{G59}
$$

$$
\Gamma^0 = \max_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi | H_{q,p}^0 | \psi \rangle^2
$$
\n(G60)

$$
\Gamma^{1} = \max_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi | H_{q,p}^{1} | \psi \rangle^{2}
$$
\n(G61)

and we used Cauchy-Schwarz in the final step. Returning to Equation [G43,](#page-28-1) we have

<span id="page-28-2"></span>
$$
\frac{\mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_r \mathbb{P}_{\rho_{q,p,r}}(l)}{\mathbb{P}_{1/d}(l)} \geq 1 - T\left(2\sqrt{\Gamma^0} + \Gamma^1\right)
$$
\n(G62)

It remains to upper bound  $\Gamma^0$  and  $\Gamma^1$ . Let's first deal with  $\Gamma^0$ .

$$
\Gamma^0 = \max_{|\psi\rangle} \mathbb{E}_{(q,p)\neq(0,0)} \langle \psi | \langle \psi | H_{q,p}^0 \otimes H_{q,p}^0 | \psi \rangle | \psi \rangle \tag{G63}
$$

$$
\leq \left| \left| \mathbb{E}_{(q,p)\neq(0,0)} H_{q,p}^0 \otimes H_{q,p}^0 \right| \right|_{\text{op}} \tag{G64}
$$

$$
\leq \sum_{S,S' \subset [K],|S|,|S'| \text{even},S,S' \neq \emptyset} \varepsilon^{|S|+|S'|} \left| \left| \mathbb{E}_{(q,p) \neq (0,0)} E_{q,p}^{\otimes S \cup S'} \right| \right|_{\text{op}} \tag{G65}
$$

$$
\leq \sum_{4 \leq k \leq 2K, k \text{ even}} (2K)^k \varepsilon^k \left| \left| \mathbb{E}_{(q,p) \neq (0,0)} E_{q,p}^{\otimes k} \right| \right|_{\text{op}} \tag{G66}
$$

Lemma [24,](#page-30-1) which is stated and proved at the end of the section, tells us that

 $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$ 

<span id="page-29-0"></span>
$$
\left| \sum_{q,p} E_{q,p}^{\otimes k} \right| \Big|_{\text{op}} \le 2^{k/2} d \tag{G67}
$$

$$
\implies \left| \left| \mathbb{E}_{(q,p)\neq(0,0)} E_{q,p}^{\otimes k} \right| \right|_{\text{op}} \le \frac{2^{k/2} d}{d^2 - 1} + \frac{1}{d^2 - 1} \le \frac{2^{k/2}}{d - 1} \tag{G68}
$$

Plugging this into Equation [G66](#page-29-0) gives

$$
\Gamma^{0} \le \frac{1}{d-1} \sum_{4 \le k \le 2K, k \text{ even}} \left(2\sqrt{2}K\varepsilon\right)^{k} \tag{G69}
$$

This is a geometric series, which is dominated by its first term since by assumption  $K \leq 1/(2\sqrt{2}\varepsilon)$ . We get

$$
\Gamma^0 = \mathcal{O}(K^4 \varepsilon^4 / d) \tag{G70}
$$

The calculation for  $\Gamma^1$  is similar.

$$
\Gamma^{1} \leq \sum_{2 \leq k \leq 2K,k \text{ even}} (2K)^{k} \varepsilon^{k} \left| \left| \mathbb{E}_{(q,p) \neq (0,0)} E_{q,p}^{\otimes k} \right| \right|_{\text{op}} \tag{G71}
$$

$$
= \mathcal{O}(K^2 \varepsilon^2 / d) \tag{G72}
$$

Returning to Equation [G62,](#page-28-2) we have

$$
\frac{\mathbb{E}_{(q,p)\neq(0,0)}\mathbb{E}_r \mathbb{P}_{\rho_{q,p,r}}(l)}{\mathbb{P}_{1/d}(l)} \geq 1 - \mathcal{O}\left(TK^2\varepsilon^2/\sqrt{d}\right)
$$
\n(G73)

By Lemma [17,](#page-24-6) our protocol A succeeds with probability at most  $(1 + \mathcal{O}(TK^2\varepsilon^2/\sqrt{\varepsilon^2})$  $(d)$ )/2. To succeed with probability By Lemma 17, our protocol A succeeds with probability at most  $(1 + O(TK^{-\epsilon})\sqrt{a})/2$ . To succeed  $2/3$ , A requires  $T = \Omega(\sqrt{d}/K^2\epsilon^2)$ . This completes the proof of Proposition [22,](#page-26-3) modulo Lemma [24.](#page-30-1)  $\Box$ 

<span id="page-29-1"></span>**Lemma 23.** Let the Hilbert space dimension d be prime. For any  $1 \le m \le k$  with k even,

$$
\left\| \sum_{q,p} D_{q,p}^{\otimes m} \otimes D_{-q,-p}^{\otimes (k-m)} \right\|_{\text{op}} = d \tag{G74}
$$

Proof. Denote

$$
\mathcal{D}(m,k) = \sum_{q,p} D_{q,p}^{\otimes m} \otimes D_{-q,-p}^{\otimes (k-m)} \tag{G75}
$$

Consider the action on a basis state  $|a_1\rangle \dots |a_k\rangle$ .

$$
\mathcal{D}(m,k)|a_1\rangle \dots |a_k\rangle \tag{G76}
$$

$$
= \sum_{q,p} e^{i\pi kq p/d} \left( (X^q)^{\otimes m} \otimes (X^{-q})^{\otimes (k-m)} \right) \left( (Z^p)^{\otimes m} \otimes (Z^{-p})^{\otimes (k-m)} \right) |a_1\rangle \dots |a_k\rangle \tag{G77}
$$

$$
= \sum_{q,p} e^{i(2\pi/d)p\left(\frac{k}{2}q + a_1 + \dots + a_m - a_{m+1} - \dots - a_k\right)} |a_1 + q\rangle \dots |a_m + q\rangle |a_{m+1} - q\rangle \dots |a_k + q\rangle \tag{G78}
$$

$$
= d|a_1 + \hat{q}\rangle \dots |a_m + \hat{q}\rangle |a_{m+1} - \hat{q}\rangle \dots |a_k - \hat{q}\rangle
$$
\n(G79)

where  $\hat{q}$  is the unique solution to

$$
\frac{k}{2}q + a_1 + \dots + a_m - a_{m+1} - \dots - a_k = 0 \mod d \tag{G80}
$$

Here we used that d is prime, so that  $\mathbb{Z}_d$  is a field.

Let g be the multiplicative inverse of  $k/2 \mod d$ . The operator  $\mathcal{D}(m, k)/d$  implements a linear map on basis vectors over  $\mathbb{Z}_{d}^{\tilde{k}}$  given by the matrix

$$
I_k + \begin{pmatrix} g & \dots & g & -g & \dots & -g \\ \vdots & \vdots & \vdots & & \vdots \\ g & \dots & g & -g & \dots & -g \end{pmatrix} \tag{G81}
$$

This matrix is invertible over  $\mathbb{Z}^k_d$  with inverse

$$
I_k + \begin{pmatrix} h & \dots & h & -h & \dots & -h \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ h & \dots & h & -h & \dots & -h \end{pmatrix} \tag{G82}
$$

where h solves

$$
g + h + (2m - k)gh = 0
$$
\n
$$
(G83)
$$

We have shown that  $\mathcal{D}(m, k)/d$  is in fact a permutation matrix. In particular,

$$
||\mathcal{D}(m,k)||_{\text{op}} = d \tag{G84}
$$

 $\Box$ 

<span id="page-30-1"></span>**Lemma 24.** Let the Hilbert space dimension  $d$  be prime. For any even  $k$ ,

$$
\left\| \sum_{q,p} E_{q,p}^{\otimes k} \right\|_{\text{op}} \le 2^{k/2} d \tag{G85}
$$

Proof. First expand

$$
E_{q,p}^{\otimes k} = \left(\chi D_{q,p} + \chi^* D_{-q,-p}\right)^{\otimes k} \tag{G86}
$$

$$
=\sum_{S\subset[k]} \chi^{|S|}(\chi^*)^{k-|S|} D_{q,p}^{\otimes S} \otimes D_{-q,-p}^{\otimes [k]\setminus S} \tag{G87}
$$

Now sum over  $q, p$  and take the operator norm.

$$
\left\| \sum_{q,p} E_{q,p}^{\otimes k} \right\|_{\text{op}} \le \frac{1}{2^{k/2}} \sum_{S \subset [k]} \left\| \sum_{q,p} D_{q,p}^{\otimes S} \otimes D_{-q,-p}^{\otimes [k] \setminus S} \right\|_{\text{op}} \tag{G88}
$$

$$
=2^{k/2}d\tag{G89}
$$

using Lemma [23.](#page-29-1)

We suspect Lemma [24](#page-30-1) is not tight, and the correct bound is 2d independent of k, but it is sufficient for our purposes.

# <span id="page-30-0"></span>Appendix H: Generalized Clifford classical shadows

In this appendix, we analyse a bosonic version of classical shadows, derived from the uniform distribution over generalized Cliffords in prime dimension.

 $\Box$ 

### <span id="page-31-2"></span>1. Review of classical shadows framework

We start by reviewing the classical shadows framework of Ref. [\[7\]](#page-5-4), introducing some generalizations that are relevant for generalized Clifford shadows. This review is based in large part on Section 2.2 of Ref. [\[31\]](#page-6-7). See also the review in [\[49\]](#page-6-25).

Let  $\mathcal H$  be a finite-dimensional Hilbert space, and let  $\mathcal B$  denote an orthonormal basis for  $\mathcal H$ . The goal of the classical shadows procedure is to estimate the expectation values  $tr(O_1\rho), \ldots, tr(O_M\rho)$  of M (possible non-Hermitian) "observables"  $O_1, \ldots, O_M$  H, with respect to an unknown state  $\rho$ . The input to the procedure consists of copies of  $\rho$ and some classical description of  $O_1, \ldots, O_M$ , and (having fixed  $\mathcal{B}$ ) the procedure is parametrised by a distribution  $\mathcal{D}$ over unitaries. For each copy of  $\rho$ , we randomly draw a unitary U from this distribution, and measure  $\rho$  in the basis  ${U^{\dagger}}|b\rangle$ <sub>b∈B</sub>.<sup>[1](#page-31-0)</sup> The quantum channel M corresponding to this process is given by

$$
\mathcal{M}(\rho) = \mathop{\mathbb{E}}_{U \sim \mathcal{D}} \sum_{b \in \mathcal{B}} U^{\dagger} |b\rangle \langle b| U \rho U^{\dagger} |b\rangle \langle b| U,\tag{H1}
$$

which can be rewritten as

$$
\mathcal{M}(\rho) = \text{tr}_1 \left[ \sum_{b \in \mathcal{B}} \mathbb{E}_{U \sim \mathcal{D}} \mathcal{U}^{\otimes 2}(|b\rangle \langle b|^{\otimes 2}) (\rho \otimes I) \right]
$$
(H2)

in order to isolate the dependence on the distribution  $\mathcal{D}$ . Here,  $tr_1$  denotes the partial trace over the first tensor component, and U denotes the unitary channel corresponding to  $U^{\dagger}$ :  $\mathcal{U}(\cdot) = U^{\dagger}(\cdot)U$ .

For certain distributions  $\mathcal{D}, \mathcal{M}$  is invertible. Then, we can define a random operator  $\hat{\rho}$  by

<span id="page-31-4"></span><span id="page-31-3"></span>
$$
\hat{\rho} := \mathcal{M}^{-1}(\hat{U}^{\dagger}|\hat{b}\rangle\langle\hat{b}|\hat{U}),\tag{H3}
$$

where  $\hat{U}$  is distributed according to D and  $\mathbb{P}[\hat{b} = |b\rangle | \hat{U} = U] = \langle b | U \rho U^{\dagger} | b \rangle$ . By construction,  $\hat{\rho}$  is an unbiased estimator for  $\rho$ :

<span id="page-31-1"></span>
$$
\mathbb{E}[\hat{\rho}] = \rho.
$$

In the literature, the term "classical shadow" is used sometimes to refer to this unbiased estimator  $\hat{\rho}$ , and sometimes to a sample of it obtained in one realisation of the above procedure (i.e.,  $\mathcal{M}^{-1}(U^{\dagger}|b\rangle\langle b|U)$  for some outcomes U and  $|b\rangle$ ). These samples can be used to estimate the expectation values  $tr(O_i \rho)$ , since

$$
\mathbb{E}[\hat{o}_i] = \text{tr}(O_i \rho),
$$

where for  $i \in [M],$ 

<span id="page-31-5"></span>
$$
\hat{o}_i := \text{tr}(O_i \hat{\rho}) = \text{tr}\left(O_i \mathcal{M}^{-1} (\hat{U}^\dagger | \hat{b} \rangle \langle \hat{b} | \hat{U})\right) \tag{H4}
$$

is the unbiased estimator for  $tr(O_i \rho)$  derived from  $\hat{\rho}$ .

To bound the number of samples of the classical shadow estimator  $\hat{\rho}$  (and hence the number of copies of  $\rho$ ) required to estimate the expectation values to within some desired precision with high probability, we consider the variances of the estimators  $\hat{o}_i$ :

$$
\text{Var}[\hat{o}_i] = \mathbb{E}[|\hat{o}_i|^2] - |\mathbb{E}[\hat{o}_i]|^2 \tag{H5}
$$

$$
= \mathop{\mathbb{E}}_{U \sim \mathcal{D}} \sum_{b \in \mathcal{B}} \langle b | U \rho U^{\dagger} | b \rangle \left| \text{tr} \left( O_i \mathcal{M}^{-1} (U^{\dagger} | b \rangle \langle b | U) \right) \right|^2 - |\text{tr} (O_i \rho)|^2 \tag{H6}
$$

$$
= \underset{U \sim \mathcal{D}}{\mathbb{E}} \sum_{b \in \mathcal{B}} \text{tr} \left[ U^{\dagger} |b\rangle \langle b| U \rho \otimes \mathcal{M}^{-1} (U^{\dagger} |b\rangle \langle b| U) O_i \otimes \mathcal{M}^{-1} (U^{\dagger} |b\rangle \langle b| U) O_i^{\dagger} \right] - |\text{tr}(O_i \rho)|^2 \tag{H7}
$$

plementing the classical shadows procedure, the application of  $U^{\dagger}$  is not necessary, as we only need the measurement statistics and not the post-measurement state.

<span id="page-31-0"></span><sup>&</sup>lt;sup>1</sup> This measurement can be implemented by applying U to  $\rho$ , then measuring in the basis  $\mathcal{B}$ , and applying  $U^{\dagger}$  to the postmeasurement state. Note, however, that for the purpose of im-

$$
= \operatorname{tr} \left[ \sum_{b \in \mathcal{B}} \mathbb{E}_{U \in \mathcal{D}} \mathcal{U}^{\otimes 3}(|b\rangle\langle b|^{\otimes 3}) \left( \mathcal{M}^{-1}(O_i) \otimes \mathcal{M}^{-1}(O_i^{\dagger}) \otimes \rho \right) \right] - |\operatorname{tr}(O_i \rho)|^2, \tag{H8}
$$

using the fact that  $M$  is self-adjoint (with respect to the Hilbert-Schmidt inner product) in the last line, so  $tr(M^{-1}(A)B) = tr(AM^{-1}(B))$  for any operators A and B. This variance can be upper-bounded by the first term, maximised over all states  $\rho$ ; this gives the square of what is often referred to as the "shadow norm" in the literature. A useful observation is that since  $tr(\hat{\rho}) = 1$ , the variance for any observable  $\hat{O}_i$  is the same as that for  $\hat{O}_i + cI$  for any  $c \in \mathbb{C}$ , so we can also also write

$$
\text{Var}[\hat{o}_i] = \text{tr}\left[\sum_{b \in \mathcal{B}} \mathop{\mathbb{E}}_{U \in \mathcal{D}} \mathcal{U}^{\otimes 3}(|b\rangle\langle b|^{\otimes 3}) \left(\mathcal{M}^{-1}(O_i + cI) \otimes \mathcal{M}^{-1}(O_i^{\dagger} + cI) \otimes \rho\right)\right] - |\text{tr}((O_i + cI)\rho)|^2. \tag{H9}
$$

If median-of-means estimators are used, it follows straightforwardly from Chebyshev's and Hoeffding's inequalities that

<span id="page-32-7"></span><span id="page-32-5"></span><span id="page-32-2"></span>
$$
N_{\text{sample}} = \mathcal{O}\left(\frac{\log(M/\delta)}{\varepsilon^2} \max_{i \in [M]} \text{Var}[\hat{o}_i]\right) \tag{H10}
$$

classical shadows samples (and hence single-copy measurements of  $\rho$ ) are sufficient to ensure that with probability at least  $1 - \delta$ , every  $tr(O_i \rho)$  is estimated to within additive error  $\varepsilon$ .

### 2. Preliminaries and notation

### a. Generalized Clifford group

The generalized (single-qudit) Clifford group in dimension d, which we will denote by  $Cl_d$ , is the normaliser of the Pauli group in the d-dimensional unitary group.<sup>[2](#page-32-0)</sup> Hence, a Clifford  $U \in \text{Cl}_d$  satisfies the property that for any  $(q, p) \in \mathbb{Z}_{d}^{2}$ ,  $U^{\dagger}D_{q,p}U = \alpha D_{q',p'}$  for some  $(q', p') \in \mathbb{Z}_{d}^{2}$  and some phase  $\alpha$ . Thus, each Clifford can be associated with a map  $\mathbb{Z}_d^2 \to \mathbb{Z}_d^2$ , and since its action under conjugation is completely specified by how  $X = D_{1,0}$  and  $Z = D_{0,1}$  are transformed, this map is linear, and can be written as a  $2 \times 2$  matrix  $C \in \mathbb{Z}_d^{2 \times 2}$  so that

<span id="page-32-1"></span>
$$
U^{\dagger} D_{q,p} U = \alpha D_{q',p'} \text{ for some phase } \alpha \qquad \Leftrightarrow \qquad C \begin{pmatrix} q \\ p \end{pmatrix} = \begin{pmatrix} q' \\ p' \end{pmatrix}
$$
 (H11)

for all  $q, p \in \mathbb{Z}_d$ . It follows from the fact that conjugation preserves commutation relations that this matrix also has to be symplectic. It turns out that conversely, for any symplectic  $2 \times 2$  matrix with entries in  $\mathbb{Z}_d$ , there exists a corresponding Clifford in the sense of Eq. [\(H11\)](#page-32-1) [\[50\]](#page-6-26).

<span id="page-32-3"></span>**Fact 1** ([\[50\]](#page-6-26)). For any  $C \in \mathbb{Z}_d^{2 \times 2}$ , there exists  $U \in \mathrm{Cl}_d$  satisfying Eq. [\(H11\)](#page-32-1) if and only if C is symplectic.

The following basic fact about symplectic  $2 \times 2$  matrices will also come in useful.

<span id="page-32-4"></span>**Fact 2.** A  $2 \times 2$  matrix C is symplectic if and only if  $det(C) = 1$ .

### b. Liouville representation

In some parts of this appendix (especially when we analyse the twirl channels of the generalized Clifford group in the following subsection), we will use Liouville representation, which is often useful for specifying quantum channels. In this representation, operators are notated using "double" kets, and a "double" bracket is used to represent the Hilbert-Schmidt inner product. By convention, all double kets are normalised with respect to the Hilbert-Schmidt norm, unless otherwise noted. Thus, for any nonzero operators  $A, B$ ,

<span id="page-32-6"></span>
$$
|A\rangle = \frac{1}{\sqrt{\text{tr}(A^{\dagger}A)}}A, \qquad \langle A|B\rangle = \frac{\text{tr}(A^{\dagger}B)}{\sqrt{\text{tr}(A^{\dagger}A)\text{tr}(B^{\dagger}B)}}, \qquad (H12)
$$

finite group, but the results in this appendix hold even if phases are included.

<span id="page-32-0"></span><sup>2</sup> Strictly speaking, we should quotient out phases so that it makes sense to write the twirl channel in Eq. [\(H15\)](#page-33-0) as an average over a

34

and we set  $|0\rangle \equiv 0$  for the zero operator. In particular, since the generalized Pauli operators are unitary (Eq. [\(A9\)](#page-7-6)) and Hilbert-Schmidt orthogonal (Proposition [8\)](#page-7-1), we have

<span id="page-33-5"></span>
$$
|D_{q,p}\rangle\!\rangle \equiv \frac{1}{\sqrt{d}} D_{q,p}, \qquad \langle\!\langle D_{q,p} | D_{q',p'} \rangle\!\rangle = \delta_{q,q'} \delta_{p,p'}.
$$
\n(H13)

As with usual (state) kets, we will freely write e.g.,  $|A\rangle|B\rangle$  in place of  $|A\rangle\otimes|B\rangle$ .

A superoperator  $\mathcal E$  acting on an operator  $A$  is represented by placing the superoperator to the left of the operator's double ket:

$$
\mathcal{E}|A\rangle = \frac{1}{\sqrt{\text{tr}(A^{\dagger}A)}}\mathcal{E}(A).
$$

We will also write  $\mathcal{E}\mathcal{E}'$  in place of  $\mathcal{E} \circ \mathcal{E}'$ .

Since the generalized Pauli operators form a Hilbert-Schmidt orthogonal basis for the space of operators acting on d-dimensional Hilbert space  $\mathcal{H}_d$ , we have the following resolution of the identity superoperator  $\mathcal{I}$ :

<span id="page-33-2"></span>
$$
\mathcal{I} = \sum_{p,q \in \mathbb{Z}_d} |D_{p,q} \rangle \langle \!\langle D_{p,q} |.
$$
\n(H14)

### 3. Uniform distribution over generalized Cliffords

In the rest of this appendix, we consider the classical shadows associated with the uniform distribution over  $Cl_d$ , the generalized (single-qudit) Cliffords in prime dimension d.

As can be seen from Eqs. [\(H2\)](#page-31-1) and [\(H8\)](#page-32-2), the measurement channel  $M$  in the classical shadows protocol depends on the chosen unitary distribution D only through its 2-fold twirl  $\mathbb{E}_{U\sim\mathcal{D}}\mathcal{U}^{\otimes2}$ , while the variances of the resulting estimates depend on  $\mathcal D$  through its 3-fold twirl  $\mathbb{E}_{U\sim\mathcal{D}}\mathcal{U}^{\otimes 3}$ . Hence, in this subsection, we evaluate the 2- and 3-fold twirl channels for the uniform distribution over generalized Cliffords, arriving at the theorem below. This then allow us to obtain explicit expressions for the measurement channel  $M$  and the variance for any observable.

For  $k \in \mathbb{Z}_{>0}$ , we use  $\mathcal{E}_d^{(k)}$  $d_d^{(k)}$  to denote the k-fold twirl channel corresponding to the uniform distribution over Cl<sub>d</sub>:

<span id="page-33-0"></span>
$$
\mathcal{E}_d^{(k)} := \frac{1}{|\mathcal{C}l_d|} \sum_{U \in \mathcal{C}l_d} \mathcal{U}^{\otimes k},\tag{H15}
$$

where, as in subsection [H 1,](#page-31-2)  $\mathcal{U}(\cdot) = U^{\dagger}(\cdot)U$ .

<span id="page-33-1"></span>**Theorem 25** (First three moments of uniform distribution over generalized Cliffords). Let  $\mathcal{E}_d^{(k)}$  $d_d^{(\kappa)}$  be defined as in Eq.  $(H15)$ . Then, for any prime d, we have

(i) 
$$
\mathcal{E}_d^{(1)} = |I\rangle\angle\langle I|
$$
,  
\n(ii)  $\mathcal{E}_d^{(2)} = |I\rangle\angle\langle I|^{\otimes 2} + |\Phi_0\rangle\angle\langle\Phi_0|$ ,  
\n(iii)  $\mathcal{E}_d^{(3)} = |I\rangle\angle\langle I|^{\otimes 3} + |\Phi_1\rangle\angle\langle\Phi_1| + |\Phi_2\rangle\angle\langle\Phi_2| + |\Phi_3\rangle\angle\langle\Phi_3| + \sum_{k=1}^{d-2} |\Psi_k\rangle\angle\langle\Psi_k| + \sum_{l=1}^{d-1} |\Upsilon_l\rangle\angle\langle\Upsilon_l|$ ,

where

<span id="page-33-4"></span><span id="page-33-3"></span>
$$
|\Phi_0\rangle := \frac{1}{\sqrt{d^2 - 1}} \sum_{\substack{q, p \in \mathbb{Z}_d \\ (q, p) \neq (0, 0)}} |D_{q, p}\rangle |D_{q, p}^\dagger\rangle \tag{H16}
$$

and

$$
|\Phi_1\rangle := \frac{1}{\sqrt{d^2 - 1}} \sum_{\substack{q, p \in \mathbb{Z}_d \\ (q, p) \neq (0, 0)}} |I\rangle\langle D_{q, p} \rangle\langle D_{q, p}^\dagger\rangle\rangle,\tag{H17}
$$

$$
|\Phi_2\rangle := \frac{1}{\sqrt{d^2 - 1}} \sum_{\substack{q, p \in \mathbb{Z}_d \\ (q, p) \neq (0, 0)}} |D_{q, p}\rangle |I\rangle |D_{q, p}^{\dagger}\rangle, \tag{H18}
$$

$$
|\Phi_3\rangle := \frac{1}{\sqrt{d^2 - 1}} \sum_{\substack{q, p \in \mathbb{Z}_d \\ (q, p) \neq (0, 0)}} |D_{q, p}\rangle |D_{q, p}^\dagger\rangle |I\rangle\tag{H19}
$$

$$
|\Psi_k\rangle := \frac{1}{\sqrt{d^2 - 1}} \sum_{\substack{q, p \in \mathbb{Z}_d \\ (q, p) \neq (0, 0)}} |D_{q, p}\rangle |D_{kq, kp}\rangle |D_{q, p}^\dagger D_{kq, kp}^\dagger\rangle \tag{H20}
$$

$$
|\Upsilon_l\rangle\!\rangle := \frac{1}{\sqrt{d(d^2-1)}} \sum_{\substack{q_1, p_1, q_2, p_2 \in \mathbb{Z}_d \\ p_1 q_2 - q_1 p_2 = l}} |D_{q_1, p_1}\rangle\!\rangle |D_{q_2, p_2}\rangle\!\rangle |D_{q_1, p_1}^\dagger D_{q_2, p_2}^\dagger\rangle\!\rangle. \tag{H21}
$$

The strategy we use to prove Theorem [25](#page-33-1) is very similar in spirit to that used to determine the 2- and 3-fold twirl channels of the matchgate group in Ref. [\[31\]](#page-6-7). In broad strokes, we start from the simple observation that each twirl channel is an orthogonal projector, and use the invariance of the twirl channel under composition with suitably chosen group elements to determine its image. The difference in the details of the proof of Theorem [25](#page-33-1) differ from those in Ref. [\[31\]](#page-6-7) stem from the difference in the structure of the adjoint representation of the Clifford group and that of the matchgate group, with the former being somewhat easier to handle since it is a discrete group.

The following facts follow straightforwardly from the fact that (for any  $k \in \mathbb{Z}_{>0}$ ) the map  $U \mapsto \mathcal{U}^{\otimes k}$  is a representation of the generalized Clifford group; see e.g., [\[51\]](#page-6-27) Proposition 2.8.

<span id="page-34-3"></span><span id="page-34-1"></span>**Fact 3.** For any  $k \in \mathbb{Z}_{>0}, \mathcal{E}_d^{(k)}$  $d_d^{(k)}$  is the orthogonal projector onto the subspace  $\{A \in \mathcal{L}(\mathcal{H}_d)^{\otimes k} : \mathcal{U}^{\otimes k}(A) = A \ \forall U \in \mathrm{Cl}_d\}.$ **Fact 4.** For any  $k \in \mathbb{Z}_{>0}$  and  $U \in \mathrm{Cl}_d$ ,

$$
\mathcal{U}^{\otimes k} \circ \mathcal{E}_d^{(k)} = \mathcal{E}_d^{(k)} = \mathcal{E}_d^{(k)} \circ \mathcal{U}^{\otimes k}.
$$

We will also make use of the following simple fact.

<span id="page-34-0"></span>**Fact 5.** Let d be a prime number. For any  $q, p \in \mathbb{Z}_d$  with  $(q, p) \neq (0, 0)$ , there exist  $q', p' \in \mathbb{Z}_d$  such that

$$
p'q - q'p = 1.
$$

*Proof.* If  $q \neq 0$ , choose any q' and set  $p' = (q'p + 1)q^{-1}$ . Otherwise, we must have  $p \neq 0$ , in which case we choose any  $p'$  and set  $q' = (p'q - 1)p^{-1}$ . □

### a. 1-fold twirl

We start by evaluating the 1-fold twirl  $\mathcal{E}_d^{(1)}$  $\frac{d^{(1)}}{d}$ , since a similar idea will be used in obtaining the 2- and 3-fold twirls. *Proof of Theorem [25\(](#page-33-1)i).* We can rewrite Eq.  $(A12)$  as

<span id="page-34-2"></span>
$$
D_{q',p'} D_{q,p} D_{q',p'}^{\dagger} = \omega^{p'q - q'p} D_{q,p},\tag{H22}
$$

with  $\omega := e^{2\pi i/d}$ . By Fact [5,](#page-34-0) there exist  $q', p'$  such that  $p'q - q'p = 1$  provided that  $(q, p) \neq (0, 0)$ . Thus, for any  $(q, p) \neq (0, 0)$ , there exists a Pauli  $U \in \mathrm{Cl}_d$  such that

$$
\mathcal{U}|D_{q,p}\rangle\!\!\!\rangle=\omega|D_{q,p}\rangle\!\!\!\rangle.
$$

Hence,

$$
\mathcal{E}_d^{(1)} |D_{q,p}\rangle = \frac{1}{d} \sum_{j=0}^{d-1} \mathcal{E}_d^{(1)} \mathcal{U}^j |D_{q,p}\rangle
$$
  
= 
$$
\frac{1}{d} \mathcal{E}_d^{(1)} \left(\sum_{j=0}^{d-1} \omega^j\right) |D_{q,p}\rangle
$$
  
= 0

for any  $(q, p) \neq (0, 0)$ , where we use Fact [4](#page-34-1) in the first line, while for  $(q, p) = (0, 0)$ , we have  $\mathcal{E}_d^{(1)}$  $\mathcal{E}_d^{(1)}|D_{0,0}\rangle\!\!\!\rangle = \mathcal{E}_d^{(1)}$  $\binom{1}{d} |I|\ = |I|\.$ Since  ${D_{q,p}}_{q,p\in\mathbb{Z}_d}$  forms a basis for the space of operators, it follows that

$$
\mathcal{E}_1=|I\rangle\!\rangle\langle\!\langle I|.
$$

<span id="page-34-4"></span>35

 $\Box$ 

# b. 2-fold twirl

Now, we evaluate the 2-fold twirl  $\mathcal{E}_d^{(2)}$  $\mathcal{L}^{(2)}_{d}$ , which will allow us to determine the measurement channel (Eq. [\(H2\)](#page-31-1)) for the generalized Clifford shadows. We start with a lemma that precludes certain basis states (in the Pauli basis) from being in the image of  $\mathcal{E}_d^{(2)}$  $\frac{d^{(2)}}{d}$ .

<span id="page-35-0"></span>**Lemma 26.** Let  $d$  be a prime number. For  $q_1, p_1, q_2, p_2 \in \mathbb{Z}_d$ ,  $\mathcal{E}_d^{(2)}$  $\frac{d^{(2)}}{d}|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle \neq 0$  only if  $(q_1+q_2,p_1+p_2)=(0,0)$ . *Proof.* The proof is very similar to that of Theorem [25\(](#page-33-1)i) above. From Eq.  $(H22)$ ,

$$
D_{q',p'}^{\otimes 2}(D_{q_1,p_1}\otimes D_{q_2,p_2})(D_{q',p'}^{\otimes 2})^{\dagger}=\omega^{p'(q_1+q_2)-q'(p_1+p_2)}D_{q_1,p_1}\otimes D_{q_2,p_2},
$$

so it follows from Fact [5](#page-34-0) that for any  $q_1, p_1, q_2, p_2 \in \mathbb{Z}_d$  with  $(q_1 + q_2, p_1 + p_2) \neq (0, 0)$ , there exists a Pauli  $U \in \mathrm{Cl}_d$ such that

$$
\mathcal{U}^{\otimes 2}|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle=\omega|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle.
$$

Hence,

$$
\mathcal{E}_d^{(2)}|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle = \frac{1}{d}\sum_{j=0}^{d-1}\mathcal{E}_d^{(2)}(\mathcal{U}^j)^{\otimes 2}|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle
$$
  
=  $\frac{1}{d}\mathcal{E}_d^{(2)}\left(\sum_{j=0}^{d-1}\omega^j\right)|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle$   
= 0.

 $\Box$ 

Next, we show that all  $D_{q,p}$  with  $(q, p) \neq (0, 0)$  are in the same orbit under the action of Cl<sub>d</sub> by conjugation (if we ignore global phases).

<span id="page-35-1"></span>**Lemma 27.** Let d be a prime number. For any  $q, p, q', p' \in \mathbb{Z}_d$  with  $(q, p), (q', p') \neq (0, 0)$ , there exists  $U \in \text{Cl}_d$  such that

$$
\mathcal{U}|D_{q,p}\rangle\!\!\!\rangle = \alpha|D_{q',p'}\rangle\!\!\!\rangle
$$

for some phase  $\alpha$ .

*Proof.* By Fact [1](#page-32-3) and Eq. [\(H11\)](#page-32-1), such a Clifford exists provided that there exists a symplectic matrix  $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$  such that

<span id="page-35-2"></span>
$$
\begin{pmatrix} w & x \\ y & z \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix} = \begin{pmatrix} q' \\ p' \end{pmatrix}.
$$

If  $q \neq 0$ , we set  $w = (q' - xp)q^{-1}$  and  $y = (p' - zp)q^{-1}$ . Then,  $\det \begin{pmatrix} w & x \\ y & z \end{pmatrix} = (q'z - xp')q^{-1}$ . By Fact [5,](#page-34-0) since  $(q', p') \neq (0, 0)$ , we can choose z, x such that  $(q'z - xp') = q$ , so that the determinant is 1—i.e., the matrix is symplectic by Fact [2.](#page-32-4) Otherwise, we must have  $p \neq 0$ , in which case we set  $x = (q' - wq)p^{-1}$  and  $z = (p' - yq)p^{-1}$ , and choose  $w, y$  such that  $(wp' - q'y) = p$  via Fact [5.](#page-34-0)  $\Box$ 

*Proof of Theorem [25\(](#page-33-1)ii).* Inserting resolutions of the identity (Eq. [\(H14\)](#page-33-2)) and using Lemma [26,](#page-35-0) we have

$$
\mathcal{E}_d^{(2)} = \sum_{q,p,q',p' \in \mathbb{Z}_d} |D_{q,p}\rangle |D_{-q,-p}\rangle \langle \langle D_{q,p}|\langle D_{-q,-p}|\mathcal{E}_d^{(2)}|D_{q',p'}\rangle|D_{-q',-p'}\rangle \langle \langle D_{q',p'}|\langle D_{-q',-p'}|\rangle \langle D_{-q',-p'}|\rangle \tag{H23}
$$

$$
= \sum_{q,p,q',p'\in\mathbb{Z}_d} |D_{q,p}\rangle\!\rangle|D_{q,p}^{\dagger}\rangle\!\rangle\langle\!\langle D_{q,p}|\langle\!\langle D_{q,p}^{\dagger}|\mathcal{E}_d^{(2)}|D_{q',p'}\rangle\!\rangle|D_{q',p'}^{\dagger}\rangle\!\rangle\langle\!\langle D_{q',p'}|\langle\!\langle D_{q',p'}^{\dagger}|\rangle\!\rangle\tag{H24}
$$

$$
=|I\rangle\|I\rangle\|\langle I|\|\langle I|+\sum_{\substack{q,p,q',p'\in\mathbb{Z}_d\\(q,p),(q',p')\neq(0,0)}}|D_{q,p}\rangle\|D_{q,p}^{\dagger}\|\langle D_{q,p}|\langle D_{q,p}|\langle D_{q',p'}|\rangle\|D_{q',p'}\rangle\|D_{q',p'}^{\dagger}\|\langle D_{q',p'}|\langle D_{q',p'}^{\dagger}|
$$
(H25)

(note that since  $\mathcal{E}_d^{(2)\dagger} = \mathcal{E}_d^{(2)}$  $\mathcal{L}_d^{(2)}$  by Fact [3,](#page-34-3) Lemma [26](#page-35-0) also implies that  $\langle D_{q_1,p_1} | \langle D_{q_2,p_2} | \mathcal{E}_d^{(2)} \rangle = 0$  if  $(q_2, p_2) \neq (-q_1, -p_1)$ . Here, the second line uses Eq. [\(A9\)](#page-7-6) and the third line follows from the obvious fact that  $\mathcal{E}_d^{(2)}$  $\binom{d}{d} |D_{0,0}\rangle = |D_{0,0}\rangle = |I\rangle.$ 

Now, we use Lemma [27](#page-35-1) to show that  $\langle D_{q,p} | \langle D_{q,p}^{\dagger} | \mathcal{E}_d^{(2)} | D_{q',p'} \rangle \rangle | D_{q',p'}^{\dagger} \rangle$  is the same for all  $(q,p)$ ,  $(q',p') \neq (0,0)$ , i.e.,

<span id="page-36-0"></span>
$$
\langle\!\langle D_{q,p}|\langle\!\langle D_{q,p}^{\dagger}|\mathcal{E}_d^{(2)}|D_{q',p'}\rangle\!\rangle|D_{q',p'}^{\dagger}\rangle\!\rangle = c
$$
\n(H26)

for some constant c. To see this, note from Lemma [27](#page-35-1) that for any  $(q'', p'') \neq (0, 0)$ , there exists  $U \in \mathrm{Cl}_d$  such that  $\mathcal{U}|D_{q',p'}\rangle\!\rangle = \alpha|D_{q'',p''}\rangle\!\rangle$  for some phase  $\alpha$ , so

<span id="page-36-1"></span>
$$
\mathcal{U}^{\otimes 2}|D_{q',p'}\rangle\langle D_{q',p'}^{\dagger}\rangle\rangle = \alpha|D_{q'',p''}\rangle\langle\alpha^*|D_{q'',p''}^{\dagger}\rangle\rangle = |D_{q'',p''}\rangle\langle D_{q'',p''}^{\dagger}\rangle\rangle
$$
(H27)

Then, use Fact [4](#page-34-1) to write

$$
\mathcal{E}_d^{(2)}|D_{q',p'}\rangle\!\rangle|D_{q',p'}^{\dagger}\rangle\!\rangle = \mathcal{E}_d^{(2)}\mathcal{U}^{\otimes 2}|D_{q',p'}\rangle\!\rangle|D_{q',p'}^{\dagger}\rangle\!\rangle = \mathcal{E}_d^{(2)}|D_{q'',p''}\rangle\!\rangle|D_{q'',p''}^{\dagger}\rangle\!\rangle.
$$

Inserting Eq. [\(H26\)](#page-36-0) into Eq. [\(H25\)](#page-35-2), we arrive at

$$
\mathcal{E}_d^{(2)} = |I\rangle\langle\!\langle I|^{\otimes 2} + c \sum_{\substack{q,p,q',p' \in \mathbb{Z}_d \\ (q,p),(q',p') \neq (0,0)}} |D_{q,p}\rangle\!\rangle\langle D_{q,p}|\langle D_{q',p'}| \langle\!\langle D_{q',p'}^\dagger| \langle D_{q',p'}^\dagger| \rangle\!\rangle\!\rangle
$$
  
= |I\rangle\langle\!\langle I|^{\otimes 2} + c|\Phi\_0\rangle\langle\!\langle \Phi\_0|,

where  $|\Phi_0\rangle$  is defined as in Eq. [\(H16\)](#page-33-3). Since  $\mathcal{E}_d^{(2)}$  $d_d^{(2)}$  is a projector (Fact [3\)](#page-34-3), c must be equal to 0 or 1. We see from Eq. [\(H27\)](#page-36-1) that for any  $U \in \mathrm{Cl}_d$ ,  $\mathcal{U}^{\otimes 2}$  permutes the basis states of the form  $|D_{q,p}\rangle\!\rangle|D_{q,p}^{\dagger}\rangle\!\rangle$  for  $(q,p) \neq (0,0)$ , without incurring any phases. Since  $|\Phi_0\rangle$  is the equal superposition over these basis states, it follows that  $\mathcal{U}^{\otimes 2}|\Phi_0\rangle = |\Phi_0\rangle$ , so  $\mathcal{E}_d^{(2)}$  $\langle d^{(2)}|\Phi_0\rangle = |\Phi_0\rangle$  and c must be 1.  $\Box$ 

### c. 3-fold twirl

Finally, we evaluate the 3-fold twirl  $\mathcal{E}_d^{(3)}$  $\mathcal{L}_d^{(5)}$ , which will allow us to analyse the variance (Eq. [\(H8\)](#page-32-2)) of estimates obtained using generalized Clifford shadows. The high-level strategy for evaluating  $\mathcal{E}_d^{(3)}$  $d_d^{(3)}$  is is essentially the same as that for evaluating the 2-fold twirl channel  $\mathcal{E}_d^{(2)}$  $\mathcal{L}^{(2)}$ . We start with the following lemma, which precludes certain basis states from being in the image of  $\mathcal{E}_d^{(3)}$  $\frac{d^{(3)}}{d}$ . This lemma is the straightforward extension of Lemma [26,](#page-35-0) which was used in evaluating  $\mathcal{E}_d^{(2)}$ <sup>(2)</sup>. (In fact, there is a natural generalization of these lemmas to  $\mathcal{E}_d^{(k)}$  $\mathcal{L}_d^{(k)}$  for any  $k \in \mathbb{Z}_{>0}$ .)

<span id="page-36-2"></span>**Lemma 28.** Let d be a prime number. For  $q_1, p_1, q_2, p_2, q_3, p_3 \in \mathbb{Z}_d$ ,  $\mathcal{E}_d^{(3)}$  $\|d_d^{(3)}|D_{q_1,p_1}\| |D_{q_2,p_2}\| |D_{q_3,p_3}\rangle \neq 0$  only if  $(q_1 +$  $q_2 + q_3, p_1 + p_2 + p_3 = (0, 0).$ 

Proof. The proof is essentially the same as that of Lemma [26,](#page-35-0) except we consider three tensor components instead of two.  $\Box$ 

Lemma [28](#page-36-2) shows that we need only consider the action of  $\mathcal{E}_d^{(3)}$  $\frac{d^{(3)}}{d}$  on basis states of the form  $|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle|D_{-q_1-q_2,-p_1-p_2}\rangle\!\rangle.$  For these states, the third tensor component is fully determined by the first two. For the purpose of the next lemma, we will say that two pairs of Paulis  $(D_{q_1,p_1}, D_{q_2,p_2})$  and  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  are in the "orbit"<sup>[3](#page-36-3)</sup> if there exists  $U \in \mathrm{Cl}_d$  such that  $\mathcal{U}^{\otimes 2} |D_{q_1,p_1}\rangle \langle D_{q_2,p_2}\rangle = \alpha |D_{q'_1,p'_1}\rangle \langle D_{q'_2,p'_2}\rangle$  for some phase  $\alpha$ , or equivalently,

<span id="page-36-4"></span>
$$
\mathcal{U}|D_{q_1,p_1}\rangle\!\rangle = \alpha_1|D_{q'_1,p'_1}\rangle\!\rangle \quad \text{and} \quad \mathcal{U}|D_{q_2,p_2}\rangle\!\rangle = \alpha_2|D_{q'_2,p'_2}\rangle\!\rangle \tag{H28}
$$

for some phases  $\alpha_1$  and  $\alpha_2$ . The next lemma is essentially the analogue of Lemma [27,](#page-35-1) but for pairs of Paulis.

Eq. [\(H30\)](#page-38-0), we will eventually choose the particular form of the basis states for  $\mathcal{L}(\mathcal{H}_d)^{\otimes 3}$  in such a way that any phases from Eq. [\(H28\)](#page-36-4) are cancelled out.

<span id="page-36-3"></span><sup>3</sup> Strictly speaking, these are not orbits in the group theoretic sense, as we allow phases in Eq. [\(H28\)](#page-36-4). However, this definition will suffice for our purposes, because as can be seen from

<span id="page-37-1"></span>**Lemma 29.** The set of pairs of Paulis  $\{(D_{q_1,p_1}, D_{q_2,p_2}) : q_1, p_1, q_2, p_2 \in \mathbb{Z}_d\}$  is partitioned into the following orbits (in the sense of Eq.  $(H28)$ ):

- a)  $\{(D_{0,0}, D_{0,0})\}$  (1 element)
- b)  $\{(D_{0,0}, D_{q,p}) : q, p \in \mathbb{Z}_d, (q,p) \neq (0,0)\}$   $(d^2-1 \text{ elements})$
- c)  $\{(D_{q,p}, D_{0,0}) : q, p \in \mathbb{Z}_d, (q,p) \neq (0,0)\}$   $(d^2-1 \text{ elements}),$
- d)  $\{(D_{q,p}, D_{kq,kp}) : q, p \in \mathbb{Z}_d, (q,p) \neq (0,0)\}\$  for  $k \in \{1, ..., d-1\}$   $(d^2-1$  elements for each k)
- e)  $\{(D_{q_1,p_1}, D_{q_2,p_2}) : q_1, p_1, q_2, p_2 \in \mathbb{Z}_d, p_1q_2 q_1p_2 = l\}$  for  $l \in \{1, \ldots, d-1\}$   $(d(d^2-1))$  elements for each l).

Proof. First, we show that these subsets indeed partition the set of all pairs of Paulis. The subsets in a), b) and c) are clearly mutually disjoint. The remaining pairs are of the form  $(D_{q_1,p_1}, D_{q_2,p_2})$  with  $(q_1, p_1), (q_2, p_2) \neq 0$ . The pairs with  $p_1q_2 - q_1p_2 \neq 0$  can be partitioned into the subsets in e). This leaves pairs  $(D_{q_1,p_1}, D_{q_2,p_2})$  with  $(q_1, p_1), (q_2, p_2) \neq 0$ and  $p_1q_2 - q_1p_2 = 0$ . Since  $(q_1, p_1), (q_2, p_2) \neq 0$ , we must have that  $q_1, q_2 \neq 0$  and/or  $p_1, p_2 \neq 0$ . If  $q_1, q_2 \neq 0$ , then we can write  $q_2 = (q_1^{-1}q_2)q_1$ , and from  $p_1q_2 - q_1p_2 = 0$ , we have  $p_2 = (q_1^{-1}q_2)p_1$ . If  $p_1, p_2 \neq 0$ , then  $q_2 = (p_1^{-1}p_2)q_1$  and  $p_2 = (p_1^{-1}p_2)p_1$ . In both cases,  $q_2 = kq_1$  and  $p_2 = kp_1$  for some  $k \in \{1, ..., d-1\}$ , which coincides with the subsets in d). It remains to check that these subsets are indeed orbits.

- a) Since  $U|D_{0,0}\rangle = |D_{0,0}\rangle$  (recall  $D_{0,0} = I$ ) for any  $U \in \mathrm{Cl}_d$ , it is clear that  $\{(D_{0,0}, D_{0,0})\}$  is an orbit.
- b) Since  $\mathcal{U}|D_{0,0}\rangle = |D_{0,0}\rangle$  for any  $U \in \text{Cl}_d$ ,  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  is in the same orbit as  $(D_{0,0}, D_{q,p})$  if and only if  $(q'_1, p'_1) = (0, 0)$  and there exists  $U \in \mathrm{Cl}_d$  such that  $\mathcal{U}[\mathcal{D}_{q,p}^{\infty}] \times |D_{q'_2, p'_2} \rangle$ . By Lemma [27,](#page-35-1) for  $(q, p) \neq (0, 0)$ , the latter is true whenever  $(q'_2, p'_2) \neq 0$ . Hence,  $\{(D_{0,0}, D_{q,p}) : q, p \in \mathbb{Z}_d^{\{2\},\{2\}} \neq (0, 0)\}$  is an orbit.
- c) Same proof as for b).
- d) For  $(q, p) \neq (0, 0)$  and  $k \neq 0$ ,  $(D_{q'_1, p'_1}, D_{q'_2, p'_2})$  is in the same orbit as  $(D_{q,p}, D_{kq,kp})$  if and only if there exists  $U \in \mathrm{Cl}_d$  such that  $\mathcal{U}|D_{q,p}\rangle = |D_{q'_1,p'_1}\rangle \rangle$  and  $\mathcal{U}|D_{kq,kp}\rangle \rangle = |D_{q'_2,p'_2}\rangle \rangle$ . By Lemma [27,](#page-35-1) there exists  $U \in \mathrm{Cl}_d$  such that  $\mathcal{U}|D_{q,p}\rangle\!\!\rangle = |D_{q'_1,p'_1}\rangle\!\!\rangle$  whenever  $(q'_1,p'_1)\neq(0,0)$ . Then, since  $D_{kq,kp}=D_{q,p}^k$ , we have  $\mathcal{U}(D_{kq,kp})\propto U^\dagger(D_{q,p}^k)U=0$  $D_{q'_1,p'_1}^k = D_{kq'_1,kp'_1}$ . Thus, all elements in the same orbit as  $(D_{q,p}, D_{kq,kp})$  are of the form  $(D_{q'_1,p'_1}, D_{kq'_1,kp'_2})$ .
- e) Finally, we show that for  $p_1q_2 q_1p_2 \neq 0$ ,  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  is in the same orbit as  $(D_{q_1,p_1}, D_{q_2,p_2})$ —i.e., there exists  $U \in \text{Cl}_d$  satisfying Eq. [\(H28\)](#page-36-4)—if and only if  $p'_1 q'_2 - q'_1 p'_2 = p_1 q_2 - q_1 p_2$ . It follows from Facts [1](#page-32-3) and [2](#page-32-4) that there exists such a Clifford U if and only if there exists a  $2 \times 2$  matrix C such that

<span id="page-37-0"></span>
$$
C\begin{pmatrix} q_1 & q_2 \\ p_1 & p_2 \end{pmatrix} = \begin{pmatrix} q'_1 & q'_2 \\ p'_1 & p'_2 \end{pmatrix}
$$
(H29)

and  $\det(C) = 1$ . Since  $\det\begin{pmatrix} q_1 & q_2 \\ q_1 & q_2 \end{pmatrix}$  $p_1$   $p_2$  $= q_1 p_2 - p_1 q_2 \neq 0$  by assumption,  $\begin{pmatrix} q_1 & q_2 \\ n_1 & n_2 \end{pmatrix}$  $p_1$   $p_2$ ) is invertible and Eq.  $(H29)$  is equivalent to  $C = \begin{pmatrix} q'_1 & q'_2 \\ p'_1 & p'_2 \end{pmatrix}$  $\bigg\{ \bigg( q_1 \bigg) q_2 \bigg)$  $p_1$   $p_2$  $\Big)^{-1}$ . Then,

$$
\det(C) = \det \begin{pmatrix} q'_1 & q'_2 \\ p'_1 & p'_2 \end{pmatrix} \det \begin{pmatrix} q_1 & q_2 \\ p_1 & p_2 \end{pmatrix}^{-1} = (q'_1 p'_2 - p'_1 q'_2)(q_1 p_2 - p_1 q_2)^{-1},
$$

which is equal to 1 if and only if  $p'_1 q'_2 - q'_1 p'_2 = p_1 q_2 - q_1 p_2$ .

 $\Box$ 

We are now ready to evaluate  $\mathcal{E}_d^{(3)}$  $\mathcal{L}_d^{(3)}$ , proving Theorem [25\(](#page-33-1)iii). Observe that the operators (Eq. [\(H17\)](#page-33-4) - [\(H21\)](#page-34-4)) appearing in our final expression for  $\mathcal{E}_d^{(3)}$  $\frac{d^{(3)}}{d}$  corresponds to the non-trivial orbits we found in Lemma [29.](#page-37-1) For each orbit of the form  $\{(D_{q_1,p_1}, D_{q_2,p_2})\}$ , we have an operator that is an equal superposition over states that are proportional to  $|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle|D_{-q_1-q_2,-p_1-p_2}\rangle\!\rangle$  (and recall that states of this form are the states not ruled out by Lemma [28\)](#page-36-2). In this sense,  $|\Phi_1\rangle$  corresponds to the orbit in Lemma [28b](#page-36-2)),  $|\Phi_2\rangle$  corresponds to the orbit in c),  $|\Phi_3\rangle$  corresponds to the orbit in d) for  $k = d - 1$ , the  $|\Psi_k\rangle$ 's correspond to the orbits in d) for  $k \neq d - 1$ , and the  $|\Upsilon_l\rangle$ 's correspond to the orbits in e).

*Proof of Theorem [25\(](#page-33-1)iii).* Inserting resolutions of the identity (Eq.  $(H14)$ ) and using Lemma [28,](#page-36-2) we have

$$
\mathcal{E}_{d}^{(3)} = \sum_{q_1, p_1, q_2, p_2, q'_1, p'_1, q'_2, p'_2 \in \mathbb{Z}_d} \langle D_{q_1, p_1} | \langle D_{q_2, p_2} | \langle D_{-q_1 - q_2, -p_1 - p_2} | \mathcal{E}_d^{(3)} | D_{q'_1, p'_1} \rangle | D_{q'_2, p'_2} \rangle | D_{-q'_1 - q'_2, -p'_1 - p'_2} \rangle
$$
  
\n
$$
\times |D_{q_1, p_1} \rangle | D_{q_2, p_2} \rangle | D_{-q_1 - q_2, -p_1 - p_2} \rangle \langle D_{q'_1, p'_1} | \langle D_{q'_2, p'_2} | \langle D_{-q'_1 - q'_2, -p'_1 - p'_2} | D_{q_1, p_1} \rangle | D_{q_2, p_2} \rangle | D_{-q_1 - q_2, -p_1 - p_2} \rangle \langle D_{q'_1, p'_1} | \langle D_{q'_2, p'_2} \rangle | D_{-q'_1 - q'_2, -p'_1 - p'_2} | D_{q_1, p_1} \rangle | D_{q_2, p_2} \rangle | D_{q_1, p_1} | D_{q_2, p_2} | D_{q_1, p_1} \rangle | D_{q'_2, p'_2} \rangle | D_{q'_1, p'_1} D_{q'_2, p'_2}^{\dagger} \rangle
$$
  
\n
$$
\times |D_{q_1, p_1} \rangle | D_{q_2, p_2} \rangle | D_{q_1, p_1}^{\dagger} D_{q_2, p_2}^{\dagger} \rangle \langle D_{q'_1, p'_1} | \langle D_{q'_2, p'_2} | \langle D_{q'_1, p'_1}^{\dagger} D_{q'_2, p'_2}^{\dagger} | D_{q'_2, p'_2} | D_{q'_1, p'_1} D_{q'_2, p'_2}^{\dagger} | D_{q'_1, p'_1} D_{q
$$

using the fact that  $D_{-q_1-q_2,-p_1-p_2} \propto D_{-q_1,-p_1}D_{-q_2,-p_2} = D_{q_1,p_1}^{\dagger}D_{q_2,p_2}^{\dagger}$  in the second equality.

Next, note from the definition of the orbits (Eq. [\(H28\)](#page-36-4)) that there exists  $U \in Cl_d$  such that  $\langle\!\langle D_{q_1,p_1} | \langle\!\langle D_{q_2,p_2} | \langle\!\langle D_{q_1,p_1}^\dagger D_{q_2,p_2}^\dagger | \mathcal{U}^{\otimes 3} | D_{q_1',p_1'} \rangle\!\rangle | D_{q_2',p_2'} \rangle\!\rangle | D_{q_2'}^\dagger$  $_{q_1',p_1'}^{\dagger}D_q^{\dagger}$  $\begin{array}{lllll} \uparrow & \uparrow & 0 & \text{if and only if} & (D_{q_1,p_1}, D_{q_2,p_2}) & \text{and} \end{array}$  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  are in the same orbit. Hence, since since  $\mathcal{E}_d^{(3)}$  $\mathcal{U}^{(3)}_d$  is the average of  $\mathcal{U}^{\otimes 3}$  for  $U \in \text{Cl}_d$ ,  $\langle\!\langle D_{q_1,p_1} | \langle\!\langle D_{q_2,p_2}^{\dagger} | \langle D_{q_1,p_1}^{\dagger} D_{q_2,p_2}^{\dagger} | \mathcal{E}_{d}^{(3)} | D_{q_1',p_1'} \rangle\!\rangle | D_{q_2',p_2'} \rangle\!\rangle | D_{q_2'}^{\dagger} |$  $_{q_1',p_1'}^{\dagger}D_q^{\dagger}$  $\langle q'_{2},p'_{2} \rangle \neq 0$  only if  $(D_{q_1,p_1}, D_{q_2,p_2})$  and  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  are in the same orbit, so we can write

$$
\mathcal{E}_{d}^{(3)} = \sum_{\text{orbits}} \sum_{\substack{(D_{q_1,p_1}, D_{q_2,p_2}),\\(D_{q'_1,p'_1}, D_{q'_2,p'_2}) \in \text{ orbit}}} \langle\!\langle D_{q_1,p_1}| \langle\!\langle D_{q_2,p_2}| \langle\!\langle D_{q_1,p_1}^{\dagger} D_{q_2,p_2}^{\dagger} | \mathcal{E}_{d}^{(3)} | D_{q'_1,p'_1} \rangle\!\rangle | D_{q'_2,p'_2} \rangle\!\rangle\!\rangle |D_{q'_1,p'_1}^{\dagger} D_{q'_2,p'_2}^{\dagger} \rangle\!\rangle \\ \times |D_{q_1,p_1} \rangle\!\rangle |D_{q_2,p_2} \rangle\!\rangle |D_{q_1,p_1}^{\dagger} D_{q_2,p_2}^{\dagger} \rangle\!\langle\!\langle D_{q'_1,p'_1}| \langle\!\langle D_{q'_2,p'_2}| \langle\!\langle D_{q'_1,p'_1}^{\dagger} D_{q'_2,p'_2}^{\dagger} | \mathcal{E}_{d'_1,p'_1}^{\dagger} D_{q'_
$$

Now, we show that the overlap  $\langle D_{q_1,p_1} | \langle D_{q_2,p_2} | \langle D_{q_1,p_1}^{\dagger} D_{q_2,p_2}^{\dagger} | \mathcal{E}_d^{(3)} | D_{q_1',p_1'} \rangle | D_{q_2',p_2'} \rangle | D_q^{\dagger}$  $_{q_1',p_1'}^{\dagger}D_q^{\dagger}$  $\mathcal{L}_{q'_2, p'_2}^{\dagger}$  is the same within each orbit, i.e., for any orbit, there is a constant  $c$  such that

<span id="page-38-0"></span>
$$
\langle D_{q_1,p_1} | \langle D_{q_2,p_2} | \langle D_{q_1,p_1}^{\dagger} D_{q_2,p_2}^{\dagger} | \mathcal{E}_d^{(3)} | D_{q'_1,p'_1} \rangle \rangle | D_{q'_2,p'_2} \rangle \rangle | D_{q'_1,p'_1}^{\dagger} D_{q'_2,p'_2}^{\dagger} \rangle \rangle = c
$$

for all  $(D_{q_1,p_1}, D_{q_2,p_2})$  and  $(D_{q'_1,p'_1}, D_{q'_2,p'_2})$  in that orbit. To see this, note from the definition of orbits that for any other  $(D_{q''_1,p''_1}, D_{q''_2,p''_2})$  in the orbit, there exist  $U \in \text{Cl}_d$  such that  $\mathcal{U}^{\otimes 2} |D_{q'_1,p'_1} \rangle |D_{q'_2,p'_2} \rangle = \alpha |D_{q''_1,p''_1} \rangle |D_{q''_2,p''_2} \rangle$  for some phase  $\alpha$ . Then,

$$
\mathcal{U}^{\otimes 3} |D_{q'_1, p'_1} \rangle \rangle |D_{q'_2, p'_2} \rangle \rangle |D_{q'_1, p'_1}^{\dagger} D_{q'_2, p'_2}^{\dagger} \rangle \rangle = \alpha |D_{q''_1, p''_1} \rangle \rangle |D_{q''_2, p''_2} \rangle \rangle \alpha^* |D_{q''_1, p''_1}^{\dagger} D_{q''_2, p''_2}^{\dagger} \rangle \rangle
$$
  
=  $|D_{q''_1, p''_1} \rangle |D_{q''_2, p''_2} \rangle \rangle |D_{q''_1, p''_1}^{\dagger} D_{q''_2, p''_2}^{\dagger} \rangle \rangle,$  (H30)

so we can use Fact [4](#page-34-1) to write

<span id="page-38-1"></span>
$$
\begin{split} \mathcal{E}_{d}^{(3)}|D_{q'_1,p'_1}\rangle\!\rangle|D_{q'_2,p'_2}\rangle\!\rangle|D_{q'_1,p'_1}^{\dagger}D_{q'_2,p'_2}^{\dagger}\rangle\!\rangle&=\mathcal{E}_{d}^{(3)}\mathcal{U}^{\otimes 3}|D_{q'_1,p'_1}\rangle\!\rangle|D_{q'_2,p'_2}\rangle\!\rangle|D_{q'_1,p'_1}^{\dagger}D_{q'_2,p'_2}^{\dagger}\rangle\!\rangle\\&=\mathcal{E}_{d}^{(3)}|D_{q''_1,p''_1}\rangle\!\rangle|D_{q''_2,p''_2}\rangle\!\rangle|D_{q''_1,p''_1}^{\dagger}D_{q''_2,p''_2}^{\dagger}\rangle\!\rangle. \end{split}
$$

Thus, noting that the states defined in Eqs. [\(H17\)](#page-33-4) - [\(H21\)](#page-34-4) are precisely the equal superpositions over the  $|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle|D_{q_1,p_1}^{\dagger}D_{q_2,p_2}^{\dagger}\rangle\rangle$  for each orbit, we have

$$
\mathcal{E}_d^{(3)} = a|I\rangle\langle\!\langle I|\delta^3 + b_1|\Phi_1\rangle\langle\!\langle\Phi_1| + b_2|\Phi_2\rangle\langle\!\langle\Phi_2| + b_3|\Phi_3\rangle\langle\!\langle\Phi_3| + \sum_{k=1}^{d-2} c_k|\Psi_k\rangle\langle\!\langle\Psi_k| + \sum_{l=1}^{d-1} d_l|\Upsilon_l\rangle\langle\!\langle\Upsilon_l|
$$
\n(H31)

for constants  $a, b_1, b_2, b_3, c_k, d_l$ . Since  $\mathcal{E}_d^{(3)}$  is a projector (Fact [3\)](#page-34-3), each of these constants must be either 0 or 1. Finally, we see from Eq. [\(H30\)](#page-38-0) and the definition of orbits (Eq. [\(H28\)](#page-36-4)) that for any  $U \in Cl_d$ ,  $\mathcal{U}^{\otimes 3}$  permutes the basis states of the form  $|D_{q_1,p_1}\rangle\!\rangle|D_{q_2,p_2}\rangle\!\rangle|D_{q_1,p_1}^{\dagger}D_{q_2,p_2}^{\dagger}\rangle$  within each orbit, without incurring any phases. Since each of the states appearing in Eq. [\(H31\)](#page-38-1) is an equal superposition over these  $|D_{q_1,p_1}\rangle |D_{q_2,p_2}\rangle |D_{q_1,p_1}^{\dagger}D_{q_2,p_2}^{\dagger}\rangle$  states for each orbit, it follows that  $\mathcal{U}^{\otimes 3}$  stabilises each of these states, and hence so does  $\mathcal{E}_d^{(3)}$  $d_d^{(3)}$ . Therefore, each of the constants in Eq. [\(H31\)](#page-38-1) must be equal to 1. $\Box$ 

# 4. Formulae for generalized Clifford shadows

Having evaluating the 2- and 3-fold twirl channels for  $Cl_d$  (Theorem [25\)](#page-33-1), we can now characterise the classical shadows corresponding to the uniform distribution over generalized Cliffords, in any prime dimension.

### a. Measurement channel

First, we determine the classical shadows measurement channel  $M$ , by substituting our expression for the 2-fold twirl channel from Theorem [25\(](#page-33-1)ii) into Eq. [\(H2\)](#page-31-1).

<span id="page-39-4"></span>**Theorem 30** (Generalized Clifford shadows measurement channel). Let M be the quantum channel defined in Eq. [\(H1\)](#page-31-3). When  $\mathcal D$  is the uniform distribution over  $Cl_d$  for some prime d and  $\mathcal B$  is the computational basis  $\{|j\rangle : j \in \mathbb{Z}_d\}, \mathcal{M}$  is given by

<span id="page-39-2"></span>
$$
\mathcal{M}(A) = \frac{1}{d+1}(\text{tr}(A)I + A),\tag{H32}
$$

for an arbitrary operator A (equivalently,  $\mathcal{M} = \frac{d}{d+1} |I|\sqrt[k]{|I| + \frac{1}{d+1}\mathcal{I}}$ ). Therefore,  $\mathcal M$  is invertible, with inverse given by

<span id="page-39-3"></span>
$$
\mathcal{M}^{-1}(A) = (d+1)A - \text{tr}(A)I.
$$
 (H33)

*Proof.* Since  $\mathbb{E}_{U\sim\mathcal{D}}\mathcal{U}^{\otimes2}=\mathcal{E}_d^{(2)}$  when  $\mathcal D$  is the uniform distribution over Cl<sub>d</sub>, Eq. [\(H2\)](#page-31-1) becomes

$$
\mathcal{M}(A) = \text{tr}_1\left[\sum_{j\in\mathbb{Z}_d} \mathcal{E}_d^{(2)}(|j\rangle\langle j|^{\otimes 2})(A\otimes I)\right].
$$

We can simplify this by observing that  $\mathcal{E}_d^{(2)}$  $\mathcal{E}_d^{(2)}(|j\rangle\langle j|^{\otimes 2}) = \mathcal{E}_d^{(2)}$  $\frac{d^{(2)}}{d}(|0\rangle\langle0|^{\otimes 2})$  for any  $j \in \mathbb{Z}_d$ . This is because for any  $j \in \mathbb{Z}_d$ , there exists  $U \in \mathrm{Cl}_d$  (specifically,  $U = (X^j)^{\dagger}$  such that  $\mathcal{U}(|j\rangle\langle j|) = |0\rangle\langle 0|$ . Hence, by Fact [4,](#page-34-1)  $\mathcal{E}_d^{(2)}$  $\langle d^{(2)}(|j\rangle\langle j|^{\otimes 2})=$  $\mathcal{E}_d^{(2)}$  $\mathcal{U}^{(2)}_{d} \circ \mathcal{U}^{\otimes 2}(|j\rangle\langle j|^{\otimes 2}) = \mathcal{E}_{d}^{(2)}$  $\mathcal{L}_d^{(2)}(|0\rangle\langle0|^{\otimes 2})$ . Thus,

<span id="page-39-1"></span>
$$
\mathcal{M}(A) = d \operatorname{tr}_1 \left[ \mathcal{E}_d^{(2)}(|0\rangle\langle 0|^{\otimes 2}) (A \otimes I) \right]. \tag{H34}
$$

We now calculate  $\mathcal{E}_d^{(2)}$  $\frac{d^{(2)}}{d}(|0\rangle\langle0|^{\otimes2})$  using Theorem [25\(](#page-33-1)ii). From Eq. [\(A5\)](#page-7-7), it is easy to see that

$$
|0\rangle\langle 0| = \frac{1}{d} \sum_{z \in \mathbb{Z}_d} Z^z = \frac{1}{d} \sum_{z \in \mathbb{Z}_d} D_{0,z}.
$$

Defining  $|\Pi_0\rangle \equiv |0\rangle\langle 0|$  for convenience, this becomes

<span id="page-39-5"></span><span id="page-39-0"></span>
$$
|\Pi_0\rangle = \frac{1}{\sqrt{d}} \sum_{z \in \mathbb{Z}_d} |D_{0,z}\rangle,
$$
 (H35)

and we want to find

$$
\mathcal{E}_d^{(2)}|\Pi_0\rangle^{\otimes 2} = (|I\rangle\langle\!\langle I|^{ \otimes 2} + |\Phi_0\rangle\langle\!\langle \Phi_0|)|\Pi_0\rangle\!\rangle^{\otimes 2}.
$$

From Eqs. [\(H13\)](#page-33-5) and [\(H35\)](#page-39-0), we obtain

$$
\langle\!\langle D_{q,p}|\Pi_0\rangle\!\rangle = \langle\!\langle D_{q,p}^\dagger|\Pi_0\rangle\!\rangle = \frac{1}{\sqrt{d}}\delta_{q,0},\tag{H36}
$$

so we have

$$
\langle I |^{\otimes 2} | \Pi_0 \rangle^{\otimes 2} = \langle I | D_{0,0} | \Pi_0 \rangle^2 = \frac{1}{d}
$$

and

$$
\langle \! \langle \Phi_0 | (|\Pi_0 \rangle \! \rangle^{\otimes 2}) = \frac{1}{\sqrt{d^2-1}} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \langle \! \langle D_{q,p} | \langle \! \langle D_{q,p}^{\dagger} | (|\Pi_0 \rangle \! \rangle^{\otimes 2}) = \frac{1}{\sqrt{d^2-1}} \frac{d-1}{d}.
$$

Thus,

$$
\mathcal{E}_d^{(2)}|\Pi_0\rangle^{\otimes 2} = \frac{1}{d}|I\rangle\|I\rangle + \frac{1}{d^2 - 1}\frac{d - 1}{d} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0) \\ q,p \in \mathbb{Z}_d}} |D_{q,p}\rangle\|D_{q,p}^\dagger\rangle
$$
  

$$
= \frac{1}{d^2}I \otimes I + \frac{1}{d^2(d+1)} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0) \\ q,p \in \mathbb{Z}_d}} D_{q,p} \otimes D_{q,p}^\dagger
$$
  

$$
= \frac{1}{d(d+1)}I \otimes I + \frac{1}{d^2(d+1)} \sum_{q,p \in \mathbb{Z}_d} D_{q,p} \otimes D_{q,p}^\dagger.
$$

Substituting this into Eq. [\(H34\)](#page-39-1) gives

$$
\mathcal{M}(A) = \frac{1}{d+1} \text{tr}(A)I + \frac{1}{d(d+1)} \sum_{q,p \in \mathbb{Z}_d} \text{tr}(D_{q,p}A)D_{q,p}^{\dagger}
$$

$$
= \frac{1}{d+1} \text{tr}(A)I + \frac{1}{d+1}A,
$$

where we use the fact that  $\{\frac{1}{\sqrt{2}}\}$  $\overline{d}D_{q,p}^{\dagger}$  forms a Hilbert-Schmidt orthonormal basis to obtain the last equality.

Thus, for the uniform distribution over generalized Cliffords (in prime dimension), M and  $\mathcal{M}^{-1}$  are depolarising channels. This is reminiscent of the fact that the measurement channel for the classical shadows associated with n-qubit Clifford circuits, analysed in Ref. [\[7\]](#page-5-4), is also a depolarising channel. In fact, the depolarising parameter in that case has the same dependence on the dimension, i.e., the measurement channel has the same form as that in Eq. [\(H32\)](#page-39-2), but with d replaced by  $2^n$ . Note, however, that n-qubit Clifford circuits are different from generalized single-qudit Cliffords with  $d = 2^n$  (except for  $n = 1$ ). Actually, it can be shown that the measurement channel for generalized Cliffords with  $d = 2^n$  is not a depolarising channel, though this calculation is outside the scope of this paper.

Substituting Eq. [\(H33\)](#page-39-3) into Eq. [\(H3\)](#page-31-4), the classical shadow estimator when D is the uniform distribution over  $Cl_d$ has the form

$$
\hat{\rho} = (d+1)\hat{U}^{\dagger}|\hat{b}\rangle\langle\hat{b}|\hat{U} - I,
$$

and the estimator for  $tr(O\rho)$  for any observable O is given by

$$
\hat{o} = \text{tr}(O\mathcal{M}^{-1}(\hat{U}^{\dagger}|\hat{b}\rangle\langle\hat{b}|\hat{U})) = (d+1)\text{tr}(O\hat{U}^{\dagger}|\hat{b}\rangle\langle\hat{b}|\hat{U}) - \text{tr}(O) \tag{H37}
$$

<span id="page-40-2"></span>
$$
= (d+1)\langle \hat{b}|\hat{U}O\hat{U}^{\dagger}|b\rangle - \text{tr}(O). \tag{H38}
$$

### b. Variance

With both  $\mathcal{E}_d^{(3)}$  $d_d^{(3)}$  and  $\mathcal{M}^{-1}$  in hand, we can now evaluate the variance, Eq. [\(H8\)](#page-32-2), for any operator O.

<span id="page-40-0"></span>**Theorem 31** (Generalized Clifford shadows variance). Let  $\hat{o}$  denote the classical shadows estimator for the expectation value  $tr(O\rho)$ , defined as in Eq. [\(H4\)](#page-31-5). When  $D$  is the uniform distribution over  $Cl_d$  for some prime d and  $B$  is the computational basis  $\{|j\rangle : j \in \mathbb{Z}_d\}$ , the variance Var $[\delta]$  of  $\delta$  for any observable O is given by

<span id="page-40-1"></span>
$$
\text{Var}[\hat{o}] = \frac{d+1}{d} ||O_0||_{H\text{-}S}^2 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p)\neq(0,0)}} \text{tr}(\widetilde{D}_{q,p}^\dagger O_0) \text{tr}(\widetilde{D}_{kq,kp}^\dagger O_0^\dagger) \text{tr}(\widetilde{D}_{kq,kp}\widetilde{D}_{q,p}\rho) - |\text{tr}(O_0\rho)|^2,\tag{H39}
$$

where  $O_0 := O - \text{tr}(O)I/d$  denotes the traceless part of O, and  $\tilde{D}_{q,p} := UD_{q,p}U^{\dagger}$  for any choice of  $U \in \text{Cl}_d$ .

Proof. From Eq. [\(H9\)](#page-32-5), we have

$$
\begin{split} \text{Var}[\hat{o}] &= \mathbb{E}[|\hat{o}|^2] - |\mathbb{E}[\hat{o}]|^2 \\ &= \text{tr}\left[\sum_{j\in\mathbb{Z}_d} \mathcal{E}_d^{(3)}(|j\rangle\langle j|^{\otimes 3})\left(\mathcal{M}^{-1}(O_0)\otimes \mathcal{M}^{-1}(O_0^\dagger)\otimes \rho\right)\right] - |\text{tr}(O_0\rho)|^2, \end{split}
$$

where  $\mathcal{M}^{-1}$  in this case is given by Eq. [\(H33\)](#page-39-3) in Theorem [30.](#page-39-4) For essentially the same reason that  $\mathcal{E}_d^{(2)}$  $\langle d^{(2)}(|j\rangle\langle j|^{\otimes 2})=$  $\mathcal{E}_d^{(2)}$  $\frac{d^{(2)}}{d}(|0\rangle\langle0|^{\otimes2})$  for any  $j \in \mathbb{Z}_d$  (see the proof of Theorem [30\)](#page-39-4), we also have  $\mathcal{E}_d^{(3)}$  $\mathcal{E}_d^{(3)}(|j\rangle\langle j|^{\otimes 3}) = \mathcal{E}_d^{(3)}$  $\int_{d}^{(3)}(|0\rangle\langle0|^{\otimes3})$  for any  $j \in \mathbb{Z}_d$ . Thus, the first term becomes

$$
\mathbb{E}[|\hat{o}|^2] = d \operatorname{tr} \left[ \mathcal{E}_d^{(3)}(|0\rangle\langle 0|^{\otimes 3}) \left( \mathcal{M}^{-1}(O_0) \otimes \mathcal{M}^{-1}(O_0^{\dagger}) \otimes \rho \right) \right].
$$

Now, we notate  $|\Pi_0\rangle\!\rangle \equiv |0\rangle\langle 0|, |\rho\rangle\!\rangle \equiv \rho, |O\rangle\!\rangle \equiv O, |O\rangle\!\rangle^{\dagger} \equiv O^{\dagger}$  in Liouville notation (note that here, we deviate from the convention in Eq. [\(H12\)](#page-32-6), in that  $|\rho\rangle, |O\rangle$ , and  $|O\rangle$ <sup>†</sup> are not necessarily normalised). Then, since  $\mathcal{E}_d^{(3)}$  $\binom{3}{d} (|0\rangle\langle0|^{\otimes 3})$  is Hermitian, we can rewrite

$$
\mathbb{E}[|\hat{o}|^2] = d \langle \langle \Pi_0 |^{\otimes 3} \mathcal{E}_d^{(3)\dagger} (\mathcal{M}^{-1} | O_0 \rangle \rangle \otimes \mathcal{M}^{-1} | O_0^{\dagger} \rangle \otimes |\rho \rangle).
$$

We begin by calculating  $\mathcal{E}_d^{(3)}$  $d^{(0)}$ . By Theorem [25\(](#page-33-1)iii),

$$
\mathcal{E}_d^{(3)}|\Pi_0\rangle^{\otimes 3} = \left(|I\rangle\langle\!\langle I|^{\otimes 3} + |\Phi_1\rangle\!\rangle\langle\!\langle\Phi_1| + |\Phi_2\rangle\!\rangle\langle\!\langle\Phi_2| + |\Phi_3\rangle\!\rangle\langle\!\langle\Phi_3| + \sum_{k=1}^{d-2} |\Psi_k\rangle\!\rangle\langle\!\langle\Psi_k| + \sum_{l=1}^{d-1} |\Upsilon_l\rangle\!\rangle\langle\!\langle\Upsilon_l|\right)|\Pi_0\rangle^{\otimes 3}.
$$

Using Eqs. [\(H35\)](#page-39-0) and [\(H36\)](#page-39-5), we find

$$
\langle I|^{\otimes 3}|\Pi_0\rangle^{\otimes 3} = \frac{1}{d^{3/2}},
$$
  

$$
\langle \Phi_i|(|\Pi_0\rangle^{\otimes 3}) = \frac{1}{d^{3/2}} \frac{d-1}{\sqrt{d^2-1}} \quad \text{for } i \in \{1, 2, 3\},
$$
  

$$
\langle \langle \Psi_k|(|\Pi_0\rangle^{\otimes 3}) = \frac{1}{d^{3/2}} \frac{d-1}{\sqrt{d^2-1}} \quad \text{for } k \in \{1, ..., d-2\},
$$
  

$$
\langle \langle \Upsilon_l|(|\Pi_0\rangle^{\otimes 3}) = 0 \quad \text{for } l \in \{1, ..., d-1\},
$$

so

$$
\mathcal{E}_d^{(3)} |\Pi_0\rangle^{\otimes 3} = \frac{1}{d^{3/2}} |I\rangle^{\otimes 3} + \frac{1}{d^{3/2}} \frac{d-1}{\sqrt{d^2-1}} \left( |\Phi_1\rangle + |\Phi_2\rangle + |\Phi_3\rangle + \sum_{k=1}^{d-2} |\Psi_k\rangle \right).
$$

Hence,

$$
\mathbb{E}[|\hat{o}|^2] = \left[\frac{1}{\sqrt{d}}\langle \!\langle I |^{\otimes 3} + \frac{1}{\sqrt{d}}\frac{d-1}{\sqrt{d^2-1}}\left( \langle \!\langle \Phi_1 | + \langle \!\langle \Phi_2 | + \langle \!\langle \Phi_3 | + \sum_{k=1}^{d-2} \langle \!\langle \Psi_k | \right) \rangle \right] (\mathcal{M}^{-1} | O_0 \rangle\!\rangle \otimes \mathcal{M}^{-1} | O_0^{\dagger} \rangle\!\rangle \otimes |\rho \rangle\!\rangle).
$$

From Eq. [\(H33\)](#page-39-3), we have

$$
\mathcal{M}^{-1}|D_{q,p}\rangle\!\rangle = (d+1)|D_{q,p}\rangle\!\rangle - \delta_{q,0}\delta_{p,0}|I\rangle\!\rangle.
$$

Using this along with the fact that  $\mathcal{M}^{-1}$  is self-adjoint, i.e.,  $\langle A|\mathcal{M}^{-1}|B\rangle = \langle \mathcal{M}^{-1}(A)|B\rangle$ , we obtain

$$
\frac{1}{\sqrt{d}}\langle I|\frac{\partial^3(\mathcal{M}^{-1}|O_0)\rangle \otimes \mathcal{M}^{-1}|O_0^{\dagger}\rangle \otimes |\rho\rangle\rangle) = \frac{1}{d^2}|\text{tr}(O_0)|^2 = 0,
$$
\n
$$
\frac{1}{\sqrt{d}}\frac{d-1}{\sqrt{d^2-1}}\langle \Phi_1|(\mathcal{M}^{-1}|O_0)\rangle \otimes \mathcal{M}^{-1}|O_0^{\dagger}\rangle \otimes |\rho\rangle\rangle) = \frac{1}{d}\text{tr}(O_0)\text{tr}(\rho O_0^{\dagger}) - \frac{1}{d^2}|\text{tr}(O_0)|^2 = 0
$$
\n
$$
\frac{1}{\sqrt{d}}\frac{d-1}{\sqrt{d^2-1}}\langle \Phi_2|(\mathcal{M}^{-1}|O_0)\rangle \otimes \mathcal{M}^{-1}|O_0^{\dagger}\rangle \otimes |\rho\rangle\rangle) = \frac{1}{d}\text{tr}(O^{\dagger})\text{tr}(\rho O_0) - \frac{1}{d^2}|\text{tr}(O_0)|^2 = 0
$$

$$
\frac{1}{\sqrt{d}}\frac{d-1}{\sqrt{d^2-1}}\langle\!\langle\Phi_3|(\mathcal{M}^{-1}|O_0)\rangle\!\rangle \otimes \mathcal{M}^{-1}|O_0^{\dagger}\rangle\!\rangle \otimes |\rho\rangle\!\rangle) = \frac{d+1}{d}\text{tr}(O_0^{\dagger}O_0) - \frac{d+1}{d^2}\text{tr}(O_0)|^2 = \frac{d+1}{d}\|O_0\|_{\text{H-S}}^2
$$
\n
$$
\frac{1}{\sqrt{d}}\frac{d-1}{\sqrt{d^2-1}}\langle\!\langle\Phi_k|(\mathcal{M}^{-1}|O\rangle\!\rangle \otimes \mathcal{M}^{-1}|O_0^{\dagger}\rangle\!\rangle \otimes |\rho\rangle\!\rangle) = \frac{d+1}{d^2}\sum_{\substack{p,q\in\mathbb{Z}_d\\(p,q)\neq(0,0)}}\text{tr}(D_{q,p}^{\dagger}O_0)\text{tr}(D_{kq,kp}^{\dagger}O_0^{\dagger})\text{tr}(D_{kq,kp}D_{q,p}\rho).
$$

Thus, we arrive at

$$
\mathbb{E}[|\hat{o}|^2] = \frac{d+1}{d} ||O_0||_{\mathcal{H}\text{-S}}^2 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p)\neq(0,0)}} \text{tr}(D_{q,p}^\dagger O_0) \text{tr}(D_{kq,kp}^\dagger O_0^\dagger) \text{tr}(D_{kq,kp} D_{q,p}\rho), \tag{H40}
$$

giving

$$
\text{Var}[\hat{o}] = \frac{d+1}{d} ||O_0||_{\text{H-S}}^2 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \text{tr}(D_{q,p}^{\dagger} O_0) \text{tr}(D_{kq,kp}^{\dagger} O_0^{\dagger}) \text{tr}(D_{kq,kp} D_{q,p} \rho) - |\text{tr}(O_0 \rho)|^2.
$$

To see that this actually holds with  $D_{q,p}$  replaced by  $\widetilde{D}_{q,p} := UD_{q,p}U^{\dagger}$  for any  $U \in \mathrm{Cl}_d$ , note that since  $\mathcal{U} \circ \mathcal{E}_d^{(3)} \circ \mathcal{U}^{\dagger}$ for any  $U \in \mathrm{Cl}_d$  from Fact [4,](#page-34-1) we can replace  $|\Phi_i \rangle, |\Psi_k \rangle, |\Upsilon_l \rangle$  with  $\mathcal{U}|\Phi_i \rangle, \mathcal{U}|\Psi_k \rangle, \mathcal{U}|\Upsilon_l \rangle$ , respectively, in all of our calculations. These have the same form as  $|\Phi_i\rangle, |\Psi_k\rangle, |\Upsilon_l\rangle$  (Eqs. [\(H17\)](#page-33-4) - [\(H21\)](#page-34-4)), respectively, except with  $D_{q,p}$ replaced by  $D_{q,p}$ , thus leading to Eq. [\(H39\)](#page-40-1).  $\Box$ 

We can sanity-check this result by comparing to that for the uniform distribution over  $n$ -qubit Clifford circuits; 2 is prime, so our results should coincide for  $d = 2$  (i.e.,  $n = 1$ ). For  $d = 2$ , Eq. [\(H40\)](#page-42-0) becomes

<span id="page-42-0"></span>
$$
\mathbb{E}[|\hat{o}|^2] = \frac{3}{2} ||O_0||_{\mathcal{H}\text{-S}}^2,
$$

since the outside sum in the second term is empty. On the other hand, For n-qubit Clifford circuits, Eq. (S43) of Ref. [\[7\]](#page-5-4) gives  $\mathbb{E}[|\hat{o}|^2] = \frac{2^n+1}{2^n+2} [\text{tr}(O_0^2) + 2 \text{tr}(\rho O_0^2)],$  which is

<span id="page-42-1"></span>
$$
\mathbb{E}[|\hat{o}|^2] = \frac{3}{4} [\text{tr}(O_0^2) + 2 \text{tr}(\rho O_0^2)] \tag{H41}
$$

for  $n = 1$ . Ref. [\[7\]](#page-5-4) considers only Hermitian  $O_0$ , so the RHS is always real, and  $\text{tr}(O_0^2) = ||O_0||_{H-S}^2$ . Now note that for  $n = 1$ ,  $O_0$  has dimension 2, so since it is traceless, we must have  $O_0^2 = aI$  for some  $a \in \mathbb{R}$ . Thus,  $||O_0||_{H-S}^2 = \text{tr}(O_0^2) = a \text{tr}(I) = 2a$ , and  $\text{tr}(\rho O_0^2) = a \text{tr}(\rho) = a = ||O_0||_{H-S}^2/2$ , so we can write Eq. [\(H41\)](#page-42-1)

$$
\mathbb{E}[|\hat{o}|^2] = \frac{3}{4} \left[ \|O_0\|_{\mathcal{H}\text{-s}}^2 + 2 \frac{\|O_0\|_{\mathcal{H}\text{-s}}^2}{2} \right] = \frac{3}{2} \|O_0\|_{\mathcal{H}\text{-s}}^2,
$$

which matches our result.

### 5. Some observables of interest

In the section, we apply our general results, Theorems [30](#page-39-4) and [31](#page-40-0) to some natural observables to consider in the qudit setting.

### a. Transition elements in stabiliser bases

First, we consider observables of the form  $U|j\rangle\langle i|U^{\dagger}$  for  $U \in \mathrm{Cl}_d$  and computational basis states  $|i\rangle$ ,  $|j\rangle$ . The expectation values of these with respect to an unknown state  $\rho$  are  $tr(U|j\rangle\langle i|U^{\dagger}) = \langle i|U^{\dagger}\rho U|j\rangle$ , which are the quantities considered in Theorem [6.](#page-4-0)

*Proof of Theorem [6.](#page-4-0)* Consider any generalized Clifford  $U \in \mathrm{Cl}_d$ , and any computational basis states  $|i\rangle$  and  $|j\rangle$  with  $i \neq j$ . We have

$$
U|j\rangle\langle i|U^{\dagger} = U X^i|j - i\rangle\langle 0|(X^i)^{\dagger}U^{\dagger} = U X^i|j'\rangle\langle 0|(U X^i)^{\dagger},
$$

defining  $j' \equiv j - i \pmod{d}$ . Hence, since  $UX^i \in \text{Cl}_d$ , we can choose  $\widetilde{D}_{q,p} = (UX^i)D_{q,p}(UX^i)^{\dagger}$  in Theorem [31,](#page-40-0) to get that for  $\hat{O} = U|j\rangle\langle i|U^{\dagger}$  (which is already traceless, for  $j \neq i$ ),

$$
\begin{split} \text{Var}[\hat{o}] \Big|_{O=U|j\rangle\langle i|U^{\dagger}} &= \frac{d+1}{d} \|U|j\rangle\langle i|U^{\dagger}\|_{\text{H-S}}^2 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p\in\mathbb{Z}_d \\ (q,p)\neq(0,0)}} \text{tr}(\widetilde{D}_{q,p}^{\dagger}U|j\rangle\langle i|U^{\dagger})\text{tr}(\widetilde{D}_{kq,kp}^{\dagger}(U|j\rangle\langle i|U^{\dagger})^{\dagger})\text{tr}(\widetilde{D}_{kq,kp}\widetilde{D}_{q,p}\rho) \\ &= \frac{d+1}{d} + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p\in\mathbb{Z}_d \\ (q,p)\neq(0,0)}} \text{tr}(D_{q,p}^{\dagger}|j'\rangle\langle 0|)\text{tr}(D_{kq,kp}^{\dagger}|0\rangle\langle j'|)\text{tr}(\widetilde{D}_{kq,kp}\widetilde{D}_{q,p}\rho) - |\text{tr}(U|j\rangle\langle i|U^{\dagger}\rho)|^2 \\ &\leq \frac{d+1}{d} + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p\in\mathbb{Z}_d \\ (q,p)\neq(0,0)}} |\langle 0|D_{q,p}^{\dagger}|j'\rangle\langle j'|D_{kq,kp}^{\dagger}|0\rangle|, \end{split}
$$

where in the second line, we use the fact that

$$
\operatorname{tr}(\widetilde{D}_{q,p}^{\dagger}U|j\rangle\langle i|U^{\dagger}) = \operatorname{tr}((UX^{i})D_{q,p}(UX^{i})^{\dagger}UX^{i}|j'\rangle\langle 0|(UX_{i})^{\dagger}) = \operatorname{tr}(|j'\rangle\langle 0|)
$$

for our choice of  $\widetilde{D}_{q,p}$ , and in the third line we use  $|\text{tr}(\widetilde{D}_{kq,kp}\widetilde{D}_{q,p}\rho)| \leq 1$ . Now, from Eq. [\(A8\)](#page-7-5), we have

<span id="page-43-0"></span>
$$
D_{q,p} = \omega^{qp/2} \sum_{j \in \mathbb{Z}_d} \omega^{jp} |j + q\rangle\langle j|,\tag{H42}
$$

from which we obtain  $|\langle 0|D_{q,p}^{\dagger}|j'\rangle = \delta_{q,j'}$  and  $|\langle j'|D_{kq,kp}^{\dagger}|0\rangle = \delta_{kq,-j'}$ , so

$$
\text{Var}[\hat{o}] \Big|_{O=U|j\rangle\langle i|U^{\dagger}} \leq \frac{d+1}{d} + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \delta_{q,j'} \delta_{kq,-j'} = \frac{d+1}{d} + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{p=1}^{d-1} \delta_{kj',-j'}.
$$

Since  $i \neq j$ , we have  $j' = j - i \neq 0$ , so  $kj' = -j'$  only for  $k = d-1$ , which is not included in the sum over k. Therefore, the second term vanishes, and we have

$$
\text{Var}[\hat{o}] \Big|_{O=U|j\rangle\langle i|U^{\dagger}} \le \frac{d+1}{d} < 2,
$$

for any choice of  $U \in \mathrm{Cl}_d$ , and  $|i\rangle, |j\rangle$  with  $i \neq j$ .

Substituting this into Eq. [\(H10\)](#page-32-7), it follows that

$$
N_{\rm sample} = \mathcal{O}\left(\frac{\log(M/\delta)}{\varepsilon^2}\right)
$$

single-copy measurements of  $\rho$  suffice to estimate any M observables of the form  $tr(U|j)\langle i|U^{\dagger}\rho\rangle = \langle i|U^{\dagger}\rho U|j\rangle$  with  $U \in \mathrm{Cl}_d$  and  $i \neq j$ , within additive error  $\varepsilon$  with high probability. Since  $|\mathrm{Cl}_d| = \mathcal{O}(d^5)$  [\[52\]](#page-6-28), there are  $\mathcal{O}(d^7)$  possible such observables,  $N_{\text{sample}} = \mathcal{O}(\log(d)/\varepsilon^2)$  suffice to estimate all of them.

By Eq. [\(H38\)](#page-40-2), if  $U' \in Cl_d$  was the Clifford sampled in one iteration of the classical shadows protocol, and  $|b\rangle$  was the computational basis state that was measured, the corresponding sample of the estimator  $\hat{o}$  for  $\langle i|U^{\dagger}\rho U|j\rangle$  is

$$
\operatorname{tr}(U|j\rangle\langle i|U^{\dagger} \mathcal{M}^{-1}(U'^{\dagger}|b\rangle\langle b|U') ) = (d+1)\langle b|U'U|j\rangle\langle i|U^{\dagger}U'^{\dagger}|b\rangle.
$$

Since  $|b\rangle, |i\rangle, |j\rangle$  are computational basis states and  $U'U \in \text{Cl}_d$ , each of  $\langle b|U'U|j\rangle$  and  $\langle i|U^{\dagger}U'^{\dagger}|b\rangle$  can be efficiently computed (classically) using the d-dimensional generalization of the Gottesman-Knill theorem [\[53\]](#page-6-29), so the classical shadows samples can be efficiently computed. $\Box$ 

On the other hand, for an observable of the form  $U|0\rangle\langle 0|U^{\dagger}$  for  $U \in Cl_d$  (which subsumes all observables  $U|i\rangle\langle i|U^{\dagger}$ for  $U \in \text{Cl}_d$  and computational states  $|i\rangle$ ), the traceless part is  $U|i\rangle\langle i|U^{\dagger} - I/d$ , and choosing  $\tilde{D}_{q,p} = U D_{q,p} U^{\dagger}$  in Theorem [31](#page-40-0) gives

$$
\begin{split} \text{Var}[\hat{o}] \Big|_{O=U|0\rangle\langle 0|U^{\dagger}} &= \frac{d+1}{d} \left(1-\frac{1}{d}\right) \\ &+ \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \text{tr}\left(\tilde{D}_{q,p}^{\dagger}\left(U|0\rangle\langle 0|U^{\dagger}-\frac{I}{d}\right)\right) \text{tr}\left(\tilde{D}_{kq,kp}^{\dagger}\left(U|0\rangle\langle 0|U^{\dagger}-\frac{I}{d}\right)\right) \text{tr}(\tilde{D}_{kq,kp}\tilde{D}_{q,p}\rho) \\ &- \left|\text{tr}\left(\left(U|0\rangle\langle 0|U^{\dagger}-\frac{I}{d}\right)\rho\right)\right|^2 \\ &= 1 - \frac{1}{d^2} + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \langle 0|D_{q,p}^{\dagger}|0\rangle\langle 0|D_{kq,kp}^{\dagger}|0\rangle \text{tr}(D_{kq,kp}D_{q,p}U^{\dagger}\rho U) - (\langle 0|U^{\dagger}\rho U|0\rangle - 1/d)^2. \end{split}
$$

From Eq. [\(H42\)](#page-43-0),

$$
\langle 0|D_{q,p}^{\dagger}|0\rangle = \delta_{q,0},
$$

so the double sum becomes

$$
\frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \delta_{q,0} \delta_{kq,0} \text{tr}(D_{kq,kp} D_{q,p} U^{\dagger} \rho U) = \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{p=1}^{d-1} \text{tr}(D_{0,kp} D_{0,p} U^{\dagger} \rho U)
$$

$$
= \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{p=1}^{d-1} \text{tr}(Z^{(k+1)p} U^{\dagger} \rho U)
$$

$$
= \frac{(d+1)(d-2)}{d^2} \text{tr}\left(\sum_{p=1}^{d-1} Z^p U^{\dagger} \rho U\right)
$$

$$
= \frac{(d+1)(d-2)}{d^2} \text{tr}((d|0\rangle\langle 0| - I)U^{\dagger} \rho U).
$$

Hence,

$$
\text{Var}[\hat{o}] \Big|_{O=U|0\rangle\langle 0|U^{\dagger}} = 1 - \frac{1}{d^2} + \frac{(d+1)(d-2)}{d^2} (d\langle 0|U^{\dagger} \rho U|0\rangle - 1) - (\langle 0|U^{\dagger} \rho U|0\rangle - 1/d)^2
$$
  
= 
$$
\frac{1}{d} + (d-1)\langle 0|U^{\dagger} \rho U|0\rangle - \langle 0|U^{\dagger} \rho U|0\rangle^2,
$$

which be  $\Omega(d)$  for certain states  $\rho$ .

# b. Displacement operators

Now, we calculate the variance for estimating the expectation values of displacement operators  $D_{a,b}$ . For  $(a, b) \neq$  $(0, 0)$ , i.e.,  $D_{a,b} \neq I$ ,  $D_{a,b}$  is traceless, so choosing  $\widetilde{D}_{q,p} = D_{q,p}$  in Theorem [31](#page-40-0) gives

$$
\text{Var}[\hat{o}] \Big|_{O=D_{a,b}} = \frac{d+1}{d} \|D_{a,b}\|_{\text{H-S}}^2 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \text{tr}(D_{q,p}^{\dagger} D_{a,b}) \text{tr}(D_{kq,kp}^{\dagger} D_{a,b}^{\dagger}) \text{tr}(D_{kq,kp} D_{q,p}\rho) - |\text{tr}(D_{a,b}\rho)|^2
$$
  

$$
= \frac{d+1}{d} (d) + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \sum_{\substack{q,p \in \mathbb{Z}_d \\ (q,p) \neq (0,0)}} \delta_{q,a} \delta_{p,b} \delta_{kq,-a} \delta_{kp,-b} \text{tr}(D_{kq,kp} D_{q,p}\rho) - |\text{tr}(D_{a,b}\rho)|^2
$$

$$
= d + 1 + \frac{d+1}{d^2} \sum_{k=1}^{d-2} \delta_{ka, -a} \delta_{kb, -b} \text{tr}(D_{ka, ka} D_{a, b} \rho) - |\text{tr}(D_{a, b} \rho)|^2.
$$

If  $a \neq 0$ , then  $ka = -a$  only for  $k = d - 1$ , which does not appear in the sum over k. Otherwise, we must have  $b \neq 0$ , and similarly no value of k in the sum satisfies  $kb = -b$ . Hence, for any  $D_{a,b} \neq I$ ,

$$
Var[\hat{o}]
$$
 $\Big|_{O=D_{a,b}} = d + 1 - |tr(D_{a,b}\rho)|^2 \ge d.$ 

This implies that if we were to use the generalized Clifford classical shadows to estimate  $tr(D_{a,b}\rho)$ , and we chose the number of samples according to the variance, via Eq. [\(H10\)](#page-32-7), the number of copies of  $\rho$  would scale with d and  $\varepsilon$  as  $d/\varepsilon^2$ . This is consistent with Theorem [3.](#page-3-2) Note, however, that Theorem [3](#page-3-2) concerns measuring  $|\text{tr}(D_{a,b}\rho)|$  for all a, b, whereas Eq. [\(H10\)](#page-32-7) calls for  $\mathcal{O}(d/\varepsilon^2)$  measurements even for estimating the expectation value of just one displacement operator  $D_{a,b}$ .
