## BALANCED TRIPLE PRODUCT  $p$ -ADIC L-FUNCTIONS AND STARK POINTS

LUCA DALL'AVA, ALEKSANDER HORAWA

ABSTRACT. Let E be an elliptic curve over  $\mathbb Q$  and  $\varrho_1, \varrho_2$ : Gal $(H/\mathbb Q) \to GL_2(L)$  be two odd Artin representations. We use p-adic methods to investigate the part of the Mordell–Weil group  $E(H) \otimes L$  on which the Galois group acts via  $\varrho_1 \otimes \varrho_2$ . When the rank of the group is two, Darmon–Lauder–Rotger used a dominant triple product p-adic L-function to study this group, and gave an *Elliptic Stark Conjecture* which relates its value outside of the interpolation range to two Stark points and one Stark unit. Our paper achieves a similar goal in the rank one setting. We first generalize Hsieh's construction of a 3-variable balanced triple product  $p$ -adic  $L$ -function in order to allow Hida families with classical weight one specializations. We then give an *Elliptic Stark Conjecture* relating its value outside of the interpolation range to a Stark point and two Stark units. As a consequence, we give an explicit p-adic formula for a point which should conjecturally lie in  $E(H) \otimes L$ . We prove our conjecture for dihedral representations associated with the same imaginary quadratic field. This requires a generalization of the results of Bertolini–Darmon–Prasanna which we prove in the appendix.

#### **CONTENTS**

#### 1. INTRODUCTION

<span id="page-0-0"></span>Let E be an elliptic curve over Q and  $\varrho_1, \varrho_2$ : Gal $(H/\mathbb{Q}) \to GL_2(L)$  be two odd Artin representations such that det  $\varrho_1 \cdot \det \varrho_2 = 1$ . We can consider the part of the Mordell-Weil group  $E(H)$  on which the Galois group Gal $(H/\mathbb{Q})$  acts via  $\rho_1 \otimes \rho_2$ ; formally:

# $E[\varrho_1 \otimes \varrho_2] = \text{Hom}_{\text{Gal}(H/\mathbb{O})}(\varrho_1 \otimes \varrho_2, E(H)_L).$

An equivariant version of the Birch–Swinnerton-Dyer conjecture then predicts that the rank of  $E[\varrho_1 \otimes \varrho_2]$ is equal to the order of vanishing of the L-function  $L(\varrho_E \otimes \varrho_1 \otimes \varrho_2, s)$  at  $s = 1$ , and the leading term of its Taylor expansion is explicitly related to the elements of  $E[\varrho_1 \otimes \varrho_2]$ . The goal of this paper is to investigate the group  $E[\rho_1 \otimes \rho_2]$  using p-adic methods when its rank is 1. We start with a brief summary before explaining the details.

When  $E[\varrho_1 \otimes \varrho_2]$  has rank 2, the analogous question was considered by Darmon, Lauder, and Rotger:

*Date*: March 11, 2024.

- <span id="page-1-2"></span>(1) They prove that there is a p-adic L-function  $\mathcal{L}_p^{\varrho_1}(\ell)$  with an interpolation property which holds for integers  $\ell \geq 3$ .<sup>1</sup> It is associated with the triple  $(E, \varrho_1, \varrho_2)$ , but it is *unbalanced* —  $\varrho_1$  plays a special role in the construction. [\[DR14\]](#page-66-0)
- (2) They conjecture a special value formula outside of the interpolation range, the rank two Elliptic Stark Conjecture:

(1.1) 
$$
\mathcal{L}_p^{\varrho_1}(1) \sim_{L^\times} \frac{\det \begin{pmatrix} \log_{E,p}(P_{1,1}) & \log_{E,p}(P_{1,2}) \\ \log_{E,p}(P_{2,1}) & \log_{E,p}(P_{2,2}) \end{pmatrix}}{\log_p(u_1)},
$$

<span id="page-1-0"></span>where  $P_{i,j} \in E(H)_L$  are points in the  $(\varrho_1 \otimes \varrho_2)$ -isotypic component and  $u_1 \in \mathcal{O}_H^{\times}$  is a unit in the  $\text{Ad}^0$   $\varrho_1$ -isotypic component. [\[DLR15,](#page-65-1) Conjecture ES]

(3) They prove [\(1.1\)](#page-1-0) when  $\rho_1$  and  $\rho_2$  are both induced from the same imaginary quadratic field in which  $p$  splits. [\[DLR15,](#page-65-1) Theorem 3.3]

When  $E[\varrho_1 \otimes \varrho_2]$  has rank 1, we achieve the same goals in the present paper:

- (1) We prove that there is a *p*-adic *L*-function  $\mathcal{L}_p^{\text{bal}}(\ell)$  with an interpolation property which holds for integers  $\ell \geq 2$ .<sup>2</sup> It is associated with the triple  $(E, \varrho_1, \varrho_2)$ , but in our case it is *balanced* —  $\rho_1$  and  $\rho_2$  play equivalent roles. [Theorem [A\]](#page-3-0)
- (2) We conjecture a special value formula outside of the interpolation range, the rank one Elliptic Stark Conjecture:

(1.2) 
$$
\mathcal{L}_p^{\text{bal}}(1) \sim \sqrt{L^{\times}} \frac{\log_{E,p}(P)}{\log_p(u_1)^{1/2} \log_p(u_2)^{1/2}}
$$

<span id="page-1-1"></span>where  $P \in E(H)_L$  is a point in the  $(\varrho_1 \otimes \varrho_2)$ -isotypic component and  $u_i \in \mathcal{O}_H^{\times}$  is a unit in the  $\text{Ad}^0$   $\varrho_i$ -isotypic component, for  $i = 1, 2$ . [Conjecture [C\]](#page-5-0)

(3) We prove [\(1.2\)](#page-1-1) when  $\varrho_1$  and  $\varrho_2$  are both induced from the same imaginary quadratic field in which  $p$  splits. [Theorem  $D$ ]

As opposed to the rank two setting, our formula  $(2)$  can be rewritten to give a p-adic analytic formula for a p-adic point:

(1.3) 
$$
\exp_{E,p}(\mathcal{L}_p^{\text{bal}}(1) \cdot \log_p(u_1)^{1/2} \cdot \log_p(u_2)^{1/2}) \in E(H_p)_L
$$

conjecturally lies in  $E(H)_L$ .

Bertolini, Seveso, and Venerucci have also been studying the rank one group  $E[\varrho_1 \otimes \varrho_2]$  using a balanced *p*-adic L-function<sup>3</sup>. Their Oberwolfach report [\[BSV20\]](#page-65-2) conjectures that there is a canonical multiple  $L_p^{\text{can}}$  of a p-adic L-function  $L_p$  whose value at  $(2,1,1)$  is equal to  $\log_{E,p}(P)$ . They explain that special cases of this conjecture have been verified in the CM setting. They give a different expression for this *p*-adic L-function using an endoscopic lift to  $GSp_4$ , and relate its non-vanishing at  $\ell = 1$  to the non-vanishing of an appropriate Selmer class. This is the subject of their forthcoming work with Andreatta [\[ABSV\]](#page-65-3).

In the rest of the introduction, we will state our results precisely and explain the new ideas which allow us to achieve these goals.

1.1. Construction of the balanced  $p$ -adic L-function. Let f be the normalized weight two modular form associated with  $E$  by the Modularity Theorem, and  $g$ ,  $h$  be the normalized weight one modular

<sup>&</sup>lt;sup>1</sup>In general, there is a 3-variable p-adic L-function  $\mathcal{L}_p^{\varrho_1}(k,\ell,m)$  with an interpolation property when  $\ell$  is *dominant*. Here, we take  $(k, \ell, m) = (2, \ell, 1)$  for simplicity.

<sup>&</sup>lt;sup>2</sup>Again, in general, there is a 3-variable p-adic L-function  $\mathcal{L}_p^{\text{bal}}(k, \ell, m)$  with an interpolation property when the weights are *balanced*. Here, we take  $(k, \ell, m) = (2, \ell, \ell)$  for simplicity.

<sup>&</sup>lt;sup>3</sup>An algorithmic study of this *p*-adic L-function, motivated by their work, has been carried out in the PhD thesis of the first-named author [\[Dal21\]](#page-65-4).

<span id="page-2-0"></span>forms associated with  $\varrho_1$ ,  $\varrho_2$ , respectively, by the work of Khare and Wintenberger [\[KW09a,](#page-66-1) [KW09b\]](#page-66-2). The analytic properties of the L-function we are interested in are understood in terms of the Garrett triple product  $L$ -function associated with  $f, g$ , and  $h$ :

$$
L(\varrho_E \otimes \varrho_1 \otimes \varrho_2, s) = L(f \times g \times h, s).
$$

Then the completed L-function  $\Lambda(f \times g \times h, s)$  satisfies a functional equation relating the value at s to the value at 2−s. The assumption that det  $\varrho_1$  det  $\varrho_2 = 1$  implies that the global root number  $\epsilon(f \times g \times h)$ is  $\pm 1$ . Since we are interested in the rank one setting, we will assume that:

$$
\epsilon(f \times g \times h) = -1
$$

(see Hypothesis [A\)](#page-42-1). Since the global root number is the product of local root numbers

$$
\epsilon(f \times g \times h) = \prod_v \epsilon_v(f \times g \times h),
$$

and  $\epsilon_{\infty}(f \times g \times h) = 1$ , the assumption amounts to the fact that there is an odd number of primes v such that  $\epsilon_v(f \times g \times h) = -1$ .

Let  $p \geq 5$  be a prime number. We assume that f, g, h are ordinary and regular at p (see Hypothesis [B\)](#page-43-0), and consider Hida families **g**, h whose weight one specializations are fixed p-stabilizations  $g_{\alpha}$ ,  $h_{\alpha}$  of g and h, respectively. Letting  $g_{\ell}, h_m$  be the weight  $\ell, m$  specializations of **g**, h, respectively, we note that

$$
\epsilon(f \times g_{\ell} \times h_m) = \prod_v \epsilon(f \times g_{\ell} \times h_m) = \prod_{v \leq \infty} \epsilon_v(f \times g_{\ell} \times h_m) \cdot \epsilon_\infty(f \times g_{\ell} \times h_m) = -\epsilon_\infty(f \times g_{\ell} \times h_m)
$$

by rigidity of automorphic types. In particular, if the weights  $(2, \ell, m)$  are balanced, i.e.  $2 \leq \ell < 2 + m$ ,  $2 \leq m < 2 + \ell$ , and  $\ell + m \equiv 0 \pmod{2}$ , we have that

$$
\epsilon(f \times g_{\ell} \times h_m) = +1,
$$

and hence we expect that generically the central L-value is non-vanishing:

$$
L(f \times g_{\ell} \times h_m, (\ell+m)/2) \neq 0,
$$

and there should be a  $p$ -adic  $L$ -function interpolating these values divided by appropriate periods. In comparison, Darmon, Lauder, and Rotger start with  $\epsilon(f \times q \times h) = +1$  in the f-dominant region and hence obtain  $\epsilon(f \times g_\ell \times h_m) = +1$  in the g-dominant region, i.e. for  $\ell > m+2$ .

There are two known constructions of  $p$ -adic  $L$ -functions interpolating the central critical  $L$ -values in the balanced region for three Hida families f, g, h. The first construction was due to Greenberg and Seveso [\[GS20\]](#page-66-3), and the second more explicit construction was given by Hsieh [\[Hsi21\]](#page-66-4). The difference between the constructions was outlined in the latter paper and it seems that Hsieh's approach is more suitable for arithmetic applications, such as the one in the present paper.

However, as observed by the first-named author in [\[Dal23a,](#page-65-5) Section 4.4.4], the ramification assumption (3) in [\[Hsi21,](#page-66-4) Theorem B] implies that the Hida families g and h cannot both have classical weight one specializations. In particular, as far as we know, there is no suitable balanced triple product  $p$ -adic L-function to study classical points with weights  $(2, 1, 1)$ .

Therefore, the first goal of our paper is to extend Hsieh's construction to a setting where the Hida families g and h do have classical weight one specializations. The final assumption we make (see Hypothesis [C\)](#page-43-1) is:

$$
\epsilon_q(f \times g \times h) = -1
$$
 implies that  $v_q(N_i) \leq 2$ ,

where  $N_1, N_2, N_3$  are the levels of f, g, h, respectively. This weakens Hsieh's assumption that  $v_q(N_i) = 1$ .

Fix an algebraic closure  $\overline{Q}$  of  $Q$  and field embeddings of  $\overline{Q}$  into  $\mathbb C$  and  $\mathbb C_p$ .

<span id="page-3-2"></span><span id="page-3-0"></span>**Theorem A** (Corollary [6.4\)](#page-44-0). Under the above hypotheses, there exist open admissible neighborhoods  $U_q$ and  $U_h$  of the classical weight 1 in the weight space, and a (square root) balanced triple product p-adic L-function  $\mathcal{L}_p^{\text{bal}}: \mathcal{U}_g \times \mathcal{U}_h \to \mathbb{C}_p$ , associated with f and the Hida families **g** and **h**. It has the following interpolation property for integers  $\ell \in \mathcal{U}_g$  and  $m \in \mathcal{U}_h$  such that  $\ell, m \geq 2$  and  $2 - \ell \leq m \leq 2 + \ell$ :

$$
\mathcal{L}_p^{\text{bal}}(\ell,m)^2 = \frac{\Lambda(f \times g_\ell \times h_m, c)}{\langle f, f \rangle \langle g_\ell, g_\ell \rangle \langle h_m, h_m \rangle} \cdot \frac{\mathcal{E}_p^{\text{bal}}(f \times g_\ell \times h_m)}{\mathcal{E}_p(g_\ell, \text{Ad}) \cdot \mathcal{E}_p(h_m, \text{Ad})} \in \overline{\mathbb{Q}},
$$

where  $c = (\ell + m)/2$  is the center of the functional equation, and

$$
\mathcal{E}_p^{\text{bal}}(f \times g_\ell \times h_m) = (1 - \alpha_f \beta_g \beta_h p^{-c})(1 - \beta_f \alpha_g \beta_h p^{-c})(1 - \beta_f \beta_g \alpha_h p^{-c})(1 - \beta_f \beta_g \beta_h p^{-c}),
$$
  

$$
\mathcal{E}_p(F_k, \text{Ad}) = (1 - \alpha_F^{-2} \chi_{F_k}(p) p^{k-1})(1 - \alpha_F^{-2} \chi_{F_k}(p) p^{k-2})
$$
  

$$
F_k \in \{g_\ell, h_m\}
$$

are as in  $[Hsi21, (1.2)]$  $[Hsi21, (1.2)]$  and  $[Hsi21, p. 416]$ , respectively.

A more general square root balanced triple product  $p$ -adic L-function for three Hida families f, g, h is constructed in Theorem [5.5.](#page-36-0)

Note that the interpolation property for our triple product  $p$ -adic L-function differs from Hsieh [\[Hsi21,](#page-66-4) Theorem B]. The three key differences (which we will expand on momentarily) are:

- Hsieh's p-adic L-function is defined on the entire weight space.
- Our interpolation property does not involve Gross periods, but rather just the Petersson norms of the three forms  $f, g_{\ell}$ , and  $h_m$ .
- The Euler factor at p in Hsieh's p-adic L-function is only  $\mathcal{E}_p^{\text{bal}}(f \times g_\ell \times h_m)$  instead of the above quotient. Indeed, the adjoint Euler factors above are absorbed by the Gross periods.

However, it seems that our  $p$ -adic  $L$ -function is the correct one for the eventual arithmetic application in the present work. For example, both the periods and the Euler factor at  $p$  closely resemble those in [\[DR14\]](#page-66-0) in the unbalanced setting. Moreover, the proof of Theorem [D](#page-5-1) below also only seems to work with this interpolation property. We expand on the differences in Remark  $5.6$ .

Next, we explain the technical novelty which allows us to loosen the ramification assumption in Hsieh. Ichino's formula  $[Ich08]$  for the central value of the triple product p-adic L-function is on the quaternion algebra D ramified at v such that  $\epsilon_v(f \times g_\ell \times h_m) = -1$ , and utilizes the Jacquet–Langlands transfers  $f^D, g_\ell^D, h_m^D$  of the three modular forms  $f, g_\ell, h_m$ . Under our assumptions, D is ramified at  $v = \infty$  and at an odd number of finite primes q.

Let q be an odd prime. As observed by Pizer [\[Piz80a\]](#page-66-6), if D is ramified at q and f is a (twist-minimal) new cusp form of weight  $k \geq 2$ , level  $q^2$ , character  $\chi$  of conductor at most q, then:

$$
\dim S_k^D(q^2, \chi)[f] = 2,
$$

i.e. there is a two-dimensional space of quaternionic modular forms for  $D^{\times}$  which transfer to the same modular form  $f$  (cf. Proposition [3.10\)](#page-17-0). This raises two questions:

- (1) For each  $(\ell, m)$ , can we choose vectors  $f^D$ ,  $g_\ell^D$ ,  $h_m^D$  associated with f, g, h and compute the associated local integrals in Ichino's integral representation?
- (2) Do there exist Hida families  $\mathbf{g}^D$ ,  $\mathbf{h}^D$  associated with the Hida families **g**, **h** such that the specializations  $g_{\ell}^D$ ,  $h_m^D$  recover the choices in question (1)?

We give a positive answer to these questions by introducing "extra Hecke operators" which recover multiplicity one in the Jacquet–Langlands correspondence.

<span id="page-3-1"></span>**Proposition B** (Proposition [3.14\)](#page-18-0). There exists an operator  $\langle \varpi_{D_q} \rangle$  on dim  $S_k^D(q^2, \chi)$  associated with a choice of local uniformizer  $\varpi_{D_q}$  of  $D_q$ , commuting with the Hecke operators. For each twist-minimal <span id="page-4-0"></span>new cusp form f, of weight  $k \geq 2$ , level  $q^2$ , and character  $\chi$  of  $\text{cond}(\chi) \leq q$ :

$$
S_k^D(q^2,\chi)[f] \cong \underbrace{S_k^D(q^2,\chi)[f]^{\langle \varpi_{D_q} \rangle = +\sqrt{\chi_q(q)}}}_{\dim=1} \oplus \underbrace{S_k^D(q^2,\chi)[f]^{\langle \varpi_{D_q} \rangle = -\sqrt{\chi_q(q)}}}_{\dim=1}.
$$

Here,  $\chi_q$  is the local component at q of the adèlization of  $\chi$ .

To answer question (1), we can choose a vector in either of the one-dimensional eigenspaces. Section [2](#page-6-0) computes the necessary local integrals in Ichino's formula. Answering question (2) is then also based on Proposition [B,](#page-3-1) although it is technical and occupies Sections [3](#page-12-0) and [4.](#page-22-0) We show that for each choice of sign +1 or −1, there is a one-dimensional space of Hida families on  $D^{\times}$  associated with the Hida families on GL2, strengthening the results in [\[Dal23b\]](#page-65-6). Theorem [4.23](#page-30-0) proves this statement also in the case of Coleman families. From it, we deduce a control theorem à la Hida, which is the content of Corollary [4.28.](#page-33-1) The proof of these results relies on the construction of auxiliary quaternionic eigenvarieties endowed with closed immersions in the classical cuspidal one. In order to construct an explicit  $p$ -adic  $L$ -function, we need to identify quaternionic Hida families with (a slight generalization of the) Λ-adic forms in [\[Hsi21\]](#page-66-4); this is done in Proposition [4.26.](#page-32-0)

Note that our choice of vectors on the quaternion algebra  $D^{\times}$  is only well-defined up to scalars. We also restrict ourselves to working with an admissible affinoid in the weight space, instead of proving a control theorem over the whole weight space. It would be interesting to generalize our control theorem to the whole weight space and answer the natural questions about Gross periods for the different Hida families associated with the choice of eigenvalues of the operators  $\langle \varpi_{D_q} \rangle$ . This could lead to a definition of an integral p-adic L-function analogous to Hsieh's.

1.2. The Elliptic Stark Conjecture. Having defined the balanced triple product p-adic L-function  $\mathcal{L}_p^{\text{bal}}$ , we turn to studying its value at the *BSD point*  $(\ell, m) = (1, 1)$  which lies outside of the interpolation range. We start by introducing the relevant arithmetic objects.

Let us briefly recall our setup: the triple  $(f, g, h)$  corresponds to a triple  $(E, \varrho_1, \varrho_2)$  of an elliptic curve E over Q, and two Artin representation  $\varrho_i$ : Gal $(H/\mathbb{Q}) \to GL(V_i)$  for two-dimensional L-vector spaces  $V_1$  and  $V_2$ . Recall that:

$$
E[V_1 \otimes V_2] = \text{Hom}_{L[\text{Gal}(H/\mathbb{Q})]}(V_1 \otimes V_2, E(H) \otimes_{\mathbb{Q}} L),
$$

and under the rank one assumption, we may choose a basis:

$$
\Phi\colon V_1\otimes V_2\to E(H)\otimes_{\mathbb Q} L,
$$

well-defined up to  $L^{\times}$ .

We fix an embedding  $H \hookrightarrow \mathbb{Q}_p^{\text{ur}}$  and let  $\sigma_p \in \text{Gal}(H/\mathbb{Q})$  be the associated Frobenius element. Under our classicality and regularity assumptions, we have that  $\varrho_i(\sigma_p) = \begin{pmatrix} \alpha_i & 0 \\ 0 & i \end{pmatrix}$  $0 \beta_i$ ! with  $\alpha_i \neq \beta_i$ . Letting  $V_i^{\alpha}$ be the  $\alpha_i$ -eigenspace of  $V_i$ , we consider a non-zero element in the one-dimensional subspace  $v_{\alpha\alpha} \in V^{\alpha\alpha}$  $V_1^{\alpha} \otimes V_2^{\alpha} \subseteq V_1 \otimes V_2$ . Finally, we let

$$
P_{\alpha\alpha} = \Phi(v_{\alpha\alpha}) \in E(H) \otimes L,
$$

which is well-defined up to  $L^{\times}$ , but depends on the choice of Frobenius eigenvalues  $\alpha_1$  and  $\alpha_2$ .

Next, we consider the adjoint representations  $\text{Ad}^0(\varrho_i) = \text{Hom}^0(V_i, V_i)$ . By [\[DLR15,](#page-65-1) Proposition 1.5], the Stark unit group

$$
U_H[\text{Ad}^0 \varrho_i] = \text{Hom}_{L[\text{Gal}(H/\mathbb{Q})]}(\text{Ad}^0 V_i, \mathcal{O}_H^{\times} \otimes L)
$$

is also of rank one, and we may choose a basis:

$$
\Psi_i\colon \operatorname{Ad}^0 V_i\to \mathcal{O}_H^\times\otimes L,
$$

<span id="page-5-2"></span>well-defined up to  $L^{\times}$ .

The eigenvalues of Ad<sup>0</sup>  $\varrho_i(\sigma_p)$  are 1,  $\frac{\alpha_i}{\beta_i}$ ,  $\frac{\beta_i}{\alpha_i}$ , and we fix eigenvectors in the  $\alpha_i/\beta_i$ -eigenspaces:

$$
v_i^{\alpha/\beta} \in (\mathrm{Ad}^0 V_i)^{\alpha_i/\beta_i}.
$$

Finally, this defines

$$
u_{i,\alpha} = \Psi_i(v_i^{\alpha/\beta}) \in \mathcal{O}_H^{\times} \otimes L,
$$

which is well-defined up to  $L^{\times}$ , but depends on the choice of Frobenius eigenvalue  $\alpha_i$ .

<span id="page-5-0"></span>Write  $r(E, \varrho_{gh})$  for the rank of  $E[\varrho_q \otimes \varrho_h]$  which is, conjecturally on BSD, equal to ord<sub>s=1</sub>L( $f \times g \times h$ , s).

**Conjecture C** (Rank one Elliptic Stark Conjecture [6.5\)](#page-45-0). If  $r(E, \varrho_{gh}) > 1$ , then  $\mathcal{L}_p^{\text{bal}}(1,1) = 0$ . If  $r(E, \varrho_{gh}) = 1$ , then:

$$
\mathcal{L}_p^{\text{bal}}(1,1)^2 \sim_{L^\times} \frac{\log_{E,p}(P_{\alpha\alpha})^2}{\log_p(u_{1,\alpha})\log_p(u_{2,\alpha})},
$$

where

$$
\log_p: (\mathcal{O}_H^{\times})_L \to H_p \otimes L
$$
 *p-adic logarithm,*  

$$
\log_{E,p}: E(H)_L \to H_p \otimes L
$$
 *p-adic formal group logarithm for E.*

Both sides of the equality depend on the same choice of  $\alpha_1$  and  $\alpha_2$ . At first glance, it seems that the right hand side depends on  $H$  and the choices associated with it, but a simple computation reveals that it does not — see Remark [6.6.](#page-45-1)

Finally, we prove that this conjecture is true if  $\rho_1$ ,  $\rho_2$  are both induced from characters of the same imaginary quadratic field. Let K be an an imaginary quadratic field and  $p$  be a prime which splits in  $K$ . Let  $\psi_g$ ,  $\psi_h$  be finite order Hecke characters of K such that  $(\psi_g \psi_h) \circ N_{K/\mathbb{Q}} = 1$ , and consider the theta series  $g = \theta_{\psi_g}$ ,  $h = \theta_{\psi_h}$ . Let  $\psi_1 = \psi_g \psi_h$  and  $\psi_2 = \psi_g \psi_h^{\sigma}$ . We introduce some explicit assumptions under which our running hypotheses hold:

- (1)  $\epsilon_q(f_K, \psi_2) = +1$  for all finite primes q of K,
- (2)  $g$  and  $h$  are ordinary and regular,
- <span id="page-5-1"></span>(3) if  $\epsilon_q(f \times g \times h) = -1$ , then  $v_q(N_1) = 1$  and  $v_q(N_2) = v_q(N_3) = 2$ ;

**Theorem D** (Theorem [6.9\)](#page-47-0). Under assumptions  $(1)$ – $(3)$  above, [C](#page-5-0)onjecture C is true.

The idea of the proof of this theorem is to factor the triple product  $p$ -adic  $L$ -function into Rankin– Selberg and Katz p-adic L-functions (Theorem [6.14\)](#page-52-1). Under our ramification hypotheses, we need a certain generalization of the result of Bertolini–Darmon–Prasanna [\[BDP13\]](#page-65-7) on Rankin–Selberg p-adic L-functions. Indeed, their result holds under the Heegner hypothesis, which is not satisfied under assumption (3) above. We loosen the Heegner hypothesis slightly to include the case of interest to us. We prove this result in Appendix [A.](#page-52-0)

In Appendix [B,](#page-57-0) we provide a digest of examples to which our conjecture and theorem apply. In future work, we hope to give numerical evidence for Conjecture [C,](#page-5-0) based on the algorithms in [\[Dal23a\]](#page-65-5).

1.3. Organization of the paper. The main technical innovation of the paper is the study of extra operators on the space of quaternionic modular forms, which facilitate our choice of test vectors for the p-adic L-function. This occupies the first three sections, which consider the local (Section [2\)](#page-6-0), global (Section [3\)](#page-12-0), and p-adic (Section [4\)](#page-22-0) Jacquet–Langlands transfers. A reader interested in the construction of the p-adic L-function may proceed directly to Section [5,](#page-33-0) where we use this choice of test vectors to generalize Hsieh's construction. The arithmetic applications are discussed in Section [6,](#page-42-0) which may also be read independently of all the previous sections. Appendix [A](#page-52-0) gives generalizations of results of Bertolini–Darmon–Prasanna which are used the proof of Theorem [D,](#page-5-1) while Appendix [B](#page-57-0) contains examples.

<span id="page-6-2"></span>Acknowledgments. We would like to thank Alan Lauder, Matteo Longo, Kimball Martin, James Newton, Kartik Prasanna, and John Voight for many helpful discussions. This work represents a natural continuation of the doctoral work of LD and he is grateful to his advisor Massimo Bertolini for introducing him to the topic of balanced p-adic L-functions and setting him out on this path. LD is also thankful to Kimball Martin for bringing his attention to the reference [\[GP91\]](#page-66-7). Many of the ideas presented here are inspired by the work of Henri Darmon, Alan Lauder, and Victor Rotger. Their numerical investigation which led to such a precise statement of their rank two *Elliptic Stark Conjecture* paved the way for our rank one version of it. In particular, AH is thankful to Victor Rotger for his [mini-course](https://people.maths.ox.ac.uk/horawa/Iwasawa2019-Rotger.pdf) at Iwasawa 2019 in Bordeaux, which inspired him to consider the question in the present work.

AH was supported by the NSF grant DMS-2001293 and UK Research and Innovation grant MR/V021931/1. LD is grateful to the Università degli Studi di Padova (Research Grant funded by PRIN 2017 "Geometric, algebraic and analytic methods in arithmetic") and Università degli Studi di Milano (Research fellowship "Motivi, regolatori e geometria aritmetica") for their financial support.

#### 2. Local JL correspondence and test vectors

<span id="page-6-0"></span>In this section, we consider a finite extension F of  $\mathbb{Q}_{\ell}$  for  $\ell \neq 2$  (which will eventually be  $\mathbb{Q}_{\ell}$ ) and three local representations  $\pi_1$ ,  $\pi_2$ ,  $\pi_3$  of  $GL_2(F)$  such that the product of their central characters is trivial.

We classify when  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$  and in all cases when  $c(\pi_1), c(\pi_2), c(\pi_3) \leq 2$ , we compute the relevant local triple product integrals on a definite quaternion algebra over F. The new contribution of this section is the computations of these local integrals when  $c(\pi_i) = 2$  for some i.

Throughout this section, we often work with Weil–Deligne representations  $\sigma_i = \sigma(\pi_i)$  associated with  $\pi_i$  via the Local Langlands Correspondence [\[BH06\]](#page-65-8). Their triple product  $\epsilon$ - and L-factors agree with the automorphic ones [\[HK04,](#page-66-8) Proposition 2.1].

For completeness, we briefly recall the explicit Local Langlands Correspondence [\[BH06,](#page-65-8) Chapter 8] for  $\ell \neq 2$ . For a character  $\chi$  of  $K^{\times}$ , for a local field K, we write  $\xi = \xi(\chi)$  for the associated character of  $W_K$  via Class Field Theory.

- (1) If  $\pi = \pi(\chi_1, \chi_2)$  is a principal series representation, then  $\sigma(\pi) = \xi(\chi_1) \oplus \xi(\chi_2)$  is reducible.
- (2) If  $\pi = \text{St} \otimes \chi$  is a twist of the Steinberg representation, then  $\sigma(\pi) = \text{Sp}(2) \otimes \xi(\chi)$  is a twist of the special representation.
- (3) If  $\pi = \pi_{\psi}$  is supercuspidal, associated with an *admissible pair*  $(K, \psi)$ , where  $K/F$  is a quadratic extension and  $\psi$  is a character of  $K^{\times}$ , then  $\sigma(\pi) = \text{Ind}_{W_K}^{W_F}(\xi(\psi) \Delta_{\psi}^{-1})$  for a character  $\Delta_{\psi}$  defined in [\[BH06,](#page-65-8) Section 34.4]. Then  $c(\pi) = 2$  if and only if  $\pi$  has depth 0 (or level 0), i.e. K is unramified over F and  $\psi$  has conductor 1 (level 0). In this case  $\Delta_{\psi}$  is the unramified quadratic character of  $K^{\times}$ .

The representations in (2) and (3) are called *discrete series*.

2.1. Local  $\epsilon$ -factors and L-factors. The following proposition classifies all cases when  $\epsilon(\sigma_1\otimes\sigma_2\otimes\sigma_3)$  = −1.

<span id="page-6-1"></span>**Proposition 2.1** (Prasad). Let  $\sigma_1, \sigma_2, \sigma_3$  be three Weil–Deligne representations of W<sub>F</sub> such that the product of their determinants is trivial. Then  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = -1$  if and only if there is a reordering  $\{\sigma'_1,\sigma'_2,\sigma'_3\} = \{\sigma_1,\sigma_2,\sigma_3\}$  such that one of the following holds:

- (1)  $\sigma'_i \cong \mathrm{Sp}(2) \otimes \det(\sigma'_i)$  for  $i = 1, 2, 3;$
- (2)  $\sigma'_1 \cong \text{Sp}(2) \otimes \det(\sigma'_1), \ \sigma'_2$  is irreducible and  $\sigma'_3 \cong (\sigma'_2)^{\vee} \otimes \det(\sigma'_1)^{-1}$ ;
- (3) there is a quadratic extension  $K/F$  and characters  $\xi_1, \xi_2, \xi_3$  such that  $\sigma'_i = \text{Ind}_{W_K}^{W_F} \xi_i$  is irreducible  $(so \xi_i^{\sigma} \neq \xi_i)$  and either  $\xi_1 \xi_2 \xi_3 = 1$  or  $\xi_1 \xi_2 \xi_3^{\sigma} = 1$  or  $\xi_1 \xi_2^{\sigma} \xi_3 = 1$  or  $\xi_1 \xi_2^{\sigma} \xi_3^{\sigma} = 1$ .

<span id="page-7-3"></span>Proof. These results are contained in [\[Pra90,](#page-66-9) Section 8]. See [\[Pra90,](#page-66-9) Proposition 8.6] for (1) and [\[Pra90,](#page-66-9) Proposition 8.5 (2). For completeness, we compute  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3)$  for  $\sigma_i = \text{Ind}_{W_K}^{W_F} \xi_i$ ; the other possibilities are dealt with similarly. First, note that:

$$
\sigma_1 \otimes \sigma_2 \otimes \sigma_3 \cong \left(\mathrm{Ind}_{W_K}^{W_F}(\xi_1 \xi_2) \otimes \sigma_3\right) \oplus \left(\mathrm{Ind}_{W_K}^{W_F}(\xi_1 \xi_2^{\sigma}) \otimes \sigma_3\right)
$$

and hence by standard properties of  $\epsilon$ -factors:

$$
\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = \epsilon \left( \operatorname{Ind}_{W_K}^{W_F}(\xi_1 \xi_2) \otimes \sigma_3 \right) \epsilon \left( \operatorname{Ind}_{W_K}^{W_F}(\xi_1 \xi_2) \otimes \sigma_3 \right)
$$
  
\n
$$
= \xi_{K/F}(-1)\epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2) \cdot \xi_{K/F}(-1)\epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2)
$$
  
\n
$$
= \epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2) \cdot \epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2)
$$
  
\n
$$
= \det(\sigma_3)(-1)\epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2) \cdot \det(\sigma_3)(-1)\epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2^{\sigma}),
$$

where  $\xi_{K/F}$  is the quadratic character of  $W_F$  associated with  $K/F$ . Tunnell's Theorem [\[Pra90,](#page-66-9) Theorem 8.2] shows that  $\det(\sigma_3)(-1)\epsilon(\sigma_3|_{W_K} \otimes \xi_1 \xi_2) = -1$  if and only if  $(\xi_1 \xi_2)^{-1} = \xi_3$  or  $(\xi_1 \xi_2)^{-1} = \xi_3^{\sigma}$ . Therefore,  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = -1$  if and only if condition (3) holds after reordering.

<span id="page-7-2"></span>We make the following symplifying hypothesis.

**Hypothesis 2.2.** For all *i*, the conductor  $c(\pi_i)$  of  $\pi_i$  is at most 2.

<span id="page-7-0"></span>In particular, if  $\sigma = \text{Ind}_{W_K}^{W_F} \chi$ , then  $K/F$  is unramified, the conductor  $c(\chi)$  of  $\chi$  is 1, and  $\chi^{\sigma} \neq \chi$ . Next, we record the L-factors in each of the cases when  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = -1$ .

Proposition 2.3. We have that:

$$
L(\sigma_1 \otimes \sigma_2 \otimes \sigma_3, s) = \begin{cases} \zeta_F(s+3)\zeta_F(s+2)^2 & case (1) \\ \zeta_F(2s+2) & case (2) \\ \zeta_F(2s) & case (3) \end{cases}
$$

Proof. In case  $(1)$ , note that:

$$
Sp(2) \otimes Sp(2) \otimes Sp(2) \cong Sp(4) \oplus Sp(2)|\cdot |\oplus Sp(2)|\cdot |
$$

and  $L(\text{Sp}(m), s) = \zeta_{\ell}(s + m - 1)$ . Part (2) follows from

$$
L(\operatorname{Sp}(2)\otimes \sigma \otimes \sigma^{\vee},s)=L(\sigma \otimes \sigma^{\vee},s+1)
$$

and [\[GJ78,](#page-66-10) Corollary 1.3], because  $\sigma \cong \sigma \otimes \eta$  for an unramified quadratic character  $\eta$ . For (3), note that:

$$
\sigma_1 \otimes \sigma_2 \otimes \sigma_3 \cong \text{Ind}_{W_K}^{W_F}(\chi_1 \chi_2 \chi_3) \oplus \text{Ind}_{W_K}^{W_F}(\chi_1 \chi_2 \chi_3^{\sigma}) \oplus \text{Ind}_{W_K}^{W_F}(\chi_1 \chi_2^{\sigma} \chi_3) \oplus \text{Ind}_{W_K}^{W_F}(\chi_1 \chi_2 \chi_3^{\sigma}).
$$

Under the assumption that  $\epsilon(\sigma_1 \otimes \sigma_3 \otimes \sigma_3) = -1$ , exactly one of these characters is trivial and the other characters are ramified. This shows that:

$$
L(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = \zeta_K(s) = \zeta_F(2s),
$$

because  $K/F$  is unramified.

<span id="page-7-1"></span>We will also need the adjoint *L*-factors.

Proposition 2.4. We have that:

$$
Ad(Sp(2) \otimes \xi) \cong Sp(3) | \cdot |,
$$
  
 
$$
Ad(Ind_{W_K}^{W_F}(\chi)) \cong Ind_{W_K}^{W_F}(\chi/\chi^{\sigma}) \oplus \chi_{K/F},
$$

and hence:

$$
L(\mathrm{Ad}(\mathrm{Sp}(2)\otimes \xi),s)=\zeta_F(s+1),
$$

$$
L(\text{Ad}(\text{Ind}_{W_K}^{W_F}(\xi))) = L(\chi_{K/F}, s) = \frac{\zeta_F(2s)}{\zeta_F(s)}.
$$

<span id="page-8-2"></span>2.2. Local Jacquet–Langlands correspondence. In cases when  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$ , the local integral should be non-vanishing on the non-split quaternion algebra  $D$  over  $F$  (cf. [\[Pra90,](#page-66-9) Theorem 1.2]). In this section, we briefly summarize the local Jacquet–Langlands correspondence following [\[BH06,](#page-65-8) Chapter 13].

The local Jacquet–Langlands correspondence is a bijection

$$
JL\colon \mathrm{Rep}^{\mathrm{ds}}(\mathrm{GL}_2(F))\to \mathrm{Rep}(D^\times)
$$

between discrete series representations of  $GL_2(F)$  and irreducible smooth admissible representations of  $D^{\times}$ . For  $\pi = \text{St} \otimes \chi$ , we have that:

$$
JL(\mathrm{St}(2)\otimes\chi)=\chi\circ\nu,
$$

where  $\nu: D^{\times} \to F^{\times}$  is the reduced norm.

For supercuspidal representations, an explicit description of the correspondence is given in [\[BH06,](#page-65-8) Section 56]. We only describe it here for supercuspidal representations of conductor two, i.e.  $\pi = \pi_{\psi}$  for the unramified quadratic extension K of F and character  $\psi$  of  $K^{\times}$  of conductor 1 such that  $\psi^{\sigma} \neq \psi$ .

Recall that  $\Delta_{\psi}$  is the unramified quadratic character of  $K^{\times}$  in this case. We then have that:

- $\bullet~~\pi_\psi\otimes\Delta_\psi\cong\pi_\psi,$
- under the local Langlands correspondence, the corresponding representation of  $W_F$  is  $\text{Ind}_{W_K}^{W_F}(\xi(\psi)\Delta_{\psi})$ .

We describe the representation

$$
\pi^D_\psi = \mathrm{JL}(\pi_\psi)
$$

explicitly. Let  $\mathcal{O}_D$  be a maximal order of D and  $\varpi_D \in \mathcal{O}_D$  be a uniformizer. We will assume that  $\varpi_D^2 = \varpi_F$  for a uniformizer  $\varpi_F$  of F. There is a filtration on  $\mathcal{O}_D^{\times}$ 

(2.1) 
$$
U_D^a = \begin{cases} \mathcal{O}_D^{\times} & a = 0 \\ 1 + \varpi_D^a \mathcal{O}_D & a \ge 1. \end{cases}
$$

Given an unramified character  $\psi$  of  $K^{\times}$ , we may extend it to a character  $\Psi$  of  $K^{\times}U_D^1$  by letting  $U_D^1$  act trivially. Then:

<span id="page-8-1"></span><span id="page-8-0"></span>
$$
\pi_{\psi}^D \cong \operatorname{c-Ind}_{F^{\times}U_D^1}^{\overline{D}^{\times}} \Psi.
$$

Let  $\pi$  be a smooth irreducible representation of  $D^{\times}$ , which is automatically finite-dimensional because  $D^{\times}/F^{\times}$  is compact. Thus  $\pi|_{U_{D}^{a}} = 1$  for  $a \gg 0$ . We define the *conductor*  $c(\pi)$  of  $\pi$  to be  $a + 1$  where a is the smallest integer such that  $\pi|_{U_D^a} = 1$ . Note that under the assumption that  $\psi$  has conductor 1,  $\pi^D_\psi$  has conductor two. For completess, we verify that all representations of  $D^{\times}$  of conductor two are obtained this way, following [\[Car84\]](#page-65-9).

Note that  $\overline{\omega}_K = \overline{\omega}_F$  because  $K/F$  is an unramfied quadratic extension, and  $k = \mathcal{O}_K/\overline{\omega}_K \mathcal{O}_K$  is a quadratic extension of  $f = \mathcal{O}_F/\varpi_F \mathcal{O}_F$ . Finally, since  $d = \mathcal{O}_D/\varpi \mathcal{O}_D$  is also a quadratic extensions of f, it is isomorphic to k. By definition, a representation of conductor two factors through

(2.2) 
$$
D^{\times}/U_D^1 \cong d^{\times} \rtimes \langle \varpi_D \rangle.
$$

Note that  $\omega_D \mathcal{O}_D \omega_D^{-1} = \mathcal{O}_D$  because the maximal order  $\mathcal{O}_D \subseteq D$  is unique, and hence conjugation by  $\varpi_D$  preserves  $d^{\times}$ . Moreover,  $\varpi_D^2 = \varpi_F$  is in the center  $F^{\times}$  of  $D^{\times}$  and hence acts trivially. In particular, we have a subgroup:  $d^{\times} \times \langle \varpi_F \rangle \subseteq d^{\times} \times \langle \varpi_D \rangle$ .

Next, observe that a character  $\psi$  of  $K^{\times}$  which is trivial on  $U_D^1$  corresponds precisely to a character of  $k^{\times} \times \langle \varpi_F \rangle$ . Therefore, we may identify  $\pi_{\psi}^D$  with the inflation of the induction  $\text{Ind}_{d^{\times} \times \langle \varpi_F \rangle}^{d^{\times} \rtimes \langle \pi_D \rangle}$  $_{d^{\times} \times (\varpi_F)}^{a \times \pi_D} \psi$ . This representation is reducible unless  $\psi^{\varpi_D} \neq \psi$ . Altogether, we get the following result.

<span id="page-9-2"></span><span id="page-9-0"></span>**Proposition 2.5.** Suppose  $\pi$  is an smooth irreducible representation of  $D^{\times}$  and that  $c(\pi) = 2$ . Then there is a character  $\psi$  of  $d^{\times} \times \langle \varpi_F \rangle$  with  $\psi^{\varpi_D} \neq \psi$  such that:

$$
\pi = \operatorname{Inf}_{D^\times/U_D^1}^{D^\times} \operatorname{Ind}_{d^\times \times \langle \varpi_F \rangle}^{d^\times \rtimes \langle \varpi_D \rangle} \psi.
$$

In particular,  $\pi$  is two-dimensional and in the basis corresponding to the decomposition above, we have:

$$
\pi(x) = \begin{pmatrix} \psi(x) & & \\ & \psi^{\varpi_D}(x) \end{pmatrix}, \qquad x \in d^{\times} \times \langle \varpi_F \rangle,
$$

$$
\pi(\varpi_D) = \begin{pmatrix} 1 \\ \psi(\varpi_F) \end{pmatrix}.
$$

Finally, if  $\omega$  is the central character of  $\pi$ , then  $\psi|_{F^{\times}} = \omega$  and the last equality may be written:

$$
\pi(\varpi_D) = \begin{pmatrix} 1 \\ \omega(\varpi_F) \end{pmatrix}.
$$

Proof. The first claim then follows from [\[Car84,](#page-65-9) Section 5.1]. The rest of the proposition is immediate.

We identify the representation  $\pi_{\psi}^{D}$  with the one described explicitly in Proposition [2.5.](#page-9-0)

2.3. Local integral for zero, two, and three supercuspidal representations of level  $\ell^2$ . Let  $\pi_1, \pi_2, \pi_3$  be irreducible admissible representations of  $GL_2(F)$  with central characters  $\omega_i$  which satisfy  $\omega_1\omega_2\omega_3 = 1$ . Let  $\sigma_1, \sigma_2, \sigma_3$  be corresponding representations of  $W_F$  such that  $\det(\sigma_1)\det(\sigma_2)\det(\sigma_3) = 1$ . As above, let D be the non-split quaternion algebra over F, and  $\pi_i^D$  be the Jacquet–Langlands transfer of  $\pi_i$  to  $D^{\times}$ .

Prasad [\[Pra90,](#page-66-9) Theorem 1.4] proves that there exists a non-zero trilinear form on  $\pi_1^D \otimes \pi_2^D \otimes \pi_3^D$  if and only if  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) = -1$ . There is a natural trilinar form:

(2.3) 
$$
I'_v(\phi) = \int\limits_{F^\times \backslash D^\times} \langle \pi(g)\phi, \widetilde{\phi} \rangle \, dg \qquad \phi \in \pi_1^D \otimes \pi_2^D \otimes \pi_3^D
$$

and the goal of this section is to choose vectors  $\phi$  and compute  $I'_v(\phi) \neq 0$  explicitly when  $\epsilon(\sigma_1 \otimes \sigma_2 \otimes \sigma_3) =$  $-1$  and  $c(\sigma_i) \leq 2$ . Here,  $\langle -, - \rangle$  is a pairing between  $\pi_1^D \otimes \pi_2^D \otimes \pi_3^D$  and its contragredient representation, and  $\widetilde{\phi}$  is the vector dual to  $\phi$  under this pairing. Recall that there were three cases (1)–(3) outlined in Proposition [2.1](#page-6-1) and we will treat each of them separately.

**Remark 2.6.** As far as we know, these are the first such results when one of the components of  $\pi_1 \times \pi_2 \times \pi_3$ is supercuspidal and  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$  so the trilinear form is on the quaternion algebra  $D^{\times}$ . When  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = +1$ , the trilinear form is on GL<sub>2</sub> and Dimitrov–Nyssen [\[DN10\]](#page-65-10) show how to choose vectors in  $\pi_1 \times \pi_2 \times \pi_3$  when at least one component is not supercuspidal.

2.3.1. Case (1): zero supercuspidal representations. Suppose  $\pi_i = \text{St}(2) \otimes \omega_i$  for  $i = 1, 2, 3$ . Then:

$$
\pi_i^D = \omega_i \circ \nu \colon D^\times \to \mathbb{C}^\times
$$

<span id="page-9-1"></span>is one-dimensional and we choose any non-zero vectors  $\phi_i \in \pi_i^D$ .

**Proposition 2.7.** For characters  $\omega_1, \omega_2, \omega_3$  of  $F^\times$  such that  $\omega_1\omega_2\omega_3 = 1$  and any non-zero vectors  $\phi_i \in \pi_i^D$ , we have that

$$
\frac{I'_v(\phi)}{\langle \phi, \widetilde{\phi} \rangle} = 2\mu(\mathcal{O}_D^\times)
$$

for  $\phi = \phi_1 \times \phi_2 \times \phi_3$ .

Proof. See the proof of [\[Woo12,](#page-66-11) Proposition 4.5].

 $\blacksquare$ 

2.3.2. Case (2): two supercuspidal representations. Consider representations  $\pi_1, \pi_2, \pi_3$  of  $GL_2(F)$  such that:

- (1)  $\pi_1$ ,  $\pi_2$  are supercuspidal,  $\pi_3 = \text{St} \otimes \omega_3$  is a twist of the Steinberg representation,
- (2) the product  $\omega_1 \cdot \omega_2 \cdot \omega_3$  of their central characters it trivial,
- (3)  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$ , i.e.  $\pi_1^{\vee} = \pi_2 \otimes \omega_3^{-1}$ .

We assume that  $\pi_1$ ,  $\pi_2$  have conductor 2 and let  $\pi_i^D$  be the representation of  $D^{\times}$  corresponding to  $\pi_i$ for  $i = 1, 2, 3$  under the the Jacquet–Langlands correspondence. Then:

- (1)  $\pi_1^D = \pi_{\psi}$  for some character  $\psi$  of  $d^{\times} \times \langle \varpi_F \rangle$  such that  $\psi|_{F^{\times}} = \omega_1$ ,
- (2)  $\pi_2^D \cong \pi_{\psi^{-1}} \otimes \omega_3^{-1},$
- <span id="page-10-0"></span>(3)  $\pi_3^D \cong \omega_3 \circ \nu$ .

**Proposition 2.8.** Let  $\pi_1, \pi_2, \pi_3$  be as above,  $\epsilon_i \in \{\pm 1\}$  for  $i = 1, 2$ , and

- (1)  $\phi_i^{\epsilon_i} \in \pi_i^D$  non-zero such that  $\pi_i^D(\varpi_D)\phi_i^{\epsilon_i} = \epsilon_i \sqrt{\omega_i(\ell)}\phi_i^{\epsilon_i}$  (cf. Proposition [2.5\)](#page-9-0),
- (2)  $\phi_3 \in \pi_3^D$  nonzero.

Then for  $\phi^{\epsilon} = \phi_1^{\epsilon_1} \times \phi_2^{\epsilon_2} \times \phi_3$ , we have that:

$$
\frac{I'_v(\phi^{\epsilon})}{\langle \phi^{\epsilon}, \widetilde{\phi^{\epsilon}} \rangle} = (1 + \epsilon_1 \epsilon_2 \sqrt{\omega_3(\ell)}) \frac{\mu(\mathcal{O}_D^{\times})}{2}.
$$

*Proof.* We simplify the notation throughout the proof and write  $\pi_i = \pi_i^D$ . We compute, using the above description of the local representations:

$$
I'_{v}(\phi^{\epsilon}) = \int_{F^{\times} \backslash D^{\times}} \langle \pi(g)\phi^{\epsilon}, \tilde{\phi}^{\epsilon} \rangle dg
$$
  
\n
$$
= \int_{\mathcal{O}_{D}^{\times}} \langle \pi(g)\phi^{\epsilon}, \tilde{\phi}^{\epsilon} \rangle dg + \int_{\mathcal{O}_{D}^{\times}} \langle \pi(g)\pi(\varpi_{D})\phi^{\epsilon}, \tilde{\phi}^{\epsilon} \rangle dg \qquad D^{\times} = F^{\times} \mathcal{O}_{D}^{\times} \cup \varpi_{D} F^{\times} \mathcal{O}_{D}^{\times}
$$
  
\n
$$
= (1 + \epsilon_{1}\epsilon_{2}\sqrt{\omega_{1}(\ell)\omega_{2}(\ell)}\omega_{3}(\ell)) \sum_{x \in d^{\times}} \langle \pi(x)\phi^{\epsilon}, \tilde{\phi}^{\epsilon} \rangle \mu(U_{D}^{1})
$$
  
\n
$$
= (1 + \epsilon_{1}\epsilon_{2}\sqrt{\omega_{3}(\ell)})\mu(U_{D}^{1}) \sum_{x \in d^{\times}} \langle \pi(x)\phi^{\epsilon}, \tilde{\phi}^{\epsilon} \rangle
$$

Finally, for  $x \in d^{\times}$ , we have that:

$$
\begin{split} &\pi_1(x)\phi_1^{\epsilon_1}=\frac{\psi(x)+\epsilon_1\psi^{\varpi_D}(x)}{2}\phi_1^++\frac{\psi(x)-\epsilon_1\psi^{\varpi_D}(x)}{2}\phi_1^-,\\ &\pi_2(x)\phi_2^{\epsilon_2}=\left(\frac{\psi^{-1}(x)+\epsilon_2\psi^{-1,\varpi_D}(x)}{2}\phi_2^++\frac{\psi^{-1}(x)-\epsilon_2\psi^{-1,\varpi_D}(x)}{2}\phi_2^-\right)\omega_3(N_{d/k}x)^{-1},\\ &\pi_3(x)\phi_3=\omega_3(N_{d/k}x)\phi_3. \end{split}
$$

We hence obtain

$$
\sum_{x \in d^{\times}} \pi(x) \phi^{\epsilon} = S_{++} \phi^{++} + S_{+-} \phi^{+-} + S_{-+} \phi^{-+} + S_{--} \phi^{--}
$$

for:

$$
S_{++} = \frac{1}{4} \sum_{x \in d^{\times}} (\psi(x) + \epsilon_1 \psi^{\varpi_D}(x)) (\psi^{-1}(x) + \epsilon_2 \psi^{-1, \varpi_D}(x)),
$$
  
\n
$$
= \frac{1}{4} |d^{\times}| (1 + \epsilon_1 \epsilon_2)
$$
  
\n
$$
S_{+-} = \frac{1}{4} \sum_{x \in d^{\times}} (\psi(x) + \epsilon_1 \psi^{\varpi_D}(x)) (\psi^{-1}(x) - \epsilon_2 \psi^{-1, \varpi_D}(x))
$$
  
\n
$$
= \frac{1}{4} |d^{\times}| (1 - \epsilon_1 \epsilon_2),
$$

$$
S_{-+} = \frac{1}{4} \sum_{x \in d^{\times}} (\psi(x) - \epsilon_1 \psi^{\varpi_D}(x))(\psi^{-1}(x) + \epsilon_2 \psi^{-1, \varpi_D}(x))
$$
  
= 
$$
\frac{1}{4} |d^{\times}| (1 - \epsilon_1 \epsilon_2),
$$
  

$$
S_{--} = \frac{1}{4} \sum_{x \in d^{\times}} (\psi(x) - \epsilon_1 \psi^{\varpi_D}(x))(\psi^{-1}(x) - \epsilon_2 \psi^{-1, \varpi_D}(x))
$$
  
= 
$$
\frac{1}{4} |d^{\times}| (1 + \epsilon_1 \epsilon_2).
$$

This shows that:

$$
\sum_{x \in d^{\times}} \pi(x)\phi^{\epsilon} = \frac{1}{2}|d^{\times}|(\phi^{\epsilon} + \phi^{-\epsilon})
$$

and hence:

$$
I_v'(\phi^\epsilon) = (1 + \epsilon_1 \epsilon_2 \sqrt{\omega_3(\ell)}) \frac{\mu(\mathcal{O}_D^\times)}{2} \langle \phi^\epsilon + \phi^{-\epsilon}, \widetilde{\phi^\epsilon} \rangle = (1 + \epsilon_1 \epsilon_2 \sqrt{\omega_3(\ell)}) \frac{\mu(\mathcal{O}_D^\times)}{2} \langle \phi^\epsilon, \widetilde{\phi^\epsilon} \rangle.
$$

The rest of the results follow.

2.3.3. Case (3): three supercuspidal representations. We next consider the case of three twist-minimal supercuspidal representations  $\pi_1, \pi_2, \pi_3$  of  $GL_2(F)$  conductor 2 such that  $\omega_1 \cdot \omega_2 \cdot \omega_3 = 1$ ; according to Proposition [2.5:](#page-9-0)

$$
\pi_i^D = \psi_{\psi_i}^D
$$

where  $\psi_i^{\sigma} \neq \psi_i$  and we note that

(2.5) 
$$
\psi_1 \psi_1^{\varpi_D} \psi_2 \psi_2^{\varpi_D} \psi_3 \psi_3^{\varpi_D} = 1.
$$

Proposition [2.1](#page-6-1) (3) classifies when  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$ . We compute the local integrals associated with all possible choices of vectors  $\phi_i^{\pm} \in \pi_i^D = \pi_{\psi_i}^D$  as in Proposition [2.8](#page-10-0) and check that  $I'_v(\phi) \neq 0$  for some  $\phi$  exactly when  $\epsilon(\pi_1 \otimes \pi_2 \otimes \pi_3) = -1$ .

<span id="page-11-1"></span>**Proposition 2.9.** Let  $\pi_1, \pi_2, \pi_3$  be as above. For  $\epsilon \in {\pm 1}^3$  let  $\phi^{\epsilon} = \phi_1^{\epsilon_1} \times \phi_2^{\epsilon_2} \times \phi_3^{\epsilon_3} \in \pi^D = \pi_1^D \times \pi_2^D \times \pi_3^D$ . Then:

<span id="page-11-0"></span>
$$
\frac{I'_v(\phi^\epsilon)}{\langle \phi^\epsilon, \widetilde{\phi^\epsilon} \rangle} = (1 + \epsilon_1 \epsilon_2 \epsilon_3) \frac{\mu(\mathcal{O}_D^\times)}{4}.
$$

*Proof.* Once again, we simplify the notation to write  $\pi_i = \pi_i^D$  etc. We proceed as in the proof of Proposition [2.8:](#page-10-0)

$$
I'_{v}(\phi^{\epsilon}) = \int_{F^{\times} \backslash D^{\times}} \langle \pi(g)\phi^{\epsilon}, \widetilde{\phi}^{\epsilon} \rangle dg
$$
  
\n
$$
= \int_{\mathcal{O}_{D}^{\times}} \langle \pi(g)\phi^{\epsilon}, \widetilde{\phi}^{\epsilon} \rangle dg + \int_{\mathcal{O}_{D}^{\times}} \langle \pi(g)\pi(\varpi_{D})\phi^{\epsilon}, \widetilde{\phi}^{\epsilon} \rangle dg \qquad D^{\times} = F^{\times} \mathcal{O}_{D}^{\times} \cup \varpi_{D} F^{\times} \mathcal{O}_{D}^{\times}
$$
  
\n
$$
= (1 + \epsilon_{1} \epsilon_{2} \epsilon_{3} \sqrt{\omega_{1}(\ell) \omega_{2}(\ell) \omega_{3}(\ell)}) \sum_{x \in d^{\times}} \langle \pi(x)\phi^{\epsilon}, \widetilde{\phi}^{\epsilon} \rangle \mu(U_{D}^{1})
$$
  
\n
$$
= (1 + \epsilon_{1} \epsilon_{2} \epsilon_{3}) \mu(U_{D}^{1}) \sum_{x \in d^{\times}} \langle \pi(x)\phi^{\epsilon}, \widetilde{\phi}^{\epsilon} \rangle.
$$

Next, we need to compute  $\Sigma$  $\sum_{x \in d^{\times}} \langle \pi(x) \phi^{\epsilon}, \phi^{\epsilon} \rangle$ . For  $x \in d^{\times}$  and  $i = 1, 2, 3$ :

$$
\pi_i(x)\phi_i^{\epsilon_i} = \frac{\psi_i(x) + \epsilon_i\psi_i^{\varpi_D}(x)}{2}\phi_i^+ + \frac{\psi_i(x) - \epsilon_i\psi_i^{\varpi_D}(x)}{2}\phi_i^-.
$$

<span id="page-12-2"></span>Therefore:

$$
\pi(x)\phi^{\epsilon} = \sum_{\eta \in \{\pm 1\}^3} s_{\eta \epsilon} \phi^{\eta},
$$
  
\n
$$
s_{\eta \epsilon} = \frac{1}{8} \prod_{i=1}^3 (\psi_i(x) + \epsilon_i \eta_i \psi_i^{\varpi_D}(x))
$$
  
\n
$$
= \frac{1}{8} \sum_{\delta \in \{0,1\}^3} (\epsilon_1 \eta_1)^{\delta_1} (\epsilon_2 \eta_2)^{\delta_2} (\epsilon_3 \eta_3)^{\delta_3} \psi_1^{\varpi_{D}^{\delta_1}}(x) \psi_2^{\varpi_{D}^{\delta_2}}(x) \psi_3^{\varpi_{D}^{\delta_3}}(x).
$$

and hence:

$$
\langle \pi(x)\phi^{\epsilon},\widetilde{\phi^{\epsilon}}\rangle=s_{\epsilon\epsilon}\langle \phi^{\epsilon},\widetilde{\phi^{\epsilon}}\rangle=\frac{1}{8}\sum_{\delta\in\{0,1\}^3}\psi_1^{\varpi_D^{\delta_1}}(x)\psi_2^{\varpi_D^{\delta_2}}(x)\psi_3^{\varpi_D^{\delta_3}}(x)\langle \phi^{\epsilon},\widetilde{\phi^{\epsilon}}\rangle.
$$

Altogether, we have that:

$$
\frac{\sum\limits_{x\in d^\times}\langle \pi(x)\phi^\epsilon,\widetilde{\phi^\epsilon}\rangle}{\langle \phi^\epsilon,\widetilde{\phi^\epsilon}\rangle}=\frac{1}{8}\cdot |d^\times|\cdot \left|\left\{\delta\in \{0,1\}^3\ \middle|\ \psi_1^{\varpi_D^{\delta_1}}\psi_2^{\varpi_D^{\delta_2}}\psi_3^{\varpi_D^{\delta_3}}=1\right\}\right|.
$$

Without loss of generality, suppose that  $\psi_1 \psi_2 \psi_3 = 1$ . We claim that then:

$$
S = \left\{ \delta \in \{0, 1\}^3 \; \middle| \; \psi_1^{\varpi_D^{\delta_1}} \psi_2^{\varpi_D^{\delta_2}} \psi_3^{\varpi_D^{\delta_3}} = 1 \right\} = \left\{ (0, 0, 0), (1, 1, 1) \right\}.
$$

By assumption,  $(0, 0, 0) \in S$  and by equation  $(2.5)$  also  $(1, 1, 1) \in S$ . To verify that S cannot be larger, suppose without loss of generality that  $(1,0,0) \in S$ , i.e.  $\psi_1^{\overline{\omega}_1} \psi_2 \psi_3 = 1$ . Then  $\psi_1^{\overline{\omega}_1} = \psi_1$ , but this contradicts the admissibility of the pair  $(K, \psi_1)$ .

<span id="page-12-0"></span>Remark 2.10. It would be interesting to treat the case of supercuspidal representations of higher conductor as well, but this would take us too far afield from the ultimate arithmetic goals of the paper.

#### 3. Global JL correspondence and test vectors

We are ready to study the global consequences of Section [2.](#page-6-0) We focus our attention on quaternionic modular forms with level structure given by orders which are *residually inert* at the primes where the quaternion algebra ramifies; the local theory considered in the previous section allows a precise understanding of such forms.

From now on,  $D$  denotes a quaternion algebra over  $\mathbb Q$  (and not a local quaternion algebra as in the previous section). For simplicity of exposition, until Section [3.6,](#page-19-0) we restrict ourselves to the case where the quaternion algebra is ramified exactly at one odd prime  $\ell$  and at infinity. However, everything we state in this section generalizes to any definite quaternion Q-algebra (see also Remark [3.15\)](#page-18-1); in particular, the results in Section [3.6](#page-19-0) and Sections [4–](#page-22-0)[6](#page-42-0) deal with the general situation.

For any place v of  $\mathbb{Q}$ , we denote  $D_v = D \otimes_{\mathbb{Q}} \mathbb{Q}_v$ , where we understand  $\mathbb{Q}_{\infty}$  to be R. Similarly, for any order  $R \subset D$  and any finite place v, we denote  $R_v = R \otimes_{\mathbb{Z}} \mathbb{Z}_v$ . As a last piece of notation, we set  $D(\mathbb{A}) = D \otimes_{\mathbb{Q}} \mathbb{A}$ , for  $\mathbb{A}$  the adèles of  $\mathbb{Q}, \widehat{D} = D \otimes_{\mathbb{Q}} \mathbb{A}_f$ , for  $\mathbb{A}_f$  the finite adèles, and  $\widehat{R} = R \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}}$ , for  $\widehat{\mathbb{Z}}$ the profinite completion of the integers.

<span id="page-12-1"></span>3.1. A remark on the structure of quaternion algebras at ramified primes. We begin by recalling a general formalism to deal with definite quaternion algebras over a local field, which will make our exposition clearer and independent of the choices of the uniformizers. Most of the content of this section can be found in [\[Voi21,](#page-66-12) Section 13]. Let  $D_{\ell}$  be a quaternion division algebra over  $\mathbb{Q}_{\ell}$  and let  $\mathbb{Q}_{\ell}(\varpi_{\ell})$  and  $\mathbb{Q}_{\ell^2}$  be, respectively, one of the two ramified quadratic extension of  $\mathbb{Q}_{\ell}$  and the unique unramified quadratic one; as  $D_{\ell}$  is division, there exists embeddings of these two fields in  $D_{\ell}$ . Consider  $\nu_{\ell}: D_{\ell} \longrightarrow \mathbb{Q}_{\ell}$  to be the reduced norm map at  $\ell$ . We extend the  $\ell$ -adic valuation  $v_{\ell}$  of  $\mathbb{Q}_{\ell}$ , to the division <span id="page-13-0"></span>algebra:  $w_{\ell} = \frac{1}{2} \cdot v_{\ell} \circ \nu_{\ell}$ . We fix

$$
\mathcal{O}_{D_{\ell}} = \{x \in D_{\ell} \mid w_{\ell}(x) \in \mathbb{Z}_{\ell}\}
$$

and denote by  $\varpi_{D_\ell} \in \mathcal{O}_{D_\ell}$  a uniformizer of  $D_\ell$ , namely an element in  $\mathcal{O}_{D_\ell}$  with valuation  $w_\ell(\varpi_{D_\ell}) = 1/2$ ; it is not difficult to notice that one can take  $\varpi_{D_\ell} = \varpi_\ell$ . Therefore, we can decompose the division algebra  $D_{\ell}$  as

$$
(3.1) \t D_{\ell} = \mathbb{Q}_{\ell^2} \oplus \varpi_{\ell} \mathbb{Q}_{\ell^2}.
$$

Denoting by  $\varpi_{\mathbb{Q}_{\ell^2}}$  the uniformizer of  $\mathbb{Q}_{\ell^2}$ , we can further write

(3.2) 
$$
D_{\ell} = \mathbb{Q}_{\ell} \oplus \varpi_{\mathbb{Q}_{\ell^2}} \mathbb{Q}_{\ell} \oplus \varpi_{\ell} \mathbb{Q}_{\ell} \oplus \varpi_{\mathbb{Q}_{\ell^2}} \varpi_{\ell} \mathbb{Q}_{\ell},
$$

with the condition  $\varpi_{\mathbb{Q}_{\ell^2}} \varpi_{\ell} = \varpi_{\ell} \overline{\varpi_{\mathbb{Q}_{\ell^2}}} = -\varpi_{\ell} \varpi_{\mathbb{Q}_{\ell^2}}$ .

3.2. Residually inert orders. We briefly recall the definition of residually inert (at  $\ell$ ) orders in D. The interested reader may consult [\[Voi21,](#page-66-12) Section 24.3], [\[HPS89a\]](#page-66-13) and [\[Piz80b\]](#page-66-14) for a more detailed exposition.

**Definition 3.1.** Let N be a positive integer prime to  $\ell$ . We say that an order  $R \subset D$  of level  $N\ell^2$  is

- residually split at the prime  $q \mid N$  if  $R_q$  is an Eichler order of level  $q^{\text{val}_q(N)}$ ;
- residually inert at  $\ell$  (also known as special or Pizer order) if there exists a ramified quadratic extension  $\mathbb{Q}_{\ell}(\varpi_{\ell})/\mathbb{Q}_{\ell}$ , such that  $R_{\ell}$  is conjugate to

$$
\mathcal{O}_{\ell} + \{x \in D_{\ell} \mid \nu_{\ell}(x) \in \ell \mathbb{Z}_{\ell}\} = \mathcal{O}_{\ell} + \varpi_{D_{\ell}} \mathcal{O}_{D_{\ell}},
$$

where  $\mathcal{O}_{\ell}$  is the ring of integers of  $\mathbb{Q}_{\ell}(\varpi_{\ell}).$ 

In order to shorten the notation, we call such a global order a *Pizer order of level*  $N\ell^2$ , however, we remark that these orders are a type of basic orders and we point to [\[Voi21,](#page-66-12) Remark 24.5.7] for a complete discussion on the different terminologies for such orders.

#### Remark 3.2.

- If the order has level  $N\ell$ , then the local order at  $\ell$  is no longer residually inert, but it is the unique maximal order in  $D_{\ell}$ . In particular, an order R of level  $N\ell^2$  is contained in an Eichler order of level  $N\ell$ .
- Adding a subscript  $\ell$  at the notation of Section [2,](#page-6-0) we notice that, by equation [\(2.1\)](#page-8-0),  $R_{\ell}^{\times} \supseteq U_{D_{\ell}}^1$ with quotient  $\mathbb{F}_{\ell}^{\times}$ . The quotient in equation [\(2.2\)](#page-8-1) recovers the observations in [\[Piz80b,](#page-66-14) proofs of Propositions 1.8 and 9.26].

For any prime  $q \neq \ell$ , we fix a  $\mathbb{Q}_q$ -linear isomorphism  $\iota_q: D_q \cong M_2(\mathbb{Q}_q)$ ; up to changing this isomorphism, we may assume that

(3.3) 
$$
\iota_q(R_q) = \left\{ \gamma \in M_2(\mathbb{Z}_q) \middle| \gamma \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{NM_2(\mathbb{Z}_q)} \right\}.
$$

At the ramified prime  $\ell$ , we assume that  $R_{\ell} = \mathcal{O}_{\ell} + \varpi_{D_{\ell}} \mathcal{O}_{D_{\ell}}$ . For the rest of this section, we fix R to be a Pizer order of level  $N\ell^2$ , and advise the reader that every time we pick a Pizer order, we are implicitly assuming the above identifications. We also introduce the following notation

$$
(3.4) \ \ U_1(R) = \left\{ r = (r_q) \in \widehat{R}^{\times} \ \middle| \ \iota_q(r_q) \equiv \begin{pmatrix} * & * \\ 0 & 1 \end{pmatrix} \pmod{NM_2(\mathbb{Z}_q)}, \text{ for } q \mid N \text{ and } r_\ell \in 1 + \varpi_{D_\ell} R_\ell \right\}.
$$

It is not difficult to notice that it is an open compact subgroup of  $\hat{B}^{\times}$  (cf. also [\[Dal23b,](#page-65-6) Lemma 2.1.3]).

3.3. Lifting characters. Let  $\chi$  be a Dirichlet character of conductor C, for C | Nl. Every such character can be lifted to a character of  $\widehat{R}^{\times}$ ; for simplicity we consider the case of  $\ell$  odd. A similar <span id="page-14-1"></span>construction works for  $\ell = 2$  and a precise recipe is provided in [\[HPS89a,](#page-66-13) Section 7.2] as we focus on the odd case. Let q be a prime and let  $\chi_q$  be the q-component of the character  $\chi$ . We define the lift  $\tilde{\chi}_q$  of  $\chi_q$  to  $R_q^{\times}$  as follows:

- (1) If  $q \mid N\ell$ , but  $q \nmid C$ , we set  $\widetilde{\chi}_q(r) = 1$  for any  $r \in R_q^{\times}$ .
- (2) If q | N and q | C, we set  $\tilde{\chi}_q(r) = \chi_q(d)$  for any  $r \in R_q^{\times}$  such that  $\iota_q(r) = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ ;
- (3) If  $q = \ell > 2$  and  $\ell \mid C$ , we fix, once and for all, an odd character  $\varepsilon_{\ell}$  with cond $(\varepsilon_{\ell}) = \ell$ . For every even character  $\phi_{\ell}$  of cond $(\phi_{\ell}) = \ell$ , we fix, once and for all, a character  $\gamma_{\ell}$  with cond $(\gamma_{\ell}) = \ell$  and such that  $\gamma_{\ell}^2 = \phi_{\ell}$ . As remarked in [\[HPS89a,](#page-66-13) Section 7.2], the particular choice of  $\varepsilon_{\ell}$  and  $\gamma_{\ell}$  is not important, but the fact that a certain choice is fixed once and for all is crucial.
	- (a) We first extend  $\varepsilon_{\ell}$  to  $R_{\ell}^{\times}$  via the composition:

$$
\mathcal{O}_{\ell}^{\times} \longrightarrow (\mathcal{O}_{\ell}/\varpi_{D_{\ell}}\mathcal{O}_{\ell})^{\times} \longrightarrow (\mathbb{Z}_{\ell}/\ell\mathbb{Z}_{\ell})^{\times}
$$
  

$$
\downarrow \qquad \qquad \downarrow \qquad \qquad \varepsilon_{\ell} \downarrow
$$
  

$$
R_{\ell}^{\times} = (\mathcal{O}_{\ell} + \varpi_{D_{\ell}}\mathcal{O}_{D_{\ell}})^{\times} \longrightarrow \overline{\mathbb{Z}_{\ell}} \longrightarrow \overline{\mathbb{Q}_{p}}^{\times}.
$$

- (b) If  $\chi_{\ell}$  is even, let  $\gamma_{\ell}$  be the *square root* character associated with it, as above. We define  $\widetilde{\chi}_{\ell}(r) = \gamma_{\ell}(\nu_{\ell}(r))$ , for any  $r \in R_{\ell}^{\times}$ . Clearly,  $\widetilde{\chi}_{\ell}(r) = \widetilde{\chi}_{\ell}(r')$  if  $r \equiv r' \pmod{\varpi_{D_{\ell}}O_{D_{\ell}}}$ .
- (c) If  $\chi_{\ell}$  is odd, then  $\chi_{\ell} = \varepsilon_{\ell} \cdot \chi'_{\ell}$ , with  $\chi'_{\ell}$  even. We then define  $\tilde{\chi}_{\ell} = \tilde{\varepsilon}_{\ell} \chi'_{\ell}$ .

<span id="page-14-0"></span>**Definition 3.3.** We denote the lift of  $\chi$  to  $\widehat{R}^{\times}$  by  $\widetilde{\chi}$ , defined as  $\widetilde{\chi} = \prod_{\substack{a \mid \mathcal{C} \\ a}}$  $\prod_{q|C}\widetilde{\chi}_q.$ 

Recall that we can define the adèlization of  $\chi$ ,

(3.5) 
$$
\chi_{\mathbb{A}} : \mathbb{Q}^{\times} \backslash \mathbb{A}^{\times}/\mathbb{R}_{+}(1+N\widehat{\mathbb{Z}})^{\times} \longrightarrow \mathbb{C}^{\times},
$$

as the unique finite order Hecke character such that  $\chi_{\mathbb{A}}((1,\ldots,1,q,1,\ldots)) = \chi(q)^{-1}$ ; then  $\chi_q(q) = \chi(q)^{-1}$ if  $q \nmid N$ .

## Remark 3.4.

- (1) The restriction of  $\tilde{\chi}$  to Z recovers the starting character  $\chi$ . At any prime q away from  $\ell$ , the lifting process of each local component  $\chi_q$  consists exactly in the adèlization of its inverse,  $(\chi_q^{-1})_{\mathbb{A}}$ .
- (2) The lifting process can be constructed compatibly with the inclusion of Pizer orders  $R \supseteq R'$ , with  $R'$  Pizer order of level  $N'\ell^2$ ,  $N \mid N'$ .
- (3) By construction, the character  $\tilde{\chi}$  is trivial on  $U_1(R)$ . More precisely, it is a character of  $(\widehat{R}/\delta(R))^\times$ , for  $\delta(R)$  the different ideal of  $\widehat{R}$  (cf. [\[HPS89a,](#page-66-13) Sections 7.1-7.2]).

3.4. Forms on definite quaternion algebras. In this section we recall the various notions of quaternionic forms and their explicit relations. We fix an odd prime  $p \neq \ell$  and an absolute closure of  $\mathbb{Q}_p$ , which we denote by  $\overline{\mathbb{Q}_p}$ .

3.4.1. Quaternionic modular forms. Let A be a commutative ring and consider the space of polynomials in two variables,  $A[X, Y]$ . We endow this module with the action of invertible matrices  $GL_2(A)$  given by

(3.6) 
$$
\gamma \cdot P(X,Y) = P((X,Y) \cdot \gamma),
$$

for any  $\gamma \in GL_2(A)$  and  $P \in A[X, Y]$ . For any  $m \in \mathbb{Z}_{\geq 0}$  we define the submodule of homogeneous polynomials of degree m and denote it by  $L_m(A)$ ; the  $GL_2(A)$ -action descends to an action on  $L_m(A)$ . In the following, the ring A will be an algebra over the ring of integers of a finite extension of  $\mathbb{Q}_p$ , for example,  $\overline{\mathbb{Q}_p}$ .

**Definition 3.5** (Quaternionic modular forms). Let R be a Pizer order of level  $N\ell^2$ , and assume that p | N. Let A be a  $\mathbb{Z}_p$ -algebra and fix an A-valued Dirichlet character  $\chi$  with conductor  $C \mid N\ell$ . A

<span id="page-15-2"></span>quaternionic modular form for  $D^{\times}$ , of weight  $k \in \mathbb{Z}_{\geq 2}$ , level structure R, and character  $\chi$ , is a continuous function  $\varphi : \widehat{D}^{\times} \longrightarrow L_{k-2}(A)$ , such that

$$
\varphi(d\hat{d}zr) = (\chi_{\mathbb{A}})^{-1}(z)\,\widetilde{\chi}(r)\,z_p^{2-k}\,(r_p^{-1}\cdot\varphi(\hat{d})),
$$

for  $d \in D^{\times}$ ,  $\hat{d} \in \widehat{D}^{\times}$ ,  $z \in \mathbb{A}_f^{\times}$ , and  $r \in \widehat{R}^{\times}$ . Here  $\widetilde{\chi}$  is the lifting constructed in Definition [3.3.](#page-14-0) We denote the space of quaternionic modular forms by  $S_k^D(R, \chi, A)$ .

Note that, for  $z \in \mathbb{A}_f^{\times} \cap \tilde{R}^{\times}$ ,  $\tilde{\chi}(z) = (\chi_{\mathbb{A}})^{-1}(z)$ , and that  $\varphi$  is right-invariant under  $U_1(R)^{(p)}$ , i.e. away from p. The space  $S_k^D(R, \chi, A)$  inherits a right-action of  $GL_2(\mathbb{Z}_p)$  given by  $\varphi_{|\gamma}(\hat{d}) = \gamma^{-1} \cdot \varphi(\hat{d})$ .

As defined, quaternionic modular forms are not the classical quaternionic modular forms considered in  $[HPS89a]$ , which are (non-unitarized) automorphic forms on D. In order to clarify the situation, as well as making explicit certain actions on the space of quaternionic modular forms (see Section [3.5\)](#page-16-0), we recall the definition of automorphic forms and algebraic quaternionic modular forms, highlighting their relations with quaternionic modular forms.

3.4.2. Automorphic forms on  $D^{\times}$ . Fix an isomorphism  $\iota : \mathbb{Q}_p \cong \mathbb{C}$  and let  $\Psi_{\infty} : D_{\infty} = D \otimes_{\mathbb{Q}} \mathbb{R} \hookrightarrow M_2(\mathbb{C})$ be an embedding such that  $\iota(\iota_p(d)) = \Psi_\infty(d)$ , for any  $d \in D^\times \subset D_p^\times$ <sup>*ι*<sub>p</sub></sup>  $\stackrel{\sim}{\cong} GL_2(\mathbb{Q}_p)$ . For any  $k ≥ 2$ , let

(3.7) 
$$
\rho_{\infty,k}^u : D_{\infty}^{\times} \longrightarrow \text{Aut}(L_{k-2}(\mathbb{C}))
$$

be the unitarized representation defined by

(3.8) 
$$
\rho_{\infty,k}^u(d_{\infty})(P(X,Y)) = |\nu_{D_{\infty}}(d_{\infty})|^{\frac{k-2}{2}} \Psi_{\infty}(d_{\infty}) \cdot P(X,Y).
$$

**Definition 3.6** (Automorphic forms on  $D^{\times}$ ). Let R and  $\chi$  be as above. We define the space  $\mathcal{A}_{k}^{D}(R,\chi)$ of automorphic forms on  $D^{\times}$ , of weight k, level R, and character  $\chi$ , as the vector space of continuous functions  $\phi: D(\mathbb{A})^{\times} \longrightarrow L_{k-2}(\mathbb{C})$ , such that

<span id="page-15-1"></span>
$$
\phi(dxd_{\infty}rz) = (\chi_{\mathbb{A}})^{-1}(z) \widetilde{\chi}(r) \rho_{\infty,k}^u(d_{\infty}^{-1}) (\phi(x)),
$$

for  $d \in D^{\times}$ ,  $d_{\infty} \in D_{\infty}^{\times}$ ,  $z \in \mathbb{A}^{\times}$ , and  $r \in R^{\times}$ .

There is a correspondence between quaternionic modular forms and automorphic forms. Precisely, to each  $\varphi \in S_k^D(R, \chi)$  we associate the automorphic form  $\Phi(\varphi) \in \mathcal{A}_k^D(R, \chi)$  defined as

(3.9) 
$$
\Phi(\varphi)(d) = \rho_{\infty,k}^u(d_{\infty}^{-1}) \Big( \iota\big(d_p \cdot \varphi(d_f)\big) \Big),
$$

<span id="page-15-0"></span>for any  $d \in D(\mathbb{A})^{\times}$ , with finite part  $d_f \in D^{\times}$ , and components  $d_p$  and  $d_{\infty}$ , respectively at p and infinity.

3.4.3. Algebraic quaternionic modular forms. In order to construct the  $p$ -adic L-function in the following Section [5,](#page-33-0) we need Hida families of quaternionic modular forms. We define them in Section [4.2,](#page-29-0) similarly to [\[Hsi21,](#page-66-4) Definition 4.1], and for this purpose we should introduce algebraic quaternionic modular forms.

Consider the Iwasawa algebra  $\Lambda = \mathbb{Z}_p[1 + p\mathbb{Z}_p]$ . For any  $z \in 1 + p\mathbb{Z}_p$ , we denote by  $[z]_\Lambda$  the group-like element of  $\Lambda$  determined by z. For  $r \ge 1$ , let  $R_{N\ell^2p^r}$  be a sequence of nested Pizer orders on level  $N\ell^2p^r$ contained in the nested sequence of Eichler order  $R_{Np^r}$ . We consider the finite set

(3.10) 
$$
X_r = D^{\times} \backslash \widehat{D}^{\times} / U_1(R_{N\ell^2 p^r}),
$$

and let  $\mathcal{O}[X_r]$  be the finitely generated  $\mathcal{O}\text{-module spanned by divisors on }X_r$ . The Iwasawa algebra  $\Lambda$ acts  $\mathbb{Z}_p$ -linearly on  $\mathcal{O}[X_r]$  via

(3.11) 
$$
[z]_{\Lambda} \cdot x = x(1, ..., 1, (\frac{z}{0}^0), 1, ...),
$$

for  $x \in X_r$ ,  $z \in 1 + p\mathbb{Z}_p$  and  $(1, \ldots, 1, \left(\begin{smallmatrix} z & 0 \\ 0 & z \end{smallmatrix}\right), 1, \ldots)$  the adèle with p-th component  $\left(\begin{smallmatrix} z & 0 \\ 0 & z \end{smallmatrix}\right)$ .

<span id="page-16-3"></span>**Definition 3.7** (Algebraic quaternionic modular forms). Let  $\chi$  be a Dirichlet character of conductor dividing  $N \ell p^r$ . We define the space of *algebraic quaternionic modular forms* of level  $R_{N \ell^2 p^r}$ , weight k and character  $\chi$  as the finite  $\Lambda$ -module

$$
\mathbb{S}_{k}^{D}(R_{N\ell^{2}p^{r}},\chi)=\left\{f\in\text{Hom}_{\text{cts}}(\mathcal{O}[X_{r}],L_{k-2}(\overline{\mathbb{Q}_{p}}))\,\middle|\,\begin{array}{c}f(xzr)=(\chi_{\mathbb{A}})^{-1}(z)\widetilde{\chi}(r)f(x)\\ \text{for all }z\in\mathbb{A}_{f}^{\times},\,r\in\widehat{R}_{N\ell^{2}p^{r}}^{\times}\end{array}\right\}.
$$

Recall that any  $\varphi \in S_k^D(R_{N\ell^2p^r},\chi)$  is not  $U_1(R_{N\ell^2p^r})$ -invariant but only  $U_1(R_{N\ell^2p^r})^{(p)}$ -invariant. The relation between  $\mathbb{S}_k^D(R_{N\ell^2p^r}, \chi)$  and  $S_k^D(R_{N\ell^2p^r}, \chi)$  is made clear via the association

(3.12) 
$$
S_k^D(R_{N\ell^2p^r}, \chi) \ni \varphi(x) \longmapsto f(x) = x_p \cdot \varphi(x) \in \mathbb{S}_k^D(R_{N\ell^2p^r}, \chi).
$$

**Remark 3.8.** We will define Hecke operators on  $\mathbb{S}_k^D(R_{N\ell^2p^r},\chi)$  momentarily (cf. Section [3.5.1\)](#page-16-1). For now, let us mention that the  $\Lambda$ -action on the space of quaternionic modular forms  $S_k^D(R_{N\ell^2 p^r}, \chi)$  takes the form of

<span id="page-16-2"></span>(3.13) 
$$
[z]_{\Lambda} \cdot \varphi(x) = z \cdot \varphi(x(1,\ldots,1,(\begin{array}{l} z & 0 \\ 0 & z \end{array}),1,\ldots)) = (\chi_{\mathbb{A},p})^{-1}(z) \varphi(x),
$$

<span id="page-16-0"></span>In other words, we can think of the  $\Lambda$ -action as a diamond operator at the prime p.

## <span id="page-16-1"></span>3.5. Operators on quaternionic modular forms.

3.5.1. Hecke operators. As in the usual setting of classical modular forms, one can define Hecke operators acting on the space of quaternionic modular forms. These are easily defined taking into account the adèlic description of these forms; for any prime  $q \neq \ell$ , let  $\varsigma_q \in \mathbb{A}_f^{\times}$  be the element characterized by  $\varsigma_{q,q} = q$  and 1 at other places. Let A be again a  $\mathbb{Z}_p$ -algebra and let  $\varphi \in S_k^D(R_{N\ell^2}, \chi, A)$ . For any  $\hat{d} \in \widehat{D}^{\times}$ , the Hecke operator  $T_q$  is determined by

(3.14) 
$$
T_q \varphi(\hat{d}) = \begin{cases} \varphi\left(\hat{d}\begin{pmatrix} 1 & 0 \\ 0 & \varsigma_q \end{pmatrix}\right) + \sum_{a \in \mathbb{Z}/q\mathbb{Z}} \varphi\left(\hat{d}\begin{pmatrix} \varsigma_q & a \\ 0 & 1 \end{pmatrix}\right) & \text{for each prime } q \nmid N\ell^2, \\ \varphi|_{\begin{pmatrix} 1 & 0 \\ 0 & p \end{pmatrix}} \left(\hat{d}\begin{pmatrix} 1 & 0 \\ 0 & \varsigma_p \end{pmatrix}\right) + \sum_{a \in \mathbb{Z}/q\mathbb{Z}} \varphi|_{\begin{pmatrix} p & a \\ 0 & 1 \end{pmatrix}} \left(\hat{d}\begin{pmatrix} \varsigma_p & a \\ 0 & 1 \end{pmatrix}\right) & \text{for } q = p \text{ and } p \nmid N, \end{cases}
$$

while the Hecke operator  $U_q$  is

(3.15) 
$$
U_q \varphi(\hat{d}) = \begin{cases} \sum_{a \in \mathbb{Z}/q\mathbb{Z}} \varphi\left(\hat{d}\begin{pmatrix} \zeta_q & a \ 0 & 1 \end{pmatrix} \right) & \text{for } q \mid N, \\ \sum_{a \in \mathbb{Z}/p\mathbb{Z}} \varphi|_{\left(\begin{matrix} p & a \ 0 & 1 \end{matrix}\right)} \left(\hat{d}\begin{pmatrix} \zeta_p & a \ 0 & 1 \end{pmatrix} \right) & \text{for } q = p \text{ and } p \mid N. \end{cases}
$$

#### Remark 3.9.

- (1) In the case of a definite quaternion algebra, one can express the action of quaternionic Hecke operators via Brandt matrices. Via these matrices we can also define Hecke operators for the primes of ramification for the quaternion algebra. As Hecke operators are compatible with the Jacquet–Langlands correspondence (up to a sign at  $\ell$ ), applied to forms which are new at  $\ell$ ,  $U_{\ell}$ will be the zero-operator. We refer the interested reader to [\[Eic73\]](#page-66-15), [\[Piz77\]](#page-66-16), [\[Piz80b\]](#page-66-14) and [\[HPS89b\]](#page-66-17) for their precise definition.
- (2) We define an Atkin–Lehner operator in Definition [3.18,](#page-20-0) following [\[Piz80b\]](#page-66-14). One can find quaternionic analogues of the local Atkin–Lehner operators in Section 9 of loc. cit. and [\[Piz77\]](#page-66-16). For what concerns diamond operators, they can be defined as in [\[Hsi21,](#page-66-4) Section 4.4].

<span id="page-17-2"></span>(3) The first-named author wishes to remark that the definition of the  $U_{\ell}$  operator provided in [\[Dal23b\]](#page-65-6) is not correctly stated. As above, one should use Brandt matrices to define it and not the involution obtained by multiplication with an element of norm  $\ell$  in  $D_{\ell}^{\times}$ . This definition is correct for Eichler orders, as it coincides (up to a sign) with the Atkin–Lehner operator. The proofs and results contained in loc. cit. are unfazed by this misstated definition.

3.5.2. Multiplicity two. A peculiar property of Pizer orders of level  $N\ell^2$  is the failure of multiplicity one for Hecke-eigenspaces of quaternionic modular forms. This phenomenon has been extensively studied in both [\[Piz80b\]](#page-66-14) and [\[HPS89b\]](#page-66-17), and it can be summarized in the following proposition.

<span id="page-17-0"></span>**Proposition 3.10** (Pizer, Hijikata–Pizer–Shemanske). Let  $f \in S_k(\Gamma_1(N\ell^2), \chi)$ <sup>new</sup> be a Hecke-eigenform, twist-minimal at  $\ell$ . Suppose that the  $\ell$ -component of  $\chi$  has conductor cond $(\chi_{\ell}) \leq \ell$ . There is an isomorphism of Hecke-eigenspaces

$$
S_k^D(R_{N\ell^2}, \chi, \mathbb{Q}_p(f))[f] = S_k(N\ell^2, \chi)[f]^{\oplus 2}.
$$

In particular, the Hecke-eigenspace  $S_k^D(R_{N\ell^2}, \chi, \mathbb{Q}_p(f))[f]$  is two-dimensional.

Remark 3.11. The Jacquet–Langlands correspondence associates to any automorphic representation  $\pi_D$  of  $D^{\times}(\mathbb{A})$  an automorphic representation  $\pi$  of  $GL_2(\mathbb{A})$ . By Strong Multiplicity One for  $GL_2$  and its inner forms, there cannot be two different automorphic representations  $\pi_D$  and  $\pi'_D$  of  $D^{\times}(\mathbb{A})$  that correspond to the same automorphic representation  $\pi$  of  $GL_2(\mathbb{A})$ . Proposition [3.10](#page-17-0) is therefore about automorphic forms, i.e. elements of  $\pi_D$  and  $\pi$ .

For GL<sub>2</sub>(A), there is a well-known theory of newforms: there is a compact open subgroup  $K_\pi \subseteq$  $GL_2(\mathbb{A}_f)$  such that  $\dim \pi_f^{K_{\pi}} = 1$ . This is no longer the case for  $D^{\times}(\mathbb{A})$ ; in fact, underlying Proposi-tion [3.10](#page-17-0) is the fact that  $\dim \pi_{D,f}^{R_{N\ell^2}^{\times}} = 2$ , which was observed locally at the prime  $\ell$  in Proposition [2.5.](#page-9-0)

3.5.3. An extra operator. Using the methods of Section [2,](#page-6-0) we can define an extra operator acting on the space of A-valued quaternionic modular forms  $S_k^D(R_{N\ell^2}, \chi, A)$ ; its nature is local, arising from the structure of the order at the prime of ramification  $\ell$ .

With a slight change of notation from Section [2,](#page-6-0) let  $\varpi_D$  be the element in  $\widehat{D}^{\times}$  defined as

$$
\varpi_D=(1,\ldots,1,\varpi_{D_\ell},1,\ldots),
$$

for  $\varpi_{D_\ell}$  a quaternionic uniformizer of  $D_\ell/\mathbb{Q}_\ell$ ; note that  $N_{\mathbb{Q}_\ell(\varpi_{D_\ell})/\mathbb{Q}_\ell}(\varpi_{D_\ell}) = \varpi_{\mathbb{Q}_\ell}$  for a uniformizer of  $\mathbb{Q}_{\ell}$ . We will choose  $\varpi_{D_{\ell}}$  so that  $\varpi_{D_{\ell}}^2 = \ell$ . Equivalently, we are fixing our chosen ramified quadratic extension  $\mathbb{Q}_{\ell}(\varpi_{D_{\ell}})$  to be  $\mathbb{Q}_{\ell}(\sqrt{\ell})$ . Notice that one can fix another choice of uniformizer and, mutatis mutandis, all the results in this section and in Section [4](#page-22-0) are similarly obtained.

**Definition 3.12.** We define the operator  $\langle \varpi_{D_{\ell}} \rangle$  on the space  $S_k^D(R_{N_{\ell^2}}, \chi, A)$  as

$$
\langle \varpi_{D_{\ell}} \rangle \varphi(\hat{d}) = \varphi \left( \hat{d} \varpi_D \right).
$$

### <span id="page-17-1"></span>Proposition 3.13.

(1) Iterating  $\langle \varpi_{D_{\ell}} \rangle$  twice, one has

$$
\langle \varpi_{D_{\ell}} \rangle^2 \varphi(\hat{d}) = \varphi \left( \hat{d} \left( 1, \ldots, 1, \varpi_{D,\ell}^2, 1, \ldots \right) \right) = \chi_N(\ell)^{-1} \varphi(\hat{d}).
$$

(2) The operator  $\langle \varpi_{D_\ell} \rangle$  commutes with the Hecke-operators.

*Proof.* We notice that  $(1, \ldots, 1, \ell, 1, \ldots) \in \mathbb{A}_f^{\times}$ , and

$$
\chi_{\mathbb{A}}^{-1}(\ell) = 1 = \chi_{\ell,\mathbb{A}}^{-1}((1,\ldots,1,\ell,1,\ldots))\,\chi_{N,\mathbb{A}}^{-1}((\ell,\ldots,\ell,1,\ell,\ldots)),
$$

hence

$$
\chi_{\ell,\mathbb{A}}^{-1} ((1,\ldots,1,\ell,1,\ldots)) = \chi_{N,\mathbb{A}} ((\ell,\ldots,\ell,1,\ell,\ldots)) = \chi_N^{-1}(\ell).
$$

<span id="page-18-2"></span>Both statements follow now from the definitions of  $\langle \varpi_{D_\ell} \rangle$ , quaternionic modular forms, and Hecke  $\phi$  operators away from  $\ell$ .

The choice of the notation  $\langle \varpi_{D_\ell} \rangle$  is justified by the above proposition; this extra operator is closer to a diamond operator than a replacement for the Hecke operator at  $\ell$ . Let us remark that  $\chi_N^{-1}$  evaluated at  $\ell$  coincides with the evaluation at the same integer of the adèlization of the character  $\chi_{\ell}$ ; this follows by the definition of the adèlization as the rational elements not prime to the conductor are mapped to 1.

<span id="page-18-0"></span>**Proposition 3.14.** Let  $f \in S_k(\Gamma_1(N\ell^2), \chi)$ <sup>new</sup> be a Hecke-eigenform, twist-minimal at  $\ell$ . As above, suppose that the  $\ell$ -component of  $\chi$  has conductor cond $(\chi_{\ell}) \leq \ell$ . The two-dimensional Hecke-eigenspace  $S_k^D(R_{N\ell^2}, \chi, A)[f]$  decomposes into one-dimensional eigenspaces under the action of  $\langle \varpi_{D_\ell} \rangle$ ,

$$
S_k^D(R_{N\ell^2}, \chi, A)[f] = S_k^D(R_{N\ell^2}, \chi, A)[f]^{\langle \varpi_{D_\ell} \rangle = +\sqrt{\chi_N^{-1}(\ell)}} \oplus S_k^D(R_{N\ell^2}, \chi, A)[f]^{\langle \varpi_{D_\ell} \rangle = -\sqrt{\chi_N^{-1}(\ell)}}.
$$

*Proof.* Let  $\pi_f$  be the automorphic representation associated with f and consider  $\pi_{f,\ell}$  its local component at  $\ell$ . By definition of automorphic forms, the quaternionic modular forms in  $S_k^D(R_{N\ell^2}, \chi, A)[f]$ correspond to (semi-)invariant vectors in the automorphic representation  $\pi_f^D$ , obtained as the Jacquet-Langlands transfer of  $\pi_f$ . In other words, we can identify  $S_k^D(R_{N\ell^2}, \chi, A)[f]$  with the space  $(\pi_f^D)^{R^{\times}}$  of (semi-)invariant vectors. By definition, the action of the operator  $\langle \varpi_{D_\ell} \rangle$  is local on the representation  $\pi^D_{f,\ell}$  and it acts as the local uniformizer  $\varpi_{D_\ell}$ . Since the representation  $\pi^D_{f,\ell}$  is a twist-minimal smooth representation of  $D_{\ell}^{\times}$  of conductor 2, we can apply Proposition [2.5](#page-9-0) and conclude the proof. Notice that the central character of  $\pi_f$  is (up to the archimedean component) the adèlization of the character  $\chi$ , thus, the central character of  $\pi_{f,\ell}$  at  $\ell$  coincides with  $\chi_{\mathbb{A},\ell}((1,\ldots,1,\ell,1,\ldots)) = \chi_N^{-1}(\ell)$ .

#### <span id="page-18-1"></span>Remark 3.15.

- (1) The result of Lemma [3.14](#page-18-0) depends only on the local representation at  $\ell$ , more precisely, on its automorphic type and its minimal conductor.
- (2) The local automorphic type, the conductor and the twist-minimality property are rigid in  $p$ -adic Hida families of modular forms (see [\[FO12,](#page-66-18) Lemma 2.14] and [\[Hsi21,](#page-66-4) Remark 3.1]).
- (3) If one considers more general quaternion algebras, the multiplicity will be given by

$$
\prod_{\substack{\ell \in \text{Ram}(D) - \{\infty\}: \\ \text{cond}_{\ell}(\pi) = \ell^2}} 2.
$$

Therefore, considering a  $\langle \varpi_{D_\ell} \rangle$ -operators for each  $\ell \in \text{Ram}(D) - \{\infty\}$ , one can recover multiplicity one for quaternionic modular forms.

(4) In the case  $\chi = 1$ , one can define a whole set of operators, defining a dihedral group of order  $2(\ell+1)$ , as in [\[Piz80b,](#page-66-14) Section 9]. Among these, by our analysis in Section [2,](#page-6-0) one can recognize the operator  $\langle \varpi_{D_{\ell}} \rangle$ , the Atkin–Lehner operator, and a few mysterious others arising from the local structure of the order. The indefinite setting has been studied in [\[dVP13\]](#page-66-19).

Our analysis is partially motivated by the explicit work of Pizer [\[Piz80b\]](#page-66-14), where the study of Pizer orders is addressed with a more elementary flavor; in particular, the above lemma provides a more explicit take on the conductor  $\ell^2$  case of the statements contained in [\[HPS89b,](#page-66-17) Section 9]. Moreover, if the central character is trivial, we recover the setting studied by Pizer. Even though the authors of loc. cit. observed and studied the higher multiplicity phenomenon without addressing how to recover one-dimensional eigenspaces, their explicit work has been a key input for our results. It also helped us to implement the operator  $\langle \varpi_{D_\ell} \rangle$  in Pizer's setting in magma [\[BCP97\]](#page-65-11). Our implementation can be found at [\[1\]](#page-66-20) and we use it to compute a first example below.

<span id="page-19-6"></span>**Example 3.16.** With the above notations, take  $\ell = 7$  and let  $f \in S_2(\Gamma_0(7^2))^{\text{new}}$ , be the unique newform of level of level  $7^2$  and trivial character. In [\[HPS89b,](#page-66-17) Example 10.5], the authors compute that the feigenspace of quaternionic modular forms of weight 2, level  $7<sup>2</sup>$  and trivial character, is generated by two forms, namely  $\varphi_1$  and  $\varphi_2$ , whose values on the ideal classes are

$$
\varphi_1 \longleftrightarrow (1, -1, 0, 0)^t, \qquad \varphi_2 \longleftrightarrow (0, 0, 1, -1)^t.
$$

Since the character is trivial, the eigenvalues of the operator  $\langle \varpi_{D_\ell} \rangle$  are  $\pm 1$ . Our implementation in magma yields the action of the  $\langle \varpi_{D_\ell} \rangle$ -operator as

$$
\langle \varpi_{D_7} \rangle \varphi_1 = \varphi_1, \qquad \langle \varpi_{D_7} \rangle \varphi_2 = -\varphi_2.
$$

,

Thus, we decompose

$$
S_2^D(R_{7^2})^{\text{new}}[f] = (S_2^D(R_{7^2})^{\text{new}}[f])^{\langle \varpi_{D_7} \rangle = +1} \oplus (S_2^D(R_{7^2})^{\text{new}}[f])^{\langle \varpi_{D_7} \rangle = -1}
$$
  
for  $(S_2^D(R_{7^2})^{\text{new}}[f])^{\langle \varpi_{D_7} \rangle = +1} = \langle \varphi_1 \rangle$  and  $(S_2^D(R_{7^2})^{\text{new}}[f])^{\langle \varpi_{D_7} \rangle = -1} = \langle \varphi_2 \rangle$ .

<span id="page-19-5"></span>For completeness, we conclude this section with an observation on the action of the operator  $\langle \varpi_{D_\ell} \rangle$ on forms which are  $\ell$ -new but *not* twist-minimal at the same prime.

**Lemma 3.17.** The  $\langle \varpi_{D_\ell} \rangle$ -eigenvalue on the space  $S_k^D(Np^n\ell^2, \chi)$  is  $\pm \sqrt{\chi_{\mathbb{A},Np^n}(\ell)^{-1}}$ .

*Proof.* Once again, looking at the local description. If  $\pi_{\ell}$  is an admissible irreducible representation of  $D_{\ell}^{\times}$  of conductor 1, then it is (inflated from) a character  $\pi_{\ell}$ :  $\langle \varpi_{D_{\ell}} \rangle \to \mathbb{C}^{\times}$ . In particular, it is determined by  $\pi_{\ell}(\varpi_{D_{\ell}})$  and once again  $\pi_{\ell}(\varpi_{\ell}^2) = \pi(\varpi_{\mathbb{Q}_{\ell}})^2 = \chi(\varpi_{\mathbb{Q}_{\ell}})^2$ .

<span id="page-19-3"></span>3.5.4. Λ-action and operators. Recall the notation introduced in Section [3.4.3;](#page-15-0) equation [\(3.13\)](#page-16-2) shows that the  $\Lambda$ -action commutes with Hecke operators and also with the  $\langle \varpi_{D_\ell} \rangle$ -operators. Considering the Λ-action on quaternionic modular forms is critical for ensuring the necessary properties of the morphisms between eigenvarieties we construct in Section [4.1.](#page-22-1) More precisely, we make use of the relation

<span id="page-19-2"></span>(3.17) 
$$
\langle \varpi_{D_{\ell}} \rangle^2 \varphi = \chi_{\mathbb{A}, \ell}(\ell) \, [\langle \ell \rangle]_{\Lambda} \cdot \varphi,
$$

<span id="page-19-0"></span>for  $\langle \ell \rangle \in 1 + p\mathbb{Z}_p$  the image of  $\ell$  under the projection  $\langle \cdot \rangle : \mathbb{Z}_p^{\times} \longrightarrow 1 + p\mathbb{Z}_p$ .

3.6. Pairings. We introduce here the general setting we deal with in Sections [4](#page-22-0) and [5.](#page-33-0) Let D be a definite quaternion algebra over  $\mathbb{Q}$ ; it is ramified at an odd number of primes  $\ell \mid \text{disc}(D)$ , for  $\text{disc}(D)$  the discriminant of D. We denote by  $R_{N_+,N_-}$  a fixed Pizer order of level  $N_+N_-$ , with  $N_- = N_-^{\text{sp}} N_-^{\text{sc}}$ , such that

<span id="page-19-1"></span>(3.18) 
$$
(N_+,\text{disc}(D))=1,
$$
  $(N_-^{\text{sp}}, N_-^{\text{sc}})=1,$   $N_-^{\text{sp}}||\text{disc}(D),$   $N_-^{\text{sc}}||\text{disc}(D)^2.$ 

We will occasionally simplify this notation to  $R_N = R_{N_+,N_-}$  where  $N = N_+N_-$ . The notation refers to the local factors of the corresponding representations of  $GL_2(\mathbb{A})$ : they are special at primes dividing  $N_-^{\text{sp}}$  and supercuspidal at primes dividing  $N_-^{\text{sc}}$ . As discussed above, we need the extra operator  $\langle \varpi_{D_\ell} \rangle$  at primes  $\ell | N_{-}^{\rm sc}$ . We remark that  $(N_{-}^{\rm sp})^2 N_{-}^{\rm sc} = \text{disc } D^2$ . Moreover, we fix  $\chi$  to be a Dirichlet character of conductor  $c \mid N_+N_-,$  and a weight  $k \in \mathbb{Z}_{\geq 2}$ .

<span id="page-19-4"></span>3.6.1. The quaternionic Petersson product. We recall here the definition of the Petersson product between quaternionic modular forms; our definition extends the one provided in [\[Hsi21,](#page-66-4) Section 4.2]. Fol-lowing [\[GS20,](#page-66-3) Section 2.1], we consider the *p*-adic norm form  $N_p: D^{\times} \backslash D^{\times} \longrightarrow \mathbb{Z}_p^{\times}$  given by

(3.19) 
$$
N_p(-) = (|\nu_{\mathbb{A}_f}(-)|_{\mathbb{A}_f} \nu_{\mathbb{A}_f}(-))_p,
$$

for  $(-)_p : \mathbb{A}_f^{\times} \longrightarrow \mathbb{Q}_p^{\times}$ , the projection to the p-component. In other words,  $N_p$  is defined as the pcomponent of the normalization of the reduced norm by the adèlic absolute value. With the notation of <span id="page-20-1"></span>[\[Hsi21,](#page-66-4) Section 4.2], we denote the *p-adic cyclotomic character* by  $\varepsilon_{cyc}$ ; this is the character

(3.20) 
$$
\varepsilon_{cyc} : \mathbb{Q}_+ \backslash \mathbb{A}_f^{\times} \longrightarrow \mathbb{Z}_p^{\times} a \mapsto (|a|_{\mathbb{A}_f} a)_p = |a|_{\mathbb{A}_f} a_p.
$$

Therefore,  $N_p = \varepsilon_{cyc} \circ \nu_{\mathbb{A}_f}$ , as the quaternion algebra D is definite.

We consider the pairing

(3.21) 
$$
(-,-)_{N_+,N_-}: S_k^D(R_{N_+,N_-}, \chi) \times S_k^D(R_{N_+,N_-}, \chi^{-1}) \longrightarrow \overline{\mathbb{Q}_p},
$$

given by

(3.22) 
$$
(\varphi_1, \varphi_2)_{N_+, N_-} = \sum_{[x] \in D^\times \backslash \widehat{D}^\times / \widehat{R}_{N_+, N_-}^\times} \frac{N_p(x)^{k-2}}{\# \Gamma_{N_+, N_-}(x)} \langle \varphi_1(x), \varphi_2(x) \rangle_{k-2},
$$

where  $\Gamma_{N_+,N_-}(x) = (D^{\times} \cap xR_{N_+,N_-}^{\times}x) \mathbb{Q}^{\times}/\mathbb{Q}^{\times}$  and

(3.23) 
$$
\langle -, - \rangle_{k-2} : L_{k-2}(\overline{\mathbb{Q}_p}) \times L_{k-2}(\overline{\mathbb{Q}_p}) \longrightarrow \overline{\mathbb{Q}_p}
$$

is the paring defined by

(3.24) 
$$
\langle X^{i}Y^{k-2-i}, X^{j}Y^{k-2-j} \rangle_{k-2} = \begin{cases} (-1)^{i} {k-2 \choose i}^{-1} & \text{if } i+j=k-2, \\ 0 & \text{if } i+j \neq k-2. \end{cases}
$$

For any  $g \in GL_2(\overline{\mathbb{Q}_p})$ , let  $\bar{g} = \det(g)g^{-1}$  be its image under the canonical involution on  $GL_2(\overline{\mathbb{Q}_p})$ . Given such g and any  $P, Q \in L_{k-2}(\overline{\mathbb{Q}_p}),$  we have:

(3.25) 
$$
\langle g \cdot P, Q \rangle_{k-2} = \langle P, \overline{g} \cdot Q \rangle_{k-2}.
$$

That implies that the pairing  $(-, -)_{N_+,N_-}$  is well defined, as

$$
N_p(xr)^{k-2} \langle \varphi_1(xr), \varphi_2(xr) \rangle_{k-2} = N_p(x)^{k-2} \nu_p(r_p)^{k-2} \langle r_p^{-1} \cdot \varphi_1(x), r_p^{-1} \cdot \varphi_2(x) \rangle_{k-2}
$$
  
\n(3.26)  
\n
$$
= \nu_p(r_p)^{k-2} \nu_p(r_p^{-1})^{k-2} N_p(x)^{k-2} \langle \varphi_1(x), \varphi_2(x) \rangle_{k-2}
$$
  
\n
$$
= N_p(x)^{k-2} \langle \varphi_1(x), \varphi_2(x) \rangle_{k-2},
$$

for  $r \in R_{N_+,N_-}^{\times}$  and  $[x] \in D^{\times} \backslash D^{\times}/R_{N_+,N_-}^{\times}$ .

<span id="page-20-0"></span>**Definition [3.1](#page-12-1)8.** With the notation of Section 3.1 (cf. also [\[Piz80b,](#page-66-14) Section 9]), let  $\tau_{N_+,N_-}^D \in \widehat{D}^\times$  the element determined by

$$
\tau_{N_+,N_-,q}^D = \begin{cases} 1 & \text{if } q \nmid N_+,N_-, \\ \iota_q^{-1}\left( \left(\begin{smallmatrix} 0 & \text{if } q \mid N_+,N_-, \\ \\ 1 & \text{if } q \mid N_+^*, \end{smallmatrix}\right) \right) & \text{if } q \mid N_+, \\ 1 & \text{if } q \mid N_-^{\text{sp}}, \\ \varpi_{\mathbb{Q}_{\ell^2}} & \text{if } q = \ell \mid N_-^{\text{sc}}. \end{cases}
$$

We define the Atkin–Lehner operator

$$
[\tau_{N_+,N_-}^D] : S_k^D(R_{N_+,N_-}, \chi) \longrightarrow S_k^D(R_{N_+,N_-}, \chi^{-1}),
$$

as

$$
[\tau_{N_+,N_-}^D]\,\varphi(x)=\tau_{N_+,N_-,p}^D\cdot\varphi(x\tau_{N_+,N_-}^D)\,\chi_{\mathbb{A}}(\nu(x)).
$$

Lemma 3.19. The Atkin-Lehner operator is a well-defined involution.

<span id="page-21-1"></span>*Proof.* It is easy to notice that the level of  $[\tau_{N_+,N_-}^D] \varphi$  is still  $R_{N_+,N_-}$ , but we need to check that its character is  $\chi^{-1}$ . Given  $r \in \widehat{R}_{N_+,N_-}^{\times}$ , we compute

$$
([\tau_{N_+,N_-}^D]\varphi)(xr) = \tau_{N_+,N_-,p}^D \cdot \varphi(x \, r \, \tau_{N_+,N_-}^D) \, \chi_{\mathbb{A}}(\nu(x)) \, \chi_{\mathbb{A}}(\nu(r)).
$$

We must only check the primes  $\ell \mid N_{-}^{\text{sc}}$ , as the local behavior at the other primes is the one of the usual Atkin–Lehner operator. Let  $\ell$  be such a prime. With the formalism of Section [3.1,](#page-12-1) we note that, for  $r = x + \varpi_{\mathbb{Q}_{\ell^2}} y + \varpi_{D_\ell} z \in R_\ell^\times$ , with  $x, y \in \mathbb{Z}_\ell$  and  $z \in \mathcal{O}_{D_\ell}$ ,

$$
r\varpi_{\mathbb{Q}_{\ell^2}}=x\varpi_{\mathbb{Q}_{\ell^2}}+\varpi_{\mathbb{Q}_{\ell^2}}y\varpi_{\mathbb{Q}_{\ell^2}}+\varpi_{D_\ell}z\varpi_{\mathbb{Q}_{\ell^2}}=\varpi_{\mathbb{Q}_{\ell^2}}(x-y\varpi_{\mathbb{Q}_{\ell^2}})+\varpi_{D_\ell}z\varpi_{\mathbb{Q}_{\ell^2}}.
$$

Therefore,  $r\varpi_{\mathbb{Q}_{\ell^2}} \equiv \varpi_{\mathbb{Q}_{\ell^2}} r \pmod{\varpi_{D_\ell} O_{D_\ell}}$ , hence  $\widetilde{\chi}_{\ell}(r \varpi_{\mathbb{Q}_{\ell^2}}) = \widetilde{\chi}_{\ell}(\varpi_{\mathbb{Q}_{\ell^2}} r)$ . As

$$
\varpi_{\mathbb{Q}_{\ell^2}}R_{N_+,N_-,\ell}=R_{N_+,N_-,\ell}\,\varpi_{\mathbb{Q}_{\ell^2}}
$$

we deduce that the operator is well defined, and inverting the character. We conclude noticing that  $[\tau_{N_+,N_-}^D][\tau_{N_+,N_-}^D]\,\varphi(x)=(\tau_{N_+,N_-,p}^D)^2\cdot \varphi\left(x(\tau_{N_+,N_-}^D)^2\right),$  and

$$
(\tau_{N_+,N_-,q}^D)^2 = \begin{cases} 1 & \text{if } q \nmid N_+,N_-, \\ -q^{v_q(N_+,N_-)} & \text{if } q \mid N_+, \\ 1 & \text{if } q \mid N_-^{\text{sp}}, \\ \varpi_{\mathbb{Q}_{\ell^2}}^2 & \text{if } q = \ell \mid N_-^{\text{sc}}. \end{cases}
$$

<span id="page-21-0"></span>Therefore,  $(\tau_{N_+,N_-,q}^D)^2 \in \mathbb{Z}_q$ , for each q.

Proposition 3.20. The pairing

$$
\langle -, - \rangle_{N_+, N_-}: S_k^D(R_{N_+, N_-}, \chi) \times S_k^D(R_{N_+, N_-}, \chi) \longrightarrow \overline{\mathbb{Q}_p}
$$

defined by  $\langle \varphi_1, \varphi_2 \rangle_{N_+,N_-} = (\varphi_1, [\tau^D_{N_+,N_-}] \varphi_2)_{N_+,N_-}$  is perfect and equivariant for both the action of the Hecke operators and of  $\langle \varpi_{D_{\ell}} \rangle$ .

Proof. The Hecke-equivariance follows exactly as in [\[Hsi21,](#page-66-4) Section 4.2] from [\[Hid06,](#page-66-21) Lemma 3.5]. Since  $\ell^2$ ||disc(D), it is not difficult to compute that  $\Gamma_{N_+,N_-}(x) = \Gamma_{N_+,N_-}(x \varpi_{D_\ell})$ . Writing temporarily  $X =$  $D^{\times}\langle D^{\times}/R_{N_{+},N_{-}}^{\times}$ , we have that:

$$
(\langle \varpi_{D_{\ell}} \rangle \varphi_{1}, \varphi_{2})_{N_{+},N_{-}} = \sum_{[x] \in X} \frac{N_{p}(x)^{k-2}}{\# \Gamma_{N_{+},N_{-}}(x)} \langle \varphi_{1}(x), \tau_{N_{+},N_{-},p}^{D} \cdot \varphi(x\tau_{N_{+},N_{-}}^{D}) \chi_{\mathbb{A}}(\nu(x))_{N_{+},N_{-}} \rangle_{k-2}
$$
  
\n
$$
= \sum_{[x] \in X} \frac{\chi_{\mathbb{A}}^{-1}(\nu(\varpi_{D_{\ell}})) N_{p}(x)^{k-2}}{N_{p}(\varpi_{D_{\ell}})^{k-2} \# \Gamma_{N_{+},N_{-}}(x)} \langle \varphi_{1}(x), \tau_{N_{+},N_{-},p}^{D} \cdot \varphi(x\varpi_{D_{\ell}}^{-1} \tau_{N_{+},N_{-}}^{D}) \chi_{\mathbb{A}}(\nu(x))_{N_{+},N_{-}} \rangle_{k-2}
$$
  
\n
$$
= \chi_{\mathbb{A}}^{-1}(\nu(\varpi_{D_{\ell}})) \sum_{[x] \in X} \frac{N_{p}(x)^{k-2}}{\# \Gamma_{N_{+},N_{-}}(x)} \langle \varphi_{1}(x), \tau_{N_{+},N_{-},p}^{D} \cdot \varphi(x\tau_{N_{+},N_{-},p}^{D} \varpi_{D_{\ell}} \nu(\varpi_{D_{\ell}})^{-1}) \chi_{\mathbb{A}}(\nu(x))_{N_{+},N_{-}} \rangle_{k-2}
$$
  
\n
$$
= (\varphi_{1}, \langle \varpi_{D_{\ell}} \rangle \varphi_{2})_{N_{+},N_{-}}
$$

where the second equality is obtained by the substitution  $x \mapsto x \varpi_{D_\ell}^{-1}$ , and we have used  $N_p(\varpi_{D_\ell})^{k-2} = 1$ and  $\varpi_{D_{\ell}}^{-1} \tau_{N_+,N_-,p}^D = \tau_{N_+,N_-,p}^D \varpi_{D_{\ell}}(-\varpi_{D_{\ell}}^{-2}) = \tau_{N_+,N_-,p}^D \varpi_{D_{\ell}} \nu(\varpi_{D_{\ell}})^{-1}$ .

3.6.2. Automorphic and quaternionic pairings. Let  $\chi_{\mathbb{A}}$  be the adèlization of  $\chi$  and  $R_{N_+,N_-}$  a Pizer order in D of level  $N_+N_-$ , we denote by  $\mathcal{A}_2^D(R_{N_+,N_-},\chi_{\mathbb{A}})$  the space of scalar-valued (i.e. weight 2) automorphic forms of level  $\hat{R}_{N_+,N_-}$  and character  $\chi_{\mathbb{A}}$ . For any two such forms  $f \in \mathcal{A}_2^D(R_{N_+,N_-},\chi_{\mathbb{A}})$  and  $f' \in \mathcal{A}_2^D(R_{N_+,N_-}, \chi_{\mathbb{A}}^{-1}),$  we define the pairing

(3.27) 
$$
\langle f, f' \rangle = \int_{\mathbb{A}^{\times} D^{\times} \setminus D(\mathbb{A})^{\times}} f(x) f'(x) dx
$$

<span id="page-22-3"></span>for dx the Tamagawa measure on  $\mathbb{A}^{\times} \backslash D(\mathbb{A})^{\times}$ .

Let  $\varphi \in S_k^D(R_{N_+,N_-}, \chi, \overline{\mathbb{Q}_p})$  be a quaternionic modular form of weight k and character  $\chi$ , and let u be a polynomial in  $L_{k-2}(\mathbb{C})$ . We can define the matrix coefficient  $\Phi_u(\varphi) \in \mathcal{A}_2^D(R_{N_+,N_-},\chi_{\mathbb{A}}^{-1})$  as  $\Phi_u(\varphi)(x) = \langle \Phi(\phi)(x), u \rangle_{k-2}$ , for any  $x \in D(\mathbb{A})^{\times}$  (recall equation [\(3.9\)](#page-15-1)). The above pairing is related to the one defined in Proposition [3.20](#page-21-0) via the following lemma.

<span id="page-22-2"></span>**Lemma 3.21.** Let  $\varphi$  be as above and consider u and v in  $L_{k-2}(\mathbb{C})$ . Hence,

$$
\langle [\tau_{N_+,N_-}^D] \Phi_u(\varphi), \Phi_v(\varphi) \rangle = \frac{\text{vol}(R_{N_+,N_-}^{\times})}{\left(N_+ N_-^{\text{sc}}\right)^{(k-2)/2} (k-1)} \langle \varphi, \varphi \rangle_{N_+,N_-} \langle u, v \rangle_{k-2}.
$$

Before proving the lemma, we remark that if R is an Eichler order of level  $N_{+}$ , the Atkin–Lehner operator becomes  $\tau_{N_+,1}^D$ , and we recover the formula in [\[Hsi21,](#page-66-4) equation (4.5)].

Proof of Lemma [3.21.](#page-22-2) This is an application of Schur orthogonality relations for linear pairings once we split the integration over  $\mathbb{A}^{\times}D^{\times}\backslash D(\mathbb{A})^{\times} = \mathbb{A}_f^{\times}D^{\times}\backslash D^{\times} \times \mathbb{R}^{\times}\backslash D_{\infty}^{\times}$ . More precisely, one can proceed as in the proof of [\[GS20,](#page-66-3) Lemma 3.2], obtaining

$$
\langle \chi_{\mathbb{A}} \, \Phi_u(\varphi), \Phi_v(\varphi) \rangle = \frac{\text{vol}(R^{\times}_{N_+,N_-})}{(k-1)} \, \langle \chi_{\mathbb{A}} \, \varphi, \varphi \rangle_{N_+,N_-} \, \langle u, v \rangle_{k-2}.
$$

The factor  $\nu \left( \tau_{N_+,N_-}^D \right)$  $\int_{0}^{(k-2)/2}$  arises from the definition of the isomorphism f in [\[GS20,](#page-66-3) equation (16)]; one must notice that they work with automorphic forms valued in the dual space  $(L_{k-2}(\mathbb{C}))^{\vee}$ , so their action at  $\infty$  is obtained by inverting  $x_{\infty}$ . Expressing everything under our definitions and our choices of normalizations we obtain the stated equality. We conclude noticing that  $\nu$   $\left(\tau_{N_+,N_-}^D\right)$  $\Big) = N_+ N_-^{\text{sc}}. \qquad \blacksquare$ 

## 4. The JL correspondence in families

<span id="page-22-0"></span>As in Section [3.6,](#page-19-0) we take D and  $R_{p^nN_+,N_-}$  for  $n \in \mathbb{Z}_{\geq 0}$  and  $p \geq 5$  a prime with  $(p, N_+N_-) = 1$ , satisfying the conditions in equation [\(3.18\)](#page-19-1). We also fix a Dirichlet character  $\chi$  of conductor  $c \mid N_+N_$ and assume that, for all primes  $q \mid N_-,$ 

(4.1) 
$$
v_q(c) = v_q(N_-^{\text{sp}}) - 1 = 0
$$
, if  $q \mid N_-^{\text{sp}}$ , and  $v_q(c) \le v_q(N_-^{\text{sc}}) - 1 = 1$  if  $q \mid N_-^{\text{sc}}$ .

This section is devoted to the study of quaternionic  $p$ -adic Hida families, with level structure given by such Pizer orders. Our eventual goal is to study a Jacquet–Langlands transfer in families for Coleman/Hida families on  $GL_2$  of level N. We show that for any collection of signs  $\epsilon_\ell$  for each  $\ell|N_{-}^{sc}$ corresponding to eigenvalues of  $\langle \varpi_{D_\ell} \rangle$ , there is a Coleman/Hida family on  $D^\times$  that transfers to a given Coleman/Hida family on GL2. To that effect, we study eigenvarieties for the Hecke algebra augmented by the extra operators  $\langle \varpi_{D_\ell} \rangle$ , and obtain an open immersion of eigenvarieties á la Chenevier [\[Che04\]](#page-65-12). The main tool is therefore Chenevier's interpolation technique, adjusted for dealing with this more general setup. We conclude with a control theorem in the spirit of Hida (see Corollary [4.28\)](#page-33-1).

The main reference for this section is Bellaiche's book [\[Bel21\]](#page-65-13), together with [\[Buz07\]](#page-65-14), [\[Che04\]](#page-65-12), and [\[Lud17\]](#page-66-22). We try to keep the discussion as brief as possible; we recall only the necessary notions and definitions, and provide references where details can be found.

<span id="page-22-1"></span>4.1. **Eigenvarieties.** Let W denote the weight space, i.e. the rigid analytic space over  $\mathbb{Q}_p$  whose  $\overline{\mathbb{Q}_p}$ points are

(4.2) 
$$
\mathcal{W}(\overline{\mathbb{Q}_p}) = \text{Hom}_{\text{cts}}(\mathbb{Z}_p^{\times}, \overline{\mathbb{Q}_p}^{\times}).
$$

We freely identify any  $\mathbb{Q}_p$ -point  $\kappa \in \mathcal{W}(\mathbb{Q}_p)$  with the corresponding character of  $\mathbb{Z}_p^{\times}$ . The space W is endowed with an admissible covering  $\mathscr C$  by admissible affinoid open subsets, as constructed in [\[Buz07,](#page-65-14) Section 6; in loc. cit. the covering is considered on the Fredholm variety, while here we prefer to deal <span id="page-23-1"></span>only with the weight space, as in [\[Bel21\]](#page-65-13), out of convenience of exposition. For any  $X = Sp(A) \in \mathscr{C}$ , we consider the space of cuspidal overconvergent  $p$ -adic modular forms as defined in  $\left[\text{Buz07}, \text{Section}\right]$ 6] and denote it by  $\mathbb{S}_{N+N-1,\chi}^{\dagger}(X)$  (in loc. cit.  $\mathbb{S}_{N+N-1,\chi}^{\dagger}(X_n)$  is denoted by  $M_n$ , for  $X_n \in \mathscr{C}$ ). This is a Banach A-module and satisfies Property (Pr) as in [\[Bel21,](#page-65-13) Section 3.1.6]. Similarly, we consider the space of cuspidal overconvergent p-adic quaternionic modular forms as defined in  $\left[\text{Buz07}, \text{Section 9}\right]$ , and denote it by  $\mathbb{S}_{N+N-, \chi}^{D, \dagger}(X)$  (in loc. cit.  $\mathbb{S}_{N+N-, \chi}^{D, \dagger}(X_n)$  is denoted by  $\mathbf{S}_{\kappa}^{D}(U; r)$ , for  $\kappa$  and  $r$  associated with  $X_n \in \mathscr{C}$ ; once again, this space is a Banach A-module and satisfies *Property* (Pr). In order to keep the discussion of this section brief, we opt to not recall the precise definition of overconvergent automorphic forms and instead refer the interested reader to [\[Buz07\]](#page-65-14) and [\[Che04\]](#page-65-12). Let us remark that this decision will not compromise the proofs of the main results as they rely only on properties and operators on classical automorphic forms.

We are interested in the eigenvectors of  $\langle \varpi_{D_{\ell}} \rangle$ , for each  $\ell \mid N_{-}^{\text{sc}}$ ; therefore, we fix once and for all a square root

(4.3) 
$$
\sqrt{\chi_{\mathbb{A},N+N-}/\ell^2(\ell)^{-1}},
$$

which we call the *positive* square root of  $\chi_{\mathbb{A},N+N-}/\ell^2(\ell)^{-1}$ . We consider the field extension

(4.4) 
$$
\mathcal{K} = \mathbb{Q}_p \left( \left\{ \sqrt{\chi_{\mathbb{A}, N_+N_-/\ell^2}(\ell)^{-1}} \right\}_{\ell|N_-^{\text{sc}}} \right)
$$

and let  $O$  be its ring of integers. Moreover, let  $I' = O[1 + p\mathbb{Z}_p]$  be the corresponding finite extension of the Iwasawa algebra  $\Lambda$ . As we will make use of equation [\(3.17\)](#page-19-2), we need to extend  $\mathbf{I}'$ , adjoining the square roots of  $[\langle \ell \rangle]_{\mathbf{I}'}$ ; we set

(4.5) 
$$
\mathbf{I} = \mathbf{I}' \left[ \left\{ \sqrt{\left[ \langle \ell \rangle \right]_{\mathbf{I}'}} \right\}_{\ell|N^{\mathrm{sc}}} \right]
$$

for the corresponding finite flat extension of  $\Lambda$ . Taking its normal closure in Frac(I) if needed, we can assume that I is a normal domain. As above, we fix a compatible choice of square roots

(4.6) 
$$
\sqrt{\left[\langle \ell \rangle \right]_{\mathbf{I}'}}
$$
, for  $\ell \mid N_{-}^{\text{sc}}$ ,

which we refer to as the *positive* square roots; we shorten the notation and set

<span id="page-23-0"></span>(4.7) 
$$
\langle \sqrt{\ell} \rangle_{\mathbf{I}} = \sqrt{\left[\langle \ell \rangle \right]_{\mathbf{I}'}}, \text{ for } \ell \mid N^{\text{sc}}_{-}.
$$

Let  $\mathbb{T}_{\mathbf{I}}$  be the polynomial algebra over **I** generated by the Hecke operators  $T_q$  for  $q \nmid pN_+N_-, U_l$  for  $l \mid pN+N_{-}^{\text{sp}}$  and the Diamond operators away form  $pN_{+}N_{-}$ ; it is the Hecke algebra away from  $\ell \mid N_{-}^{\text{sc}}$ , and we remark that  $\mathbb{T}_{\mathbf{I}}$  is a commutative algebra over **I** with a distinguished element, the  $U_p$  operator. We extend the Λ-action defined in Section [3.5.4](#page-19-3) to an I-action via the group-like elements. Similarly, we consider corresponding I-action on the space of p-adic modular forms and automorphic forms (cf. [\[Hsi21,](#page-66-4) Section 2.3]).

Getting back to Banach modules, for any  $X = Sp(A)$  as above, there exist ring homomorphisms,

(4.8) 
$$
\psi_X : \mathbb{T}_{\mathbf{I}} \longrightarrow \text{End}_A(\mathbb{S}^{\dagger}_{N+N-, \chi}(X))
$$
 and  $\psi_X^D : \mathbb{T}_{\mathbf{I}} \longrightarrow \text{End}_A(\mathbb{S}^{D, \dagger}_{N+N-, \chi}(X)),$ 

such that the image of the  $U_p$ -operator under each map defines a compact operator (see [\[Buz07,](#page-65-14) Section 6, Lemma 12.2]). Moreover, for any  $X' = Sp(A') \in \mathscr{C}$ , the A'-modules  $\mathbb{S}_{N+N-,\chi}^{\dagger}(X) \widehat{\otimes}_A A'$  and  $\mathbb{S}_{N+N-,\chi}^{\dagger}(X')$ (resp.  $\mathbb{S}_{N+N_-,\chi}^{D,\dagger}(X)\widehat{\otimes}_A A'$  and  $\mathbb{S}_{N+N_-,\chi}^{D,\dagger}(X')$ ) are *linked* (see [\[Bel21,](#page-65-13) Definition 3.5.1]), as the **I**-action commutes with Hecke operators (cf. Section [3.5.4\)](#page-19-3).

<span id="page-24-3"></span><span id="page-24-2"></span>4.1.1. Classical eigenvarieties. By [\[Bel21,](#page-65-13) Theorem 3.6.3] (cf. [\[Che04,](#page-65-12) Theoreme 6.3.6]), there exist two cuspidal eigenvarieties  $\mathscr{E}_{GL_2}$  and  $\mathscr{E}_D$  associated, respectively, with the eigenvariety data

(4.9) 
$$
\mathscr{D}_{N+N-,\chi}^{\mathrm{GL}_2} = (\mathcal{W}, \mathbb{T}_{\mathbf{I}}, U_p, \mathbb{S}_{N+N-,\chi}^{\dagger}, \psi_{\mathrm{GL}_2}) \quad \text{and} \quad \mathscr{D}_{N+N-,\chi}^D = (\mathcal{W}, \mathbb{T}_{\mathbf{I}}, U_p, \mathbb{S}_{N+N-,\chi}^{D,\dagger}, \psi_D).
$$

We recall that the eigenvariety  $\mathscr{E}_{GL_2}$  (resp.  $\mathscr{E}_D$ ) is a rigid analytic space over K endowed with

- a locally finite morphism  $\omega_{GL_2}: \mathscr{E}_{GL_2} \longrightarrow \mathcal{W}$  (resp.  $\omega_D: \mathscr{E}_D \longrightarrow \mathcal{W}$ ), called the *weight map*;
- a morphism of rings  $\psi_{GL_2} : \mathbb{T}_{\mathbf{I}} \longrightarrow \mathcal{O}(\mathscr{E}_{GL_2})$  (resp.  $\psi_D : \mathbb{T}_{\mathbf{I}} \longrightarrow \mathcal{O}(\mathscr{E}_D)$ ), which sends  $U_p$  to an invertible function;
- the morphism  $\omega_{\mathrm{GL}_2} \times \psi_{\mathrm{GL}_2}(U_p)^{-1} : \mathscr{E}_{\mathrm{GL}_2} \longrightarrow \mathcal{W} \times \mathbb{A}^1_{\mathrm{rig}} \text{ (resp. } \omega_D \times \psi_D(U_p)^{-1} : \mathscr{E}_D \longrightarrow \mathcal{W} \times \mathbb{A}^1_{\mathrm{rig}} \text{)}$ is finite([\[Bel21,](#page-65-13) Proposition 3.7.7]).

The general definition of eigenvariety satisfies analogous properties and it can be found in [\[Bel21,](#page-65-13) Definition 3.6.2].

## Remark 4.1.

- (1) By [\[Bel21,](#page-65-13) Theorem 3.6.3], there exists an eigenvariety for each eigenvariety data and it is unique up to unique isomorphism.
- (2) The eigenvariety construction of  $\mathscr{E}_D$  provided in [\[Buz07\]](#page-65-14) applies in our case, as the adèlization  $\widehat{R}^{\times}$  is a compact open subset of  $\widehat{D}^{\times}$ ; cf. [\[Dal23b,](#page-65-6) Lemma 2.3].
- (3) By  $[Bel21, Proposition 3.7.7],$  all the eigenvarieties over W are separated; moreover, as in [\[Lud17\]](#page-66-22), it is enough for us to work with the reduced rigid analytic space associated with each eigenvariety.

<span id="page-24-0"></span>Hypothesis 4.2. From now on, we assume all the eigenvarieties we consider throughout this note are reduced and separated.

**Lemma 4.3** ([\[Buz07,](#page-65-14) Lemma 5.9]). Let  $(\mathscr{E}, \psi, \omega)$  be either  $(\mathscr{E}_{GL_2}, \psi_{GL_2}, \omega_{GL_2})$  or  $(\mathscr{E}_D, \psi_D, \omega_D)$ . For any discretely valued extension  $K'/K$ , the association

$$
\mathscr{E}(\mathcal{K}') \longrightarrow \mathrm{Hom}_{\mathrm{ring}}(\mathbb{T}_{\mathbf{I}}, \mathcal{K}') \times \mathcal{W}(\mathcal{K}') \qquad \text{mapping} \qquad z \longmapsto (\, [h \mapsto \psi(h)(z)], \, \omega(z)),
$$

defines a bijection between the K'-valued points of  $\mathscr E$  and the set of K'-valued systems of eigenvalues with non-zero  $U_p$ -eigenvalue.

<span id="page-24-1"></span>Remark 4.4. Lemma [4.3](#page-24-0) holds for any general eigenvariety([\[Bel21,](#page-65-13) Theorem 3.7.1]).

**Proposition 4.5** (*p*-adic extension of the JL correspondence). The Jacquet–Langlands correspondence extends uniquely to a closed immersion

$$
\mathscr{E}_D \xrightarrow{JL_p} \mathscr{E}_{\mathrm{GL}_2}
$$

compatible with the eigenvariety structure, that is,  $\omega_D = \omega_{GL_2} \circ JL_p$  and  $\psi_D = JL_p^* \circ \psi_{GL_2}$ .

Before proving the proposition, we need to recall the notion of arithmetic points on  $W(\overline{\mathbb{Q}_p})$ .

**Definition 4.6.** We say that  $\kappa \in \mathcal{W}(\overline{\mathbb{Q}_p})$  is classical if there exists a point  $z \in \mathscr{E}_{GL_2}(\overline{\mathbb{Q}_p})$  such that  $\omega_{GL_2}(z) = \kappa$  and z corresponds to a classical modular form; we denote by  $\mathcal{W}^{cl}(\overline{\mathbb{Q}_p})$  the set of classical points. We say that  $\kappa \in \mathcal{W}(\overline{\mathbb{Q}_p})$  is *arithmetic* if there exists a point  $z \in \mathscr{E}_{GL_2}(\overline{\mathbb{Q}_p})$  such that  $\omega_{GL_2}(z) = \kappa$ and z corresponds to a form of weight-character  $\kappa = (k, \varepsilon) \in \mathcal{W}(\overline{\mathbb{Q}_p}) = \text{Hom}(\mathbb{Z}_p^{\times}, \overline{\mathbb{Q}_p}^{\times})$  with  $k \in \mathbb{Z}_{\geq 2}$  and  $\varepsilon$  a p-adic character of finite order. We denote by  $\mathcal{W}^{\text{arith}}(\overline{\mathbb{Q}_p})$  the set of arithmetic points. By Coleman classicality's theorem [\[Col97,](#page-65-15) Theorem 1.1], we know that arithmetic points of small slope are classical.

*Proof of Proposition [4.5.](#page-24-1)* We want to apply [\[Lud17,](#page-66-22) Proposition 2.10]. We define the very Zariski-dense (see [\[Bel21,](#page-65-13) Definition 3.8.1]) subset  $Z \subset \mathscr{E}_D(\overline{\mathbb{Q}_p})$ , as the set of arithmetic  $\overline{\mathbb{Q}_p}$ -points z such that  $\omega_D(z) \in \mathcal{W}^{\text{arith}}(\overline{\mathbb{Q}_p})$ . Coleman's classicality theorem combined with [\[HPS89b,](#page-66-17) Theorem 7.17] (cf. also

<span id="page-25-1"></span>Proposition [3.10\)](#page-17-0) implies that both  $\mathscr{E}_D$  and  $\mathscr{E}_{GL_2}$  are endowed with a *classical structure* (see [\[Bel21,](#page-65-13) Definition 3.8.5]) given by classical forms over  $W^{\text{arith}}(\overline{\mathbb{Q}_p})$ . [\[Bel21,](#page-65-13) Proposition 3.8.6] tells us that the subset of all classical points  $\mathscr{Z} \subset \mathscr{E}_D$  is very Zariski-dense in  $\mathscr{E}_D$ , thus, setting  $Z = \mathscr{Z}(\overline{\mathbb{Q}_p})$  we can assume it to be very Zariski-dense in  $\mathscr{E}_D(\overline{\mathbb{Q}_p})$ ; Z embeds in  $\mathscr{E}_{GL_2}(\overline{\mathbb{Q}_p})$  by the classical *Jacquet–Langlands* correspondence and Strong Multiplicity One for automorphic representations. More precisely, Lemma [4.3](#page-24-0) defines an injective association

$$
JL_p: \mathscr{E}_D^{\text{cl}}(\overline{\mathbb{Q}_p}) \ni z \longleftrightarrow \pi_z^D \longmapsto \pi_z \longleftrightarrow JL_p(z) \in \mathscr{E}_{\text{GL}_2}^{\text{cl}}(\overline{\mathbb{Q}_p}),
$$

where  $\pi_z^D$  is the automorphic representation over  $D^{\times}(\mathbb{A})$  associated with the classical point z and  $\pi_z =$  $JL(\pi_z^D)$ . This inclusion is compatible with the structure of the two eigenvarieties by definition of the map. The uniqueness is ensured by the reducedness of the eigenvarieties together with [\[BC09,](#page-65-16) Lemma 7.2.7] and Lemma [4.3.](#page-24-0)

4.1.2. The extended eigenvariety. The Hecke algebra  $\mathbb{T}_{I}$  acts on quaternionic modular forms with  $R_{p^{n}N_{+},N_{-}}$ level structure and, for each  $\ell \mid N_{-}^{\text{sc}}$ , we can extend  $\mathbb{T}_{I}$  by adjoining the operator  $\langle \varpi_{D_{\ell}} \rangle$ .

**Definition 4.7.** We define the  $K$ -algebra

$$
\widetilde{\mathbb{T}}_{\mathbf{I}} = \mathbb{T}_{\mathbf{I}} \Big[ \langle \varpi_{D_{\ell}} \rangle \Big| \ell \mid N^{\text{sc}}_{-} \Big]
$$

endowed with the canonical injection  $\mathbb{T}_{I} \hookrightarrow \tilde{\mathbb{T}}_{I}$ . We refer to it as the *extended Hecke algebra*. By Proposition [3.13](#page-17-1) and equation [\(3.17\)](#page-19-2),  $\widetilde{T}_{I}$  is commutative.

While the algebra  $\mathbb{T}_{\mathbf{I}}$  acts on both  $\mathbb{S}_{N+N-,\chi}$  and  $\mathbb{S}_{N+N-,\chi}^D$ ,  $\mathbb{T}_{\mathbf{I}}$  acts only on  $\mathbb{S}_{N+N-,\chi}^D$ . We can consider the tuple

(4.10) 
$$
\widetilde{\mathscr{D}}_{N+N-, \chi}^{D} = (\mathcal{W}, \widetilde{\mathbb{T}}_{\mathbf{I}}, U_p, \mathbb{S}_{N+N-, \chi}^{D, \dagger}, \psi_D),
$$

<span id="page-25-0"></span>which defines an eigenvariety datum, as one only needs to prove the following lemma.

**Lemma 4.8.** For any pair of affinoid subdomains,  $X' = Sp(A') \subseteq X = Sp(A) \subset W$  with  $X, X' \in \mathscr{C}$ , the A'-modules  $\mathbb{S}_{N+N_{-},\chi}^{D,\dagger}(X)\widehat{\otimes}_A A'$  and  $\mathbb{S}_{N+N_{-},\chi}^{D,\dagger}(X')$  are linked (see [\[Bel21,](#page-65-13) Definition 3.5.1]) under  $\widetilde{\mathbb{T}}_I$ .

Proof. We apply [\[Bel21,](#page-65-13) Lemma 3.5.2] to [\[Buz07,](#page-65-14) Lemma 12.2]; we must prove that the two morphisms are  $\tilde{T}_{I}$ -equivariant. The first inclusion morphism is  $T_{I}$ -equivariant (recall that we are changing the structure only at the ramified places). Thus, the properties of  $\langle \varpi_{D_\ell} \rangle$  in Proposition [3.13](#page-17-1) together with the relation in Section [3.5.4](#page-19-3) imply the  $\tilde{T}_{I}$ -equivariance of both morphisms.

We deduce the following proposition.

**Proposition 4.9.** There exists a reduced eigenvariety associated with the datum  $\widetilde{\mathscr{D}}_{N+N-,,\chi}^D$ , which we denote by  $(\widetilde{\mathcal{E}}_D, \widetilde{\omega}_D, \widetilde{\psi}_D)$ . We will refer to it as the extended eigenvariety for D.

This variety plays the role of an auxiliary eigenvariety, whose points parameterize system of Hecke eigenvalues with finite  $U_p$ -slope together with a collection of additional eigenvalues associated with the  $\langle \varpi_{D_\ell} \rangle$ -operators. In particular, applying Lemma [4.3](#page-24-0) to the inclusion  $\mathbb{T}_{\mathbf{I}} \hookrightarrow \mathbb{T}_{\mathbf{I}}$ , we obtain a morphism on the  $\mathbb{C}_p$ -points of the eigenvarieties. This canonical map extends to a morphism of eigenvarieties; in fact, more is true.

**Proposition 4.10.** The canonical inclusion  $\mathbb{T}_I \hookrightarrow \widetilde{\mathbb{T}}_I$  defines a unique finite morphism,

$$
\widetilde{\pi}: \widetilde{\mathscr{E}}_D \longrightarrow \mathscr{E}_D,
$$

compatible with the eigenvariety structure. Moreover, it sends classical points to classical points.

<span id="page-26-2"></span>Proof. We follow the proof of [\[Lud17,](#page-66-22) Proposition 3.15] and construct the map on the local pieces of the eigenvariety. More precisely, we take  $\widetilde{\mathscr{E}}_{D,X} = \widetilde{\omega}_{D}^{-1}(X) \subset \widetilde{\mathscr{E}}_D$ , for any  $X = \text{Sp}(A)$  in the admissible covering  $\mathscr C$ . We consider the admissibile covering  $\{\widetilde{\mathscr E}_{D,X}(U)\}_U$  indexed over connected open affinoids  $U \subseteq X$ ; by construction, each  $\mathscr{E}_{D,X}(U)$  is an affinoid  $Sp(\mathbb{T}_{\mathbf{I}}(U))$ , for

$$
\widetilde{\mathbb{T}}_{\mathbf{I}}(U) = \mathrm{Im}\left(\widetilde{\mathbb{T}}_{\mathbf{I}} \otimes_{\mathcal{K}} \mathcal{O}(U) \longrightarrow \mathrm{End}_{\mathcal{O}(U)}\left(\left(\mathbb{S}_{N_+N_-,\chi}^{D,\dagger}(X) \widehat{\otimes}_{\mathcal{O}(X)} \mathcal{O}(U)\right)^{\text{finite slope}}\right)\right)^{\text{red}}
$$

the reduced image of  $\widetilde{\mathbb{T}}_I \otimes_{\mathcal{K}} \mathcal{O}(U)$ . For any U as above,  $\mathbb{T}_I \hookrightarrow \widetilde{\mathbb{T}}_I$  induces the inclusion  $\mathbb{T}_I(U) \hookrightarrow \widetilde{\mathbb{T}}_I(U)$ ; therefore, we obtain

$$
\iota_U^* : \widetilde{\mathcal{E}}_{D,X}(U) \longrightarrow \mathcal{E}_{D,X}(U).
$$

Note that the  $\mathscr{E}_{D,X}(U)$  form an admissible covering of  $\mathscr{E}_{D,X}$ . The composition of  $\iota_U^*$  with the natural inclusion  $\mathscr{E}_{D,X}(U) \hookrightarrow \mathscr{E}_{D,X}$  determines the morphism

$$
\widetilde{\pi}_U : \widetilde{\mathscr{E}}_{D,X}(U) \longrightarrow \mathscr{E}_{D,X}.
$$

Let X' be an admissible open in  $\mathscr C$  and take  $U \subset X$  and  $U' \subset X'$ , connected open affinoids. Up to refining the covering, we can assume that  $X \subseteq X'$ . Invoking [\[Buz07,](#page-65-14) Lemma 5.2] as in [\[Lud17,](#page-66-22) Proposition 3.15], we deduce that  $\widetilde{\pi}_U|_{\widetilde{\mathscr{E}}_{D,X}(U \cap U')} = \widetilde{\pi}_{U \cap U'}$ , therefore the morphisms  $\widetilde{\pi}_U$  glue compatibly. Again, the uniqueness is ensured by the reducedness of the eigenvarieties together with [\[BC09,](#page-65-16) Lemma 7.2.7] and Lemma [4.3.](#page-24-0) Let now z be a classical point in  $\widetilde{\mathcal{E}}_D(\overline{\mathbb{Q}_p})$ . Such z corresponds to a classical eigenform  $\varphi_z$  identified by a system of Hecke and  $\langle \varpi_{D_\ell} \rangle$ -eigenvalues for  $\ell \mid N_-^{\text{sc}}$ , say  $\widetilde{\lambda}_z$ . The morphism  $\widetilde{\pi}$ , by construction, maps  $\lambda_z$  to the eigensystem  $\lambda_z$  obtained by forgetting the  $\langle \varpi_{D_\ell} \rangle$ -eigevalues. Lemma [4.3](#page-24-0) shows that  $\pi(z)$  is classical. Finiteness follows from the relation

$$
\langle \varpi_{D_{\ell}} \rangle^2 - \chi_{N+N-{\ell}^2}(\ell)^{-1} \cdot [\langle \ell \rangle]_{\mathbf{I}} = 0
$$

obtained from equation [\(3.17\)](#page-19-2).

4.1.3. Idempotents. For any  $\ell \mid N_{-}^{\text{sc}}$ , recall the square root operators  $\langle \sqrt{\ell} \rangle_{\text{I}}$  defined in equation [\(4.7\)](#page-23-0). They are invertible elements of the algebra I, as the  $[\langle \ell \rangle]_I$  are invertible. Therefore, they determine invertible operators. We can hence define idempotents in **I** and on  $\mathbb{S}_{N+N-2,\chi}^D$ .

<span id="page-26-0"></span>**Definition 4.11.** For each prime  $\ell \mid N_-^{\text{sc}}$ , we set

$$
e_{\pm}^{D_{\ell}} = \frac{1}{2} \left( \mathbb{1} \mp \frac{1}{\langle \sqrt{\ell} \rangle_{\mathbf{I}}} \frac{1}{\sqrt{\chi_{\mathbb{A},N_+N_-/\ell^2}(\ell)^{-1}}} \langle \varpi_{D_{\ell}} \rangle \right).
$$

Moreover, for each tuple of signs  $\epsilon = (\epsilon_{\ell})_{\ell|N_{-}^{sc}} \in {\{\pm 1\}}^{\#\{\ell|N_{-}^{sc}\}}$ , we define a canonical idempotent

$$
e_{\epsilon}^D = \prod_{\ell \mid N^{\text{sc}}_-} e_{\epsilon_{\ell}}^{D_{\ell}}.
$$

#### Remark 4.12.

(1) It is immediate from the definition that the sum  $e_+^{D_\ell} + e_-^{D_\ell}$  is the identity element 1 in  $\tilde{T}_I$ . Therefore, the sum of all these idempotents is

$$
\sum_{\epsilon\in\{\pm1\}^{\#\{\ell|N^{\text{sc}}_-\}} }e^D_\epsilon=1.
$$

(2) The operators  $\langle \sqrt{\ell} \rangle_{\mathbf{I}}$  take care of the p-component of the square root as explained by equation [\(3.13\)](#page-16-2).

## <span id="page-26-1"></span>Proposition 4.13.

<span id="page-27-2"></span>(1) Let  $\kappa = (k, \kappa_p) \in \mathcal{W}^{cl}(\overline{\mathbb{Q}_p})$  be any weight-character and let  $n = \max\{1, v_p(\text{cond}(\kappa_p))\}$ . For any  $\ell \mid N_{-}^{\text{sc}}, \text{ let } S_k^{D, \pm}(p^n N_+N_-, \chi \kappa_p) = e_{\pm}^{D_{\ell}} S_k^D p^n N_+N_-, \chi \kappa_p).$  There is a canonical decomposition

$$
S_k^D(p^n N_+ N_-, \chi \kappa_p) = S_k^{D,+}(p^n N_+ N_-, \chi \kappa_p) \oplus S_k^{D,-}(p^n N_+ N_-, \chi \kappa_p).
$$

(2) The projectors  $e_{\pm}^{D_{\ell}}$  are orthogonal with respect to the quaternionic Petersson inner product defined in Section [3.6.1.](#page-19-4)

*Proof.* It is clear that the two idempotents  $e_{\pm}^{D_{\ell}}$  give rise to projectors on  $S_k^D(p^nN\ell^2, \chi\kappa_p)$ , satisfying the identity  $1 = e_+^{D_\ell} + e_-^{D_\ell}$ , i.e.  $e_-^{D_\ell} = 1 - e_+^{D_\ell}$ . Therefore, for any  $\varphi \in S_k^D(p^n N \ell^2, \chi \kappa_p)$ , we compute  $e_{\pm}^{D_{\ell}}e_{\mp}^{D_{\ell}}\varphi = 0$ , in fact,  $e_{\pm}^{D_{\ell}}e_{\mp}^{D_{\ell}}\varphi = e_{\pm}^{D_{\ell}}e_{\pm}^{D_{\ell}}\varphi = e_{\pm}^{D_{\ell}}\varphi - e_{\pm}^{D_{\ell}}\varphi = e_{\pm}^{D_{\ell}}\varphi = 0$ . This proves (1). Part (2) follows from Proposition [3.20](#page-21-0) and equation [\(3.13\)](#page-16-2).

4.1.4. The extended eigenvarieties of idempotent type. We fix one of the idempotents in Definition [4.11,](#page-26-0) say  $e_{\epsilon}^D$ , and consider the tuple

(4.11) 
$$
e_{\epsilon}^{D} \widetilde{\mathscr{D}}_{N_{+}N_{-},\chi}^{D} = (\mathcal{W}, \widetilde{\mathbb{T}}_{\mathbf{I}}, U_{p}, e_{\epsilon}^{D} \mathbb{S}_{N_{+}N_{-},\chi}^{D,\dagger}, \psi_{D}).
$$

**Proposition 4.14.** There exists a unique reduced eigenvariety associated with the datum  $e_{\epsilon}^D \widetilde{\mathscr{D}}_{N+N-, \chi}^D$ , which we denote by  $(\widetilde{\mathscr{E}}_{D}^{\epsilon}, \widetilde{\omega}_{D}^{\epsilon} = \widetilde{\omega}_{D|_{\widetilde{\mathscr{E}}_{D}^{\epsilon}}}, \widetilde{\psi}_{D})$  and we will refer to it as the extended eigenvariety for D. D

*Proof.* The above Proposition [4.13](#page-26-1) guarantees that the projection by  $e_{\epsilon}^{D}$  (which is linear and continuous) produces Banach modules satisfying *Property*  $(Pr)$  (see [\[Bel21,](#page-65-13) Exercise 3.1.23]). Since  $e_{\epsilon}^D$  commutes with all Hecke operators, Lemma [4.8](#page-25-0) shows that the modules are still linked.

<span id="page-27-1"></span>Proposition 4.15. The natural map

$$
\widetilde{\iota}^{\epsilon} : \widetilde{\mathscr{E}}_D^{\epsilon} \longrightarrow \widetilde{\mathscr{E}}_D,
$$

is the unique closed immersion compatible with the eigenvariety structure. Moreover,  $\widetilde{\mathscr{E}}_D$  is the disjoint union of the images of  $\widetilde{\mathscr{E}}_{D}^{\epsilon}$ , for all the  $\epsilon \in \{\pm 1\}^{\#\{\ell|N^{\text{sc}}_-\}}$ .

Proof. This is just [\[Bel21,](#page-65-13) Exercise 3.7.2 and Exercise 3.6.4], together with the direct sum decomposition of Proposition [4.13.](#page-26-1) Alternatively, one can also consider an approach similar to the proof of [\[Lud17,](#page-66-22) Proposition 2.10].

<span id="page-27-0"></span>**Proposition 4.16.** The morphism  $\widetilde{JL}_p^{\epsilon}$  of eigenvarieties, obtained by composition,

$$
\widetilde{JL}_p^{\epsilon} = JL_p \circ \widetilde{\pi} \circ \widetilde{\iota}^{\epsilon} : \widetilde{\mathscr{E}}_D^{\epsilon} \longrightarrow \mathscr{E}_{\mathrm{GL}_2}
$$

is a closed immersion.

Proof. The morphism preserves the eigenvariety structures and it is finite, by composition of finite morphisms of eigenvarieties; recall that closed immersions are finite by definition, see e.g. [\[FvdP04,](#page-66-23) Definition 4.5.7 and Definition 4.10.1]. As in the proof of [\[Lud17,](#page-66-22) Lemma 2.9], we consider an affinoid  $V \subset \mathcal{W} \times \mathbb{A}^1_{\text{rig}}$ , its preimage  $X = (\widetilde{\omega}_D^{\epsilon} \times \widetilde{\psi}_D(U_p)^{-1})^{-1}(V)$  in  $\widetilde{\mathscr{E}}_D^{\epsilon}$ , and the natural surjective map

$$
\widetilde{\psi}_D \otimes (\widetilde{\omega}_D^{\epsilon} \times \widetilde{\psi}_D(U_p)^{-1})^* \colon \widetilde{\mathbb{T}}_{\mathbf{I}} \otimes_K \mathcal{O}(V) \longrightarrow \mathcal{O}(X).
$$

To prove that  $\widetilde{JL}_p^{\epsilon}$  is a closed immersion, it is enough to show that the restriction

$$
\widetilde{\psi}_D \otimes (\widetilde{\omega}_D^{\epsilon} \times \widetilde{\psi}_D(U_p)^{-1})^* : \mathbb{T}_{\mathbf{I}} \otimes_K \mathcal{O}(V) \longrightarrow \mathcal{O}(X).
$$

is still surjective. This follows by the finiteness of  $\mathcal{O}(X)$  as a  $\mathcal{O}(V)$ -module (see Section [4.1.1\)](#page-24-2) and from the relation

$$
\widetilde{\psi}_D(\langle \varpi_{D_\ell} \rangle) = \epsilon_{\ell} \sqrt{\chi_{\mathbb{A}, \ell}(\ell)} \; \widetilde{\psi}_D(\langle \sqrt{\ell} \rangle_{\mathbf{I}}), \text{ for all } \ell \mid N_-^{\text{sc}}.
$$

We can hence follow through the proof of [\[Lud17,](#page-66-22) Proposition 2.10], considering finite subsets  $I_V \subset \mathbb{T}_I$ containing the operators  $\langle \sqrt{\ell} \rangle_{\rm I}$  for  $\ell \mid N_-^{\rm sc}$  $-\frac{1}{2}$ .

<span id="page-28-2"></span>We can summarize the above eigenvarieties and their morphisms in the following commutative diagrams:

4.1.5. The image of  $\widetilde{JL}_p^{\epsilon}$  $\bar{p}$ . We conclude this section with a couple of interesting observations which strengthen the comparison between our immersion and Chenevier's one. As explained in [\[Che05,](#page-65-17) Section 2.1.1, Section 4.6, and Proposition 4.7.(b)], one can construct a reduced closed rigid analytic subvariety  $\mathscr{E}_{GL_2}^{tr=0} \subseteq \mathscr{E}_{GL_2}$  whose classical points correspond to forms which are new at the primes dividing the discriminant of D.

<span id="page-28-1"></span>**Proposition 4.17.** The morphism  $J L_p$  is an isomorphism onto  $\mathscr{E}_{\text{GL}_2}^{\text{tr}=0}$ .

*Proof.* By Proposition [4.5](#page-24-1) and the above discussion, we know that  $JL_p$  is a closed immersion. Note that classical points are dense both in  $\mathscr{E}_{GL_2}^{tr=0}$  and in  $\mathscr{E}_D$ , and hence it is enough to show that

$$
JL_p(\mathscr{E}_D^{\text{cl}}) \supseteq \mathscr{E}_{\text{GL}_2}^{\text{tr}=0,\text{cl}}
$$

<span id="page-28-0"></span>in order to prove that the morphism is surjective. Each point in  $\mathscr{E}_{GL_2}^{tr=0,cl}$  corresponds to a Hecke eigenform which, under our assumptions, can be transferred to the quaternion algebra.

**Proposition 4.18.** The morphism  $\widetilde{\pi}_{|\widetilde{\mathscr{E}}_D^{\varepsilon}}$  is an isomorphism onto its image.

*Proof.* We would like to apply [\[BC09,](#page-65-16) Proposition 7.2.8], but  $\text{Im}(\widetilde{\pi}_{|\widetilde{\mathscr{E}}_D^{\varepsilon}})$  is not necessarily an eigenvariety. However, modifying the sets  $I_V$  as in the proof of Proposition [4.16,](#page-27-0) the proof of [\[BC09,](#page-65-16) Proposition 7.2.8] applies verbatim to our setup.

**Corollary 4.19.** The composition  $\widetilde{\pi} \circ \widetilde{\iota}^{\epsilon}$  is an open and closed immersion. Therefore,  $\widetilde{JL}_p^{\epsilon}$  $_p$  is an open and closed immersion into  $\mathscr{E}_{GL_2}^{tr=0}$ .

Proof. The first assertion follows by combining Proposition [4.18](#page-28-0) with Proposition [4.15.](#page-27-1) The second one follows from Proposition [4.17.](#page-28-1)

<span id="page-29-1"></span>**Remark 4.20.** For any two distinct choices of signs,  $\epsilon$  and  $\epsilon'$ , the images of the eigenvarieties  $\widetilde{\mathscr{E}}_D^{\epsilon}$  and  $\widetilde{\mathcal{E}}_D^{\epsilon'}$  are not disjoint in  $\mathcal{E}_{\text{GL}_2}$ , since their intersection contains the twist-minimal forms.

<span id="page-29-0"></span>4.2. Families of quaternionic modular forms. This section and the next one contain the main results we employ in the construction of the triple product p-adic L-function, namely the existence of families of quaternionic modular forms of finite slope. We follow the definition given in [\[Che04,](#page-65-12) Section 6.2.6], and restrict our attention to the two eigenvarieties

(4.14) 
$$
\mathscr{E}_{GL_2} \sim (\mathcal{W}, \mathbb{T}_{\mathbf{I}}, U_p, \mathbb{S}_{N+N-, \chi}^{\dagger}, \psi_{GL_2})
$$
 and  $\widetilde{\mathscr{E}}_D^{\epsilon} \sim (\mathcal{W}, \widetilde{\mathbb{T}}_{\mathbf{I}}, U_p, e_{\epsilon}^D \mathbb{S}_{N+N-, \chi}^{D, \dagger}, \widetilde{\psi}_D^{\epsilon}).$ 

To  $\mathbb{S}_{N+N-, \chi}^{\dagger}$  (resp.  $e_{\epsilon}^{D} \mathbb{S}_{N+N-, \chi}^{D, \dagger}$ ), one can associate a *sheaf of Banach modules* on W, which we denote by  $\mathscr{S}_{N+N-, \chi}^{\dagger}$  (resp.  $\mathscr{S}_{N+N-, \chi}^{D,\epsilon,\dagger}$ ); this geometric object is roughly obtained glueing the Banach modules of overconvergent forms compatibly. As we are only interested in its sheaf nature, we do not recall the precise definition here, but refer the reader to [\[Che04,](#page-65-12) Section 3] and [\[Che05,](#page-65-17) Section 1] for a thorough discussion. Let  $\mathscr{T}_{\mathbf{I}}^{\mathrm{GL}_2}$  be the closure of  $\mathbb{T}_{\mathbf{I}}$  in

(4.15) 
$$
\mathcal{E}_{\mathbf{I}}^{\mathrm{GL}_2} = \left\{ h \in \mathrm{End}(\mathscr{S}^{\dagger}_{N_+N_-, \chi}) \middle| h \text{ is integral and rational} \right\},
$$

where the topology is the coarsest topology such that, for any open affinoid  $X \in \mathcal{W}$ , the restriction map

(4.16) 
$$
\mathcal{E}_{\mathbf{I}}^{\mathrm{GL}_2} \longrightarrow \mathrm{End}^{\mathrm{cts}}_{\mathcal{O}_X(X)}(\mathbb{S}_{N+N-,X}^{\dagger}(X))
$$

is continuous; here  $\text{End}^{\text{cts}}_{\mathcal{O}_X(X)}(\mathbb{S}^\dagger_{N+N_{-\cdot},X}(X))$  is endowed with the topology induced by the supremum norm. Analogously (cf. [\[Che04,](#page-65-12) Proposition 4.5.4] and equation [\(3.17\)](#page-19-2)), we define  $\widetilde{\mathfrak{I}}^{D,\epsilon}$  as the closure of  $\widetilde{\mathbb{T}}_{I}$  in

(4.17) 
$$
\mathcal{E}_{\mathbf{I}}^{D,\epsilon} = \left\{ h \in \text{End}(\mathscr{S}_{N+N-,X}^{D,\epsilon,\dagger}) \middle| h \text{ is integral and rational} \right\}.
$$

Let  $(\mathscr{E}, \mathcal{W}, \mathbb{S}^{\dagger}, \psi, \omega, \mathscr{T})$  be either the tuple

(4.18) 
$$
(\mathscr{E}_{GL_2}, \mathcal{W}, \mathbb{S}_{N+N-,X}^{\dagger}, \psi_{GL_2}, \omega_{GL_2}, \mathscr{T}_{\mathbf{I}}^{GL_2})
$$
 or  $(\widetilde{\mathscr{E}}_D^{\epsilon}, \mathcal{W}, e_{\epsilon}^D \mathbb{S}_{N+N-,X}^{D,\dagger}, \widetilde{\psi}_D^{\epsilon}, \widetilde{\omega}_D^{\epsilon}, \widetilde{\mathscr{T}}_{\mathbf{I}}^{D,\epsilon}).$ 

For any open affinoid  $\mathcal{U}$  in  $\mathcal{W}$ , we denote the submodule of *power-bounded elements* by

(4.19) 
$$
\mathcal{O}(\mathcal{U})^0 = \left\{ s \in \mathcal{O}(\mathcal{U}) \, | \, |s(u)| \leq 1 \text{ for all } u \in \mathcal{U} \right\}.
$$

If U is reduced, which is always the case if U is small enough,  $\mathcal{O}(\mathcal{U})^0$  is compact in  $\mathcal{O}(\mathcal{U})$  (see [\[BC09,](#page-65-16) Lemma 7.2.11]). The same definition applies for any affinoid  $\mathcal{X} \subset \mathcal{E}$ .

**Definition 4.21** (Families of quaternionic cusp forms). Let  $\kappa \in \mathcal{W}(\mathbb{C}_p)$  and let  $\varphi \in \omega^{-1}(\kappa)$  be a padic overconvergent cuspidal form. We define a family of quaternionic cuspidal modular forms passing through  $\varphi$  as the collection of

- an affinoid open  $\mathcal{U} \subseteq \mathcal{W}, \kappa \in \mathcal{U}(\mathbb{C}_n);$
- an affinoid  $\mathcal{X} \subset \mathscr{E}$ , endowed with a finite morphism  $\varphi \colon \mathcal{X} \longrightarrow \mathcal{U}$ , surjective when restricted to any irreducible component of  $\mathcal{X}$ ;
- a  $\mathbb{C}_p$ -point  $x_0 \in \mathcal{X}(\mathbb{C}_p)$  such that  $\varphi(x_0) = \kappa$ ;
- a continuous ring homomorphism  $\lambda: \mathscr{T} \longrightarrow \mathcal{O}_{\mathcal{X}}(\mathcal{X})^0;$

satisfying:

• for all  $x \in \mathcal{X}(\mathbb{C}_p)$ , there exists a form  $\varphi_x \in \mathcal{S}^{\dagger}(\mathcal{X}) \cap \omega^{-1}(\omega(x))$ , such that, for all  $h \in \mathcal{F}$ ,

$$
h(\varphi_x) = \lambda(h)(x) \varphi_x;
$$

• the form  $\varphi$  is such that one can take  $\varphi_{x_0} = \varphi$ .

<span id="page-30-1"></span>We say that the family is parameterized by  $\mathcal{X}$ , and that it has slope  $\alpha$  (resp. finite slope) if every form  $\varphi_x$  in the family has slope  $v_p(\lambda(U_p)(x)) = \alpha$  (resp.  $v_p(\lambda(U_p)(x))$ ) is finite). We call a family of slope 0 a Hida family, while we refer to families of finite slope bigger equal than 0 as *Coleman families*.

#### Remark 4.22.

- (1) By [\[Bel21,](#page-65-13) Proposition 6.2.7], if there exists a classical point in a family, then the classical points are dense in the family.
- (2) All the eigenvarieties we consider are equidimensional of dimension one([\[Bel21,](#page-65-13) Proposition  $3.7.5$ ]).

<span id="page-30-0"></span>**Theorem 4.23.** For any Coleman family  $f$  on  $\mathcal{E}_{GL_2}$ , there exist at most a unique Coleman family on  $\widetilde{\mathscr{E}}_{D}^{\epsilon}$ , of the same slope, lifting **f**. Moreover, there exist a family  $\varphi$  on  $\widetilde{\mathscr{E}}_{D}^{\epsilon}$ , for each choice of signs  $\epsilon$ , corresponding to f, if f passes through a classical point whose corresponding form is supercuspidal at each prime  $\ell \mid N^{\text{sc}}_{-}.$ 

*Proof.* Let  $(\mathcal{U}, \kappa, \mathcal{X}, x_0, \mathbf{f} : \mathcal{X} \to \mathcal{U})$  be a Coleman family on  $\mathscr{E}_{GL_2}$  and  $(\widetilde{JL_p}^{\epsilon})^{-1}(\{x_0\})$  be the preimage of  $x_0$ . It is either empty or it contains a unique point  $x_0^{D,\epsilon} \in \widetilde{\mathscr{E}}_D^{\epsilon}$ . If  $(\widetilde{JL_p}^{\epsilon})^{-1}(\lbrace x_0 \rbrace) = \emptyset$ , up to shrinking X, and hence U, we can assume that  $\mathcal{X} \cap \text{Im}(\widetilde{JL_p}^{\epsilon}) = \emptyset$  (by Proposition [4.16\)](#page-27-0). Therefore, there is no family on  $\widetilde{\mathscr{E}}_{D}^{\epsilon}$  lifting  $(\mathcal{U}, \kappa, \mathcal{X}, x_0, \mathbf{f} : \mathcal{X} \to \mathcal{U})$ . Suppose now that  $x_0^{D,\epsilon} = (\widetilde{\mathcal{IL}_p}^{\epsilon})^{-1}(x_0)$ . Since  $\mathcal{X}$ can be taken to be an open affinoid and closed immersions are finite,  $\mathcal{X}_D^{\epsilon} = (\widetilde{J L_P^{\epsilon}})^{-1}(\mathcal{X})$  is an open affinoid (see [\[FvdP04,](#page-66-23) discussion after Definition 4.5.7]). We hence define  $\varphi^{\epsilon} = \int_{-\infty}^{\infty} \widetilde{J L_p}^{\epsilon}$ . As above, up to shrinking  $\mathcal{X}$ , and hence  $\mathcal{U}$ , we can assume that  $\mathcal{X}$  is contained in  $\text{Im}(\widetilde{J L_p}^{\epsilon})$ , therefore  $\varphi^{\epsilon}$  is a finite morphism, surjective when restricted to any irreducible component. As  $\widetilde{JL_p}^{\epsilon}$  is an eigenvariety morphism, we obtain  $\varphi^{\epsilon}(x_0^{D,\epsilon}) = \kappa$ . It remains to lift the ring homomorphism  $\lambda$ . Consider now the quotient map

$$
\widetilde{\mathbb{T}}_{\mathbf{I}} \cong \frac{\mathbb{T}_{\mathbf{I}}[X_{\ell}]_{\ell|N^{\text{sc}}}}{(X_{\ell}^2 - \chi_{\mathbb{A},\ell}(\ell)[\ell]_{\mathbf{I}})_{\ell|N^{\text{sc}}_{\mathbf{I}}}} \longrightarrow \mathbb{T}_{\mathbf{I}},
$$

determined by the choice of signs  $\epsilon$ , obtained by sending

$$
X_{\ell}\longmapsto \epsilon_{\ell}\sqrt{\chi_{\mathbb{A},\ell}(\ell)}\,\langle \sqrt{\ell}\rangle_{\mathbf{I}},\ \text{for each}\ \ell\mid N^{\text{sc}}_{-}.
$$

This map defines, for any such affinoid open  $V \subseteq W$ , a diagram

$$
\begin{CD} \widetilde{\mathbb{T}}_{\mathbf{I}} & \longrightarrow \operatorname{Im}(\widetilde{\mathbb{T}}_{\mathbf{I}} \to \operatorname{End}^{\mathrm{cts}}_{\mathcal{O}_{\mathcal{V}}(\mathcal{V}))}(\mathbb{S}_{N_{+}N_{-},\chi}^{D,\epsilon,\dagger}(\mathcal{V}))) \longrightarrow \cdots \longrightarrow \mathcal{O}_{\mathcal{X}_{D}^{\epsilon}}(\mathcal{X}_{D}^{\epsilon})^{0} \\ & & \downarrow \qquad \qquad \downarrow \qquad \qquad (\widetilde{\mathcal{H}_{p}}^{\epsilon})^{*} \Bigg\uparrow \qquad \qquad (\widetilde{\mathcal{H}_{p}}^{\epsilon})^{*} \Bigg\uparrow \qquad \qquad (\widetilde{\mathcal{H}_{p}}^{\epsilon})^{*} \Bigg\uparrow \qquad \qquad \downarrow \qquad \qquad \downarrow \qquad \qquad (\widetilde{\mathcal{H}_{p}}^{\epsilon})^{*} \Bigg\uparrow \qquad \qquad \downarrow \qquad \downarrow \qquad \
$$

where the first square is a commutative square of continuous algebra homomorphisms, with the second vertical map obtained from the Jacquet–Langlands correspondence (cf. Section [3.5.1\)](#page-16-1) and the chosen quotient map. We can define  $\lambda_V^D$  as the composition of morphisms in the right hand side square, where  $\lambda_V$ is the restriction of  $\lambda$ . Let us remark that the function  $\tilde{\lambda}_V^D(\langle \varpi_{D_\ell} \rangle) \in \mathcal{O}_V(\mathcal{V})^0$  obtained by composition is the constant function  $\tilde{\lambda}^D(\langle \varpi_{D_\ell} \rangle)(x) = \epsilon_\ell \sqrt{\chi_{\mathbb{A},\ell}(\ell)} \langle \sqrt{\ell} \rangle_{\mathbf{I}},$  for all  $x \in \mathcal{X}$  (cf. Lemma [3.17\)](#page-19-5). The morphism  $\widetilde{\lambda}_{\mathcal{V}}^D$  is a continuous ring homomorphism. It remains to extend  $\widetilde{\lambda}_{\mathcal{V}}^D$  to  $\widetilde{\mathfrak{I}}^{D,\epsilon}$ . We start noticing that the defined morphisms  $\widetilde{\lambda}_{\nu}^D$  glue compatibly, as the  $\lambda_{\nu}$  do. Moreover,  $\widetilde{\mathfrak{I}}^{D,\epsilon}$  is a commutative **I**-algebra, hence the translates of  $\text{Im}(\tilde{T}_{\mathbf{I}} \to \text{End}^{\text{cts}}_{\mathcal{O}_{\mathcal{V}}(\mathcal{V}))}(\mathbb{S}_{N+N-, \chi}^{D,\epsilon,\dagger}(\mathcal{V})))$  define an open covering. The uniqueness of the lift, as well as the invariance of the slope, follow now from the construction of  $\varphi^{\epsilon}$ . .

## Remark 4.24.

<span id="page-31-2"></span>(1) In the above proof, we note that fixing the eigenvalue of each  $\langle \varpi_{D_\ell} \rangle$ , shows that

$$
\operatorname{Im}(\widetilde{\mathbb{T}}_{\mathbf{I}} \to \operatorname{End}^{\mathrm{cts}}_{\mathcal{O}_{\mathcal{V}}(\mathcal{V})}(\mathbb{S}_{N+N-, \chi}^{D,\epsilon,\dagger}(\mathcal{V}))) = \operatorname{Im}(\mathbb{T}_{\mathbf{I}} \to \operatorname{End}^{\mathrm{cts}}_{\mathcal{O}_{\mathcal{V}}(\mathcal{V})}(\mathbb{S}_{N+N-, \chi}^{D,\epsilon,\dagger}(\mathcal{V}))).
$$

(2) We must stress the fact that the sequence  $\{U_p^{n}\}_n$  still converges in  $\widetilde{\mathfrak{I}}^{D,\epsilon}$ , as it does so in each closure  $\text{Im}(\widetilde{\mathbb{T}}_{\mathbf{I}} \to \text{End}^{\text{cts}}_{\mathcal{O}_{\mathcal{V}}(\mathcal{V})}(\mathbb{S}_{N+N_-,\chi}^{D,\epsilon,\dagger}(\mathcal{V}))).$ 

<span id="page-31-1"></span>4.3. Λ-adic quaternionic forms and Hida families. Even though Theorem [4.23](#page-30-0) guarantees the existence of Coleman families, we need a more explicit way to describe them. In particular we restrict our attention to Hida families.

4.3.1. Λ-adic quaternionic forms. We keep the notation introduced in Section [3.4.3](#page-15-0) and fix a chain of inclusions of orders

$$
(4.20) \t R_{N_+,N_-} \supset R_{pN_+,N_-} \supset R_{p^2N_+,N_-} \supset \cdots \supset R_{p^nN_+,N_-} \supset \cdots \supset R_{p^{\infty}N_+,N_-},
$$

for

(4.21) 
$$
R_{p^{\infty}N_+,N_-} = \left\{ r \in \widehat{R}_{N_+,N_-} \middle| \iota_p(r_p) = \left( \begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix} \right) a, d \in \mathbb{Z}_p^{\times}, b \in \mathbb{Z}_p \right\}.
$$

Considering the set

(4.22) 
$$
X_{\infty} = D^{\times} \backslash \widehat{D}^{\times} / U_1(R_{p^{\infty}N_+,N_-}),
$$

for

(4.23) 
$$
U_1(R_{p^{\infty}N_+,N_-}) = \left\{ r \in U_1(R_{N_+,N_-}) \middle| \iota_p(r_p) = \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} a \in \mathbb{Z}_p^{\times}, b \in \mathbb{Z}_p \right\},
$$

we have the natural quotient maps

$$
(4.24) \t\t X_{\infty} \longrightarrow X_m \longrightarrow X_n,
$$

for any  $m > n$ . We also take  $P_n = ((1 + T)^{p^n} - 1)$ , a height one prime ideal in  $\Lambda = \mathbb{Z}_p[1 + p\mathbb{Z}_p] \cong \mathbb{Z}_p[T]$ , for  $T = \langle 1 + p \rangle_{\Lambda} - 1$ . Recall that we define the diamond operators as in [\[Hsi21,](#page-66-4) Section 4.4]. We extend the notion of Λ-adic forms provided in loc. cit. as follows.

**Definition 4.25.** Let  $S^D(R_{N_+,N_-},\Lambda)$  be the space of functions  $f: X_\infty \longrightarrow \Lambda$ , such that, for any  $z \in$  $1+p\mathbb{Z}_p,$ 

$$
\mathbf{f}(xz) = \mathbf{f}(x)\langle z\rangle^2 \langle z\rangle^{-1}_{\Lambda},
$$

and, for any  $n$  sufficiently large,

<span id="page-31-0"></span>
$$
\mathbf{f} \pmod{P_n} \colon X_\infty \longrightarrow \Lambda/P_n
$$

factors through  $X_n$ . We call it the space of  $\Lambda$ -adic quaternionic modular forms of level  $R_{N_+,N_-}$ .

By construction,

(4.25) 
$$
\mathbf{S}^D(R_{N_+,N_-},\Lambda)=\varprojlim_n \text{Hom}_{\Lambda}(\mathbb{Z}_p[X_n],\Lambda/P_n) \otimes_{\Lambda,\iota_2} \Lambda,
$$

for  $\iota_2: \Lambda \longrightarrow \Lambda$  the  $\mathbb{Z}_p$ -algebra morphism (twisting the action at p) defined by

(4.26) 
$$
\iota_2 \colon T \longmapsto (1+T)^{-2}(1+p)^2 - 1.
$$

Therefore, the A-module  $S^D(R_{N_+,N_-},\Lambda)$  is compact and endowed with the Hecke action defined by

(4.27) 
$$
t \cdot \mathbf{f}(x) = \mathbf{f}(t \cdot x)
$$
, for any  $t \in \widetilde{\mathbb{T}}_{\mathbf{I}}$  and  $x \in X_{\infty}$ .

<span id="page-32-1"></span>Recall the notation of Section [3.5.4.](#page-19-3) For any Dirichlet character  $\chi$  modulo  $N_+N_-p$ , valued in  $\mathbb{Z}_p$ , we define

(4.28)

$$
\mathbf{S}^{D}(R_{N_+,N_-},\chi,\Lambda)=\left\{\mathbf{f}\in\mathbf{S}^{D}(R_{N_+,N_-},\Lambda)\}\Bigg|\begin{array}{c}\mathbf{f}(xzr)=(\chi_{\mathbb{A}})^{-1}(z)\widetilde{\chi}(r)f(x)\,\langle\varepsilon_{cyc}(z)\rangle^{2}\,[\langle\varepsilon_{cyc}(z)\rangle]_{\Lambda}\\ \text{for all }z\in\mathbb{A}_{f}^{\times},\,r\in\widehat{R}_{p^{\infty}N_+,N_-}^{\times}\end{array}\right\},
$$

and, for any finite flat extension  $\Lambda'/\Lambda$  and any  $\Lambda'$ -valued Dirichlet character  $\chi$ , we set

(4.29) 
$$
\mathbf{S}^D(R_{N_+,N_-},\Lambda')=\mathbf{S}^D(R_{N_+,N_-},\Lambda)\otimes_{\Lambda}\Lambda'\supseteq \mathbf{S}^D(R_{N_+,N_-},\chi,\Lambda').
$$

From equation [\(4.25\)](#page-31-0), we deduce the compactness of  $S^D(R_{N_+,N_-},\Lambda)$ , hence the ordinary projector  $e^{\text{ord}} = \lim_{n \to \infty} U_p^{n!}$  converges in End<sub>Λ</sub>( $\mathbf{S}^D(R_{N_+,N_-},\Lambda)$ ), as it converges in each End<sub>Λ</sub>( $\mathbb{Z}_p[X_n]$ ). We define

$$
(4.30)\qquad \qquad e^{\text{ord}}\mathbf{S}^D(R_{N_+,N_-},\chi,\Lambda')
$$

as the space of ordinary Λ-adic quaternionic forms.

4.3.2. *Hida families*. The ordinary projector  $e^{ord}$  determines an idempotent in endomorphism ring of quaternionic modular forms and this implies a decomposition into the ordinary and non-ordinary components of the eigenvarieties, which we will denote by the corresponding superscript. We obtain the following diagram of eigenvarieties:

(4.31)  
\n
$$
\begin{array}{ccc}\n & \widetilde{JL}_{p}^{\epsilon} & \longrightarrow & \widetilde{T}_{\mathbf{I}} \\
& \downarrow^{\epsilon} & \longrightarrow & \widetilde{C}_{D}^{\text{ord}} \\
& & \downarrow^{\pi} & \longrightarrow & \uparrow \\
& & \downarrow^{\pi} & \longrightarrow & \downarrow^{\text{ord}} \\
& & \mathcal{E}_{D}^{\text{ord}} & \xrightarrow{JL_{p}} & \mathcal{E}_{\text{GL}_{2}}^{\text{ord}} & \mathbb{T}_{\mathbf{I}}.\n\end{array}
$$

<span id="page-32-0"></span>All the results obtained in Section [4.1](#page-22-1) descend to the ordinary eigenvarieties.

**Proposition 4.26.** Let  $(U, X, \varphi, \lambda)$  be a Hida family on  $\widetilde{\mathscr{E}}_D^{\epsilon}$  (that is, a family in  $\widetilde{\mathscr{E}}_D^{\epsilon, \text{ord}}$ ), and suppose that it contains a classical point. Up to shrinking it, we can identify the family  $(U, \mathcal{X}, \varphi, \lambda)$  with the  $\mathcal{O}(\mathcal{U})^0$ -adic module

$$
(e^{\operatorname{ord}}\mathbf{S}^D(R_{N_+,N_-},\mathcal{O}(\mathcal{U})^0))[\varphi] = \left\{ \mathbf{f} \in \mathbf{S}^D(R_{N_+,N_-},\Lambda) \otimes_{\Lambda} \mathcal{O}(\mathcal{U})^0 \; \middle| \; t \cdot \mathbf{f} = \lambda_{\varphi}(t) \mathbf{f}, \text{ for } t \in \widetilde{\mathbb{T}}_{\mathbf{I}} \right\},\
$$
  
where  $\lambda_{\varphi} = \omega_{\mathrm{GL}_2}^* \circ \lambda \colon \widetilde{\mathcal{J}_{\mathbf{I}}}^{D,\epsilon} \longrightarrow \mathcal{O}(\mathcal{U})^0.$ 

*Proof.*The weight map  $\omega_{GL_2}$  is étale at cuspidal ordinary classical points ([\[Bel21,](#page-65-13) Theorem 7.6.4 and Remark 7.6.6], where the weight is shifted by 2) and, by [\[Che04,](#page-65-12) Proposition 6.2.7], these points are dense in the family. We deduce that  $\mathcal{O}(\mathcal{X}) \cong \mathcal{O}(\widetilde{JL}_p^{\epsilon}(\mathcal{X}))$  is a finite flat algebra over  $\mathcal{O}(\mathcal{U})$ , hence finite flat over I. Up to shrinking  $U$  to a subaffinoid in the admissible covering  $\mathscr{C}$ , and intersecting its preimage with X, we can identify  $\widetilde{JL}_p^{\epsilon}(\mathcal{X}) = \mathcal{U}$  by [\[FvdP04,](#page-66-23) Lemma 8.1.3] (restrict  $\omega_{GL_2}$  to a suitable wide open affinoid neighborhood in  $\mathcal{X}$ , hence shrink  $\mathcal{U}$  to a be contained in the wide open neighborhood of the target affinoid). Therefore,  $\omega_{GL_2}$  becomes an isomorphism. Let now f be an element in  $(e^{ord}S^D(R_{N_+,N_-},\Lambda)\otimes_\Lambda \mathcal{O}(\mathcal{U})^0)[\varphi]$ ; by equation [\(4.25\)](#page-31-0), it is uniquely characterized by the sequence

$$
\left\{ \mathbf{f} \pmod{P_n} \right\} : X_n \longrightarrow \mathcal{O}(\mathcal{U})^0 \otimes_{\Lambda} {\Lambda}/{P_n} \right\}_{n \gg 1}
$$

.

For *n* big enough we consider the specialization map  $\lambda_{\varphi,n}$  defined as

$$
\lambda_{\varphi,n}\colon \widetilde{\mathbb{T}}_{\mathbf{I}}\longrightarrow \widetilde{\mathscr{T}}_{\mathbf{I}}^{D,\epsilon}\stackrel{\lambda_{\varphi}}{\longrightarrow} \mathcal{O}(\mathcal{U})^0\longrightarrow \mathcal{O}(\mathcal{U})^0\otimes_{\Lambda}\Lambda/P_n.
$$

Up to  $\mathcal{O}(\mathcal{U})^0$ -constants, we can then associate each **f** (mod  $P_n$ ) to

$$
x_n = (\lambda_{\boldsymbol{\varphi},n}(t))_{t \in \widetilde{\mathbb{T}}_1} \in \mathcal{X}(\mathcal{O}(\mathcal{U})^0 \otimes_{\Lambda} {\Lambda}/P_n),
$$

<span id="page-33-3"></span>where  $x_n$  corresponds to the system of eigenvalues associated with the quaternionic modular form **f** (mod  $P_n$ ). Note that here we are using the fact that, up to further shrinking  $U$ ,  $\mathcal{O}(U)^0$  is a finitely generated compact  $\Lambda$ -module. We have then proved the sought-for identification.

Let now  $(\mathcal{U}, \mathcal{X}, \varphi, \lambda)$  be a Hida family on  $\widetilde{\mathscr{E}}_D^{\epsilon}$  and let  $\varphi^{\mathrm{GL}_2}$  be the ordinary family corresponding to it. We consider the space of Λ-adic classical Hida families and its eigenspace

<span id="page-33-2"></span>
$$
(4.32) \quad (e^{\mathrm{ord}}\mathbf{S}^{\mathrm{GL}_2}(\Gamma_1(N_+N_-),\Lambda)\otimes_\Lambda\mathcal{O}(\mathcal{U})^0)[\boldsymbol{\varphi}^{\mathrm{GL}_2}] = \left\{\mathbf{f}\in\mathcal{O}(\mathcal{U})^0[\![T]\!]\right|\mid t\cdot\mathbf{f}=\lambda_{\boldsymbol{\varphi}^{\mathrm{GL}_2}}(t)\mathbf{f}, \text{ for } t\in\mathbb{T}_\mathbf{I}\right\}.
$$

**Theorem 4.27.** Suppose that  $\varphi^{GL_2}$  contains a classical point. Up to shrinking U, there exists an isomorphism of rank one  $\mathcal{O}(\mathcal{U})^0\text{-modules}$ 

$$
(e^{\operatorname{ord}}\mathbf{S}^D(R_{N_+,N_-},\Lambda)\otimes_\Lambda{\mathcal O}({\mathcal U})^0)[\pmb{\varphi}]\cong (e^{\operatorname{ord}}\mathbf{S}^{\operatorname{GL}_2}(\Gamma_1(N_+N_-),\Lambda)\otimes_\Lambda{\mathcal O}({\mathcal U})^0)[\pmb{\varphi}^{\operatorname{GL}_2}].
$$

Proof. Proceeding as in the proof of Proposition [4.26,](#page-32-0) up to shrink the family, we can assume it to be étale over the weight space and identify it with the corresponding neighborhood  $U$ . Moreover, we can assume that all the points are minimal [\[Bel21,](#page-65-13) Lemma 7.4.8], therefore the corresponding eigespaces are one-dimensional. The isomorphism in the statement is then obtained keeping track of the constants in  $\mathcal{O}(\mathcal{U})^0$ . By Strong Multiplicity One on  $GL_2$  and finite flatness of  $\mathcal{O}(\mathcal{U})^0$  over **I**, we deduce that

$$
(e^{\mathrm{ord}}\mathbf{S}^D(R_{N_+,N_-},\Lambda)\otimes_\Lambda \mathcal{O}(\mathcal{U})^0)[\varphi]\otimes_{\mathcal{O}(\mathcal{U})^0}\mathrm{Frac}(\mathcal{O}(\mathcal{U})^0)\cong \mathrm{Frac}(\mathcal{O}(\mathcal{U})^0).
$$

The rank-1 statement follows now from the  $GL_2$ -case. An alternative approach can be obtained combining [\[Bel21,](#page-65-13) Theorem 7.6.4, Theorem 8.1.5 and Lemma 8.1.1], keeping in mind that we are considering cuspidal eigenvarieties and the closed immersions of eigenvarieties of [\[Bel21,](#page-65-13) Theorem 7.2.3] hold true.

We are now ready to state the control theorem generalizing [\[Dal23b,](#page-65-6) Theorem 4.10]. Notice that the specialization morphism can be made explicit as in [\[Hsi21,](#page-66-4) Theorem 4.2].

<span id="page-33-1"></span>**Corollary 4.28** (Hida's Control Theorem). For any arithmetic weight  $(k, \varepsilon_n) \in \mathcal{W}(\mathbb{C}_n) \cap \mathcal{U}$ ,

$$
(e^{\mathrm{ord}}\mathbf{S}^D(R_{N_+,N_-},\mathcal{O}(\mathcal{U})^0))[\varphi]\otimes_A \Lambda/P_{(k,\varepsilon_n)}\cong (e^{\mathrm{ord}}S_k^D(R_{p^nN_+,N_-}))[\varphi_{(k,\varepsilon_n)}].
$$

Proof. The above Theorem [4.27](#page-33-2) together with Strong Multiplicity One and Proposition [3.14](#page-18-0) imply the isomorphism between the rank 1 modules in the statement.

Remark 4.29. In the introduction (Section [1\)](#page-0-0) we already pointed out that the condition for having weight one classical specializations in a family  $\varphi^{\mathrm{GL}_2}$  are rather strict. In the setting of this section, this condition can be read easily from the level  $N_$ : a family will not contain classical weight one specializations unless  $N_-^{\text{sp}} = 1$ , i.e.  $N_- = N_-^{\text{sc}}$ . Therefore, throughout the rest of the paper, we will work under this assumption.

## 5. BALANCED TRIPLE PRODUCT  $p$ -ADIC  $L$ -FUNCTION

<span id="page-33-0"></span>In this section, we prove our main theorem about the existence of balanced  $p$ -adic  $L$ -functions and their interpolation property.

5.1. Definition of the *p*-adic L-function. Let  $\mathbf{F} = (\mathbf{f}, \mathbf{g}, \mathbf{h})$  be the triple product of primitive Hida families of tame conductors  $(N_1, N_2, N_3) \in \mathbb{N}^3$  and characters  $(\chi_1, \chi_2, \chi_3)$ . Let  $N = \text{lcm}(N_1, N_2, N_3)$ . For any classical weight  $(k_1, k_2, k_3)$ , we write  $(f_{k_1}, g_{k_2}, h_{k_3}) = \mathbf{F}(k_1, k_2, k_3)$ ; moreover, we let:

$$
\Sigma^- = \{ \ell \text{ finite } | \epsilon_{\ell}(f_{k_1} \times g_{k_2} \times h_{k_3}) = -1 \},
$$

which is independent of the choice of  $(k_1, k_2, k_3)$  by the rigidity of automorphic types.

We make the following assumptions:

- <span id="page-34-0"></span>•  $|\Sigma^{-}|$  is odd; then there exists a definite quaternion algebra D over Q ramified exactly at the places in  $\Sigma^-$  (and infinity),
- if  $\ell \in \Sigma^-$ , then  $v_{\ell}(N) \leq 2$  (this is an improvement on Hsieh's [\[Hsi21\]](#page-66-4) assumption that  $v_{\ell}(N) = 1$ ).

We now choose test vectors on the quaternionic group  $D^{\times}(\mathbb{A})$ . First, we write

(5.1)  $\Sigma_*^{-,sc} = \{ \ell \in \Sigma^- \mid * \text{ is supercuspidal at } \ell \}$  for  $* \in \{f, g, h\},\$ 

(5.2) 
$$
\Sigma^{-,\text{sc}} = \Sigma_f^{-,\text{sc}} \cup \Sigma_g^{-,\text{sc}} \cup \Sigma_h^{-,\text{sc}} \subseteq \Sigma^-,
$$

(5.3) 
$$
\Sigma^{-,n} = \{ \ell \in \Sigma^- \mid n \text{ of } \pi_{f,\ell}, \pi_{g,\ell}, \pi_{h,\ell} \text{ are supercuspidal} \} \qquad \text{for } n \in \{0,1,2,3\}.
$$

Once again, these sets only depend on f, g, h.

Recall from Proposition [2.1](#page-6-1) that  $\Sigma^- = \Sigma^{-,0} \sqcup \Sigma^{-,2} \sqcup \Sigma^{-,3}$ . The computations of the local integrals at  $\ell \in \Sigma^-$  are in Propositions [2.7,](#page-9-1) [2.8,](#page-10-0) [2.9,](#page-11-1) respectively.

Next, we choose the signs which determine the Hida families on  $D^{\times}$ :

$$
\epsilon_* \in \{\pm 1\}^{\Sigma_*^{-,sc}} \qquad \text{for } * \in \{f, g, h\},
$$
  

$$
\epsilon = (\epsilon_f, \epsilon_g, \epsilon_h).
$$

To shorten the notation from Section [4.3](#page-31-1) we will write  $eS^{D,\epsilon}(N,\psi,\mathcal{U})$  for the space of Λ-adic quaternionic forms  $e^{\text{ord}}S^D(R_{N_+,N_-},\psi_{\mathbb A}^{-1},\mathcal O(\mathcal U)^0)$  where the extra Hecke operators act accordingly to the choice of signs  $\epsilon$ . Then by Theorem [4.23](#page-30-0) and Proposition [4.26,](#page-32-0) for any classical point of the weight space there exist an open admissible affinoid neighborhood  $\mathcal{U} = \mathcal{U}_1 \times \mathcal{U}_2 \times \mathcal{U}_3$  of this point, and elements:

$$
(\mathbf{f}^{D,\epsilon_f}, \mathbf{g}^{D,\epsilon_g}, \mathbf{h}^{D,\epsilon_h}) \in eS^{D,\epsilon_f}(N_1, \psi_1, \mathcal{U}_1)[\mathbf{f}] \times eS^{D,\epsilon_g}(N_2, \psi_2, \mathcal{U}_2)[\mathbf{g}] \times eS^{D,\epsilon_h}(N_2, \psi_2, \mathcal{U}_3)[\mathbf{h}].
$$

Note that these choices are only well-defined up to elements in  $\mathcal{O}(\mathcal{U})^{\times} = \mathcal{O}(\mathcal{U}_1)^{\times} \hat{\otimes} \mathcal{O}(\mathcal{U}_2)^{\times} \hat{\otimes} \mathcal{O}(\mathcal{U}_3)^{\times}$ .

Finally, we bring these forms to the common level  $N$ , following  $[Hsi21,$  Definition 4.8].

## Definition 5.1.

- (1) Define the adjustments of levels  $\mathbf{d}_f$ ,  $\mathbf{d}_g$ ,  $\mathbf{d}_h$  as in [\[Hsi21,](#page-66-4) Section 3.4]. At  $\ell \in \Sigma^{-,\text{sc}}$ , we make no additional adjustment.
- (2) Consider the sets  $\Sigma_{*,0}^{\text{IIb}}$  as in [\[Hsi21,](#page-66-4) Section 3.4] and define:

$$
(\mathbf{f}^{D\star,\epsilon_f}, \mathbf{g}^{D\star,\epsilon_g}, \mathbf{h}^{D\star,\epsilon_h}) \in e^{S^{D,\epsilon_f}}(N_1, \psi_1, \mathcal{U}_1)[\mathbf{f}] \times e^{S^{D,\epsilon_g}}(N_2, \psi_2, \mathcal{U}_2)[\mathbf{g}] \times e^{S^{D,\epsilon_h}}(N_3, \psi_3, \mathcal{U}_2)[\mathbf{h}]
$$

by

$$
\begin{aligned} \mathbf{f}^{D\star,\epsilon_f} &= \sum_{I\subseteq\Sigma^{\mathrm{IIb}}_{f,0}} (-1)^{|I|} \beta_I(f)^{-1} V_{\mathbf{d}_f/n_f} \mathbf{f}^{D,\epsilon_f},\\ \mathbf{g}^{D\star,\epsilon_f} &= \sum_{I\subseteq\Sigma^{\mathrm{IIb}}_{g,0}} (-1)^{|I|} \beta_I(g)^{-1} V_{\mathbf{d}_g/n_g} \mathbf{g}^{D,\epsilon_g},\\ \mathbf{h}^{D\star,\epsilon_h} &= \sum_{I\subseteq\Sigma^{\mathrm{IIb}}_{h,0}} (-1)^{|I|} \beta_I(h)^{-1} V_{\mathbf{d}_h/n_h} \mathbf{f}^{D,\epsilon_h}. \end{aligned}
$$

We now define an unnormalized version of the triple product p-adic L-function.

**Definition 5.2.** Let  $\mathcal{R} = \mathcal{O}(\mathcal{U}) = \mathcal{O}(\mathcal{U}_1) \hat{\otimes}_{\mathcal{O}} \mathcal{O}(\mathcal{U}_2) \hat{\otimes}_{\mathcal{O}} \mathcal{O}(\mathcal{U}_3)$ .

- (1) Define the triple product  $\mathbf{F}^{D\star,\epsilon} \colon (D^{\times} \backslash \widehat{D}^{\times})^3 \to \mathcal{R}$  by  $\mathbf{F}^{D\star,\epsilon} = \mathbf{f}^{D\star,\epsilon_f} \boxtimes \mathbf{g}^{D\star,\epsilon_g} \boxtimes \mathbf{h}^{D\star,\epsilon_h}$ .
- (2) The associated theta element is:

$$
\Theta_{\mathbf{F}^{D\star,\epsilon}} = (\mathbf{F}^{D\star,\epsilon})^*(\Delta_\infty^\dagger) \in \mathcal{R},
$$

where  $\Delta_{\infty}^{\dagger}$  is the *regularized diagonal cycle* from [\[Hsi21,](#page-66-4) Definition 4.6].

<span id="page-35-1"></span>Since  $\mathbf{F}^{D\star,\epsilon}$  is only well-defined up to scalars, so is  $\Theta_{\mathbf{F}^{D\star,\epsilon}}$ . To define the genuine p-adic L-function, we will divide  $\Theta_{\mathbf{F}^{D^*,\epsilon}}$  by the Petersson norm of  $\mathbf{F}^{D^*,\epsilon}$ .

Recall the quaternionic Petersson product introduced in Section [3.6.1.](#page-19-4) Considering such pairing, for **f** and  $f' \in S^D(N+N_-, \chi, I)$  we define

(5.4) 
$$
\mathbf{B}_{N_+,N_-,\alpha}(\mathbf{f},\mathbf{f}') = \sum_{[x]\in D^\times\backslash \widehat{D}^\times/\widehat{R}_{N_+p^\alpha,N_-}^\times} \frac{\chi_{\mathbb{A}}(\nu_{\mathbb{A}_f}(x)) \langle N_p(x)\rangle [\langle N_p(x)\rangle] \mathbf{I}}{\# \Gamma_{N_+p^\alpha,N_-}(x)} \mathbf{f}\left(x \tau_{N_+p^\alpha,N_-}^D\right) \mathbf{f}'(x).
$$

As in [\[Hsi21,](#page-66-4) Definition 4.3], we obtain a Hecke-equivariant I-bilinear pairing

(5.5) 
$$
\mathbf{B}_N : e\mathbf{S}^D(N, \chi, \mathbf{I}) \times e\mathbf{S}^D(N, \chi, \mathbf{I}) \to \mathbf{I},
$$

(5.6) 
$$
\mathbf{B}_{N}(\mathbf{f}, \mathbf{f}') = \varprojlim_{\alpha} \mathbf{B}_{N, \alpha}(\mathbf{f}, \mathbf{f}') \in \varprojlim_{\alpha} \mathbf{I}/P_{\alpha} = \mathbf{I}
$$

such that for every arithmetic point  $\kappa = (k, \epsilon)$  and integer  $\alpha \ge \max\{1, v_p(\text{cond}(\epsilon))\}$ , we have (cf. [\[Hsi21,](#page-66-4) Proof of Lemma 4.4])

(5.7) 
$$
\mathbf{B}_N(\mathbf{f}, \mathbf{f}')(\kappa) = (-1)^k \langle \mathbf{U}_p^{-\alpha} \mathbf{f}_{\kappa}, \mathbf{f}_{\kappa}' \rangle_{N+p^{\alpha}, N_-}.
$$

**Definition 5.3.** For  $f^D \in eS^D(N, \chi, O(U))$ , the *Petersson inner product* of  $f^D$  is

$$
\eta_{\mathbf{f}^D} = \mathbf{B}_N(\mathbf{f}^D, \mathbf{f}^D) \in \mathcal{O}(\mathcal{U})
$$

and the *Petersson norm* of  $f^D$  is:

$$
\|\mathbf{f}^D\| = \eta_{\mathbf{f}^D}^{1/2} \in \operatorname{Frac} \mathcal{O}(\mathcal{U}).
$$

Similarly, for a triple product  $\mathbf{F}^D = \mathbf{f}^D \boxtimes \mathbf{g}^D \boxtimes \mathbf{h}^D$ , its *Petersson norm* is:

$$
\|\mathbf{F}^{D}\| = \|\mathbf{f}^{D}\| \cdot \|\mathbf{g}^{D}\| \cdot \|\mathbf{h}^{D}\| \in \text{Frac}\,\mathcal{O}(\mathcal{U}).
$$

Before defining the  $p$ -adic L-function we recall two more technical points from [\[Hsi21\]](#page-66-4), related to the choice of test vectors at primes dividing  $N^+$ :

- There is a twist  $\mathbf{F}' = (\mathbf{f} \otimes \chi_1, \mathbf{g} \otimes \chi_2, \mathbf{h} \otimes \chi_3)$  by Dirichlet characters  $\chi_1, \chi_2, \chi_3$  modulo M with  $M^2|N^+$  such that  $\chi_1\chi_2\chi_3 = 1$  and  $\mathbf{F}'$  satisfies Hypothesis 6.1 of loc. cit. (see also Remark 6.2).
- There is a *fudge factor*  $f_{\mathbf{F}'} = \prod_{\mathbf{F} \in \mathcal{F}} f(\mathbf{F})$  $q|N+$  $f_{\mathbf{F}',q} \in \mathcal{R}^{\times}$  defined in Proposition 6.12 of loc. cit., and, enlarging  $\mathcal O$  if necessary, we have that  $\sqrt{f_{\mathbf{F}'} } \in \mathcal{R}^{\times}$ .

By [\[Hsi21,](#page-66-4) Lemma 6.11], there exists  $\epsilon^{\Sigma^-}(\mathbf{F}) \in \mathcal{R}^\times$  such that

$$
\epsilon^{\Sigma^-}(\mathbf{F})(\kappa) = \epsilon^{\Sigma^-} (f_{\kappa_1}) \epsilon^{\Sigma^-} (g_{\kappa_2}) \epsilon^{\Sigma^-} (h_{\kappa_3})
$$

<span id="page-35-0"></span>is the product of the away-from- $\Sigma^-$  parts of the root numbers.

**Definition 5.4.** The (genuine) square root balanced triple product p-adic L-function associated with  $\bf{F}$ and  $\epsilon$  is:

$$
\mathcal{L}_{\mathbf{F},\epsilon}^{\text{bal}}(\kappa) = \frac{\Theta_{\mathbf{F}^{\prime D*,\epsilon}}}{\|\mathbf{F}^{D*,\epsilon}\|} \cdot 2^{-\frac{|\Sigma^-|+1-k_1-k_2-k_3}{2}} \cdot (N^-)^{-1/2} \cdot \epsilon^{\Sigma^-}(\mathbf{F})^{-1/2} \cdot \sqrt{\mathfrak{f}_{\mathbf{F}'}}^{-1} \prod_{\ell \in \Sigma^{-,\text{sc}}} \frac{\ell^{k_1+k_2+k_3-13/2}}{\sqrt{\zeta_\ell(2)}} \in \text{Frac } \mathcal{R}.
$$

5.2. The interpolation property. Consider the subset of *arithmetic points* in  $U$ :

$$
(5.8) \quad \mathcal{U}^{\text{arith}} = \left\{ \kappa = (k_1, k_2, k_3, \chi_1, \chi_2, \chi_3) \in \mathcal{U}_1^{\text{arith}} \times \mathcal{U}_2^{\text{arith}} \times \mathcal{U}_3^{\text{arith}} \middle| k_1 + k_2 + k_3 \equiv 0 \pmod{2} \right\},
$$

and let  $\mathcal{U}^{\text{bal}}$  be the subset of *balanced arithmetic points*:

(5.9) 
$$
\mathcal{U}^{\text{bal}} = \left\{ \kappa = (k_1, k_2, k_3, \chi_1, \chi_2, \chi_3) \in \mathcal{U}^{\text{arith}} \mid k_1 + k_2 + k_3 > 2k_i \text{ for all } i = 1, 2, 3 \right\}.
$$

<span id="page-36-2"></span><span id="page-36-0"></span>**Theorem 5.5.** For an arithmetic point  $\kappa = (k_1, k_2, k_3, \chi_1, \chi_2, \chi_3) \in \mathcal{U}^{\text{bal}}$  in the balanced range we have:

$$
(\mathcal{L}_{\mathbf{F},\epsilon}^{\mathrm{bal}}(\kappa))^2=\frac{\Gamma_{\mathbf{V}_{\kappa}^{\dagger}}(0)\cdot L(\mathbf{V}_{\kappa}^{\dagger},0)}{(\sqrt{-1})^{k_1+k_2+k_3-1}\langle\mathbf{F}_{\kappa},\mathbf{F}_{\kappa}\rangle}\cdot\mathcal{E}_p^{\mathrm{bal}}(\mathbf{V}_{\kappa})\cdot\prod_{q\in\Sigma_{\mathrm{exc}}} (1-q^{-1})^2\cdot\prod_{\ell\in\Sigma^{-,2}}\frac{1+\epsilon_{\ell,1}\epsilon_{\ell,2}\sqrt{\omega_3(\ell)}}{2}\prod_{\ell\in\Sigma^{-,3}}\frac{1+\epsilon_{\ell,1}\epsilon_{\ell,2}\epsilon_{\ell,3}}{4},
$$

where  $\mathcal{E}_p(V_\kappa)$  is an Euler factor defined by:

$$
\mathcal{E}_p^{\mathrm{bal}}(\mathbf{V}_{\kappa}) = \frac{\mathcal{E}_p(\mathrm{Fil}_{\mathrm{bal}}^+\mathbf{V}_{\kappa})}{\mathcal{E}_p(\mathbf{F}_{\kappa}, \mathrm{Ad})}
$$

and  $\mathcal{E}_p(\mathbf{F}_{\kappa}, \text{Ad})$  is a modified adjoint Euler factor [\(5.12\)](#page-37-0).

In particular,  $\mathcal{L}_{\mathbf{F},\epsilon}^{\text{bal}} \neq 0$  only if  $\epsilon$  satisfies:

- (1) if  $\ell \in \Sigma^{-,2}$ , then  $\epsilon_{\ell} = (\epsilon_{\ell,1}, \epsilon_{\ell,2})$ : if the special representation is a twist of Steinberg by  $\omega_3$  such that  $\omega_3(\ell) = 1$ , then  $\epsilon_{\ell,1} \cdot \epsilon_{\ell,2} = 1$ ,
- <span id="page-36-1"></span>(2) if  $\ell \in \Sigma^{-,3}$ , then  $\epsilon_{\ell,1} \cdot \epsilon_{\ell,2} \cdot \epsilon_{\ell,3} = 1$ .

Remark 5.6. In this extended remark, we compare our p-adic L-function to the one defined by Hsieh  $[Hsi21,$  Theorem B. The main difference is that his p-adic L-function is defined without normalizing by the Petersson norm  $\|\mathbf{F}^{D*,\epsilon}\|$  on the quaternion algebra. As a result, note that Gross periods ([\[Hsi21,](#page-66-4) Definition 4.12]) do not feature in the interpolation formula for our  $p$ -adic L-function.

We instead use the above definition for two reasons:

- (1) It seems that this is the correct p-adic L-function to state an Elliptic Stark Conjecture [6.5](#page-45-0) for. For example, we will soon see in Theorem  $6.9$  that it is this *p*-adic *L*-function that admits a natural factorization in the CM case.
- (2) We did not prove the analogue of Theorem 4.5 in loc. cit.: that the I-modules  $eS^{D,\pm}(N,\mathbf{I})[\lambda_{\mathbf{f}}^D]$  are free of rank one over the whole algebra I. Instead, we satisfy ourselves with the local statement in Theorems [4.23](#page-30-0) and [4.27,](#page-33-2) because it is enough for our arithmetic applications. However, this means that our choices of vectors  $\mathbf{F}^{D\star,\epsilon}$  are only well-defined up to scalars, and hence only the quotient by the Petersson norm is well-defined.

The terminology *genuine* p-adic L-function is inspired by the discussion after  $[Hsi21]$ , Theorem A. The advantage is that it is independent of choices, but the disadvantage is that it is only an element of Frac  $\mathcal R$ and not R.

The denominators of  $\mathcal{L}_{\mathbf{F},\epsilon}^{bal}$  should be captured by the congruence module of  $\mathbf{F}^{D*,\epsilon}$ , which in turn should be related to the congruence module for  $\bf{F}$  (see [\[Hsi21,](#page-66-4) Remark 7.8]). Indeed, if one could choose vectors  $f^{D,\pm} \in eS^{D,\pm}(N,\mathbf{I})[\lambda_f^D]$  as in [\[Hsi21,](#page-66-4) Theorem 4.5], then one could also define a p-adic L-function in I⊗ $\hat{I} \hat{\otimes} I$ , generalizing the one constructed in loc. cit. It would then differ from our genuine p-adic Lfunction by  $\sqrt{\eta_{\mathbf{F}'}D\star,\epsilon}$  and one could presumably show that  $\eta_{\mathbf{F}'}D\star,\epsilon}$  is a generator for the congruence module as in [\[Hsi21,](#page-66-4) Section 7.2]. We decided to defer these questions to future work.

**Remark 5.7.** Note that the Euler factor at  $p$ :

$$
\mathcal{E}_p(\mathbf{V}_{\kappa}) = \frac{\mathcal{E}_p(\mathrm{Fil}_{\mathrm{bal}}^+\mathbf{V}_{\kappa})}{\mathcal{E}_p(\mathbf{F}_{\kappa}, \mathrm{Ad})}
$$

is analogous to the Euler factor for the unbalanced p-adic L-function constructed by Darmon–Rotger [\[DR14,](#page-66-0) Theorem 1.3]:

$$
\frac{\mathcal{E}(f,g,h)}{\mathcal{E}_0(f)\mathcal{E}_1(f)} = \frac{(1 - \beta_f \alpha_g \alpha_h p^{-c})(1 - \beta_f \alpha_g \beta_h p^{-c})(1 - \beta_f \beta_g \alpha_h p^{-c})(1 - \beta_f \beta_g \beta_h p^{-c})}{(1 - \beta_f^2 \chi_f^{-1}(p)p^{1-k})(1 - \beta_f^2 \chi_f^{-1}(p)p^{-k})}.
$$

The proof of Theorem [5.5](#page-36-0) will occupy the rest of this section and amounts to generalizing the results of [\[Hsi21,](#page-66-4) Section 4]. We split it into two parts:

• an intermediate interpolation property obtained from Ichino's formula [\[Ich08\]](#page-66-5), with factors coming from certain normalized local zeta integrals,

<span id="page-37-4"></span>• the evaluation of the local zeta integrals.

5.3. An intermediate interpolation property. We start by proving the analogue of [\[Hsi21,](#page-66-4) Corollary 4.13], which gives an interpolation property up to certain local factors.

<span id="page-37-3"></span>Proposition 5.8. Let:

(5.10) 
$$
\mathscr{I}_{\Pi_{\kappa,q}}^* = \begin{cases} I_q(\phi_q^* \otimes \widetilde{\phi}_q^*) \cdot B_{\Pi_q} \cdot \frac{\zeta_q(1)^2}{|N|_q^2 \zeta_q(2)^2} \cdot \omega_{F,q}^{-1}(\mathbf{d}_F) |\mathbf{d}_F^{k-2}|_q & \text{for } q | N^+, \\ I_q(\phi_q \otimes \widetilde{\phi}_q) \cdot B_{\Pi_q} \cdot q \frac{\zeta_q(1)^5}{\zeta_q(2)^3} \cdot \omega_{F,q}^{-1}(\mathbf{d}_F) |\mathbf{d}_F^{k-2}|_q & \text{for } q \in \Sigma^{-,2}, \\ I_q(\phi_q \otimes \widetilde{\phi}_q) \cdot B_{\Pi_q} \cdot q \frac{\zeta_q(1)^4}{\zeta_q(2)^2} \cdot \omega_{F,q}^{-1}(\mathbf{d}_F) |\mathbf{d}_F^{k-2}|_q & \text{for } q \in \Sigma^{-,3} \end{cases}
$$

be the normalized local zeta integral at  $q|(N/d^-)$ , with  $I_q(\phi_q^* \otimes \phi_q^*)$  defined in equation [\(5.13\)](#page-37-1), and let:

(5.11) 
$$
\mathscr{I}_{\Pi_{\kappa,q}}^{\text{bal}} = I_p^{\text{ord}}(\phi_p, \breve{\mathbf{t}}_n) \cdot B_{\Pi_p^{\text{ord}}}^{[n]} \frac{\omega_{F,p}^{1/2}(-p^{2n})|p|_p^{-n(k_1+k_2+k_3)}}{\alpha_p(F)^{2n} \zeta_p(2)^2}.
$$

be the normalized p-adic zeta integral defined in [\[Hsi21,](#page-66-4) (4.21)] (see loc. cit. for details).

Then for  $\kappa = (\kappa_1, \kappa_2, \kappa_3) \in \mathcal{U}^{\text{bal}}$  in the balanced range, we have the interpolation formula:

$$
\frac{\Theta_{\mathbf{F}^{D\star}}(\kappa)^2}{\langle F^D,F^D\rangle} = 2^{\#\Sigma^{-,0}+1-k_1-k_2-k_3} \cdot N^{-} \cdot \frac{L(1/2,\Pi_\kappa) \cdot \epsilon^{\Sigma^-}(f_{k_1})\epsilon^{\Sigma^-}(g_{k_2})\epsilon^{\Sigma^-}(h_{k_3})}{\langle f_{k_1},f_{k_1}\rangle \langle g_{k_2},g_{k_2}\rangle \langle h_{k_3},h_{k_3}\rangle} \cdot \frac{\mathscr{I}_{\Pi_{\kappa,p}}^{\rm bal}}{\mathcal{E}_p(\mathbf{F}_\kappa,\mathrm{Ad})} \cdot \prod_{q|(N/d^-)} \mathscr{I}_{\Pi_{\kappa,q}}^{\star}.
$$

where  $f_{k_1}, g_{k_2}, h_{k_3}$  are the newforms associated with the specializations of **F** at  $\kappa$ ,

<span id="page-37-1"></span><span id="page-37-0"></span>
$$
\epsilon^{\Sigma^-}(F) = \prod_{\ell \mid N/d^-} \epsilon(1/2, \pi_{F,\ell}) |N_F|_{\ell}^{(2-k_i)/2} \in \widehat{\mathbb{Z}}_{(p)}^{\times}
$$

is the away-from- $\Sigma^-$  part of the root number of  $F \in \{f_{k_1}, g_{k_2}, h_{k_3}\}$ , and

(5.12) 
$$
\mathcal{E}_p(\mathbf{F}_{\kappa}, \mathrm{Ad}) = \mathcal{E}_p(f_{k_1} \mathrm{Ad}) \mathcal{E}_p(g_{k_2}, \mathrm{Ad}) \mathcal{E}_p(h_{k_3}, \mathrm{Ad}).
$$

is the modified Euler factor in  $[Hsi21, (3.10)].$  $[Hsi21, (3.10)].$ 

*Proof.* Let  $\kappa = (\kappa_1, \kappa_2, \kappa_3)$  for  $\kappa_i = (k_i, \chi_i)$ . We write

(5.13) 
$$
I_{\ell}(\phi_{\ell} \otimes \widetilde{\phi_{\ell}}) = \frac{L(1,\Pi_{v},\mathrm{Ad})}{\zeta_{\ell}(2)^{2}L(1/2,\Pi_{v})} \cdot \frac{I'_{\ell}(\phi_{\ell} \otimes \phi_{\ell})}{\langle \phi_{\ell}, \widetilde{\phi_{\ell}} \rangle}
$$

for the normalized local integrals. Then Ichino's Formula [\[Ich08,](#page-66-5) Theorem 1.1, Remark 1.3] gives the following expression (by combining [\[Hsi21,](#page-66-4) p. 473, proof of Proposition 4.10] with Lemma [3.21\)](#page-22-2):

<span id="page-37-2"></span>(5.14) 
$$
\frac{I(\varrho(\check{\mathbf{t}}_n)\phi_F^{D*})^2}{\langle F^D, F^D \rangle} = \frac{\text{vol}(\widehat{\mathcal{O}}_D^{\times})}{8} \cdot \frac{\zeta_{\mathbb{Q}}(2)^2 L(1/2, \Pi)}{L(1, \Pi, \text{Ad})} \cdot I_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi_p}, \check{\mathbf{t}}_n) \prod_{q \in \Sigma^- \cup \{\infty\}} I_q(\phi_q \otimes \widetilde{\phi}_q) \prod_{q \notin p \cup \Sigma^-} I_q(\phi_q^* \otimes \widetilde{\phi}_q^*) \cdot \omega_F^{-1/2}(\hat{N}_1^+) \omega_{F,p}^{-1}(p^n) \alpha_p(F)^{2n} \prod_{i=1}^3 \frac{\text{vol}(\widehat{R}_{N_i p^{2n}}^{\times})}{(N_i^+ N_i^{-\text{sc}} p^{2n})^{(k_i-2)/2}(k_i-1)},
$$

where

$$
\langle F^D,F^D\rangle=\langle U_p^{-n}f^D,f^D\rangle_{N_1p^n}\langle U_p^{-n}g^D,g^D\rangle_{N_2p^n}\langle U_p^{-n}h^D,h^D\rangle_{N_3p^n}.
$$

Next, we use the volume formula from [\[Piz80b,](#page-66-14) Theorem 3.4]:

$$
\text{vol}(\widehat{R}_{N}^{\times}) = \frac{48}{N} \prod_{q||N} \zeta_{q}(1) \prod_{q^{2}||N} \zeta_{q}(2) \prod_{q|N^{+}} \frac{\zeta_{q}(2)}{\zeta_{q}(1)}
$$

$$
= \frac{48}{\left[\text{SL}_2(\mathbb{Z}) : \Gamma_0(N)\right]} \prod_{q||N^{-}} \frac{1+q^{-1}}{1-q^{-1}} \prod_{q^2||N^{-}} \frac{1+q^{-1}}{1-q^{-2}}
$$

$$
= \frac{48}{\left[\text{SL}_2(\mathbb{Z}) : \Gamma_0(N)\right]} \prod_{q||N^{-}} \frac{\zeta_q(1)^2}{\zeta_q(2)} \prod_{q^2||N^{-}} \zeta_q(1).
$$

<span id="page-38-4"></span>Using this, the final factor in equation [\(5.14\)](#page-37-2) becomes:

<span id="page-38-1"></span>
$$
(5.15) \qquad \prod_{i=1}^{3} \frac{48}{(N_i^+ N_i^{-,sc} p^{2n})^{(k_i-2)/2} [\text{SL}_2(\mathbb{Z}) : \Gamma_0(N_i p^{2n})](k_i-1)} \prod_{q \mid |N_i^{-}} \frac{\zeta_q(1)^2}{\zeta_q(2)} \prod_{q^2 \mid |N_i^{-}} \zeta_q(1).
$$

As we will need it shortly, we also record that:

<span id="page-38-3"></span>(5.16) 
$$
\frac{\text{vol}(\widehat{O}_D^{\times})}{\text{vol}(\widehat{R}_N^{\times})^2} = \frac{1}{48} \prod_{q||N^{-}} q \frac{1}{\zeta_q(1)} \prod_{q^2||N^{-}} q^3 \frac{\zeta_q(1)}{\zeta_q(2)^2} \prod_{q|N^{+}} \frac{\zeta_q(1)^2}{|N|_q^2 \zeta_q(2)^2}.
$$

Next, we recall the relationship between the Petersson norm of a newform  $f$  and the adjoint  $L$ value [\[Hsi21,](#page-66-4) (2.18)]:

(5.17) 
$$
\langle f, f \rangle_{\Gamma_0(N)} = \frac{\left[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)\right]}{2^k w(f)} \cdot L(1, \pi, \mathrm{Ad}) \cdot \prod_{q|N} B_{\pi_q},
$$

where  $B_{\pi_q}$  are given by [\[Hsi21,](#page-66-4) (2.18)]. In particular:

<span id="page-38-2"></span>(5.18) 
$$
L(1,\Pi,\mathrm{Ad}) = \prod_{i=1}^{3} \langle f_i^{\circ}, f_i^{\circ} \rangle \frac{2^{k_i} w(f_i^{\circ})}{[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N_i p^{c_i})]} \prod_{q|N} B_{(\pi_i)_q},
$$

where  $f_i^{\circ}$  is the newform associated with  $f_i$  and its level is  $Np^{c_i}$ . We will write  $B_{\Pi_{F,q}} = B_{\pi_{1,q}} B_{\pi_{2,q}} B_{\pi_{3,q}}$ , as in loc. cit..

<span id="page-38-0"></span>Finally, Hsieh [\[Hsi21,](#page-66-4) Proposition 4.9] gives a relationship between  $I(\varrho(\check{\mathbf{t}}_n)\phi_F^{D\star})$  and  $\Theta_{\mathbf{F}^{D\star}}(\underline{Q})$ :

(5.19) 
$$
\Theta_{\mathbf{F}^{D*}}(\kappa) = \frac{1}{\text{vol}(\widehat{R}_{N}^{\times})} I(\varrho(\mathbf{t}_{n}) \phi_{F}^{D*}) \cdot \frac{\omega_{F,p}^{1/2}(p^{n})|p|^{-\frac{k_{1}+k_{2}+k_{3}}{2}}}{\alpha_{p}(F)^{n} \zeta_{p}(2)} \frac{1}{\omega_{F}^{1/2}(\widehat{\mathbf{d}}_{f}) \mathbf{d}_{F}^{(\underline{k}-2)/2}}.
$$

Next, we put all of these facts together to get:

$$
\frac{\Theta_{\mathbf{F}^{D*}}(\kappa)^2}{\langle F^D, F^D \rangle} = \frac{1}{\text{vol}(\widehat{R}_N^\times)^2} \frac{I(\varrho(\check{\mathbf{t}}_n)\phi_F^{D*})^2}{\langle F^D, F^D \rangle} \cdot \frac{\omega_{F,p}(p^n)|p^n|^{-(k_1+k_2+k_3)}}{\alpha_p(F)^{2n}\zeta_p(2)^2} \frac{1}{\omega_F(\hat{\mathbf{d}}_f)\mathbf{d}_F^{k-2}} \tag{5.19}
$$

$$
=\frac{\text{vol}(\hat{\mathcal{O}}_D^{\times})}{\text{8vol}(\hat{R}_N^{\times})^2} \cdot \frac{\zeta_{\mathbb{Q}}(2)^2 L(1/2, \Pi)}{L(1, \Pi, \text{Ad})}
$$
(5.14)

$$
I_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi_p}, \mathbf{t}_n) \prod_{q \in \Sigma^- \cup \{\infty\}} I_q(\phi_q \otimes \widetilde{\phi}_q) \prod_{q \notin p \cup \Sigma^-} I_q(\phi_q^* \otimes \widetilde{\phi}_q^*)
$$
  
\n
$$
\cdot \omega_F^{-1/2}(\hat{N}_1^+) \omega_{F,p}^{-1}(p^n) \alpha_p(F)^{2n} \prod_{i=1}^3 \frac{\text{vol}(\widehat{R}_{N_ip^{2n}}^{\times})}{(N_i^+ N_i^{-,\text{sc}} p^{2n})^{k_i - 2/2}(k_i - 1)}
$$
  
\n
$$
\frac{\omega_{F,p}(p^n)|p^n|^{-(k_1 + k_2 + k_3)}}{\alpha_p(F)^{2n} \zeta_p(2)^2} \frac{1}{\omega_F(\widehat{\mathbf{d}}_f) \mathbf{d}_F^{k-2}}
$$
  
\n
$$
= \frac{\text{vol}(\hat{\mathcal{O}}_D^{\times})}{\text{Svol}(\widehat{R}_N^{\times})^2} \cdot \frac{\zeta_{\mathbb{Q}}(2)^2 L(1/2, \Pi)}{L(1, \Pi, \text{Ad})}
$$
  
\n
$$
\cdot I_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi_p}, \mathbf{t}_n) \prod_{q \in \Sigma^- \cup \{\infty\}} I_q(\phi_q \otimes \widetilde{\phi}_q) \prod_{q \notin p \cup \Sigma^-} I_q(\phi_q^* \otimes \widetilde{\phi}_q^*)
$$
  
\n
$$
\cdot \left( \prod_{i=1}^3 \frac{48}{(N_i^+ N_i^{-,\text{sc}} p^{2n})^{(k_i - 2)/2} [\text{SL}_2(\mathbb{Z}) : \Gamma_0(N_i p^{2n})](k_i - 1)} \prod_{q \mid |N_i^-} \frac{\zeta_q(1)^2}{\zeta_q(2)} \prod_{q^2 \mid |N_i^-} \zeta_q(1) \right)
$$

<span id="page-39-0"></span>
$$
\frac{p^{6n}}{\zeta_p(2)^2} \frac{\omega_F^{-1/2}(\hat{N}_1^+)}{\omega_F(\hat{R}_f)\mathbf{d}_F^{k-2}} = \frac{48^3 \text{vol}(\hat{\mathcal{O}}_D^{\times})}{8 \text{vol}(\hat{R}_N^{\times})^2} \cdot \frac{\zeta_Q(2)^2 L(1/2, \Pi)}{\langle f^{\circ}, f^{\circ} \rangle \langle g^{\circ}, g^{\circ} \rangle \langle h^{\circ}, h^{\circ} \rangle} \cdot \left(\prod_{q|N} B_{\Pi_{F,q}}\right) \cdot 2^{-k_1 - k_2 - k_3} w(f^{\circ}) w(g^{\circ}) w(h^{\circ}) \qquad (5.18)
$$
\n
$$
\cdot P_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi}_p, \widetilde{t}_n) \prod_{q \in \Sigma^- \cup \{\infty\}} I_q(\phi_q \otimes \widetilde{\phi}_q) \prod_{q \notin p \cup \Sigma^-} I_q(\phi_q^{\star} \otimes \widetilde{\phi}_q^{\star})
$$
\n
$$
\cdot \left(\prod_{i=1}^3 \frac{1}{(N_i^+ N_i^-)^{s c}} \frac{1}{2} (k_i - 1) \right) \left(\prod_{q|N^-} \frac{\zeta_q(1)^6}{\zeta_q(2)^3} \right) \left(\prod_{q \in \Sigma^- \cdot 3} \frac{\zeta_q(1)^4}{\zeta_q(2)} \right) \left(\prod_{q \in \Sigma^- \cdot 3} \zeta_q(1)^3 \right)
$$
\n
$$
\cdot \left(\prod_{i=1}^3 [\text{SL}_2(\mathbb{Z}) : \Gamma_0(p^{c_i})] p^{-2n} (1 + p^{-1})^{-1} \right) \frac{p^{6n}}{\zeta_p(2)^2} \frac{\omega_F^{-1/2}(\hat{N}_1^+)}{\omega_F(\hat{d}_f) \mathbf{d}_F^{k-2}}
$$
\n
$$
= 2^5 3^2 \cdot \frac{\zeta_Q(2)^2 L(1/2, \Pi)}{\langle f^{\circ}, f^{\circ} \rangle \langle g^{\circ}, g^{\circ} \rangle \langle h^{\circ}, h^{\circ} \rangle} \cdot \left(\prod_{q|N} B_{\Pi_{F,q}}\right) \cdot 2^{-k_1 - k_2 - k_3} w(f^{\circ}) w(g^{\circ}) w(h^{\circ})
$$

Next, we recall the computation of some of factors from [\[Hsi21,](#page-66-4) p. 474, p. 478]:

(5.20) 
$$
I_{\infty}(\phi_{\infty} \otimes \widetilde{\phi}_{\infty}) = (4\pi^2)^{-1}(k_1 - 1)(k_2 - 1)(k_3 - 1)
$$
  
(5.21) 
$$
I_q(\phi_q \otimes \widetilde{\phi}_q) = 2\zeta_q(1)^{-2}
$$
 for  $q||N^-$ ,

(5.22) 
$$
B_{\Pi_q} = (-1) \frac{\zeta_q(2)^3}{\zeta_q(1)^3} \quad \text{for } q \mid N^-.
$$

Plugging these into the above equations and recalling that  $\zeta_{\mathbb{Q}}(2) = \frac{\pi}{6}$  and  $\omega_{F,q}^{1/2}(N_f^+)B_{\Pi_q} = B_{\Pi_{F,q}}$  for  $q \neq p$  $q \neq p$  $q \neq p$  by definition ([\[Hsi21,](#page-66-4) p. 477]), we can simplify the final expression in the chain of equalities to:

$$
\frac{\Theta_{\mathbf{F}^{D*}}(\kappa)^2}{\langle F^D, F^D \rangle} = (-2)^{\#\Sigma^{-,0}} 2^{1-k_1-k_2-k_3} \cdot N^- \cdot \frac{L(1/2,\Pi)}{\langle f^{\circ}, f^{\circ} \rangle \langle g^{\circ}, g^{\circ} \rangle \langle h^{\circ}, h^{\circ} \rangle} \cdot \left(\prod_{q|N/d^{-}} B_{\Pi_q}\right) \cdot w(f^{\circ})w(g^{\circ})w(h^{\circ})
$$
  

$$
\cdot I_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi_p}, \mathbf{t}_n) \prod_{q^2||N^{-}} I_q(\phi_q \otimes \widetilde{\phi_q}) \prod_{q|N^{+}} I_q(\phi_q^{\star} \otimes \widetilde{\phi_q}^{\star})
$$
  

$$
\cdot \left(\prod_{i=1}^3 \frac{1}{(N_i^+ N_i^{-,\text{sc}})^{\frac{k_i-2}{2}}}\right) \left(\prod_{q \in \Sigma^{-,2}} q^3 \frac{\zeta_q(1)^5}{\zeta_q(2)^3}\right) \left(\prod_{q \in \Sigma^{-,3}} q^3 \frac{\zeta_q(1)^4}{\zeta_q(2)^2}\right) \left(\prod_{q|N^{+}} \frac{\zeta_q(1)^2}{|N|_q^2 \zeta_q(2)^2}\right)
$$
  

$$
\cdot \left(\frac{[\text{SL}_2(\mathbb{Z}) : \Gamma_0(p^{c_i})]}{1+p^{-1}}\right) \zeta_p(2)^{-2} \frac{\omega_F^{-1/2}(\hat{N}^{-})}{\omega_F(\hat{\mathbf{d}}_f)\mathbf{d}_F^{\underline{k}-2}}.
$$

Next, we recall that for  $F\in \{f,g,h\}\text{:}$ 

$$
w(F) = \prod_{\ell < \infty} \epsilon(1/2, \pi_{F,\ell})
$$

$$
=\epsilon(1/2,\pi_{F,p})\prod_{q\vert\vert N^{-}}\epsilon(1/2,\pi_{F,q})\prod_{q\vert N/d^{-}}\epsilon(1/2,\pi_{F,q})
$$

<span id="page-40-2"></span>and for  $q||N^-$ :

$$
-1 = \epsilon(1/2, \Pi_q) = \omega_{F,q}^{-1/2}(q) \epsilon(1/2, \pi_{f_1,q}) \epsilon(1/2, \pi_{f_2,q}) \epsilon(1/2, \pi_{f_3,q}).
$$

We define the away-from- $\Sigma^-$  part of the conductor to be:

$$
\epsilon^{\Sigma^-}(F) = \prod_{q|N/d^-} \epsilon(1/2, \pi_{F,q}) |N_F|_q^{(2-\underline{k})/2} \in \widehat{\mathbb{Z}}_{(p)}^{\times}.
$$

This gives:

$$
\frac{\Theta_{\mathbf{F}^{D*}}(\kappa)^2}{\langle F^D, F^D \rangle} = 2^{\# \Sigma^{-,0} + 1 - k_1 - k_2 - k_3} \cdot N^{-} \cdot \frac{L(1/2, \Pi)}{\langle f^{\circ}, f^{\circ} \rangle \langle g^{\circ}, g^{\circ} \rangle \langle h^{\circ}, h^{\circ} \rangle} \cdot \epsilon^{\Sigma^{-}}(f^{\circ}) \cdot \epsilon^{\Sigma^{-}}(g^{\circ}) \cdot \epsilon^{\Sigma^{-}}(h^{\circ})
$$
  

$$
\cdot I_p^{\text{ord}}(\phi_p \otimes \widetilde{\phi_p}, \mathbf{t}_n) B_{\Pi_{F,p}} \left( \prod_{i=1}^3 \frac{[\text{SL}_2(\mathbb{Z}) : \Gamma_0(p^{c_i})] \epsilon(1/2, \pi_{f_i, p})}{1 + p^{-1}} \right) \cdot \zeta_p(2)^{-2}
$$
  

$$
\cdot \prod_{q \in \Sigma^{-,2}} I_q(\phi_q \otimes \widetilde{\phi_q}) B_{\Pi_q} q \frac{\zeta_q(1)^5}{\zeta_q(2)^3} \omega_{F,q}^{-1}(\hat{\mathbf{d}}_f) |\mathbf{d}_F^{k-2}|_q
$$
  

$$
\cdot \prod_{q \in \Sigma^{-,3}} I_q(\phi_q \otimes \widetilde{\phi_q}) B_{\Pi_q} q \frac{\zeta_q(1)^4}{\zeta_q(2)^2} \omega_{F,q}^{-1}(\hat{\mathbf{d}}_f) |\mathbf{d}_F^{k-2}|_q
$$
  

$$
\cdot \prod_{q \mid N^+} I_q(\phi_q^* \otimes \widetilde{\phi}_q^*) B_{\Pi_q} \frac{\zeta_q(1)^2}{|N|_q^2 \zeta_q(2)^2} \omega_{F,q}^{-1}(\hat{\mathbf{d}}_f) |\mathbf{d}_F^{k-2}|_q.
$$

To finish the proof, we recall from [\[Hsi21,](#page-66-4) p. 477] that:

$$
(5.23) \qquad \frac{B_{\Pi_{p}^{\text{ord}}}}{B_{\Pi_{F,p}}} = \omega_{f,p}^{1/2}(-p^{-2n}) \prod_{i=1}^{3} \frac{\alpha_{f_i,p} |\cdot|_p^{1/2}(p^{2n})}{\epsilon(1/2,\pi_{f_i,p})} \cdot \frac{[\text{SL}_2(\mathbb{Z}) : \Gamma_0(p^{c_i})]}{1+p^{-1}} \cdot \mathcal{E}_p(f_i, \text{Ad}).
$$

5.4. Computation of local factors. By Proposition [5.8,](#page-37-3) proving Theorem [5.5](#page-36-0) amounts to computing the local factors. For p and  $q|N^+$ , they were already computed by Hsieh.

## <span id="page-40-0"></span>Proposition 5.9 (Hsieh).

(1) We have that:

$$
\mathscr{I}_{\Pi_{\kappa,p}}^{\text{bal}} = \mathcal{E}_{\text{bal}}(\Pi_{\kappa,p}) \cdot \frac{1}{L(1/2,\Pi_{\kappa,p})}.
$$

(2) For  $q|N^+$ :

$$
\mathscr{I}_{\Pi_{\kappa,q}}^{\star} = \mathfrak{f}_{\mathbf{F},q}(\kappa) \cdot \begin{cases} (1+q^{-1})^2 & \text{if } q \in \Sigma_{\text{exc}}, \\ 1 & \text{otherwise} \end{cases}
$$

*Proof.* Part (1) is [\[Hsi21,](#page-66-4) Proposition 5.6] and part (2) is [Hsi21, Proposition 6.12].

<span id="page-40-1"></span>Therefore, it remains to compute  $\mathscr{I}_{\Pi_{\kappa,\ell}}$  for  $\ell \in \Sigma^-$  such that  $\ell^2 || N$ , i.e. for  $\ell \in \Sigma^{-,2}$  and  $\ell \in \Sigma^{-,3}$ .

**Proposition 5.10.** Suppose  $\ell \in \Sigma^{-,2}$  and  $\omega_{F,\ell} = 1$ . Then:

$$
\mathscr{I}_{\Pi_{\kappa,\ell}}^\star=-\frac{1+\epsilon_1\epsilon_2\sqrt{\omega_3(\ell)}}{2}\frac{\ell^{-2(k_1+k_2+k_2)+13}}{\zeta_\ell(2)}.
$$

Proof. We use:

• Proposition [2.8:](#page-10-0)

$$
\frac{I'_\ell(\phi^{\epsilon_\ell}_\ell\otimes \widetilde{\phi^{\epsilon_\ell}_\ell})}{\langle \phi^{\epsilon_\ell}_\ell,\widetilde{\phi^{\epsilon_\ell}_\ell}\rangle}=\frac{1+\epsilon_1\epsilon_2(\sqrt{\omega_3(\ell)})}{2},
$$

• Propositions [2.3,](#page-7-0) [2.4:](#page-7-1)

$$
L(s,\Pi_{\ell},\mathrm{Ad})=\zeta_{\ell}(s+1)(\zeta_{\ell}(2s)/\zeta_{\ell}(s))^2, \qquad L(s,\Pi_{\ell})=\zeta_{\ell}(s+1/2)^2.
$$

<span id="page-41-1"></span>Therefore:

$$
I_{\ell}(\phi_{\ell}^{\epsilon_{\ell}} \otimes \widetilde{\phi_{\ell}^{\epsilon_{\ell}}}) = \frac{\zeta_{\ell}(2)\zeta_{\ell}(2)^2}{\zeta_{\ell}(2)^2\zeta_{\ell}(1)^2\zeta_{\ell}(1)^2} \frac{1+\epsilon_1\epsilon_2\sqrt{\omega_3(\ell)}}{2} = \frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)^4} \frac{1+\epsilon_1\epsilon_2\sqrt{\omega_3(\ell)}}{2}.
$$

Note that  $B_{\pi_{\ell}} = 1$  if  $\pi_{\ell}$  is supercuspidal and  $\pi_{\ell} \otimes \xi \cong \pi_{\ell}$  for the unramified quadratic character  $\xi$  of  $\mathbb{Q}_{\ell}^{\times}$  (cf. [\[Col18,](#page-65-18) Section 4.2]). Therefore,  $B_{\Pi_{\ell}} = B_{\pi_1} B_{\pi_2} B_{\pi_3} = (-1) \frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)}$  (similarly to [\[Hsi21,](#page-66-4) p. 478]). Altoghether, we have that:

$$
\mathscr{I}_{\Pi_{\kappa,\ell}}^{\star} = -\frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)^{4}} \frac{1 + \epsilon_{1}\epsilon_{2}\sqrt{\omega_{3}(\ell)}}{2} \frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)} \ell \frac{\zeta_{\ell}(1)^{5}}{\zeta_{\ell}(2)^{3}} |\mathbf{d}_{F}^{k-2}|_{\ell} \n= -\frac{1 + \epsilon_{1}\epsilon_{2}\sqrt{\omega_{3}(\ell)}}{2} \frac{\ell |\ell|_{\ell}^{2(k_{1} + k_{2} + k_{2} - 6)}}{\zeta_{\ell}(2)},
$$

<span id="page-41-0"></span>as claimed.

**Proposition 5.11.** Suppose  $\ell \in \Sigma^{-,3}$  and  $\omega_{F,\ell} = 1$ . Then:

$$
\mathscr{I}_{\Pi_{\kappa,\ell}}^{\star} = \frac{1 + \epsilon_1 \epsilon_2 \epsilon_3}{4} \frac{\ell^{-2(k_1 + k_2 + k_3) + 13}}{\zeta_{\ell}(2)}.
$$

Proof. We use:

• Proposition [2.9:](#page-11-1)

$$
\frac{I'_{\ell}(\phi_{\ell}^{\epsilon_{\ell}} \otimes \widetilde{\phi_{\ell}^{\epsilon_{\ell}}})}{\langle \phi_{\ell}^{\epsilon_{\ell}}, \widetilde{\phi_{\ell}^{\epsilon_{\ell}}}\rangle} = \frac{1 + \epsilon_1 \epsilon_2 \epsilon_3}{4},
$$

• Propositions [2.3,](#page-7-0) [2.4:](#page-7-1)

$$
L(s,\Pi_{\ell},\mathrm{Ad})=(\zeta_{\ell}(2s)/\zeta_{\ell}(s))^3, \qquad L(s,\Pi_{\ell})=\zeta_{\ell}(2s).
$$

Therefore:

$$
I_{\ell}(\phi_{\ell}^{\epsilon_{\ell}} \otimes \widetilde{\phi_{\ell}^{\epsilon_{\ell}}}) = \frac{\zeta_{\ell}(2)^{3}}{\zeta_{\ell}(2)^{2}\zeta_{\ell}(1)^{3}\zeta_{\ell}(1)} \frac{1 + \epsilon_{1}\epsilon_{2}\epsilon_{3}}{4} = \frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)^{4}} \frac{1 + \epsilon_{1}\epsilon_{2}\epsilon_{3}}{4}.
$$

Moreover,  $B_{\Pi_\ell} = 1.$  Altogether, we have that:

$$
\mathscr{I}_{\Pi_{\kappa,\ell}}^{\star} = \frac{\zeta_{\ell}(2)}{\zeta_{\ell}(1)^{4}} \frac{1 + \epsilon_{1}\epsilon_{2}\epsilon_{3}}{4} \cdot \ell \frac{\zeta_{\ell}(1)^{4}}{\zeta_{\ell}(2)^{2}} \omega_{F,\ell}^{-1}(d_{f}^{k-2})|d_{F}^{k-2}|_{\ell}
$$

$$
= \frac{1 + \epsilon_{1}\epsilon_{2}\epsilon_{3}}{4} \frac{\ell |\ell|_{\ell}^{2(k_{1} + k_{2} + k_{3} - 6)}}{\zeta_{\ell}(2)},
$$

as claimed.

## 5.5. Finishing the proof of Theorem [5.5.](#page-36-0) Putting everything together gives the interpolation property.

*Proof of Theorem [5.5.](#page-36-0)* We compute using the definition of  $\mathcal{L}_{\mathbf{F},\epsilon}^{\text{bal}}$ .

$$
\begin{split} (\mathcal{L}_{\mathbf{F},\epsilon}^{\mathrm{bal}}(\kappa))^{2} &= \frac{\Theta_{\mathbf{F}^{\prime D^{\star},\epsilon}}^{2}}{||\mathbf{F}^{D\star,\epsilon}||^{2}} \cdot 2^{-(|\Sigma^{-}|+1-k_{1}-k_{2}-k_{3})} \cdot \epsilon^{\Sigma^{-}}(\mathbf{F})(\kappa)^{-1} \cdot \mathfrak{f}_{\mathbf{F}^{\prime}}(\kappa)^{-1} \prod_{\ell \in \Sigma^{-,\mathrm{sc}}} \frac{\ell^{2(k_{1}+k_{2}+k_{3})-13}}{\zeta_{\ell}(2)} \\ &= \frac{L(1/2,\Pi_{\kappa})}{\langle\mathbf{F}_{\kappa},\mathbf{F}_{\kappa}\rangle} \cdot \frac{\mathscr{I}_{\Pi_{\kappa,p}}^{\mathrm{bal}}}{\zeta_{p}(\mathbf{F}_{\kappa},\mathrm{Ad})} \cdot \prod_{\ell^{2}||N^{-}} \mathscr{I}_{\Pi_{\kappa,\ell}}^{\star} \frac{\ell^{2(k_{1}+k_{2}+k_{3})-13}}{\zeta_{\ell}(2)} \cdot \prod_{q|N^{+}} I_{\Pi_{\kappa,q}}^{\star} \cdot f_{\mathbf{F}^{\prime}}(\kappa)^{-1} \\ &= \frac{L(1/2,\Pi_{\kappa})}{\langle\mathbf{F}_{\kappa},\mathbf{F}_{\kappa}\rangle} \cdot \frac{\mathcal{E}_{\mathrm{bal}}(\Pi_{\kappa,p})}{L(1/2,\Pi_{\kappa,p})\mathcal{E}_{p}(\mathbf{F}_{\kappa},\mathrm{Ad})} \cdot \prod_{\ell \in \Sigma^{-,2}} \frac{1+\epsilon_{1}\epsilon_{2}\sqrt{\omega_{3}(\ell)}}{2} \prod_{\ell \in \Sigma^{-,3}} \frac{1+\epsilon_{1}\epsilon_{2}\epsilon_{3}}{4} \cdot \prod_{q \in \Sigma_{\mathrm{exc}}} \frac{1}{(1+q^{-1})^{2}} \end{split}
$$

using Proposition [5.8](#page-37-3) for the second equality and Propositions [5.9,](#page-40-0) [5.10,](#page-40-1) [5.11](#page-41-0) for the final one. This proves the theorem.

### 6. Application: Elliptic Stark Conjecture in rank one

<span id="page-42-2"></span><span id="page-42-0"></span>We are now ready to discuss the analogue of the Elliptic Stark Conjecture of Darmon–Lauder– Rotger [\[DLR15\]](#page-65-1) in this setting. We will consider the restriction of  $\mathcal{L}_p^{\text{bal}}$  to the weights  $(k_1, k_2, k_3)$  =  $(2, \ell, m)$  with the goal of studying the point  $(2, 1, 1)$  which is not balanced and hence lies outside of the interpolation range.<sup>4</sup> We state a conjecture expressing this value in terms of arithmetic data and prove it in some special cases.

6.1. Statement of the conjecture. Let E be an elliptic curve over  $\mathbb Q$  and let  $V_p(E)$  be the associated padic Galois representation. Let  $\varrho: G_{\mathbb{Q}} \to GL(V_{\varrho})$  be an Artin representation, i.e. a complex continuous Galois representation, which factors through a finite quotient Gal $(H/\mathbb{Q})$  of  $G_{\mathbb{Q}}$ , with coefficients in a finite extension L of Q. We consider the Hasse–Weil–Artin L-series  $L(E, \rho, s)$  associated with the padic Galois repersentation  $V_p(E) \otimes V_q$  of  $G_{\mathbb{Q}}$ . The equivariant version of the Birch–Swinnerton-Dyer Conjecture asserts that the analytic rank of  $L(E, \varrho, s)$  at  $s = 1$  is equal to the rank of the  $V_{\varrho}$ -isotypic component of  $E(H) \otimes L$ :

$$
\mathrm{ord}_{s=1}L(E,\varrho,s)=\dim_L \mathrm{Hom}_{G_\mathbb{Q}}(V_\varrho,E(H)\otimes L).
$$

Note that the value  $L(E, \rho, s)$  at  $s = 1$  is outside of the convergence region of the Euler product defining the L-function. We put ourselves in a situation where the analytic continuation and functional equation for the L-function  $L(E, \varrho, s)$  is known:

- let f be the modular form of level  $N_1$  associated with the elliptic curve E of conductor  $N_1$ ,
- suppose that  $\varrho = \varrho_{gh} = \varrho_g \otimes \varrho_h$  for two odd irreducible two-dimensional Artin representations  $\varrho_q$  and  $\varrho_h$ ; let g and h be the modular forms of conductors  $N_2$  and  $N_3$  corresponding to  $\varrho_q$  and  $\rho_h$ , respectively.

Then

$$
L(E, \varrho_{gh}, s) = L(f \times g \times h, s)
$$

is the triple product L-function studied by Garret. We assume that:

$$
\det \varrho_g \det \varrho_h = 1,
$$

i.e. if  $\chi$  is the character of g, then  $\chi^{-1}$  is the character of h. Then the representation  $V_E \otimes V_g \otimes V_h$  is self-dual, and hence there is a functional equation with the root number  $\epsilon(E, \varrho_{gh}) = \pm 1$ . Moreover, the global root number is a product of finite local root numbers:

$$
\epsilon(E, \varrho_{gh}) = \prod_{v \mid \text{lcm}(N_1, N_2, N_3)} \epsilon_v(E, \varrho_{gh}),
$$

because  $\epsilon_{\infty}(E, \varrho_{gh}) = 1$ .

In the seminal work [\[DLR15\]](#page-65-1), Darmon–Lauder–Rotger studied the L-value  $L(E, \varrho_{gh}, s)$  when the analytic rank is even and at least two, using  $p$ -adic analytic method. Therefore, they assume that  $\epsilon(E, \varrho_{gh}) = 1$ , and in fact that  $\epsilon_v(E, \varrho_{gh}) = 1$  for all v.

In rank two, they proposed the Elliptic Stark Conjecture: a formula relating the value of a triple product p-adic L-function associated with f, g, h to a regulator of p-adic logarithms of points on  $E(H) \otimes L$ and a p-adic logarithm of a Stark unit.

<span id="page-42-1"></span>The main motivation for our work is to develop a rank one version of this conjecture. Our first hypothesis is therefore.

**Hypothesis A.** The global root number  $\epsilon(E, \varrho_{gh})$  is -1. Therefore, there is an odd number of finite places v such that

$$
\epsilon_v(E, \varrho_{gh}) = -1.
$$

<sup>&</sup>lt;sup>4</sup>We hope that using  $\ell$  for the weight instead of the prime of supersingular type will cause no confusion to the reader.

<span id="page-43-3"></span>Next, we want to construct a balanced p-adic L-function associated with the L-function  $L(E, \rho_{gh}, s)$  =  $L(f \times g \times h, s)$ . Under Hypothesis [A,](#page-42-1) this L-function vanishes at  $s = 1$ . However, if we consider Hida families associated with g and h, and the L-value  $L(f \times g_\ell \times h_\ell, s)$  for  $\ell \geq 2$ , then

$$
\epsilon_{\infty}(f \times g_{\ell} \times h_{\ell}) = -1, \qquad \epsilon_{v}(f \times g_{\ell} \times h_{\ell}) = \epsilon_{v}(E, \varrho_{gh}) \text{ for } v \text{ finite,}
$$

$$
\epsilon(f \times g_{\ell} \times h_{\ell}) = +1.
$$

In particular, we expect that the central L-value for  $L(f \times g_\ell \times h_\ell, s)$  is generically non-vanishing and hence there should be a non-vanishing  $p$ -adic  $L$ -function interpolating these values.

To define the Hida families, assume that g and h are ordinary at p and consider p-stabilizations of g and h. For  $F \in \{g, h\}$ ,  $F \in S_1(N, \chi_F)$ , suppose the Hecke polynomial is:

$$
x^{2} - a_{p}(F)x + \chi_{F}(p) = (x - \alpha_{p}(F))(x - \beta_{p}(F))
$$

with roots  $\alpha_p(F)$  and  $\beta_p(F)$ . We then have p-stabilizations  $F_\alpha, F_\beta \in S_1(Np, \chi_F)$  such that:

$$
U_p F_\alpha = \alpha F_\alpha, \quad U_p F_\beta = \beta F_\beta.
$$

We will assume that F is regular, i.e.  $\alpha_p(F) \neq \beta_p(F)$ , and hence it has two distinct p-stabilizations.

<span id="page-43-0"></span>We then make the following classicality hypothesis.

**Hypothesis B.** Assume that f is ordinary at p. For  $F \in \{g, h\}$ , F is ordinary and regular at p (i.e.  $\varrho_g$ is irreducible and  $\varrho_g(\sigma_p)$  has two distinct eigenvalues for the Frobenius  $\sigma_p$ ), and it is not the theta series of a character of a real quadratic field in which  $p$  splits.

Under this hypothesis, Darmon–Lauder–Rotger, based on results of Cho and Vatsal and of Bellaïche and Dimitrov, proved that there are no non-classical p-adic modular forms in the generalized eigenspace of  $F_{\alpha}$ .

<span id="page-43-2"></span>**Proposition 6.1** ([\[DLR15,](#page-65-1) Proposition 1.1]). Under Hypothesis [B,](#page-43-0) the natural inclusion:

$$
S_1(Np, \chi_F)_{\mathbb{C}_p}[F_\alpha] \hookrightarrow S_1^{\text{oc,ord}}(N, \chi_F)[F_\alpha]
$$

is an isomorphism of  $\mathbb{C}_p$ -vector spaces.

By Proposition [6.1,](#page-43-2) there exist Hida families  $\mathbf{g}_{\alpha}$  and  $\mathbf{h}_{\alpha}$  whose specializations at weight one are  $g_{\alpha}$ and  $h_{\alpha}$ , respectively.

We want to consider a balanced p-adic L-function  $\mathcal{L}_p^{\text{bal}}$  associated with f and the Hida families  $\mathbf{g}_{\alpha}$  and  $h_{\alpha}$ . Therefore, we need to make another hypothesis which will guarantee that Hypothesis [2.2](#page-7-2) needed to construct the balanced p-adic L-function is satisfied.

<span id="page-43-1"></span>**Hypothesis C.** For each prime q such that  $\epsilon_q(E, \varrho_{gh}) = -1$ ,  $v_q(N_i) \leq 2$  for  $i = 1, 2, 3$ .

Under this hypothesis, we have constructed a balanced triple product  $p$ -adic  $L$ -function associated with the triple f, g, h, and the Elliptic Stark Conjecture concerns its value at  $(2, 1, 1)$ , which is outside of the range of interpolation.

**Definition 6.2.** Let f, g, h be three modular forms of weights 2, 1, 1 satisfying Hypotheses [A,](#page-42-1) [B,](#page-43-0) [C.](#page-43-1) Let  $f_{\alpha}$ ,  $g_{\alpha}$ ,  $h_{\beta}$  be ordinary p-stabilizations of f, g, and h, and consider Hida families f, g, h specializing to p-stabilizations  $f_{\alpha}, g_{\alpha}, h_{\alpha}$  of f, g, h, respectively. Define the 2-variable triple product p-adic L-function by:

$$
\mathcal{L}_p^{\text{bal},f} = 2^{-\#\Sigma^{-,3}} \cdot \prod_{q \in \Sigma_{\text{exc}}} (1 - q^{-1})^{-2} \cdot \mathcal{E}_p(f_\alpha, \text{Ad}) \cdot \mathcal{L}_{\mathbf{f} \times \mathbf{g} \times \mathbf{h}, \pm 1}^{\text{bal}}
$$
  
using Definition 5.4 for  $\epsilon_q = \begin{cases} (+1, +1) & q \in \Sigma^{-,2}, \\ (+1, +1, +1) & q \in \Sigma^{-,2}. \end{cases}$ 

FIGURE 1. We fix  $k = 2$ , and consider two weights  $\ell, m$  with  $\ell + m \equiv 0 \pmod{2}$ . We indicate the four regions for the weights  $\ell$ , m;  $\Sigma^F$  is the region where F is dominant, and  $\Sigma^{\text{bal}}$  is the region where the weights are balanced and  $\ell, m \geq 2$ . We also indicate the point  $(\ell, m) = (1, 1)$  where our Elliptic Stark Conjecture [6.5](#page-45-0) applies.

**Remark 6.3.** One could presumably weaken or even remove the assumption that f is ordinary at p by defining the 2-variable p-adic L-function directly, instead of considering a Hida family through  $f_{\alpha}$  and referring to the 3-variable p-adic L-function. However, we decided not to pursue this point here.

<span id="page-44-0"></span>As a corollary to Theorem [5.5,](#page-36-0) we get the following interpolation property.

Corollary 6.4. For  $\ell, m \geq 2$  such that  $2 - \ell \leq m \leq 2 + \ell$  and  $\ell + m \equiv 0 \pmod{2}$ :

$$
\mathcal{L}_p^{\text{bal},f}(\ell,m)^2 = \frac{\Lambda(f \times g_\ell \times h_m, (\ell+m)/2)}{\langle f, f \rangle \langle g_\ell, g_\ell \rangle \langle h_m, h_m \rangle} \cdot \mathcal{E}_p^{\text{bal}}(\mathbf{V}_\kappa) \cdot \mathcal{E}_p(f_\alpha, \text{Ad}),
$$

where  $\Lambda(f \times g_\ell \times h_m, s)$  is the completed triple product L-function.

The value  $\mathcal{L}_p^{\text{bal},f}(1,1) = \mathcal{L}_{\mathbf{f} \times \mathbf{g} \times \mathbf{h},\epsilon}^{\text{bal}}(2,1,1)$  will be expressed in terms of arithmetic data associated with the triple  $(E, \varrho_g, \varrho_h)$ . We introduce this next.

Let  $\sigma_p \in \text{Gal}(H/\mathbb{Q})$  be the Frobenius at p associated with an embedding  $H \to \mathbb{Q}_p^{\text{ur}}$ . Under Hypothe-sis [B,](#page-43-0) for  $F \in \{g, h\}$ , we have that

$$
\varrho_F(\sigma_p) = \begin{pmatrix} \alpha_p(F) & 0 \\ 0 & \beta_p(F) \end{pmatrix}
$$

and we may hence consider the one-dimensional eigenspace  $V_F^{\alpha} \subseteq V_F$  for  $\sigma_p$  associated with the eigenvalue  $\alpha(F)$ . This determines a one-dimensional L-subspace:

$$
V_{\alpha\alpha} = V_g^{\alpha} \otimes V_h^{\alpha} \subseteq V_g \otimes V_h
$$

and we fix an element  $v_{\alpha\alpha} \in V_{\alpha\alpha}$ . On the other hand, under Hypothesis [A,](#page-42-1) we expect that  $r(E, \varrho_{gh}) =$  $\dim_L \text{Hom}_{G_{\mathbb{Q}}}(V_{gh}, E(H) \otimes L) \geq 1$ . If  $\dim_L \text{Hom}_{G_{\mathbb{Q}}}(V_{gh}, E(H) \otimes L) = 1$ , we choose its basis

$$
\Phi\colon V_{gh}\to E(H)\otimes L,
$$

and let

$$
E(H)^{V_{gh}}_{L} = \Phi(V_{gh}) \subseteq E(H) \otimes L.
$$

We will consider the point:

$$
\Phi(v_{\alpha\alpha}) \in E(H)^{V_{gh}}_{L} \subseteq E(H) \otimes L.
$$

<span id="page-45-2"></span>Next, associated with  $F \in \{g, h\}$ , we have an adjoint representation  $Ad_F = Hom^0(V_F, V_F)$ , with Frobenius eigenvalues 1,  $\frac{\alpha_p(F)}{\beta_p(F)}$ ,  $\frac{\beta_p(F)}{\alpha_p(F)}$  $\frac{\rho_p(\mathbf{F})}{\alpha_p(\mathbf{F})}$ . By [\[DLR15,](#page-65-1) Proposition 1.5], we have that

$$
\mathrm{Hom}_{G_{\mathbb{Q}}}(\mathrm{Ad}_F,\mathcal{O}_{H_F}^\times\otimes L)
$$

is one-dimensional. Let  $\varphi$  be its basis and consider

$$
(\mathcal{O}_{H_F}^{\times})_L^{\mathrm{Ad}_F} = \varphi(\mathrm{Ad}_F) \subseteq \mathcal{O}_{H_F}^{\times} \otimes L.
$$

Under the extra assumption that  $\alpha_p(F) \neq -\beta_p(F)$  or  $\rho_F$  is induced from a character of an imaginary quadratic field in Hypothesis [B,](#page-43-0) the subspace

$$
U_{F_{\alpha}} = \left\{ u \in (\mathcal{O}_{H_F}^{\times})_L^{\mathrm{Ad}_F} \middle| \sigma_p(u) = \frac{\alpha_p(F)}{\beta_p(F)} \right\}
$$

<span id="page-45-0"></span>is one-dimensional [\[DLR15,](#page-65-1) Lemma 1.6]. In any case, we let  $u_{F_{\alpha}} \in U_{F_{\alpha}}$  be a non-torsion element.

Conjecture 6.5 (Elliptic Stark Conjecture, rank one case). Assume Hypotheses [A,](#page-42-1) [B,](#page-43-0) [C](#page-43-1) and that  $r(E, \varrho_{gh}) \geq 1$ . If  $r(E, \varrho_{gh}) > 1$ , then  $\mathcal{L}_p^{\text{bal},f}(1,1) = 0$ . If  $r(E, \varrho_{gh}) = 1$ , then:

$$
\mathcal{L}_p^{\text{bal},f}(1,1) \sim \sqrt{L^\times} \frac{\log_{E,p}(\Phi(v_{\alpha\alpha}))}{\log_p(u_{g_\alpha})^{1/2} \log_p(u_{h_\alpha})^{1/2}},
$$

where

$$
\log_p: (\mathcal{O}_H^{\times})_L \to H_p \otimes L
$$
  
\n
$$
\log_{E,p}: E(H)_L \to H_p \otimes L
$$
  
\n
$$
p\textrm{-}adic formal group logarithm for E.
$$

<span id="page-45-1"></span>Remark 6.6. We would like to thank Alan Lauder for suggesting the following sanity check. The left hand side in the conjecture is independent of the number field  $H$ , whereas the right hand side seems to depend on the Frobenius  $\sigma_p \in \text{Gal}(H/\mathbb{Q})$  and its eigenvalues for the Artin representations  $\varrho_g$  and  $\varrho_h$ . However, the Frobenius  $\sigma_p$  acts on the right hand side as:

$$
\frac{(\alpha_p(g)\alpha_p(h))^2}{\frac{\alpha_p(g)}{\beta_p(g)}\frac{\alpha_p(h)}{\beta_p(h)}} = \alpha_p(g)\alpha_p(h)\beta_p(g)\beta_p(h)
$$

$$
= \chi_g(p)\chi_h(p)
$$

$$
= 1.
$$

**Remark 6.7.** Taking the formal group law exponential  $\exp_{E,p}$ , we get an interesting formula for a p-adic point on the elliptic curve E which is conjecturally in  $E(H) \otimes L$ :

$$
\exp_p(\mathcal{L}_p^{f,bal}(1,1)\log_p(u_{g_{\alpha}})^{1/2}\log_p(u_{h_{\alpha}})^{1/2}) \stackrel{?}{\in} E(H)^{V_{gh}}_{L} \subseteq E(H) \otimes L.
$$

6.2. **Proof in the CM case.** Let  $K/\mathbb{Q}$  be an imaginary quadratic field of discriminant  $-D_K$  in which p splits. The next goal of the paper is to prove the Elliptic Stark Conjecture [6.5](#page-45-0) in the case when  $\varrho_g$  and  $\rho_h$  are representations induced from Dirichlet characters of K.

6.2.1. Statement of the theorem. Let  $\psi: G_K \to \mathbb{C}^\times$  be a finite order character of conductor  $\mathfrak{c} \subseteq \mathcal{O}_K$ . We can then consider the associated Artin representation representation

$$
V_{\psi} = \operatorname{Ind}_{G_K}^{G_{\mathbb{Q}}} \psi \colon G_{\mathbb{Q}} \to \operatorname{GL}_2(\mathbb{C})
$$

with determinant  $\chi = \det V_{\psi} = \psi \circ \text{Tr}$ , where  $\text{Tr} : G^{\text{ab}}_{\mathbb{Q}} \to G^{\text{ab}}_K$  is the transfer map. The weight one modular form associated with this Artin representation is explicitly constructed as a theta series for the character of  $\mathbb{A}_K^{\times}$  corresponding to  $\psi$ :

$$
\theta_{\psi} \in M_1(D_K \cdot N_{K/\mathbb{Q}}(\mathfrak{c}), \chi).
$$

<span id="page-46-4"></span>Moreover,  $\theta_{\psi}$  is a cusp form if and only if  $\psi^{\sigma} \neq \psi$  where  $\sigma$  is a generator of Gal(K/Q). We will only be interested in this case.

We consider two finite order characters  $\psi_g$  and  $\psi_h$  such that  $\chi_h = \chi_g^{-1}$ , where  $\chi_g = \psi_g \circ \text{Tr}$  and  $\chi_h = \psi_h \circ \text{Tr}$ , and  $\psi_g^{\sigma} \neq \psi_g$ ,  $\psi_h^{\sigma} \neq \psi_h$ . Then we have associated modular forms

$$
g = \theta_{\psi_g} \in S_1(N_g, \chi) \qquad h = \theta_{\psi_g} \in S_1(N_h, \overline{\chi}).
$$

Write  $\mathfrak{c}_\star$  for the conductor of  $\psi_\star$  for  $\star \in \{g, h\}.$ 

The goal is to study the Elliptic Stark Conjecture [6.5](#page-45-0) in this example. We have a factorization

$$
V_{gh}=V_{\psi_g}\otimes V_{\psi_h}\cong V_{\psi_g\psi_h}\oplus V_{\psi_g\psi_h^{\sigma}},
$$

and we will write

$$
\psi_1 = \psi_g \psi_h^{\sigma}, \ \psi_2 = \psi_g \psi_h.
$$

This corresponds to the factorization of L-functions

$$
L(E, \varrho_{gh}, s) = L(E/K, \psi_1, s)L(E/K, \psi_2, s).
$$

<span id="page-46-0"></span>Hypothesis [A](#page-42-1) is hence equivalent to the following hypothesis.

Hypothesis A'. We have that:

$$
\epsilon(E/K, \psi_1) \cdot \epsilon(E/K, \psi_2) = -1,
$$

i.e. without loss of generality,  $\epsilon(E/K, \psi_1) = +1$ ,  $\epsilon(E/K, \psi_2) = -1$ .

Next, we want to work out when Hypothesis [B](#page-43-0) holds in this case. The values  $\alpha_p, \beta_p$  depend on the splitting of  $p$  in  $K$ :

$$
\{\alpha_p, \beta_p\} = \begin{cases} {\psi(\sigma_{\mathfrak{p}}), \psi(\sigma_{\overline{\mathfrak{p}}})} & \text{if } (p) = \mathfrak{p}\overline{\mathfrak{p}} \text{ splits,} \\ {\{\sqrt{\psi(\sigma_p)}, -\sqrt{\psi(\sigma_p)}\}} & \text{if } (p) \text{ is inert.} \end{cases}
$$

.

<span id="page-46-1"></span>Therefore, Hypothesis [B](#page-43-0) amounts to the following.

**Hypothesis B'.** For  $\psi \in {\psi_a, \psi_h}$ :

- $\theta_{\psi}$  is ordinary at p,
- $\theta_{\psi}$  is not also the theta series of a character of a real quadratic field in which p splits,
- when p splits in K,  $\psi(\sigma_{\mathfrak{p}}) \neq \psi(\sigma_{\overline{\mathfrak{p}}}).$

<span id="page-46-2"></span>Finally, Hypothesis [C](#page-43-1) is that for each prime  $\ell$  such that  $\epsilon_{\ell}(E_K, \psi_1) \cdot \epsilon_{\ell}(E_K, \psi_2) = -1$ , we have that  $v_{\ell}(N_f), v_{\ell}(N_{K/\mathbb{Q}}\mathfrak{c}_g), v_{\ell}(N_{K/\mathbb{Q}}\mathfrak{c}_h) \leq 2$ . For simplicity, we make a slightly stronger assumption.

**Hypothesis C'.** For each prime  $\ell$  of K such that  $\epsilon_{\ell}(E_K, \psi_1) \cdot \epsilon_{\ell}(E_K, \psi_2) = -1$ , we have that:

- $\epsilon_{\ell}(E_K, \psi_2) = +1$ ,
- $v_{\ell}(N_f) = 1$ ,  $v_{\ell}(N_{K/\mathbb{Q}}c_q) = 2$ ,  $v_{\ell}(N_{K/\mathbb{Q}}c_h) = 2$ .

Moreover, for each prime q of K such that  $\epsilon_q(E_K, \psi_1) \cdot \epsilon_q(E_K, \psi_2) = +1$ , we have that  $\epsilon_q(E_K, \psi_1) = +1$ and  $\epsilon_q(E_K, \psi_2) = +1.$ 

Remark 6.8. We expect that the results of the section still hold under the weaker assumption, by replacing of Appendix [A](#page-52-0) by a generalization of the results of Brooks [\[HB15\]](#page-66-24), and by calculating the local integrals when all three representations are supercuspidal.

We consider three arithmetic quantities associated with our data of f,  $\psi_q$ ,  $\psi_h$ :

• following [\[Gro87,](#page-66-25) Section 11] (more generally, [\[CST14\]](#page-65-19)),

<span id="page-46-3"></span>(6.1) 
$$
c_{f,\psi_1} = \pi_f \left( \sum_{\sigma \in \text{Gal}(H/\mathbb{Q})} \psi_1^{-1}(\sigma) s^{\sigma} \right),
$$

<span id="page-47-4"></span>where  $\pi_f$  is the projection onto the f-isotypic component of an appropriate Shimura set S and  $s \in S$  is a Heegner point for  $H_{c(\psi_1)}/K;$ 

• following  $[DLR15, p. 37]$  (cf.  $[LZZ18, Definition 3.3.1]$ ),

<span id="page-47-3"></span>(6.2) 
$$
P_{\psi_2} = \pi_f \left( \sum_{\sigma \in \text{Gal}(H/K)} \psi_2^{-1}(\sigma) t^{\sigma} \right) \in E(H)_{L}^{\psi_2}
$$

where  $\pi_f$  is the modular parametrization by an appropriate Shimura curve X and  $t \in X$  is a Heegner point for  $H_{c(\psi_2)}/K;$ 

• following [\[DLR15,](#page-65-1) p. 38], for  $\psi_0 \in {\psi_g/\psi_g^{\sigma}, \psi_h/\psi_h^{\sigma}}$ , we let

<span id="page-47-2"></span>(6.3) 
$$
u_{\psi_0} = \sum_{\sigma \in \text{Gal}(H/K)} \psi_0^{-1}(\sigma) u^{\sigma} \in (\mathcal{O}_H^{\times})_L^{\psi_0}
$$

where u is an elliptic unit for  $H_{c(\psi_0)}/K$  and the unit group is written additively.

<span id="page-47-0"></span>**Theorem 6.9.** Let K be an imaginary quadratic field and p be a prime which splits in K. Then, under Hypothesis [A',](#page-46-0) [B',](#page-46-1) [C',](#page-46-2) the rank one Elliptic Stark Conjecture [6.5](#page-45-0) holds. Explicitly, if  $r(E_K, \psi_1) = 0$  and  $r(E_K, \psi_2) = 1$ , then there is an explicit constant  $\lambda \in \sqrt{L^{\times}}$  such that:

$$
\mathcal{L}_{p}^{f,\mathrm{bal}}(1,1)=\lambda \cdot \overbrace{\langle c_{f,\psi_{1}},c_{f,\psi_{1}} \rangle^{1/2}}^{\in \sqrt{L^{\times}}}\cdot \frac{\log_{E,p}(P_{\psi_{2}})}{\log_{p}(u_{\psi_{g}/\psi_{g}^{\sigma}})^{1/2}\log_{p}(u_{\psi_{h}/\psi_{h}^{\sigma}})^{1/2}},
$$

where  $\langle -, - \rangle$  is the height pairing on S.

**Remark 6.10.** The factor  $\langle c_{f,\psi_1}, c_{f,\psi_1} \rangle^{1/2} \in L^{\times}$  could, of course, be combined with  $\lambda \in \sqrt{L^{\times}}$  in the formula. However, we include it here, because it seems to describe the "arithmetic" contribution to the special value associated with the character  $\psi_1$ . It is quite interesting that this factor has a similar form to the other (non-algebraic) factors, and may therefore be relevant to an integral version of the result or to similar results in other settings.

The proof of this theorem is based on a factorization of the  $p$ -adic  $L$ -function corresponding to the factorization

$$
L(E, \varrho_{gh}, s) = L(E/K, \psi_1, s) \cdot L(E/K, \psi_2, s).
$$

Following [\[DLR15,](#page-65-1) Section 3.2], we recall two related *p*-adic *L*-functions.

6.2.2. The Katz p-adic L-function for K [\[Kat76\]](#page-66-27). Let  $\Sigma$  be the set of characters of K of conductor dividing a fixed integral ideal  $\mathfrak{c} \subseteq \mathcal{O}_K$ . We then define  $\Sigma_K = \Sigma_K^{(2)} \cup \Sigma_K^{(2')}$  where:

$$
\Sigma_K^{(2)} = \{ \psi \in \Sigma \text{ of infinity type } (\kappa_1, \kappa_2) \text{ with } \kappa_1 \ge 1, \, \kappa_2 \le 0 \},
$$
  

$$
\Sigma_K^{(2')} = \{ \psi \in \Sigma \text{ of infinity type } (\kappa_1, \kappa_2) \text{ with } \kappa_1 \le 0, \, \kappa_2 \ge 1 \}.
$$

Katz defined a p-adic L-function

$$
\mathcal{L}_p(K)\colon \widehat{\Sigma}_K\to\mathbb{C}_p
$$

defined on the p-adic completion  $\widehat{\Sigma}_K$  of  $\Sigma_K$  with the interpolation property

<span id="page-47-1"></span>(6.4) 
$$
\mathcal{L}_p(K)(\psi) = \mathfrak{a}(\psi) \cdot \mathfrak{e}(\psi) \cdot \mathfrak{f}(\psi) \cdot \frac{\Omega_p^{\kappa_1 - \kappa_2}}{\Omega^{\kappa_1 - \kappa_2}} \cdot L_{\mathfrak{e}}(\psi^{-1}, 0) \qquad \text{for } \psi \in \Sigma_K^{(2)},
$$

where:

- $\mathfrak{a}(\psi) = (\kappa_1 1)\pi^{-\kappa_2}$ ,  $\mathfrak{e}(\psi) = (1 \psi(\mathfrak{p})p^{-1})(1 \psi^{-1}(\overline{\mathfrak{p}}))$  and  $\mathfrak{f}(\psi) = D_K^{\kappa_2/2} 2^{-\kappa_2}$ ,
- $\Omega \in \mathbb{C}^{\times}$  and  $\Omega_p \in \mathbb{C}_p^{\times}$  are CM periods attached to K, cf. [\[BDP12,](#page-65-20) (2-15), (2-17)],
- $L_c(\psi^{-1}, s)$  is the c-depleted Hecke L-function associated with  $\psi^{-1}$ .

<span id="page-48-2"></span>It satisfies a functional equation of the form

<span id="page-48-1"></span>(6.5) 
$$
\mathcal{L}_p(K)(\psi) = \mathcal{L}_p(K)((\psi^{\sigma})^{-1}N_{K/\mathbb{Q}}),
$$

relating the values in  $\Sigma_K^{(2)}$  to  $\Sigma_K^{(2')}$ .

A finite order Hecke character  $\psi$  has trivial infinity type and hence lies outside  $\Sigma_K$ , i.e. outside the interpolation range [\(6.4\)](#page-47-1); however it still belongs to  $\widehat{\Sigma}_K$ . Katz proves a p-adic Kroenecker limit formula  $[DLR15, (47)]$ :

<span id="page-48-0"></span>(6.6) 
$$
\mathcal{L}_p(\psi) = \frac{-1}{24N_{K/\mathbb{Q}}\mathfrak{c}} \mathfrak{e}(\psi) \log_p(u_\psi),
$$

for  $\psi$  of finite order,

for  $u_{\psi}$  defined in [\(6.3\)](#page-47-2).

FIGURE 2. The following diagram shows the diagram of infinity types  $(\kappa_1, \kappa_2)$  for the characters in  $\Sigma$ . We indicate interpolation region  $\Sigma_K^{(2)}$  for the Katz *p*-adic *L*-function in blue  $(6.4)$ , the functional equation  $(6.5)$  with the axis of symmetry given by the dotted line, and the point where the p-adic Kroenecker limit formula [\(6.6\)](#page-48-0) is valid. The dashed line is the central critical line

6.2.3. The BDP p-adic Rankin L-function for f and K. For any character  $\psi$  of K with infinity type  $(\kappa_1, \kappa_2)$ , we consider the Rankin–Selberg L-function associated with f and  $\theta_{\psi}$ :

$$
L(f, \psi, s) = L(f \times \theta_{\psi}, s - (\kappa_1 + \kappa_2 + 1)/2).
$$

When the conductor of  $\psi$  is coprime to the level  $N_f$  of f, a p-adic L-function was constructed in [\[BDP13\]](#page-65-7) and a special value formula outside of the interpolation range was proved.

Assume Hypothesis [A.1,](#page-53-0) i.e.  $N_f = N_+N_-$  and  $N_-$  is a square-free product of finite primes. Let  $c \ge 1$ be a positive integer relatively prime to  $pN^+$  and divisible by  $N^-$ . Bertolini–Darmon–Prasanna assume that  $N_ = 1$ , but we prove the analogue of their results in Appendix [A.](#page-52-0)

Let  $\Sigma_{f,c}$  be the set of characters defined in Definition [A.4,](#page-54-0) so that for  $\psi \in \Sigma_{f,c}$ ,  $L(f, \psi, s)$  is self-dual and has  $s = 0$  as its central critical point. Note that  $\Sigma_{f,c}$  naturally decomposes as

$$
\Sigma_{f,c} = \Sigma_{f,c}^{(1)} \cup \Sigma_{f,c}^{(2)} \cup \Sigma_{f,c}^{(2')},
$$
  
\n
$$
\Sigma_{f,c}^{(1)} = \{ \psi \text{ of infinity type } (1,1) \mid \psi \circ \text{Tr} = 1 \},
$$

$$
\Sigma_{f,c}^{(2)} = \{ \psi \text{ of infinity type } (\kappa + 2, -\kappa) \text{ for } \kappa \ge 1 \},
$$
  

$$
\Sigma_{f,c}^{(2')} = \{ \psi \text{ of infinity type } (-\kappa, \kappa + 2) \text{ for } \kappa \ge 1 \}.
$$

<span id="page-49-2"></span>We next summarize Theorem [A.5](#page-54-1) which is a generalization of the main results of [\[BDP13\]](#page-65-7). There is a  $p$ -adic  $L$ -function

$$
\mathcal{L}_p(f,K) \colon \widehat{\Sigma}_{f,c} \to \mathbb{C}_p^\times
$$

defined on the *p*-adic completion  $\hat{\Sigma}_{f,c}$  of  $\Sigma_{f,c}$  with the interpolation property

<span id="page-49-0"></span>(6.7) 
$$
\mathcal{L}_p(f,K)(\psi) = \mathfrak{a}(f,\psi) \cdot \mathfrak{e}(f,\psi)^2 \cdot \mathfrak{f}(f,\psi) \cdot \frac{\Omega_p^{4\kappa+4}}{\Omega^{4\kappa+4}} \cdot L(f,\psi^{-1},0) \qquad \psi \in \Sigma_{f,c}^{(2)},
$$

where

\n- \n
$$
\mathfrak{a}(f,\psi) = \kappa! (\kappa+1)! \pi^{2\kappa+1}, \, \mathfrak{e}(f,\psi) = 1 - a_p(f)\psi^{-1}(\overline{\mathfrak{p}}) + \psi^{-2}(\overline{\mathfrak{p}})p,
$$
\n
\n- \n
$$
\mathfrak{f}(f,\psi) = (2/c\sqrt{D_K})^{2\kappa+1} \cdot \prod_{q \mid c_0} \frac{q - \chi_K(q)}{q - 1} \cdot \prod_{q \mid c_-} \frac{q^2}{1 - q^2} \cdot \omega(f,\psi)^{-1}, \text{ and } \omega(f,\psi) \in \overline{\mathbb{Q}} \text{ is defined in [BDP13, (5.1.11)].}
$$
\n
\n

Next, for a finite order character  $\psi$  of K, we have that  $\psi N_K \in \Sigma_{f,c}^{(1)}$  which is outside of the interpolation range [\(6.7\)](#page-49-0) and Bertolini–Darmon–Prasanna prove the following p-adic Gross–Zagier formula:

<span id="page-49-1"></span>(6.8) 
$$
\mathcal{L}_p(f,K) = \left(1 - \frac{a_p(f)}{\psi(\overline{\mathfrak{p}})p} + \frac{1}{\psi^2(\overline{\mathfrak{p}})p}\right)^2 \cdot \log_p(P_\psi)^2,
$$

for  $P_{\psi}$  defined in [\(6.2\)](#page-47-3).

FIGURE 3. The following diagram shows the diagram of infinity types  $(\kappa_1, \kappa_2)$  for the character in  $\Sigma$ . We indicate interpolation region  $\Sigma_{f,c}^{(2)}$  for the BDP p-adic L-function in blue [\(6.4\)](#page-47-1), the expected functional equation with the axis of symmetry given by the dotted line, and the point where the  $p$ -adic Gross–Zagier formula  $(6.8)$  is valid.

<span id="page-50-1"></span>6.2.4. Gross' formula. The following formula was originally discovered by Gross [\[Gro87,](#page-66-25) Proposition 11.2] in a special case and proved in full generality in [\[CST14,](#page-65-19) Theorem 1.10]:

(6.9) 
$$
\frac{L^{(\Sigma)}(f,\psi,1)}{\pi^2\langle f,f\rangle} = 2^3 \frac{\langle c_{f,\psi},c_{f,\psi}\rangle}{[\mathcal{O}_c^{\times}:\mathbb{Z}^{\times}]^2 c \sqrt{D_K}},
$$

for  $c_{f,\chi}$  defined in [\(6.1\)](#page-46-3) and  $\Sigma = \{v \text{ places dividing } (N, c)\}\.$  In particular,  $\frac{\sqrt{D_K}L(f,\psi,1)}{\pi^2 \langle f,f \rangle}$  lies in the number field  $\mathbb{Q}(f, \psi)$ .

6.2.5. Explicit CM Hida families. We follow [\[DLR15,](#page-65-1) Section 3.2] to recall Hida's construction of an explicit CM Hida family **F** specializing in weight one to  $F_{\alpha} \in \{g_{\alpha}, h_{\alpha}\}\$ . Recall that for a finite order character  $\psi$  of K such that  $\psi^{\sigma} \neq \psi$ , we have an associated cusp form:

<span id="page-50-0"></span>
$$
\theta_{\psi} \in S_1(D_K N_{K/\mathbb{Q}}(\mathfrak{c}), \chi).
$$

We fix a character  $\lambda$  of infinity type  $(0, 1)$  and conductor  $\bar{p}$  and valued in  $\mathbb{Q}(\lambda)$ . Let  $\mathbb{Q}_p(\lambda)$  be the *p*-adic completion of  $\mathbb{Q}(\lambda)$  determined by a fixed embedding  $\mathbb{Q}(\lambda) \hookrightarrow \overline{\mathbb{Q}_p}$ . We have that

$$
\mathcal{O}_{\mathbb{Q}_p(\lambda)}^{\times} = \mu \times W
$$

where  $\mu$  is finite and W is a free  $\mathbb{Z}_p$ -module, and we write

$$
\langle -\rangle\colon \mathcal{O}_{\mathbb{Q}_p(\lambda)}^\times\to W
$$

for the projection.

For  $\psi \in {\psi_q, \psi_h}$  and every integer  $k \geq 1$ , define

(6.10) 
$$
\psi_{k-1}^{(p)} = \psi \langle \lambda \rangle^{k-1}
$$

which is independent on the choice of  $\lambda$ , and let

(6.11) 
$$
\psi_{k-1}(\mathfrak{q}) = \begin{cases} \psi_{k-1}^{(p)}(\mathfrak{q}) & \mathfrak{q} \neq \overline{\mathfrak{p}}, \\ \chi_F(p)p^{k-1}/\psi_{k-1}^{(p)}(\mathfrak{p}) & \mathfrak{q} = \overline{\mathfrak{p}}. \end{cases}
$$

Then the ordinary p-stabilization of the associated theta series:

(6.12) 
$$
F_k = \theta_{\psi_{k-1}} \in S_k(D_K N_{K/\mathbb{Q}}(\mathfrak{c}(\psi_F)), \chi_F)
$$

is the weight k specialization of the Hida family  $\mathcal F$  and, by definition,  $F_1 = F$ .

6.2.6. Factorization of the p-adic L-function. We are now ready prove the factorization of the triple product balanced p-adic L-function. We start by recalling the factorization of the classical L-functions, then analyze the periods, and finally deal with the auxillary factors. The resulting statement is Theorem [6.14](#page-52-1) below.

Note that the norm  $N_K$  from K to Q can be regarded as a Hecke character of K of infinity type  $(1, 1)$ . Since  $\langle \lambda \rangle$  has infinity type  $(0, 1)$ ,  $\langle \lambda \lambda^{\sigma} \rangle$  has infinity type  $(1, 1)$  and we may identify it with  $N_K$ .

Note that:

$$
V_{g_\ell}\otimes V_{h_\ell}=V_{\psi^{(p)}_{g,\ell-1}}\otimes V_{\psi^{(p)}_{h,\ell-1}}\cong V_{\psi^{(p)}_{g,\ell-1}\psi^{(p)}_{h,\ell-1}}\oplus V_{\psi^{(p)}_{g,\ell-1}\psi^{(p),\sigma}_{h,\ell-1}}
$$

and

$$
\psi_{g,\ell-1}^{(p)} \cdot \psi_{h,\ell-1}^{(p)} = \psi_g \cdot \psi_h \cdot \langle \lambda \rangle^{2\ell-2} = \psi_2 \langle \lambda \rangle^{2\ell-2}
$$
  

$$
\psi_{g,\ell-1}^{(p)} \cdot \psi_{h,\ell-1}^{(p),\sigma} = \psi_g \cdot \psi_h^{\sigma} \cdot \langle \lambda \lambda^{\sigma} \rangle^{\ell-1} = \psi_g \psi_h^{\sigma} N_K^{\ell-1} = \psi_1 N_K^{\ell-1}.
$$

Via the Artin formalism, the above results in a factorization of the triple product L-function:

$$
L(f \times g_{\ell} \times h_{\ell}, s) = L(f_K \times \psi_2 \langle \lambda \rangle^{2\ell - 2}, s) \cdot L(f_K \times \psi_1, s - (\ell - 1)),
$$

<span id="page-51-2"></span>where  $\theta_{\psi_1(\lambda)^{2k-2}}$  has weight  $2k-1$  and  $\theta_{\psi_2}$  has weight 1.

By Corollary [6.4,](#page-44-0) we know that  $\mathcal{L}_p^{\text{bal},f}(\ell,\ell)$  is related to:

$$
L(f \times g_{\ell} \times h_{\ell}, \ell) = L(f_K \times \psi_2 \langle \lambda \rangle^{2\ell - 2}, \ell) \cdot L(f_K \times \psi_1, 1)
$$
  
= 
$$
L(f_K \times \psi_2 \langle \lambda \rangle^{2\ell - 2} N_K^{-\ell}, 0) \cdot L(f_K \times \psi_1, 1).
$$

More specifically, dividing by the period  $\langle f, f \rangle \langle g_\ell, g_\ell \rangle \langle h_\ell, h_\ell \rangle$ , we have:

<span id="page-51-0"></span>(6.13) 
$$
\frac{L(f \times g_{\ell} \times h_{\ell}, \ell)}{\langle f, f \rangle \langle g_{\ell}, g_{\ell} \rangle \langle h_{\ell}, h_{\ell} \rangle} = \frac{1}{\langle g_{\ell}, g_{\ell} \rangle \langle h_{\ell}, h_{\ell} \rangle} \cdot L(f_K \times \psi_2 \langle \lambda \rangle^{2\ell - 2} N_K^{-\ell}, 0) \cdot \frac{L(f_K \times \psi_1, 1)}{\langle f, f \rangle}.
$$

Note that

$$
\Psi_{gh}(\ell) = \psi_2^{-1} \langle \lambda \rangle^{-2\ell+2} N_K^{\ell} \in \Sigma_K^{(2)}
$$

has infinity type  $(\ell, -\ell + 2)$ , so by equation [\(6.7\)](#page-49-0):

$$
(6.14)\qquad L(f_K \times \Psi_{gh}(\ell)^{-1},0) = \mathfrak{a}(\Psi_{gh}(\ell))^{-1} \cdot \mathfrak{e}(f,\Psi_{gh}(\ell))^{-1} \cdot \mathfrak{f}(\Psi_{gh}(\ell))^{-1} \cdot \frac{\Omega^{4\ell-4}}{\Omega_p^{4\ell-4}} \cdot \mathcal{L}_p(f,K)(\Psi_{gh}(\ell)).
$$

Next, define for  $F \in \{g, h\}$ 

$$
\Psi_F(\ell) = \psi_{F,\ell-1}^{-2} \chi_F N_K^{\ell}
$$

and recall fact from [\[DLR15,](#page-65-1) Lemma 3.8]: for some K-admissible functions  $f_2(k)$ ,  $f_3(k)$ 

(6.15) 
$$
\mathcal{L}_p(K)(\Psi_F(\ell)) = \frac{\mathfrak{e}(\Psi_F(\ell))\mathfrak{f}(\Psi_F(\ell))}{\mathfrak{f}_2(\ell)\cdot\mathfrak{f}_3(\ell)} \cdot \langle F_\ell, F_\ell\rangle \cdot \left(\frac{\pi\Omega_p}{\Omega}\right)^{2\ell-2}.
$$

Thus equation [\(6.13\)](#page-51-0) becomes

$$
\frac{\Lambda(f \times g_{\ell} \times h_{\ell}, \ell)}{\langle f, f \rangle \langle g_{\ell}, g_{\ell} \rangle \langle h_{\ell}, h_{\ell} \rangle} \cdot \mathcal{L}_{p}(K)(\psi_{g}(\ell)) \cdot \mathcal{L}_{p}(K)(\psi_{h}(\ell)) = \frac{\mathfrak{e}(\Psi_{g}(\ell))\mathfrak{f}(\Psi_{g}(\ell))\mathfrak{e}(\Psi_{h}(\ell))\mathfrak{f}(\Psi_{h}(\ell))}{\mathfrak{f}_{2}(\ell)^{2}\mathfrak{f}_{3}(\ell)^{2}\mathfrak{e}(f, \Psi_{gh}(\ell))\mathfrak{f}(\Psi_{gh}(\ell))} \cdot \mathcal{L}_{p}(f, K)(\Psi_{gh}(\ell)) \cdot \frac{L(f_{K} \times \psi_{1}, 1)}{\pi^{2} \langle f, f \rangle},
$$

where we have canceled the factor  $\mathfrak{a}(\Psi_{gh}(\ell))$  with the other powers of  $\pi$  and the Γ-factors for the triple product L-function.

Next, using Corollary [6.4,](#page-44-0) we get that:

$$
\mathcal{L}_p^{\mathrm{bal},f}(\ell,\ell)^2 \cdot \mathcal{L}_p(K)(\psi_g(\ell)) \cdot \mathcal{L}_p(K)(\psi_h(\ell)) = \mathcal{E}(\ell) \cdot \mathcal{F}(\ell) \cdot \mathcal{L}_p(f,K)(\Psi_{gh}(\ell)) \cdot \frac{L(f_K \times \psi_1,1)}{\pi^2 \langle f,f \rangle},
$$

where

(6.16) 
$$
\mathcal{E}(\ell) = \frac{\mathcal{E}_p^{\text{bal}}(\mathbf{V}_{\kappa}) \cdot \mathcal{E}_p(f_{\alpha}, \text{Ad}) \cdot \mathfrak{e}(\Psi_g(\ell)) \cdot \mathfrak{e}(\Psi_h(\ell))}{\mathfrak{e}(f, \Psi_{gh}(\ell))},
$$

(6.17) 
$$
\mathcal{F}(\ell) = 2^{3-2\ell} \frac{\mathfrak{f}(\Psi_g(\ell)) \mathfrak{f}(\Psi_h(\ell))}{\mathfrak{f}_2(\ell)^2 \mathfrak{f}_3(\ell)^2 \mathfrak{f}(\Psi_{gh}(\ell))}.
$$

**Lemma 6.11.** For any  $\ell \geq 0$ ,

$$
\mathcal{E}(\ell) = (1 - \beta_f \psi_1(\mathfrak{p}) p^{-1})(1 - \beta_f \psi_1(\overline{\mathfrak{p}}) p^{-1}).
$$

Proof. We recall that

$$
L_p(\theta_{\psi_{\ell-1}}, s) = L_{\mathfrak{p}}(\psi_{\ell-1}, s) \cdot L_{\overline{\mathfrak{p}}}(\psi_{\ell-1}, s)
$$

and hence for  $F \in \{g, h\}$ 

$$
\alpha_F = \psi_F(\mathfrak{p}) \langle \lambda(\mathfrak{p}) \rangle^{\ell-1}
$$
  

$$
\beta_F = \chi_F(p) p^{\ell-1} / \alpha_F = p^{\ell-1} \psi_F(\overline{\mathfrak{p}}) \langle \lambda(\mathfrak{p}) \rangle^{1-\ell}.
$$

We first check that for  $F \in \{g, h\}$ :

<span id="page-51-1"></span>(6.18) 
$$
\mathcal{E}_p(F_{\alpha,\ell}, \mathrm{Ad}) = \mathfrak{e}(\Psi_F(\ell)),
$$

<span id="page-52-2"></span>Indeed, according to [\[Hsi21,](#page-66-4) p. 416]

$$
\mathcal{E}_p(F_{\alpha,\ell},\mathrm{Ad}) = (1 - \alpha_F^{-2} \chi_F(p) p^{\ell-1}) (1 - \alpha_F^{-2} \chi_F(p) p^{\ell-2})
$$
  
= 
$$
(1 - \psi_F(\mathfrak{p})^{-2} \langle \lambda(\mathfrak{p}) \rangle^{-2\ell+2} \chi_F(p) p^{\ell-1}) (1 - \psi_F(\mathfrak{p})^{-2} \langle \lambda(\mathfrak{p}) \rangle^{-2\ell+2} \chi_F(p) p^{\ell-2}),
$$

while

$$
\begin{split} \mathfrak{e}(\Psi_{F}(\ell)) &= (1 - \Psi_{F}(\ell)(\mathfrak{p})p^{-1})(1 - \Psi_{F}(\ell)^{-1}(\overline{\mathfrak{p}})) \\ &= (1 - \psi_{F,\ell-1}^{-2}(\mathfrak{p})\chi_{F}(p)p^{\ell}p^{-1})(1 - (\psi_{F,\ell-1}^{-2}(\overline{\mathfrak{p}})\chi_{F}(p)p^{\ell})^{-1}) \\ &= (1 - \psi_{F}(\mathfrak{p})^{-2}\langle\lambda(\mathfrak{p})\rangle^{-2\ell+2}\chi_{F}(p)p^{\ell-1})(1 - (\chi_{F}(p)p^{\ell-1}/(\psi_{F}(\mathfrak{p})\langle\lambda(\mathfrak{p})\rangle)^{\ell-1})^{2}\chi_{F}(p)^{-1}p^{-\ell}) \\ &= (1 - \psi_{F}(\mathfrak{p})^{-2}\langle\lambda(\mathfrak{p})\rangle^{-2\ell+2}\chi_{F}(p)p^{\ell-1})(1 - \psi_{F}(\mathfrak{p})^{-2}\langle\lambda(\mathfrak{p})\rangle^{-2\ell+2}\chi_{F}(p)p^{\ell-2}), \end{split}
$$

verifying equation [\(6.18\)](#page-51-1).

Therefore, we have:

 $\mathcal{E}_p^{\text{bal}}(V_\kappa) \cdot \mathcal{E}_p(f_\alpha, \text{Ad}) \cdot \mathfrak{e}(\Psi_g(\ell)) \mathfrak{e}(\Psi_h(\ell)) = (1 - \alpha_f \beta_g \beta_h p^{-\ell})(1 - \beta_f \alpha_g \beta_h p^{-\ell})(1 - \beta_f \beta_g \alpha_h p^{-\ell})(1 - \beta_f \beta_g \beta_h p^{-\ell})$  $=(1-\alpha_f(\psi_g\psi_h)(\overline{\mathfrak{p}})\langle\lambda(\mathfrak{p})\rangle^{2-2\ell}p^{\ell-2})(1-\beta_f(\psi_g\psi_h^{\sigma})(\mathfrak{p})p^{-1})(1-\beta_f(\psi_g\psi_h^{\sigma})(\overline{\mathfrak{p}})p^{-1})(1-\beta_f(\psi_g\psi_h)(\overline{\mathfrak{p}})\langle\lambda(\mathfrak{p})\rangle^{2-2\ell}p^{\ell-2})$ It remains to observe that:

$$
\begin{split} \mathfrak{e}(f, \Psi_{gh}(\ell)) &= (1 - \alpha_f \Psi_{gh}^{-1}(\overline{\mathfrak{p}}))(1 - \beta_f \Psi_{gh}^{-1}(\overline{\mathfrak{p}})) \\ &= (1 - \alpha_f \psi_2(\overline{\mathfrak{p}}) \langle \lambda(\overline{\mathfrak{p}}) \rangle^{2\ell - 2} p^{-\ell} (1 - \beta_f \psi_2(\overline{\mathfrak{p}}) \langle \lambda(\overline{\mathfrak{p}}) \rangle^{2\ell - 2} p^{-\ell}) \\ &= (1 - \alpha_f (\psi_g \psi_h)(\overline{\mathfrak{p}}) \langle \lambda(\overline{\mathfrak{p}}) \rangle^{2\ell - 2} p^{-\ell} (1 - \beta_f (\psi_g \psi_h)(\overline{\mathfrak{p}}) \langle \lambda(\overline{\mathfrak{p}}) \rangle^{2\ell - 2} p^{-\ell}), \end{split}
$$

and use  $\mathfrak{p}\overline{\mathfrak{p}}=(p).$ 

Remark 6.12. Note that:

$$
L_p(f_K \times \psi_1, s)^{-1} = (1 - \alpha_f \psi_1(\overline{\mathfrak{p}}) p^{-s})(1 - \beta_f \psi_1(\overline{\mathfrak{p}}) p^{-s})(1 - \alpha_f \psi_1(\mathfrak{p}) p^{-s})(1 - \beta_f \psi_1(\mathfrak{p}) p^{-s})
$$

and hence the factor  $\mathcal{E}(\ell)$  is part of the local L-factor at p of  $L(f_K \times \psi_1, 1)$ .

**Lemma 6.13.** The function  $\mathcal{F}(\ell)$  is  $K(\psi_q, \psi_h)$ -admissible according to [\[DLR15,](#page-65-1) Definition 3.5], i.e. it extends to an element of Frac  $\mathcal{O}(\mathcal{U})$  and  $\mathcal{F}(1) \in K(\psi_g, \psi_h)^\times$ .

*Proof.* This follows from the same argument as the proof of  $[DLR15, Lemma 3.6]$ .

<span id="page-52-1"></span>Altogether, this gives the following result.

Theorem 6.14. There is a factorization:

$$
\mathcal{L}_p^{\text{bal},f}(\ell,\ell)^2 \cdot \mathcal{L}_p(K)(\psi_g(\ell)) \cdot \mathcal{L}_p(K)(\psi_h(\ell)) = \mathcal{F}(\ell) \cdot \mathcal{L}_p(f,K)(\Psi_{gh}(\ell)) \cdot \frac{L(f_K \times \psi_1,1)}{\langle f,f \rangle} \cdot \mathcal{E}(\ell).
$$

Then Theorem [6.9](#page-47-0) follows by evaluating the above factorization at  $\ell = 1$  and using equations [\(6.6\)](#page-48-0), [\(6.8\)](#page-49-1), and [\(6.9\)](#page-50-0).

#### Appendix A. A generalization of results of Bertolini–Darmon–Prasanna

<span id="page-52-0"></span>A.1. Statement of the results. Let f be a weight two cuspidal eigenform for  $\Gamma_0(N)$ , which we assume to have trivial Nebentypus for simplicity. Let K be an imaginary quadratic field of discriminant  $-D_K$ and p be a prime which splits in K. For any Hecke character  $\psi$  of K with infinity type  $(\kappa_1, \kappa_2)$ , we consider the Rankin–Selberg L-function associated with f and  $\theta_{\psi}$ :

$$
L(f, \psi, s) = L(f \times \theta_{\psi}, s - (\kappa_1 + \kappa_2 + 1)/2).
$$

<span id="page-53-3"></span>We will assume the condition:

$$
\psi|_{\mathbb{A}^\times} = |\cdot|^2,
$$

where  $|\cdot|$  is the norm character of Q, which ensures the L-function  $L(f, \psi, s)$  is self-dual with central critical value at  $s = 0$ .

Under the Heegner hypothesis (if  $q|N$ , then q is either split of ramified in K and if  $q^2|N$ , then q is split in K) and the assumption that the conductor of  $\psi$  is coprime to the level N of f, Bertolini, Darmon, and Prasanna [\[BDP13\]](#page-65-7) constructed a p-adic L-function interpolating the critical values  $L(f, \psi^{-1}, 0)$  when  $\kappa_1 \geq 1$  and  $\kappa_2 \leq 0$ , and proved a special value formula for  $\kappa_1 = \kappa_2 = 0$ .

<span id="page-53-0"></span>The goal of this appendix is to reprove their result, allowing a squarefree product of inert primes to divide N.

# **Hypothesis A.1.** If  $q^2|N$ , then q is split in K.

<span id="page-53-1"></span>Instead, we make the following assumption on the conductor of  $\psi$  under which  $\epsilon_q(f, \psi) = +1$  at the inert primes q dividing N.

<span id="page-53-2"></span>**Hypothesis A.2.** Let  $N_0$  be the product of primes dividing N which are inert in K. Then the conductor of  $\psi$  is divisible exactly by  $N_0$  and coprime to  $N/N_0$ .

**Remark A.3.** The weak Heegner hypothesis allows a product  $N_$  of an even number of inert primes to divide N. Assuming that the conductor of  $\psi$  is coprime to  $N$  — the opposite to Hypothesis [A.2](#page-53-1) — we have that  $\epsilon_q(f, \psi) = -1$  for all primes  $q|N_-$ . The integral representation for the Rankin–Selberg L-function is then on a Shimura curve associated with a quaternion algebra of discriminant  $N_$ . A generalization of the results of Bertolini–Darmon–Prasanna to this setting was obtained by Brooks [\[HB15\]](#page-66-24).

As mentioned above, our Hypothesis [A.2](#page-53-1) instead forces  $\epsilon_q(f, \psi) = +1$  at all primes  $q|N_0$ , and in fact we will assume that  $\epsilon_q(f, \psi) = +1$  for all q, so that the integral representation for  $L(f, \psi, s)$  is still on the modular curve. This is why we do not require the parity assumption.

Finally, combining the results of this appendix with the results of Brooks, one could presumably allow  $N_0 \cdot N_-|N$  where  $N_-$  is a product of an even number of inert primes, and the conductor of  $\psi$  is divisible exactly by  $N_0$ , and coprime to  $N/N_0$ . We decided not to pursue this generality here.

Under Hypothesis [A.1,](#page-53-0) there is an ideal  $\mathfrak{N}$  of  $\mathcal{O}_K$  of norm  $NN_0$ ; we fix such an ideal. Given an integer  $c \ge 1$  divisible exactly by  $N_0$  and coprime to  $(N/N_0)D_K$ , we consider an order  $\mathcal{O}_c$  of  $\mathcal{O}_K$  of conductor c. Setting  $\mathfrak{N}_c = \mathfrak{N} \cap \mathcal{O}_c$ , we have:

$$
\mathcal{O}_c/\mathfrak{N}_c\cong \mathbb{Z}/N\mathbb{Z}.
$$

Indeed, for  $q|N$  coprime to c, if  $q|q$  then

$$
\mathcal{O}_{c,q}/\mathfrak{N}_{c,q}\cong \mathcal{O}_{K,q}/\mathfrak{N}_{q}\cong \mathbb{Z}/(q^{v_q(N)})\mathbb{Z}.
$$

Moreover, for  $q|N_0$ ,  $\mathcal{O}_{c,q} = \mathbb{Z} + q\mathcal{O}_{K_q}$  and:

$$
\mathcal{O}_{c,q}/\mathfrak{N}_{c,q}=(\mathbb{Z}+q\mathcal{O}_{K_q})/q\mathcal{O}_{K_q}\cong \mathbb{Z}/q\mathbb{Z}.
$$

Note that for  $q|N_0, 1+q\mathcal{O}_{K_q} \subseteq \mathcal{O}_{c,q}^{\times} \subseteq \mathcal{O}_{K_q}^{\times}$  and

$$
\mathcal{O}_{c,q}^{\times}/(1+q\mathcal{O}_{K_q}) \longleftrightarrow \mathcal{O}_{K_q}^{\times}/(1+q\mathcal{O}_{K_q}) \longrightarrow \mathcal{O}_{K_q}^{\times}/\mathcal{O}_{c,q}^{\times}
$$

$$
\downarrow \cong \qquad \qquad \downarrow \cong \qquad \qquad \downarrow \cong \qquad \qquad \downarrow \cong
$$

$$
\mathbb{F}_q^{\times} \xrightarrow{\qquad \qquad \mathbb{F}_{q^2}^{\times}/\mathbb{F}_q^{\times}}
$$

In particular, a character of  $\mathcal{O}_{K_q}^{\times}$  which is trivial on  $\mathcal{O}_{c,q}^{\times}$  has conductor at most 1 and is trivial on  $\mathbb{F}_q^{\times} \subseteq \mathbb{F}_{q^2}^{\times}.$ 

<span id="page-54-2"></span><span id="page-54-0"></span>**Definition A.4.** Let  $\Sigma_{f,c}$  denote the set of Hecke characters  $\psi$  of K such that:

- (1)  $\psi|_{\widehat{\mathcal{O}}_c^{\times}} = 1$ , but for  $q|N_0, \psi_q|_{\mathcal{O}_{K,q}^{\times}} \neq 1$ ,
- (2) the infinity type  $(\kappa_1, \kappa_2)$  of  $\psi$  satisfies  $\kappa_1 + \kappa_2 = 2$ ,
- (3)  $\psi \psi^{\sigma} = |\cdot|^2$ ,
- (4)  $\epsilon_q(f, \psi^{-1}) = +1$  for all finite primes q.

By the above discussion, if  $\psi \in \Sigma_{f,c}$ , then  $\psi_q$  for  $q|N_0$  has conductor 1 and  $\psi|_{\mathbb{Z}_q^{\times}} = 1$ . In particular, assumption (1) in the definition implies Hypothesis [A.2.](#page-53-1) If  $N_0 = 1$ , this agrees with  $\Sigma_{f,cc}$  in [\[BDP13\]](#page-65-7). The final condition is automatic except possibly for the primes in the set:

$$
S(f) = \{q \mid q \text{ divides } N \text{ and } D_K\}.
$$

For example, if N is coprime to  $D_K$ ,  $S(f) = \emptyset$ .

For  $\psi \in \Sigma_{f,c}$ ,  $L(f, \psi, s)$  is self-dual and has  $s = 0$  as its central critical point. Moreover,  $\Sigma_{f,c}$  naturally decomposes as

$$
\Sigma_{f,c} = \Sigma_{f,c}^{(1)} \cup \Sigma_{f,c}^{(2)} \cup \Sigma_{f,c}^{(2')},
$$
  
\n
$$
\Sigma_{f,c}^{(1)} = \{ \psi \text{ of infinity type } (1,1) \},
$$
  
\n
$$
\Sigma_{f,c}^{(2)} = \{ \psi \text{ of infinity type } (\kappa + 2, -\kappa) \text{ for } \kappa \ge 1 \},
$$
  
\n
$$
\Sigma_{f,c}^{(2')} = \{ \psi \text{ of infinity type } (-\kappa, \kappa + 2) \text{ for } \kappa \ge 1 \}.
$$

#### <span id="page-54-1"></span>Theorem A.5.

(1) There is a p-adic L-function  $\mathcal{L}_p(f,K) \colon \Sigma_{f,c} \to \mathbb{C}_p^{\times}$  defined on the p-adic completion  $\Sigma_{f,c}$  of  $\Sigma_{f,c}$ with the following interpolation property:

$$
\frac{\mathcal{L}_p(f, K)(\psi)}{\Omega_p^{4\kappa + 4}} = \mathfrak{a}(f, \psi) \cdot \mathfrak{e}(f, \psi)^2 \cdot \mathfrak{f}(f, \psi) \cdot \frac{L(f, \psi^{-1}, 0)}{\Omega^{4\kappa + 4}} \qquad \psi \in \Sigma_{f, c}^{(2)},
$$

where

- $a(f, \psi) = \kappa! (\kappa + 1)! \pi^{2\kappa + 1}, \, \mathfrak{e}(f, \psi) = 1 a_p(f) \psi^{-1}(\overline{\mathfrak{p}}) + \psi^{-2}(\overline{\mathfrak{p}}) p,$
- $f(f, \psi) = (2/c\sqrt{D_K})^{2\kappa+1} \prod_{k=1}^{n}$  $q|c/N_0$  $q-\chi_K(q)$  $\frac{\chi_K(q)}{q-1}$   $\prod_{q\mid N}$  $q|N_0$  $\frac{q^2-1}{q^2} \cdot \omega(f, \psi)^{-1}$ , and  $\omega(f, \psi) \in \overline{\mathbb{Q}}$  is defined in [\[BDP13,](#page-65-7) (5.1.11)].
- (2) For a finite order character  $\psi$  of K,  $\psi N_K \in \Sigma_{f,c}^{(1)}$  which is outside of the interpolation range [\(6.7\)](#page-49-0), there is a p-adic Gross–Zagier formula:

$$
\mathcal{L}_p(f,K) = \left(1 - \frac{a_p(f)}{\psi(\overline{\mathfrak{p}})p} + \frac{1}{\psi^2(\overline{\mathfrak{p}})p}\right)^2 \cdot \log_p(P_\psi)^2,
$$

for  $P_{\psi}$  defined by:

$$
P_{\psi} = \pi_f \left( \sum_{\sigma \in \text{Gal}(H_c/K)} \psi^{-1}(\sigma) t^{\sigma} \right) \in E(H_c)_{L}^{\psi_2}
$$

for a Heegner point t for  $H_c/K$ .

Remark A.6. We remark that Liu–Zhang–Zhang [\[LZZ18\]](#page-66-26) proved a formula similar to part (2) of the above theorem for any abelian variety parameterized by a Shimura curve over a totally real field. In particular, in the case of Shimura curves over  $\mathbb{Q}$ , they removed all the ramification hypothesis in [\[BDP13,](#page-65-7) [HB15\]](#page-66-24).

However, their construction of the p-adic L-function does not have an interpolation property as explicit as (1). More specifically, (1) can be interpreted as an equality in  $\overline{Q}$  (or even an explicit finite extension of  $\mathbb{Q}$ ), having fixed embeddings  $\overline{\mathbb{Q}} \hookrightarrow \mathbb{C}$ ,  $\mathbb{C}_p$ . Crucially, the CM periods  $\Omega$  and  $\Omega_p$  make both sides algebraic.

<span id="page-55-2"></span>The interpolation property of Liu–Zhang–Zhang is not an equality of algebraic numbers and relies on an identification  $\mathbb{C} \cong \mathbb{C}_p$ . In particular, the CM periods do not show up in their interpolation property, and we have not find a direct way to deduce the above result from their work.

A.2. An explicit Waldspurger formula. The crux of the proof of Theorem [A.5](#page-54-1) is to give an explicit version of Waldspurger's formula, generalizing [\[BDP13,](#page-65-7) Theorem 4.6].

<span id="page-55-1"></span>**Theorem A.7.** Let f be a normalized eigenform in  $S_2(N)$  and let  $\psi \in \Sigma_{f,c}^{(2)}$  be a Hecke character of K of infinity type  $(2 + j, -j)$ . Suppose also that c and  $D_K$  are odd, and let  $w_K$  denote the number of roots of unity in K. Then:

$$
C(f, \psi, c) \cdot L(f, \psi^{-1}, 0) = \left| \sum_{[\mathfrak{a}] \in \mathrm{Pic}(\mathcal{O}_c)} \chi^{-1}(\mathfrak{a}) N \mathfrak{a}^{-j} \cdot (\delta_k^j f)(\mathfrak{a}^{-1}, t_{\mathfrak{a}}) \right|,
$$

where the representatives of the ideal classes in  $Pic(\mathcal{O}_{c})$  are chosen to be coprime to the  $\mathfrak{N}_{c}$  and the constant  $C(f, \psi, c) \in \mathbb{C}$  is given by:

$$
C(f,\chi,c)=\frac{1}{4}\pi^{k+2j-1}\Gamma(j+1)\Gamma(k+j)w_K|D_K|^{1/2}\cdot c\operatorname{vol}(\mathcal{O}_c)^{-\ell}\cdot 2^{\#S_f}\cdot \prod_{q|c/N_0}\frac{q-\chi_K(q)}{q-1}\cdot \prod_{q|N_0}\frac{q^2-1}{q^2}.
$$

Proof. The proof in [\[BDP13,](#page-65-7) Section 4] can be applied verbatim to our case, until the local calculations in Section 4.6. The extra local integral is then computed in the next section, resulting in Proposition [A.8.](#page-57-1)  $\blacksquare$ 

A.3. The key computation. The assumption in [\[BDP13\]](#page-65-7) that the conductor of  $\psi$  is coprime to the level N of f is used in the explicit computations of the local zeta integrals in Section 4.6. We use the same notation as loc. cit. but consider the following extra setting:

- let  $\mathbb{Q}_{q^2} = \mathbb{Q}_q[\varpi]$  where  $\varpi^2 \in \mathbb{Q}_q^{\times}$  is a unit is the unramified quadratic extension of  $\mathbb{Q}_q$ , and let  $\sigma$ be the non-trivial automorphism of  $\mathbb{Q}_{q^2}$  over  $\mathbb{Q}_q$ ,
- $\psi$  is an anticyclomotic character of  $\mathbb{Q}_{q^2}^{\times}$  of conductor  $r \geq 1$  such that  $\psi \neq \psi^{\sigma}$  and  $\psi|_{\mathbb{Q}_q^{\times}} = 1$ , (here, anticyclotomic means that  $\psi \psi^{\sigma} = 1$ ; in particular, note that  $\psi^2 \neq 1$ ),
- $\pi$  is the Steinberg representation St of  $GL_2(\mathbb{Q}_q)$ .

Analogously to p. 1118 of loc. cit. we consider:

$$
J(\varsigma,\vartheta)=\int\limits_{N_{\mathbb{Q}_{q^2}/\mathbb{Q}_q}(\mathbb{Q}_{q^2}^\times)}W_F(d(a))W_{\Theta,\varsigma}(d(a))\Phi_\vartheta^s(d(a))|a|^{-1}d^\times a.
$$

As written, the equation in [\[BDP13\]](#page-65-7) involves the integral of  $\mathbb{Q}_q^{\times}$ , but tracing back the reference [\[Pra06,](#page-66-28) Section 3] reveals this is the correct generalization at inert places.

We also recall from Proposition 4.24 of loc. cit. that:

$$
W_{\Theta,\varsigma}(d(a)) = \int_{\mathbb{Q}_{q^2}^{(1)}} \varsigma(h^{-1}(h')^{\sigma}) \psi(hh')\,dh
$$

for any h' such that  $N(h') = a$ , where

$$
\mathbb{Q}_{q^2}^{(1)} = \{x \in \mathbb{Q}_{q^2} \mid N(x) = 1\} \subseteq \mathbb{Z}_{p^2}^{\times}
$$

and the Haar measure is normalized so that  $\text{vol}(\mathbb{Q}_{q^2}^{(1)})$  $\binom{1}{q^2} = 1.$ 

We recall that the group of norm one elements in the unramified quadratic extension of  $\mathbb{Q}_p$  has the following description:

<span id="page-55-0"></span>(A.2) 
$$
\mathbb{Q}_{q^2}^{(1)} = \left\{ \frac{t}{t^{\sigma}} \middle| t \in \mathbb{Z}_{q^2}^{\times} \right\}.
$$

Therefore,

$$
W_{\Theta,\varsigma}(d(a)) = \int_{\mathbb{Z}_{q^2}^{\times}} \varsigma((th')^{\sigma}/t)\psi(th'/t^{\sigma}) dt.
$$

We choose:

•  $\varsigma = \mathbf{I}_{\mathbb{Z}_q + q^r \varpi \mathbb{Z}_q}$ , the indicator function of  $\mathbb{Z}_q + q^r \varpi \mathbb{Z}_q \subseteq \mathbb{Z}_q + \varpi \mathbb{Z}_q = \mathbb{Z}_{q^2}$ ,

• 
$$
\vartheta = \mathbf{I}_{(\mathbb{Z}_q + q^r \mathbb{Z}_q \varpi)j}
$$
 where  $j = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ 

•  $W_F(d(a)) = |a| \mathbf{I}_{\mathbb{Z}_q}(a)$ , since  $\pi = \text{St}$  (cf. Proposition 4.23 of loc. cit.).

Then  $\varsigma((th')^{\sigma}/t) = 1$  if and only if

$$
(th')^{\sigma}/t \in \mathbb{Z}_q + q^r \varpi \mathbb{Z}_q.
$$

For  $x \in \mathbb{Z}_{q^2}$ , the condition  $x \in \mathbb{Z}_q + q^r \varpi \mathbb{Z}_q$  is equivalent to  $v_q(x - x^{\sigma}) \geq r$ . Therefore, the above condition is simply:

$$
v_q((t^{\sigma})^2(h')^{\sigma} - t^2h') \geq r.
$$

Next, we observe that for  $v(h') \geq r$ , this condition is automatic, and in this case:

WΘ,ς (d(a)) = ψ(h ′ ) Z Z × q2 (ψ/ψ<sup>σ</sup> )(t) dt = 0 ψ/ψ<sup>σ</sup> 6= 1.

Since  $W_F(d(a)) = |a| \mathbf{I}_{\mathbb{Z}_q}(a)$  and  $h'(h')^{\sigma} = a$ , the remaining part of the integral  $J(\varsigma, \vartheta)$  has  $0 \leq$  $v_q(h') \leq r-1$ . Fix  $m = v(h')$  and write  $h' = q^m \cdot u$  for  $u \in \mathbb{Z}_{q^2}^{\times}$ . Then:

$$
(t^{\sigma})^2 (h')^{\sigma} - t^2 h' = q^m ((t^{\sigma})^2 u^{\sigma} - t^2 u),
$$

and the condition on the valuation can be concisely written as

$$
t^2 u \equiv (t^2 u)^{\sigma} \mod q^{r-m}.
$$

Dividing both sides by the unit  $tt^{\sigma}$  gives the equivalent condition:

$$
tu/t^{\sigma} \equiv (tu/t^{\sigma})^{\sigma} \mod q^{r-m}.
$$

Finally, this shows that:

$$
\int_{v_q(a)=2m} W_F(d(a))W_{\Theta,\varsigma}(d(a))|a|^{s-1}d^{\times}a = \int_{u,t\in\mathbb{Z}_{q^2}^{\times} \atop t\mu/t^{\sigma}\equiv (tu/t^{\sigma})^{\sigma} \bmod q^{r-m}} \psi(tu/t^{\sigma}) d^{\times}u d^{\times}t
$$

$$
= \int_{v,t\in\mathbb{Z}_{q^2}^{\times} \atop t\mu/t^{\sigma}\equiv v^{\sigma} \bmod q^{r-m}} \psi(v) d^{\times}v \qquad v=t/t^{\sigma}u.
$$

Now, if  $m \ge 1$ , this final integral is 0, because there exists  $v_0 \in \mathbb{Z}_{q^2}^{\times}$  such that  $v_0 \equiv 1 \mod q^{r-m}$  and  $\psi(v_0) \neq 1.$ 

For  $v \in \mathbb{Z}_{q^2}^{\times}$  such that  $v \equiv v^{\sigma} \mod q^r$ , there exists  $v_0 \in \mathbb{Z}_q^{\times}$  such that  $v_0 \equiv v \mod q^r$ , and hence

$$
\psi(v) = \psi(v_0) = 1,
$$

since  $\psi|_{\mathbb{Z}_q^{\times}}=1$ . Altogether, this shows that:

$$
J(\varsigma,\vartheta)=\text{vol}(\mathbb{Z}_{q^2}^\times)\cdot \text{vol}\{v\in\mathbb{Z}_{q^\times}^\times\ |\ v\equiv v^\sigma\ \text{mod}\ q^r\}.
$$

<span id="page-57-2"></span>Next, recall that the measure is normalized so that  $vol(\mathbb{Q}_q^{(1)})$  $\binom{1}{q^2}$  = 1 and hence by equation [\(A.2\)](#page-55-0), we also have vol $(\mathbb{Z}_{q^2}^{\times}) = 1$ . To compute  $J(\varsigma, \vartheta)$ , it remains to compute the index of

$$
S = \{ v \in \mathbb{Z}_{q^2}^\times \mid v \equiv v^\sigma \bmod q^r \}
$$

in  $\mathbb{Z}_{q^2}^{\times}$ . We consider the intersection of S with the filtration  $U_n = 1 + q^n \mathbb{Z}_{q^2}^{\times}$  on  $U_0 = \mathbb{Z}_{q^2}^{\times}$ . Clearly, for  $n \ge r$ ,  $S_n = S \cap U_n = U_n$  because the condition  $v^{\sigma} \equiv v \mod p^r$  is automatically satisfied. The successive quotients of the filtration are:

$$
U_0/U_1 \cong \mathbb{F}_{q^2}^{\times}
$$

$$
U_n/U_{n+1} \cong \mathbb{F}_{q^2}
$$

and for  $n < r$  the condition  $v \equiv v^{\sigma} \mod q^r$  gives:

$$
S_0/S_1 \cong \mathbb{F}_q^{\times},
$$
  

$$
S_n/S_{n+1} \cong \mathbb{F}_q.
$$

Overall, this shows that:

$$
[\mathbb{Z}_{q^2}^{\times} : S] = \frac{q^2 - 1}{q - 1} \cdot q^{r - 1}.
$$

Therefore, finally:

$$
J(\varsigma,\vartheta) = \frac{q-1}{q^{r-1}(q^2-1)}.
$$

<span id="page-57-1"></span>We rephrase this result as in Section 4.6 of loc. cit.

**Proposition A.8.** For the above choices of  $\varsigma$  and  $\vartheta$ , we have

$$
J(\varsigma,\vartheta) = \frac{1}{q^r} \frac{q-1}{q+1} \cdot L_q(\pi_f, \pi_{\overline{\eta'}}, s) L_q(2s, \epsilon_K)^{-1}|_{s=1/2}.
$$

Proof. We recall that:

• 
$$
L_q(1, \epsilon_K) = \frac{1}{1 + 1/q} = \frac{q}{q+1}
$$
,

• by  $[Jac72, Theorem 15.1], since  $\pi = St$ , we have$ 

$$
L(s, \pi \times \pi_{\psi}) = L(s, \pi_{\psi} \otimes |\cdot|^{1/2}) = L(s + 1/2, \pi_{\psi}) = L(s + 1/2, \psi),
$$

and hence:

$$
L(1/2, \pi \times \pi_{\psi}) = L(1, \psi) = \frac{1}{1 - \psi(q)q^{-2}} = \frac{1}{1 - q^{-2}} = \frac{q^2}{q^2 - 1}.
$$

Thus:

$$
\frac{I(\varsigma,\vartheta)}{L_q(\pi_f,\pi_{\overline{\eta'}},s)L_q(2s,\epsilon_K)^{-1}|_{s=1/2}} = \frac{q-1}{q^{r-1}(q^2-1)}\frac{q^2-1}{q^2}\frac{q}{q+1} = \frac{1}{q^r}\cdot\frac{q-1}{q+1}.
$$

A.4. **Finishing the proof.** Theorem [A.5](#page-54-1) is again proved by following [\[BDP13,](#page-65-7) Section 5] word-for-word, and replacing Theorem 4.6 of loc. cit, with Theorem [A.7](#page-55-1) above.

## Appendix B. Examples

<span id="page-57-0"></span>The hypotheses of Conjecture [6.5](#page-45-0) and Theorem [6.9](#page-47-0) may seem quite restrictive at first glance, so in this section we collect many examples where they are satisfied. Even though we have only provided evidence for the conjecture in the CM case so far, we still wish to give instances where the conjecture could be verified numerically by adapting the algorithms in [\[Dal23a\]](#page-65-5). We hope to carry out this numerical verification in future work.

<span id="page-58-1"></span>We divide the examples into four categories, namely:

- (1)  $h = g^*$ , weight 1 forms with CM by the same field K;
- (2)  $h \neq g^*$ , weight 1 forms with CM by the same field K;
- (3)  $h = g^*$ , weight 1 forms without CM;
- (4)  $h \neq g^*$ , weight 1 forms without CM.

Recall that we denote the form obtained by complex conjugation from g by  $g^*$  and that its corresponding representation is the contragredient of  $\pi_g$ . In the CM cases, K represents the imaginary quadratic field. As in the previous sections, we denote the various analytic ranks by  $r(E_K) = \text{ord}_{s=1}(L(E_K, s))$ , and  $r(E_K, \psi) = \text{ord}_{s=1}(L(E_K, \psi, s))$ . We always consider elliptic curves with analytic (and algebraic) rank 0 over Q. In the first two categories of examples, we keep track of which among the various Hypotheses [A,](#page-42-1) [B,](#page-43-0) [C,](#page-43-1) [A',](#page-46-0) [B',](#page-46-1) and [C'](#page-46-2) is satisfied. All our computations are made with the help of magma [\[BCP97\]](#page-65-11) and we make extensive use of the LMFDB Database [\[LMF24\]](#page-66-30); all the labels refer to items listed there. We developed a simple procedure for computing the Hecke characters  $\psi_q$  and  $\psi_h$  and hence studying order of vanishing of the L-functions; these routines can be found at  $[2]$ . In the following tables, we highlight the primes of supercuspidal type in blue.

<span id="page-58-0"></span>B.1. CM case,  $h = g^*$ . We consider here the case of  $h = g^*$  with CM by K. In this situation, the two characters  $\psi_1$  and  $\psi_2$  of Section [6](#page-42-0) are, respectively, 1 and  $\psi = \psi_g \psi_h^{\sigma} = \psi_g/\psi_g^{\sigma}$ , for  $\sigma$  the generator of  $Gal(K/\mathbb{Q})$ . For each example below, we checked that Hypotheses [A',](#page-46-0) [B',](#page-46-1) and [C](#page-43-1) are satisfied, so the Elliptic Stark Conjecture [6.5](#page-45-0) applies. The stronger hypothesis  $C'$ , under which Theorem [6.9](#page-47-0) applies, is only sometimes satisfied so we separate the examples into Tables [1](#page-59-0) and [2,](#page-60-0) accordingly.

<span id="page-60-1"></span><span id="page-60-0"></span>TABLE 2. Examples where  $h = g^*$ , both with CM by K. Hypotheses [A',](#page-46-0) [B',](#page-46-1) and [C](#page-43-1) are satisfied, so Conjecture [6.5](#page-45-0) applies. However, Theorem [6.9](#page-47-0) does not apply as Hypothesis [C'](#page-46-2) is not satisfied.

B.2. **CM case,**  $h \neq g^*$ . We consider here the case of  $h \neq g^*$  with CM by the same field K and we collect the examples into two tables. Note that, differently from the previous section (Section [B.1\)](#page-58-0), we have  $\psi_1, \psi_2 \neq 1$ , hence it becomes difficult to check Hypothesis [C'](#page-46-2) for the examples in Table [3](#page-61-0) and Table [4.](#page-62-0) This last condition can be checked by explicitly recovering the Hecke characters  $\psi_1$  and  $\psi_2$  via [\[2\]](#page-66-31) and computing the local  $\epsilon$ -factors. We list a few forms satisfying all the Hypotheses [A',](#page-46-0) [B',](#page-46-1) and [C](#page-43-1) in Table [3.](#page-61-0) In these examples, Hypothesis [C'](#page-46-2) represents a rather strict assumption but, as observed in Remark [A.3,](#page-53-2) it can be relaxed by extending [\[HB15\]](#page-66-24). Some pairs are related by a twist of a Dirichler character, while others are not. The latter represents the most interesting situation and one can notice that the Artin representation  $V_g \otimes V_h$  decomposes as direct sum of two irreducible two-dimensional Artin representations. The second table of this section, that is, Table [4](#page-62-0) presents a few examples not satisfying Hypothesis  $C'$ , i.e. ones where Theorem [6.9](#page-47-0) does not apply, but Conjecture [6.5](#page-45-0) does.

<span id="page-62-1"></span><span id="page-62-0"></span>TABLE 4. Examples where  $h \neq g^*$  both with CM by the same field K. Hypotheses [A',](#page-46-0) [B',](#page-46-1) and [C](#page-43-1) are satisfied; Conjecture [6.5](#page-45-0) applies.

Remark B.1. It is not automatic that finding the right level and character produces a situation where our work applies. By Proposition [2.1](#page-6-1) (2)([\[Pra90,](#page-66-9) Proposition 8.5]), in order to obtain local sign  $\varepsilon_{\ell}(E, \varrho_{gh}) = -1$ , the supercuspidal representations  $\pi_{g,\ell}$  and  $\pi_{h,\ell}$  need to satisfy  $\pi_{g,\ell} \cong \pi_{h,\ell}^* = \pi_{h^*,\ell}$ . There are several examples which fail this final condition:

- g: [2023.1.c.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2023/1/c/a/) [2023.1.c.b](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2023/1/c/b/) and h: [2023.1.c.c,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2023/1/c/c/) [2023.1.c.d;](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2023/1/c/d/)
- g: [2527.1.d.c,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2527/1/d/c/) [2527.1.d.d](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2527/1/d/d/) and h: [2527.1.d.f.](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2527/1/d/f/)

B.3. Non-CM case,  $h = g^*$ . In this section we report a few examples to which our Conjecture [6.5](#page-45-0) applies, but the form  $g$  does not have CM, so Theorem  $6.9$  does not. We divide the examples depending on the projective image of the Artin representation associated with g.

B.3.1. RM but no CM:. We begin by giving examples of some weight 1 modular forms with RM by a field  $F/\mathbb{Q}$  but without CM. When  $h = g^*$ , we once again have

$$
(B.1) \t\t V_g \otimes V_{g^*} = \mathrm{Ind}_{\mathbb{Q}}^F(\mathbb{1}) \oplus V_{\psi},
$$

<span id="page-63-0"></span>for  $\psi = \psi_g / \psi_g^{\sigma}$ ; here  $\sigma$  is a generator of  $Gal(F/\mathbb{Q})$ .

E	Level	$\mathfrak{g}$	Level	$r(E_F) + r(E_F,\psi)$	F	$\mathcal{p}$
15.a1	$3\cdot 5$	$1025.1$ .i.a.	$5^2 \cdot 41$	$0 + 1$	$\mathbb{Q}(\sqrt{5})$	11

30.a1	$2 \cdot 3 \cdot 5$	1025.1.f.a.	$5^2 \cdot 41$	$0 + 1$	$\mathbb{Q}(\sqrt{5})$	11
39.a1	$3 \cdot 7$	396.1.d.a	$2^2 \cdot 3^2 \cdot 11$	$0 + 1$	$\mathbb{Q}(\sqrt{11})$	5

TABLE 5. Examples where  $h = g^*$ , both with RM by  $F$ ;  $r(E_F)$  and  $r(E_F, \psi)$  are computed.

B.3.2. A4: To compute these examples, we make wide use of the technical remarks in [\[DLR15,](#page-65-1) Section 5.1]. In this situation,  $V_g \otimes V_{g^*}$  decomposes as  $1 \oplus \text{Ad}_g$ , for  $\text{Ad}_g$  the adjoint representation of g. Therefore it is enough to compute the order of vanishing  $\text{ord}_{s=1}L(E, \text{Ad}_g, s)$ . Let H be the Galois field defined by the *projective* Artin representation associated with g, let  $h(x)$  be a degree 4 polynomial whose splitting field is H. Denoting by M the field generated by a single root of  $h(x)$ , by [\[DLR15,](#page-65-1) Section 5.1.1], we have

(B.2) 
$$
r(E, \text{Ad}_g) = \text{ord}_{s=1}L(E, \text{Ad}_g, s) = r(E_M) - r(E).
$$

Hence,  $\operatorname{ord}_{s=1}L(f \times g \times h, 1) = r(E_M)$ .

TABLE 6. Examples where  $h = g^*$  is an exotic form of projective type  $A_4$ ;  $r(E_M)$  and  $r(E_H)$  are computed.

E	Level	$\mathfrak{g}$	Level	r(E)	$r(E_M)$	$r(E_H)$	Polynomial of $M$	$\mathfrak{p}$

		33.a1 $3 \cdot 11$ 968.1.h.a $2^3 \cdot 11^2$	$0 + 1$	$5\overline{)}$
		55.a1 $5 \cdot 11$ 968.1.h.a $2^3 \cdot 11^2$	$0 + 1$	23

<span id="page-64-0"></span>TABLE 7. Examples where  $h = g^*$  is an exotic form of projective type  $S_4$ ;  $r(E)$  and  $r(E, \text{Ad}_q)$  are computed.

We report here a few more modular forms to which our setting applies, but computing the corresponding analytic ranks seems computationally demanding: [1224.1.m.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/1224/1/m/a/) [1224.1.m.b,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/1224/1/m/b/) [1800.1.l.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/1800/1/l/a/) and [1800.1.l.b.](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/1800/1/l/b/)

B.3.4.  $A_5$ : Unfortunately, computing examples with forms of projective image  $A_5$  seems out of reach at the present moment, due to the difficulty of computing Artin representations over degree 60 number fields. Even trying to address the problem as in [\[DLR15,](#page-65-1) Section 5.1.2], as the computation of the unique subfield of degree 2 contained in the Artin field is demanding. However, we list here a few modular forms to which our setting should apply: [1825.1.y.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/1825/1/y/a/) [2079.1.dd.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/2079/1/dd/a/) [3069.1.cd.a,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/3069/1/cd/a/) [3069.1.cd.b,](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/3069/1/cd/b/) and [3168.1.cb.a.](https://www.lmfdb.org/ModularForm/GL2/Q/holomorphic/3168/1/cb/a/)

B.4. **Non-CM case,**  $h \neq g^*$ . Computing examples in this setting is rather challenging, but we present a few examples of dihedral forms with RM and no CM, and exotic ones with  $S_4$  projective image. In both cases, we only consider forms  $g$  and  $h$  with are related by a twist by Dirichlet character.

B.4.1. RM but no CM:. In this situation, we consider g and h with RM by the same field  $\mathbb{Q}(\sqrt{5})$ . We write  $V_g \otimes V_h = \text{Ind}_{\mathbb{Q}(\sqrt{5})}^{\mathbb{Q}}(\psi_g) \otimes \text{Ind}_{\mathbb{Q}(\sqrt{5})}^{\mathbb{Q}}(\psi_h) \text{Ind}_{\mathbb{Q}(\sqrt{5})}^{\mathbb{Q}}(\psi_g \psi_h) \oplus \text{Ind}_{\mathbb{Q}(\sqrt{5})}^{\mathbb{Q}}(\psi_g \psi_h^{\sigma}).$ 

TABLE 8. Examples where  $h \neq g^*$  are dihedral forms, both with RM by  $\mathbb{Q}(\sqrt{5})$  and without CM.

E Level		$\mathfrak{g}$	Level	$r(E_F, \psi_q \psi_h) + r(E_F, \psi_q \psi_h^{\sigma})$	
		$\boldsymbol{h}$	Level		$\mathcal{p}$

B.4.2.  $S_4$ : We consider the case of  $g \neq h^*$  but  $h = g \otimes \chi$ , for  $\chi$  a Dirichlet character. In this situation, the representation  $V_g \otimes V_h$  decomposes as  $\rho_1 \oplus \rho_3$  for  $\rho_d$  a d-dimensional Artin representation,  $d = 1, 3$ .

E Level		$\mathfrak g$	Level	$r(E, \rho_1) + r(E, \rho_3)$
