# Effects of diffusion and advection on predator prey dynamics in an advective patchy environment 

Qi Wang *

#### Abstract

In this paper, we consider a specialist predator-prey patchy model over the closed stream network. We study the dynamics and the asymptotic profiles of positive steady states according to the mortality rate of the specialist predators, advection and diffusion rates. We verify that the specialist predators can successfully invade as long as the mortality rate is sufficiently small. On the other hand, the impacts of diffusion and advection on the asymptotic profiles of positive steady states and on the concentration of the species are given.

Keywords: Patchy environment; Predator-prey system; Global dynamics; Asymptotic profiles Mathematics Subject Classification (2010): 34D05, 34D23, 37C75, 92D25, 92D40

## 1 Introduction

It is well-known that whether the individuals survive or not in a predominantly unidirectional flow environments (such as streams, rivers, lakes or oceans) depends on both the environment and the growth of interacting species. Sometimes, despite the flow induced washout, the species can always persist in their habitats for many generations. This phenomenon is so-called "drift paradox" [19, 20, 23]. To explain this paradox, Speirs and Gurney [29] proposed a reaction-diffusion-advection equation and indicated that the persistence of single species is possible when the flow speed is slow relative to the diffusion and the stream is long enough. Intuitively, the predominantly unidirectional flow will carry individuals to the downstream end or drive individuals out of the system, which may be crowded or hostile. However, random dispersal may drive them to some favorable locations in the upstream [7]. Therefore, one can see the joint impacts of both undirectional and directed dispersal rates on the population dynamics of the species are usually complicated and have attracted the attention of many researchers [6,9,11,17,18,20,29].

In real ecological advective environments, there are various inter-specific relationships including competition, predation. The two-species reaction-diffusion-advection competition models have been widely studied in $[4,10,11,13-15,21,30-32,35-38]$. Among them, some results illustrate the conditions under which the species $u$ or $v$ is stable/unstable. Various results on the global dynamics of the two-species reaction-diffusion-advection competition models are also presented.

Regarding the dynamics of two species competition models in a river network, the authors in $[1-3,7,8]$ investigated a two-species Lotka-Volterra competition patchy model over a inland stream. Let $n \geq 3$, $\boldsymbol{u}=\left(u_{1}, u_{2}, \cdots, u_{n}\right)$ and $\boldsymbol{v}=\left(v_{1}, v_{2}, \cdots, v_{n}\right)$ be the population densities of two competing species, respectively, where $u_{i}$ and $v_{i}$ are the densities in patch $i$. Suppose that the dispersal patterns of the individuals and the configuration of the patches are shown in Fig.??

[^0]The competition patchy model over the stream network in Fig. ?? in [1-3, 7,8$]$ is:

$$
\begin{cases}\frac{\mathrm{d} u_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{1} D_{i j}+q_{1} Q_{i j}\right) u_{j}+r_{i} u_{i}\left(1-\frac{u_{i}+v_{i}}{k_{i}}\right), & i \in\{1,2, \cdots, n\}, t>0  \tag{1.1}\\ \frac{\mathrm{~d} v_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{2} D_{i j}+q_{2} Q_{i j}\right) v_{j}+r_{i} v_{i}\left(1-\frac{u_{i}+v_{i}}{k_{i}}\right),, & i \in\{1,2, \cdots, n\}, t>0 \\ \boldsymbol{u}(0)=\boldsymbol{u}_{0} \geq, \not \equiv 0, \boldsymbol{v}(0)=\boldsymbol{v}_{0} \geq, \not \equiv 0\end{cases}
$$

where $d_{1}, d_{2}$ are random movement rates; $q_{1}, q_{2}$ represent directed movement rates; the matrices $D=$ $\left(D_{i j}\right)$ and $Q=\left(Q_{i j}\right)$ are the random movement pattern and directed drift pattern of individuals, respectively, where

$$
D=\left(\begin{array}{cccccc}
-1 & 1 & 0 & \cdots & \cdots & 0  \tag{1.2}\\
1 & -2 & 1 & \cdots & \cdots & 0 \\
0 & \ddots & \ddots & \ddots & & \\
\vdots & & \ddots & \ddots & \ddots & \\
0 & \cdots & \cdots & 1 & -2 & 1 \\
0 & \cdots & \cdots & \cdots & 1 & -1
\end{array}\right), Q=\left(\begin{array}{cccccc}
-1 & 0 & 0 & \cdots & \cdots & 0 \\
1 & -1 & 0 & \cdots & \cdots & 0 \\
0 & \ddots & \ddots & \ddots & & \\
\vdots & & \ddots & \ddots & \ddots & \\
0 & \cdots & \cdots & 1 & -1 & 0 \\
0 & \cdots & \cdots & \cdots & 1 & 0
\end{array}\right)
$$

Recently, Chen, Liu and Wu [2] considered (1.1) with three patches. They studied if one species is treated as a resident species, whether the other species can invade or not under some assumptions on the carrying capacity.

Predation is another common phenomenon in advective environments. For instance, herbivorous zooplankton and phytoplankton in water columns. Compared with the competitive systems, up to now, the studies of the evolution of dispersal in predator-prey systems under advective environments are relatively few. How do the prey persist in advective environments and avoid predations successfully? How do the predators invade the prey and coexist in advective environments? To better understand these issues, Hilker and Lewis [5] proposed the following predator-prey system in advective environments.

$$
\begin{cases}N_{t}=d_{1} N_{x x}-q N_{x}+f(N, P) N, & x \in(0, L), t>0  \tag{1.3}\\ P_{t}=d_{2} P_{x x}-\tau q P_{x}+g(N, P) P, & x \in(0, L), t>0\end{cases}
$$

Here $N(x, t)$ and $P(x, t)$ are the population densities of the prey and predator species at time $t$ and location $x$, respectively. $d_{1}, d_{2}$ are dispersal rates, $q$ denotes the effective advection rate of the prey, $L$ is the domain length. The function $f(N, P)$ is given by

$$
\begin{equation*}
f(N, P)=r_{1}(x)\left(1-\frac{N}{K_{1}(x)}\right)-a P \tag{1.4}
\end{equation*}
$$

and the function $g(N, P)$ is given by

$$
\begin{equation*}
g(N, P)=\beta a N-\gamma \text { or } g(N, P)=r_{2}(x)\left(1-\frac{P}{K_{2}(x)}\right)+\beta a N \tag{1.5}
\end{equation*}
$$

where $r_{i}(x)(i=1,2)$ and $K_{i}(x)(i=1,2)$ account for the intrinsic growth rate and the carrying capacity of the prey and predators at location $x$, respectively, $a$ is the predation rate, $\beta$ is the trophic conversion efficiency, and $\gamma$ is the mortality rate of the predators.

By numerical simulations and traveling wave speed approximations, Hilker and Lewis achieved the coexistence, extinction of both species and survival of one species. Based on [5], some mathematicians studied the dynamics of the predator-prey model in open advective environments further [12, 25, 26, 34]. Furthermore, Wang et al. in $[27,33]$ investigated the dynamics of some predator-prey models in closed advective environments and obtained some significant outcomes.

Motivated by [2, 27], in this paper we let $n \geq 3, \boldsymbol{N}=\left(N_{1}, N_{2}, \cdots, N_{n}\right), \boldsymbol{P}=\left(P_{1}, P_{2}, \cdots, P_{n}\right)$ and consider the following specialist predator-prey patchy model over the closed stream network in Fig.??:

$$
\begin{cases}\frac{\mathrm{d} N_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}+r_{i} N_{i}\left(1-\frac{N_{i}}{k_{i}}\right)-a N_{i} P_{i}, & i \in\{1,2, \cdots, n\}, t>0  \tag{1.6}\\ \frac{\mathrm{~d} P_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) P_{j}+P_{i}\left(\beta a N_{i}-\gamma\right),, & i \in\{1,2, \cdots, n\}, t>0 \\ \boldsymbol{N}(0) \geq, \neq \mathbf{0}, \boldsymbol{P}(0) \geq, \neq \mathbf{0}\end{cases}
$$

where $N_{i}$ and $P_{i}$ are the densities of the prey and predator in patch $i$ respectively. Here $r_{i}(i \in$ $\{1,2, \cdots, n\})$ and $k_{i}(i \in\{1,2, \cdots, n\})$ account for the intrinsic growth rate and the carrying capacity of the prey in patch $i$, respectively. The meanings of $a, \beta, \gamma$ are the same as them in (1.5).

The goal of this paper is to study the dynamics of system (1.6), and investigate the similarities or differences between (1.6) and the specialist predator-prey model in [27].

For convenience, we set $\mathcal{A}=\{1,2, \cdots, n\}, \mathcal{B}=\{2, \cdots, n-1\}, \mathcal{C}=\{1, \cdots, n-1\}, \boldsymbol{r}=\left(r_{1}, r_{2}, \cdots, r_{n}\right)$, $\boldsymbol{r}+b=\left(r_{1}+b, r_{2}+b, \cdots, r_{n}+b\right), r_{\max }=\max _{i \in \mathcal{A}} r_{i}, r_{\min }=\min _{i \in \mathcal{A}} r_{i}$. We write $\boldsymbol{r} \geq \mathbf{0}(\boldsymbol{r} \gg \mathbf{0})$ if $r_{i} \geq 0\left(r_{i}>0\right)$ for all $i \in \mathcal{A}$, and $\boldsymbol{r}>\mathbf{0}$ if $\boldsymbol{r} \geq \mathbf{0}$ and $\boldsymbol{r} \neq \mathbf{0}:=(0, \cdots, 0)$.

At the end of this section, we make some assumptions throughout this paper:

$$
\begin{equation*}
\boldsymbol{r}, \boldsymbol{k} \gg \mathbf{0}, d_{1}, d_{2}, a, \beta, \tau>0, q \geq 0 \text { and there exist } i \neq j \text { such that } k_{i} \neq k_{j} . \tag{H}
\end{equation*}
$$

The rest of this paper is organized as follows. In Section 2, we state the main results. In Section 3, we provide some preliminary results. In Section 4, we show our main results.

## 2 Main Results

Before describing precisely the outcome of our paper, we first recall some existing results on the dynamics of the following single-species model:

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} N_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}+r_{i} N_{i}\left(1-\frac{N_{i}}{k_{i}}\right), \quad i \in \mathcal{A}, t>0  \tag{2.1}\\
\boldsymbol{N}(0)>\mathbf{0}
\end{array}\right.
$$

It is known in [2, Lemma 2.2](see also [16]) that system (2.1) admits a unique positive steady state, denoted by $\boldsymbol{\theta}=\left(\theta_{1}, \cdots, \theta_{n}\right) \gg 0$, which is globally asymptotically stable for any $d_{1}>0$ and $q \geq 0$.

We are now in a position to state our main results.
Theorem 2.1. Suppose (H) hold. Let $(\boldsymbol{N}(t), \boldsymbol{P}(t))$ be the solution of (1.6). There exists a critical curve $\gamma=\gamma^{*}\left(q, d_{1}, d_{2}\right) \in(0,+\infty)$ continuously dependent on $q, d_{1}, d_{2}$ such that:
(1) if $\gamma>\gamma^{*}$, then $(\boldsymbol{N}(t), \boldsymbol{P}(t))$ converges uniformly to $(\boldsymbol{\theta}, \mathbf{0})$ as $t \rightarrow+\infty$;
(2) if $\gamma<\gamma^{*}$, then system (1.6) is uniformly persistent in the sense that there exists $\eta>0$ such that the solution $(\boldsymbol{N}(t), \boldsymbol{P}(t))$ satisfies $\liminf _{t \rightarrow+\infty}(N(t))_{\text {min }} \geq \eta, \liminf _{t \rightarrow+\infty}(P(t))_{\min } \geq \eta$. Moreover, system (1.6) admits a positive steady state.

Remark 2.1. Theorem 2.1 indicates that the dynamical behavior of system (1.6) is depicted completely by the critical curve $\gamma=\gamma^{*}\left(q, d_{1}, d_{2}\right)$. More precisely, $\gamma=\gamma^{*}\left(q, d_{1}, d_{2}\right)$ classifies the dynamical behavior of system (1.6) into two scenarios: (i) coexistence; and (ii) persistence of prey only. Biologically, a large death rate of the predators makes it difficult to invade, while the predators can invade successfully only when the mortality rate of the predators is less than the critical mortality rate $\gamma^{*}$.

Theorem 2.2. Suppose $(\mathbf{H})$ hold. The threshold value $\gamma^{*}\left(q, d_{1}, d_{2}\right)$ satisfies the following properties:
(1) $\lim _{q \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\beta a k_{n}$ for $d_{1}, d_{2}>0$;
(2) $\lim _{d_{1} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\beta a \sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}}$ for $d_{2}>0, q \geq 0$;
(3) if $q \geq \max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, 2 r_{\max }\right\}$, then $\lim _{d_{1} \rightarrow 0^{+}} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\mu\left(k_{n}\right)$ for $d_{2}>0, q>0$, where $\mu\left(k_{n}\right)>0$ is the principal eigenvalue of the following system

$$
\left\{\begin{array}{l}
-\left(d_{2}+\tau q\right) \vartheta_{1}+d_{2} \vartheta_{2}=\mu\left(k_{n}\right) \vartheta_{1}  \tag{2.2}\\
\left(d_{2}+\tau q\right) \vartheta_{j-1}+\left(-2 d_{2}-\tau q\right) \vartheta_{j}+d_{2} \vartheta_{j+1}=\mu\left(k_{n}\right) \vartheta_{j}, j \in \mathcal{B} \\
\left(d_{2}+\tau q\right) \vartheta_{n-1}-d_{2} \vartheta_{n}+\beta a k_{n} \vartheta_{n}=\mu\left(k_{n}\right) \vartheta_{n}
\end{array}\right.
$$

and $\mu\left(k_{n}\right)$ is strictly increasing with respect to $k_{n}$;
(4) $\lim _{d_{1} \rightarrow 0^{+}} \gamma^{*}\left(0, d_{1}, d_{2}\right)=\lambda_{1}\left(d_{2}, 0, \beta a \boldsymbol{k}\right)>0$ for $d_{2}>0$, where $\lambda_{1}\left(d_{2}, 0, \beta a \boldsymbol{k}\right)$ is defined in subsection 3.1;
(5) $\lim _{d_{2} \rightarrow 0^{+}} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\max \left\{\beta a \theta_{1}-\tau q, \cdots, \beta a \theta_{n-1}-\tau q, \beta a \theta_{n}\right\}$, and $\lim _{d_{2} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\sum_{i=1}^{n} \beta a \theta_{i}}{n}$ for $d_{1}>0, q \geq 0$.

Remark 2.2. It is easy to see that $\mu(0)=0$.
Theorem $2.2(1),(2)$ and (5) indicate that in closed advective patchy environments $\gamma^{*}\left(q, d_{1}, d_{2}\right)$ has a positive lower bound for any $q \geq 0$ and $d_{1}, d_{2}>0$. This implies that if the prey's diffusion rate $d_{1}>0$ is fixed, then the specialist predators can invade successfully as long as their death rate is suitably small. For a small diffusion rate $d_{1}$ of the prey, (3) and (4) show that the specialist predators can always invade successfully in both non-advective and advective environments. Moreover, given sufficiently small death rate of the specialist predators, when the carrying capacity of the prey at patch $n$ increases, it is more convenient for the predators to invade. This phenomenon is different from the one in [27], where they verified that it is difficult for the specialist predators to invade in advective environments, when $d_{1}$ is small enough.

Next, we investigate the asymptotic profiles of the positive steady state $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$.
Theorem 2.3. Suppose ( $\mathbf{H})$ hold, and $0<\gamma<\beta a k_{n}$. Let $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ be a positive steady state of (1.6). Then it satisfies $\left(N_{i}^{*}, P_{i}^{*}\right) \rightarrow(0,0)$ uniformly for $i \in \mathcal{C}$ as $q \rightarrow+\infty$, and $\left(N_{n}^{*}, P_{n}^{*}\right) \rightarrow\left(\frac{\gamma}{\beta a}, \frac{1}{a}\left(r_{n}-\frac{r_{n}}{k_{n}} \frac{\gamma}{\beta a}\right)\right)$ as $q \rightarrow+\infty$.

Theorem 2.4. Suppose (H) hold, $0<\gamma<\beta a k_{\text {min }}$. Let $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ be a positive steady state of (1.6). Then it satisfies

$$
\begin{equation*}
\left(N_{i}^{*}, P_{i}^{*}\right) \rightarrow\left(\frac{\gamma}{\beta a},\left(1+\frac{\tau q}{d_{2}}\right)^{i-1} \frac{\sum_{j=1}^{n} r_{j}\left(1-\frac{\gamma}{\beta a k_{j}}\right)}{\frac{d_{2} a}{\tau q}\left[\left(1+\frac{\tau q}{d_{2}}\right)^{n}-1\right]}\right) \tag{2.3}
\end{equation*}
$$

uniformly for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$.
Theorem 2.5. Suppose (H) hold, $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$, and $q>\max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{2 \beta a N_{n}^{*}}{\tau}\right\}$. Let $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ be a positive steady state of (1.6). Then it satisfies $\left(N_{i}^{*}, P_{n}^{*}\right) \rightarrow\left(\theta_{i}, 0\right)$ as $d_{2} \rightarrow 0^{+}$. Moreover,

$$
\begin{equation*}
\max _{i \in \mathcal{C}}\left(P_{i}^{*}-P_{n}^{*}\left(\frac{d_{1}}{d_{2}+\tau q}\right)^{n-i}\right) \rightarrow 0 \text { as } d_{2} \rightarrow 0^{+} \tag{2.4}
\end{equation*}
$$

Theorem 2.6. Suppose $(\mathbf{H})$ hold, $0<\gamma<\frac{\beta a \sum_{i}^{n} \theta_{i}}{n}$. Let $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ be a positive steady state of (1.6). Then it satisfies $\left(N_{i}^{*}, P_{n}^{*}\right) \rightarrow\left(\hat{\theta}_{i}, z\right)$ as $d_{2} \rightarrow+\infty$, where $\left(\hat{\theta}_{i}, z\right)$ satisfies

$$
\begin{cases}\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) \hat{\theta}_{j}+\hat{\theta}_{i}\left(r_{i}-\frac{r_{i}}{k_{i}} \hat{\theta}_{i}-a z\right)=0, & i \in \mathcal{A}  \tag{2.5}\\ \beta a \sum_{i=1}^{n} \hat{\theta}_{i}=\gamma n, & i \in \mathcal{A}\end{cases}
$$

Theorem 2.3 implies that sufficiently large advection will affect the distribution of species in the network. More precisely, two species will coexist and concentrate at the patch $n$ if the advection rate is large enough. Theorems 2.4 and 2.6 show that two species can coexist for large diffusion rates. Theorem $2.2(5)$ and 2.5 illustrate the successful invasion of the specialist predators once diffusion rate $d_{2}$ is enough small, but their population density tends to zero as the diffusion rate tends to zero. This phenomenon is partially due to the lack of other food sources of the specialist predators except the prey. Another reason is that the specialist predators cannot catch up with the prey when their diffusion rate is sufficiently small.

## 3 Preliminaries

In this section, we aim to exhibit some fundamental results, which will be utilized in later sections.

### 3.1 The linear eigenvalue problem

We first consider an auxiliary linear eigenvalue problem.

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) \phi_{j}+h_{i} \phi_{i}=\lambda \phi_{i}, \quad i \in \mathcal{A} \tag{3.1}
\end{equation*}
$$

where $d>0, q \geq 0$. It is well-known from [1,2] that problem (3.1) admits a unique principal eigenvalue $\lambda_{1}(d, q, \boldsymbol{h})=s\left(d D+q Q+\operatorname{diag}\left(h_{i}\right)\right)\left(\right.$ which is the spectral bound of $\left.d D+q Q+\operatorname{diag}\left(h_{i}\right)\right)$ associated with a nonnegative eigenvector $\phi=\left(\phi_{1}, \cdots, \phi_{n}\right)>0$, since the matrix $d D+q Q+\operatorname{diag}\left(h_{i}\right)$ is irreducible and essentially nonnegative for any $d>0, q \geq 0$, where $D$ and $Q$ are defined by (1.2).

Lemma 3.1. Let $D$ and $Q$ be defined in (1.2), $d, q>0$, and $\lambda_{1}(d, q, \boldsymbol{h})$ be the principal eigenvalue of (3.1). Suppose that $\boldsymbol{h} \gg \mathbf{0}$ and there exist $i \neq j$ such that $h_{i} \neq h_{j}$. Then, we have the following:
(i) for each fixed $d>0, \lambda_{1}(d, q, \boldsymbol{h})$ is strictly decreasing with respect to $q$ in $[0,+\infty)$ when $h_{1} \geq \cdots \geq h_{n}$ with at least one strict inequality, and $\lambda_{1}(d, q, \boldsymbol{h})$ is strictly increasing with respect to $q$ when $h_{1} \leq \cdots \leq h_{n}$ with at least one strict inequality;
(ii) $\lim _{q \rightarrow+\infty} \lambda_{1}(d, q, \boldsymbol{h})=h_{n}$;
(iii) $\lim _{d \rightarrow 0} \lambda_{1}(d, q, \boldsymbol{h})=\max \left\{h_{1}-q, \cdots, h_{n-1}-q, h_{n}\right\}$ and $\lim _{d \rightarrow+\infty} \lambda_{1}(d, q, \boldsymbol{h})=\frac{\sum_{i=1}^{n} h_{i}}{n}$;
(iv) if $\boldsymbol{h}>\boldsymbol{g}$, then $\lambda_{1}(d, q, \boldsymbol{h}) \geq \lambda_{1}(d, q, \boldsymbol{g})$, and the equality holds only if $\boldsymbol{h}=\boldsymbol{g}$.

Proof: The proofs of (i)-(iii) are standard and we refer to [1] for the proofs. We now show the statement (iv). Indeed, we can rewrite (3.1) as the following forms:

$$
\left\{\begin{array}{l}
-(d+q) \phi_{1}+d \phi_{2}+h_{1} \phi_{1}=\lambda_{1} \phi_{1}  \tag{3.2}\\
(d+q) \phi_{j-1}+(-2 d-q) \phi_{j}+d \phi_{j+1}+h_{j} \phi_{j}=\lambda_{1} \phi_{j}, j \in \mathcal{B} \\
(d+q) \phi_{n-1}-d \phi_{n}+h_{n} \phi_{n}=\lambda_{1} \phi_{n}
\end{array}\right.
$$

Differentiating (3.2) with respect to $h_{1}$, we have

$$
\left\{\begin{array}{l}
-(d+q) \frac{\partial \phi_{1}}{\partial h_{1}}+d \frac{\partial \phi_{2}}{\partial h_{1}}+h_{1} \frac{\partial \phi_{1}}{\partial h_{1}}+\phi_{1}=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{1}+\lambda_{1} \frac{\partial \phi_{1}}{\partial h_{1}}  \tag{3.3}\\
(d+q) \frac{\partial \phi_{j-1}}{\partial h_{1}}+(-2 d-q) \frac{\partial \phi_{j}}{\partial h_{1}}+d \frac{\partial \phi_{j+1}}{\partial h_{1}}+h_{j} \frac{\partial \phi_{j}}{\partial h_{1}}=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{j}+\lambda_{1} \frac{\partial \phi_{j}}{\partial h_{1}}, j \in \mathcal{B}, \\
(d+q) \frac{\partial \phi_{n-1}}{\partial h_{1}}-d \frac{\partial \phi_{n}}{\partial h_{1}}+h_{n} \frac{\partial \phi_{n}}{\partial h_{1}}=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{n}+\lambda_{1} \frac{\partial \phi_{n}}{\partial h_{1}} .
\end{array}\right.
$$

Multiplying the first(second,third) equation of (3.3) by $\phi_{1}\left(\phi_{j}, \phi_{n}\right)$ and the first(second,third) equation of (3.2) by $\frac{\partial \phi_{1}}{\partial h_{1}}\left(\frac{\partial \phi_{j}}{\partial h_{1}}, \frac{\partial \phi_{n}}{\partial h_{1}}\right)$, and subtracting each other, it then follows that

$$
\left\{\begin{array}{l}
d\left(\frac{\partial \phi_{2}}{\partial h_{1}} \phi_{1}-\phi_{2} \frac{\partial \phi_{1}}{\partial h_{1}}\right)+\phi_{1}^{2}=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{1}^{2}  \tag{3.4}\\
(d+q)\left(\frac{\partial \phi_{j-1}}{\partial h_{1}} \phi_{j}-\phi_{j-1} \frac{\partial \phi_{j}}{\partial h_{1}}\right)+d\left(\frac{\partial \phi_{j+1}}{\partial h_{1}} \phi_{j}-\phi_{j+1} \frac{\partial \phi_{j}}{\partial h_{1}}\right)=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{j}^{2}, j \in \mathcal{B} \\
(d+q)\left(\frac{\partial \phi_{n-1}}{\partial h_{1}} \phi_{n}-\phi_{n-1} \frac{\partial \phi_{n}}{\partial h_{1}}\right)=\frac{\partial \lambda_{1}}{\partial h_{1}} \phi_{n}^{2}
\end{array}\right.
$$

Let $b_{i}=\left(\frac{d}{d+q}\right)^{i-1}$. Then we have that $b_{i} d=b_{i+1}(d+q)$. This implies that

$$
\begin{align*}
& b_{1} d\left(\frac{\partial \phi_{2}}{\partial h_{1}} \phi_{1}-\phi_{2} \frac{\partial \phi_{1}}{\partial h_{1}} \phi_{1}^{\prime}\right)+b_{2}(d+q)\left(\frac{\partial \phi_{1}}{\partial h_{1}} \phi_{2}-\phi_{1} \frac{\partial \phi_{2}}{\partial h_{1}}\right) \\
& +b_{2} d\left(\frac{\partial \phi_{3}}{\partial h_{1}} \phi_{2}-\phi_{3} \frac{\partial \phi_{2}}{\partial h_{1}}\right)+b_{3}(d+q)\left(\frac{\partial \phi_{2}}{\partial h_{1}} \phi_{3}-\phi_{2} \frac{\partial \phi_{3}}{\partial h_{1}}\right) \\
& +b_{3} d\left(\frac{\partial \phi_{4}}{\partial h_{1}} \phi_{3}-\phi_{4} \frac{\partial \phi_{3}}{\partial h_{1}}\right)+b_{4}(d+q)\left(\frac{\partial \phi_{3}}{\partial h_{1}} \phi_{4}-\phi_{3} \frac{\partial \phi_{4}}{\partial h_{1}}\right)  \tag{3.5}\\
& +\cdots \\
& +b_{n-1} d\left(\frac{\partial \phi_{n}}{\partial h_{1}} \phi_{n-1}-\phi_{n} \frac{\partial \phi_{n-1}}{\partial h_{1}}\right)+b_{n}(d+q)\left(\frac{\partial \phi_{n-1}}{\partial h_{1}} \phi_{n}-\phi_{n-1} \frac{\partial \phi_{n}}{\partial h_{1}}\right) \\
& -0
\end{align*}
$$

Then by (3.4) and (3.5), there holds

$$
\begin{equation*}
\frac{\partial \lambda_{1}}{\partial h_{1}}\left(b_{1} \phi_{1}^{2}+\cdots+b_{n} \phi_{n}^{2}\right)=b_{1} \phi_{1}^{2}>0 \tag{3.6}
\end{equation*}
$$

Therefore, $\frac{\partial \lambda_{1}}{\partial h_{1}}>0$. Similarly, one can have that $\frac{\partial \lambda_{1}}{\partial h_{i}}>0$ for all $i \in \mathcal{A}$. The proof is completed.
Lemma 3.2. Let $D$ and $Q$ be defined in (1.2), $d>0, q \geq 0$, and $\lambda_{1}(d, q, \boldsymbol{h})$ be the principal eigenvalue of (3.1). Suppose that $\boldsymbol{h} \gg \mathbf{0}$. If $h_{1}=h_{2}=\cdots=h_{n}:=h_{0}$, then $\lambda_{1}(d, q, \boldsymbol{h})=h_{0}$ for all $d>0, q \geq 0$.

Indeed this lemma can be deduced directly, we omit the proof here.

### 3.2 Properties of the positive steady state of single species model

Recall that for $d_{1}>0$ and $q>0,(2.1)$ possesses a unique positive steady state $\boldsymbol{\theta}=\left(\theta_{1}, \cdots, \theta_{n}\right) \gg 0$, which satisfies

$$
\begin{equation*}
\sum_{l=1}^{n}\left(d_{1} D_{i l}+q Q_{i l}\right) \theta_{l}+r_{i} \theta_{i}\left(1-\frac{\theta_{i}}{k_{i}}\right)=0, \quad i \in \mathcal{A} \tag{3.7}
\end{equation*}
$$

i.e.

$$
\left\{\begin{array}{l}
-\left(d_{1}+q\right) \theta_{1}+d_{1} \theta_{2}+r_{1} \theta_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)=0  \tag{3.8}\\
\left(d_{1}+q\right) \theta_{j-1}+\left(-2 d_{1}-q\right) \theta_{j}+d_{1} \theta_{j+1}+r_{j} \theta_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)=0, j \in \mathcal{B} \\
\left(d_{1}+q\right) \theta_{n-1}-d_{1} \theta_{n}+r_{n} \theta_{n}\left(1-\frac{\theta_{n}}{k_{n}}\right)=0
\end{array}\right.
$$

Then we collect some useful results for $\boldsymbol{\theta}$.
Lemma 3.3. Suppose $d_{1}>0, q \geq 0$. Then we have
(i) $\frac{\min _{i \in \mathcal{A}} b_{i} k_{i}}{b_{i}} \leq \theta_{i} \leq \frac{\max _{i \in \mathcal{A}} b_{i} k_{i}}{b_{i}}$, where $b_{i}=\left(\frac{d}{d+q}\right)^{i-1}$;
(ii) if $k_{1} \leq k_{2} \leq \cdots \leq k_{n}$, then $\theta_{1} \leq \theta_{2} \leq \cdots \leq \theta_{n}$;
(iii) if $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$, then $\theta_{i}$ is strictly increasing with respect to $i$;
(iv) if $q \geq \max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, 2 r_{\max }\right\}$, then for $i \in \mathcal{C}$

$$
\begin{equation*}
\theta_{n}\left(\frac{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}{d_{1}}\right)^{i-n}<\theta_{i}<\theta_{n}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{i-n} \tag{3.9}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\lim _{q \rightarrow+\infty} \theta_{n}=\lim _{d_{1} \rightarrow 0} \theta_{n}=k_{n} \tag{3.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{q \rightarrow+\infty} \max _{i \in \mathcal{A}}\left(\theta_{i}-\theta_{n}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right)=\lim _{d_{1} \rightarrow 0} \max _{i \in \mathcal{A}}\left(\theta_{i}-\theta_{n}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right)=0 \tag{3.11}
\end{equation*}
$$

(v) $\lim _{d_{1} \rightarrow+\infty} \theta_{i}=\frac{\sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}}$;
(vi) for $d_{1}>0$ small, if $q=0$, then $\max _{i \in \mathcal{A}}\left|\theta_{i}-k_{i}\right|<C_{*} d_{1}$ where $C_{*}=\frac{2 \max _{i \in \mathcal{A}}\left(\sum_{l=1}^{n} D_{i l} k_{l}\right)}{r_{\min }}$.

Proof: (i) Let $b_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1}$ and $w_{i}=b_{i} \theta_{i}(i \in \mathcal{A})$. We see that $w_{i}$ satisfies

$$
\left\{\begin{array}{l}
\left(d_{1}+q\right)\left(w_{2}-w_{1}\right)+r_{1}\left(1-\frac{w_{1}}{b_{1} k_{1}}\right) w_{1}=0  \tag{3.12}\\
d_{1} w_{j-1}+\left(-2 d_{1}-q\right) w_{j}+\left(d_{1}+q\right) w_{j+1}+r_{j}\left(1-\frac{w_{j}}{b_{j} k_{j}}\right) w_{j}=0, j \in \mathcal{B} \\
d_{1}\left(w_{n-1}-w_{n}\right)+r_{n}\left(1-\frac{w_{n}}{b_{n} k_{n}}\right) w_{n}=0
\end{array}\right.
$$

If $w_{1}=\max _{i \in \mathcal{A}} w_{i}$, then $w_{2}-w_{1} \leq 0$, which implies from the first equation of (3.12) that $w_{i} \leq w_{1} \leq$ $b_{1} k_{1}$. Similarly, if $w_{n}=\max _{i \in \mathcal{A}} w_{i}$, then $w_{i} \leq w_{n} \leq b_{n} k_{n}$. If $w_{i_{0}}=\max _{i} w_{i}$ for some $i_{0} \in \mathcal{B}$, then $w_{i_{0}-1}-2 w_{i_{0}}+w_{i_{0}+1} \leq 0$. The second equation of (3.12) then yields that $w_{i} \leq w_{i_{0}} \leq b_{i_{0}} k_{i_{0}}$. Therefore, $w_{i} \leq \max _{i \in \mathcal{A}} b_{i} k_{i}$ and $\theta_{i} \leq \frac{\max _{i \in \mathcal{A}} b_{i} k_{i}}{b_{i}}$. Another inequality $\frac{\min _{i \in \mathcal{A}} b_{i} k_{i}}{b_{i}} \leq \theta_{i}$ can be obtained similarly.
(ii) Set $a_{l}=\frac{\theta_{l+1}-\theta_{l}}{\theta_{l}}(l \in \mathcal{C})$. Then following equations can be deduced directly by (3.8).

$$
\left\{\begin{array}{l}
d_{1} a_{1}-q+r_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)=0  \tag{3.13}\\
d_{1}\left[\left(a_{j}-a_{j-1}\right) \theta_{j}+a_{j-1}^{2} \theta_{j-1}\right]-q a_{j-1} \theta_{j-1}+r_{j} \theta_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)=0, j \in \mathcal{B} \\
q-d_{1} a_{n-1}+r_{n} \frac{\theta_{n}}{\theta_{n-1}}\left(1-\frac{\theta_{n}}{k_{n}}\right)=0
\end{array}\right.
$$

Suppose that $a_{1} \leq 0$. By the first equation in (3.13), we conclude that $k_{1}>\theta_{1}$. Then $k_{2} \geq k_{1}>\theta_{1} \geq$ $\theta_{2}$. This implies that $1-\frac{\theta_{2}}{k_{2}}>0$ and further $\left(a_{2}-a_{1}\right) \theta_{2}+a_{1}^{2} \theta_{1}<0$ by the second equation of (3.13) with $j=2$. Thus $a_{2}<a_{1} \leq 0$, which implies that $\theta_{3}<\theta_{2}<k_{2} \leq k_{3}, 1-\frac{\theta_{3}}{k_{3}}>0$. By the second equation of (3.13) with $j=3$, we arrive at $a_{3}<a_{2}$. Thus, by induction, it follows that

$$
\begin{equation*}
a_{n-1}<\cdots<a_{1} \leq 0 \tag{3.14}
\end{equation*}
$$

which indicates that

$$
\begin{equation*}
\theta_{n}<\theta_{n-1}<\cdots<\theta_{2} \leq \theta_{1}<k_{1} \leq \cdots \leq k_{n} \tag{3.15}
\end{equation*}
$$

However, the third equation of (3.13) yields that

$$
\begin{equation*}
d_{1} a_{n-1}=q+r_{n} \frac{\theta_{n}}{\theta_{n-1}}\left(1-\frac{\theta_{n}}{k_{n}}\right)>0 \tag{3.16}
\end{equation*}
$$

a contradiction to (3.14). Therefore, $a_{1}>0$.
Suppose that $a_{2} \leq 0$. Using the second equation in (3.8) with $j=2$ (which is equivalent to $r_{2} \theta_{2}(1-$ $\left.\frac{\theta_{2}}{k_{2}}\right)+d_{1} a_{2} \theta_{2}-\left(d_{1}+q\right) a_{1} \theta_{1}=0$ ), we arrive at $k_{3} \geq k_{2}>\theta_{2} \geq \theta_{3}$. It then follows from the second equation in (3.13) with $j=3$ that $a_{3}<a_{2} \leq 0$. Thus $\theta_{4}<\theta_{3} \leq \theta_{2}<k_{2} \leq k_{3} \leq k_{4}$. By induction, there holds

$$
\begin{equation*}
a_{n-1}<\cdots<a_{2} \leq 0, \tag{3.17}
\end{equation*}
$$

and furthermore $\theta_{n}<\cdots<\theta_{3} \leq \theta_{2}<k_{n}$, which contradicts to the third equation in (3.13). Hence $a_{2}>0$. By the similar methods as above, we reach that $\theta_{n}>\cdots>\theta_{1}$.
(iii) By a transformation $v_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{\frac{i-1}{2}} \theta_{i}$, we can get that

$$
\left\{\begin{array}{l}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(v_{2}-v_{1}\right)+\left(r_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}\right) v_{1}=0,  \tag{3.18}\\
\sqrt{d_{1}\left(d_{1}+q\right)}\left(v_{j-1}-2 v_{j}+v_{j+1}\right)+\left(r_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}\right) v_{j}=0, j \in \mathcal{B}, \\
\left(d_{1}+q\right) \theta_{n-1}-d_{1} \theta_{n}+r_{n} \theta_{n}\left(1-\frac{\theta_{n}}{k_{n}}\right)=0 .
\end{array}\right.
$$

Since $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$, we see from the first and second equations of (3.18) that $v_{1}<v_{2}<\cdots<v_{n}$. Therefore, $\theta_{1}<\theta_{2}<\cdots<\theta_{n}$.
(iv) Set $\Theta_{i}=\theta_{n}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{i-n}$. By direct calculations, we obtain from $q \geq 2 r_{\text {max }}$ that

$$
\begin{align*}
& \sum_{l=1}^{n}\left(d_{1} D_{1 l}+q Q_{1 l}\right) \Theta_{l}+r_{1} \Theta_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)=-\left(d_{1}+q\right) \Theta_{1}+d_{1} \Theta_{2}+r_{1} \Theta_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right) \\
& =\theta_{n}\left[\left(-d_{1}-q\right)\left(\frac{d_{1}+q-2 r_{\text {max }}}{d_{1}}\right)^{1-n}+d_{1}\left(\frac{d_{1}+q-2 r_{\text {max }}}{d_{1}}\right)^{2-n}+r_{1}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{1-n}\left(1-\frac{\theta_{1}}{k_{1}}\right)\right] \\
& <\theta_{n}\left(\frac{d_{1}+q-2 r_{\text {max }}}{d_{1}}\right)^{1-n}\left(-d_{1}-q+d_{1}\left(\frac{d_{1}+q-2 r_{\text {max }}}{d_{1}}\right)+r_{\text {max }}\right) \leq 0, \tag{3.19}
\end{align*}
$$

and

$$
\begin{align*}
& \sum_{l=1}^{n}\left(d_{1} D_{j l}+q Q_{j l}\right) \Theta_{l}+r_{j} \Theta_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)=\left(d_{1}+q\right) \Theta_{j-1}+\left(-2 d_{1}-q\right) \Theta_{j}+d_{1} \Theta_{j+1}+r_{j} \Theta_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right) \\
& =\theta_{n}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{j-n-1}\left[\frac{q-2 r_{\max }}{d_{1}}\left(d_{1}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)-d_{1}-q\right)\right. \\
& \left.+r_{1}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)-r_{1}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right) \frac{\theta_{j}}{k_{j}}\right], \\
& <\theta_{n}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{j-n-1}\left[d_{1}+q+\left(r_{\max }-2 d_{1}-q\right)\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)\right. \\
& \left.+d_{1}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{2}\right] \leq 0, j \in \mathcal{B} . \tag{3.20}
\end{align*}
$$

Now, set $u_{i}=\Theta_{i}-\theta_{i}$ satisfying

$$
\begin{equation*}
\sum_{l=1}^{n}\left(d_{1} D_{j l}+q Q_{j l}\right) u_{l}+r_{j} u_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)<0, j \in \mathcal{C} \tag{3.21}
\end{equation*}
$$

Clearly, $u_{n}=0$. By a further transformation $u_{i}=z_{i}\left(\frac{d_{1}}{d_{1}+q}\right)^{\frac{1-i}{2}}$, we get that

$$
\left\{\begin{array}{l}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(z_{2}-z_{1}\right)+\left(r_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}\right) z_{1}<0,  \tag{3.22}\\
\sqrt{d_{1}\left(d_{1}+q\right)}\left(z_{j-1}-2 z_{j}+z_{j+1}\right)+\left(r_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}\right) z_{j}<0, j \in \mathcal{B} .
\end{array}\right.
$$

If there exists $i_{0} \in \mathcal{B}$ such that $0 \geq z_{i_{0}}=\min _{i \in \mathcal{A}} z_{i}$, then $\left(z_{i_{0}-1}-2 z_{i_{0}}+z_{i_{0}+1}\right) \geq 0$. Since $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$ leads to $r_{i_{0}}\left(1-\frac{\theta_{i_{0}}}{k_{i_{0}}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}<0$, then there holds

$$
\begin{equation*}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(z_{i_{0}-1}-2 z_{i_{0}}+z_{i_{0}+1}\right)+\left(r_{i_{0}}\left(1-\frac{\theta_{i_{0}}}{k_{i_{0}}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}\right) z_{i_{0}} \geq 0 \tag{3.23}
\end{equation*}
$$

which is a contradiction. Hence, $z_{i}>\min \left\{0, z_{1}\right\}$ for $i \in \mathcal{C}$. If $z_{1}<0$, then $z_{2}>z_{1}$. By $q \geq r_{\max }+$ $2 \sqrt{d_{1} r_{\max }}$, there holds

$$
\begin{equation*}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(z_{2}-z_{1}\right)+\left(r_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}\right) z_{1}>0 \tag{3.24}
\end{equation*}
$$

which contradicts to (3.22). Hence $z_{1} \geq 0$, and therefore $z_{i}>0$, that is, $\theta_{i}<\Theta_{i}$ for $i \in \mathcal{C}$. This proves the second inequality in (3.9).

Next, set $\vartheta_{i}=\theta_{n}\left(\frac{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}{d_{1}}\right)^{i-n}$. Then we have from $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$ that

$$
\begin{equation*}
\sum_{l=1}^{n}\left(d_{1} D_{i l}+q Q_{i l}\right) \vartheta_{i}+r_{i} \vartheta_{i}\left(1-\frac{\theta_{i}}{k_{i}}\right)>\sum_{l=1}^{n}\left(d_{1} D_{i l}+q Q_{i l}\right) \vartheta_{i}-r_{\max } \vartheta_{i} \frac{\theta_{n}}{k_{\min }}>0 \tag{3.25}
\end{equation*}
$$

By the same arguments, the first inequality in (3.9) also holds.
A direct summation of the equation of $\theta_{i}$ gives

$$
\begin{equation*}
\sum_{i=1}^{n} r_{i} \theta_{i}=\sum_{i=1}^{n} r_{i} \frac{\theta_{i}^{2}}{k_{i}} \tag{3.26}
\end{equation*}
$$

It then follows from (3.9) that

$$
\begin{equation*}
\theta_{n}^{2} \min _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} \sum_{i=1}^{n}\left(\frac{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}{d_{1}}\right)^{2 i-2 n} \leq r_{\max } \theta_{n} \sum_{i=1}^{n}\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{i-n} \tag{3.27}
\end{equation*}
$$

which implies that

$$
\begin{equation*}
\min _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} \theta_{n} \frac{1-\left(\frac{d_{1}}{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}\right)^{2 n}}{1-\left(\frac{d_{1}}{d_{1}+q+\frac{2 r_{\text {max }}}{k_{\text {min }}} \theta_{n}}\right)^{2}}<\frac{r_{\max }}{1-\frac{d_{1}}{d_{1}+q-2 r_{\max }}} . \tag{3.28}
\end{equation*}
$$

Obviously, for sufficiently large $q$ or sufficiently small $d_{1}$, we have that

$$
\begin{equation*}
1-\left(\frac{d_{1}}{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}\right)^{2 n} \geq \frac{1}{2}, 1-\left(\frac{d_{1}}{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}\right)^{2}>0, \text { and } 1-\frac{d_{1}}{d_{1}+q-2 r_{\max }} \geq \frac{1}{2} \tag{3.29}
\end{equation*}
$$

Hence, we can deduce that

$$
\begin{equation*}
\min _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} \theta_{n}<4 r_{\max }, \text { for } q \gg 1 \text { or } d_{1} \ll 1 \tag{3.30}
\end{equation*}
$$

Next, we show the desired limit. Dividing (3.26) by $\theta_{n}$, we then observe that

$$
\begin{equation*}
\theta_{n} \sum_{i=1}^{n} \frac{r_{i}}{k_{i}}\left(\frac{\theta_{i}}{\theta_{n}}\right)^{2}=\sum_{i=1}^{n} r_{i} \frac{\theta_{i}}{\theta_{n}} \tag{3.31}
\end{equation*}
$$

Since

$$
\begin{equation*}
\left(\frac{d_{1}+q+\frac{2 r_{\max }}{k_{\min }} \theta_{n}}{d_{1}}\right)^{i-n} \leq \frac{\theta_{i}}{\theta_{n}} \leq\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{i-n} \tag{3.32}
\end{equation*}
$$

then we see that

$$
\begin{equation*}
\lim _{q \rightarrow+\infty} \frac{\theta_{i}}{\theta_{n}}=\lim _{d_{1} \rightarrow 0} \frac{\theta_{i}}{\theta_{n}}=0, \lim _{q \rightarrow+\infty} \frac{\theta_{i}}{\theta_{n}}=\lim _{d_{1} \rightarrow 0}\left(\frac{\theta_{i}}{\theta_{n}}\right)^{2}=0, \text { for } i \in \mathcal{C} \tag{3.33}
\end{equation*}
$$

which, together with (3.30), allows us to obtain the limit (3.10).
In view of (3.9), we reach that

$$
\begin{equation*}
\theta_{n}\left(\left(\frac{d_{1}}{d_{1}+q+\frac{2 r_{\text {max }}}{k_{\text {min }}} \theta_{n}}\right)^{n-i}-\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right) \leq \theta_{i}-\theta_{n}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i} \leq \theta_{n}\left(\left(\frac{d_{1}}{d_{1}+q-2 r_{\max }}\right)^{n-i}-\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right) . \tag{3.34}
\end{equation*}
$$

Therefore, the limit (3.11) is correct.
(v) By statement (i), we have that $\theta_{i}$ is uniformly bounded for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$. Dividing the system (3.8) by $d_{1}$ leads to

$$
\left\{\begin{array}{l}
\theta_{2}-\theta_{1}-\frac{q}{d_{1}} \theta_{1}+\frac{r_{1}}{d_{1}} \theta_{1}\left(1-\frac{\theta_{1}}{k_{1}}\right)=0,  \tag{3.35}\\
\left(1+\frac{q}{d_{1}}\right) \theta_{j-1}+\left(-2-\frac{q}{d_{1}}\right) \theta_{j}+\theta_{j+1}+\frac{r_{j}}{d_{1}} \theta_{j}\left(1-\frac{\theta_{j}}{k_{j}}\right)=0, j \in \mathcal{B}, \\
\left(1+\frac{q}{d_{1}}\right) \theta_{n-1}-\theta_{n}+\frac{r_{n}}{d_{1}} \theta_{n}\left(1-\frac{\theta_{n}}{k_{n}}\right)=0 .
\end{array}\right.
$$

Then we have that

$$
\begin{equation*}
\theta_{1}=\theta_{2}=\cdots=\theta_{n}:=\rho \geq 0, \tag{3.36}
\end{equation*}
$$

as $d_{1} \rightarrow+\infty$. By applying the statement (i) again, one can get that $\rho>0$. Adding (3.35) up, we get

$$
\begin{equation*}
\sum_{i=1}^{n} r_{i} \theta_{i}\left(1-\frac{\theta_{i}}{k_{i}}\right)=0 \tag{3.37}
\end{equation*}
$$

which means that $\lim _{d_{1} \rightarrow+\infty} \theta_{i}=\rho=\frac{\sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}}$.
(vi) The idea of the proof of this statement is to get a sequence of appropriate upper and lower solutions in terms of $d_{1}$. For each $d_{1}>0$, letting $\bar{\theta}_{i}=k_{i}+C_{*} d_{1}$, we compute

$$
\begin{align*}
& \sum_{l=1}^{n}\left(d_{1} D_{i l} \bar{\theta}_{l}\right)+\frac{r_{i}}{k_{i}} \bar{\theta}_{i}\left(k_{i}-\bar{\theta}_{i}\right)=d_{1}\left(\sum_{l=1}^{n} D_{i l} k_{l}-C_{*} r_{i}\left(1+C_{*} \frac{d_{1}}{k_{i}}\right)\right)  \tag{3.38}\\
& \leq d_{1}\left(\sum_{l=1}^{n} D_{i l} k_{l}-C_{*} r_{i}\right) \leq 0,
\end{align*}
$$

i.e. $\overline{\boldsymbol{\theta}}$ is an upper solution.

Setting $\underline{\theta}_{i}=k_{i}-C_{*} d_{1}$, we see that for $d_{1}>0$ small, $\underline{\theta}_{i}>0$. Then we compute, for $d_{1}>0$ small

$$
\begin{align*}
& \sum_{l=1}^{n}\left(d_{1} D_{i l} \underline{\theta}_{l}\right)+\frac{r_{i}}{k_{i}} \underline{\theta}_{i}\left(k_{i}-\underline{\theta}_{i}\right)=d_{1}\left(\sum_{l=1}^{n} D_{i l} k_{l}+C_{*} r_{i}-C_{*}^{2} \frac{d_{1} r_{i}}{k_{i}}\right) \\
& =d_{1}\left(\sum_{l=1}^{n} D_{i l} k_{l}+\frac{1}{2} C_{*} r_{i}+C_{*} r_{i}\left(\frac{1}{2}-C_{*} \frac{d_{1}}{k_{i}}\right)\right) \geq d_{1}\left(\sum_{l=1}^{n} D_{i l} k_{l}+\frac{1}{2} C_{*} r_{i}\right) \geq 0 \tag{3.39}
\end{align*}
$$

i.e. $\underline{\theta}$ is a lower solution. Clearly, $\bar{\theta}_{i}>\underline{\theta}_{i}$. Therefore, by the similar arguments in the proof of [2, Lemma $2.2]$ (see also [16]), we have that $\bar{\theta}_{i}>\theta_{i}>\underline{\theta}_{i}$, and statement (vi) is correct. This ends the proof.

### 3.3 Maximum Principle

In this subsection, we shall introduce some important maximum/comparison principles.
Lemma 3.4 (Strong maximum principle I). Let $\boldsymbol{w}$ satisfies

$$
\left\{\begin{array}{l}
-(d+q) w_{1}+(d+q) w_{2}+c_{1} w_{1} \geq 0  \tag{3.40}\\
d w_{j-1}+(-2 d-q) w_{j}+(d+q) w_{j+1}+c_{j} w_{j} \geq 0, j \in \mathcal{B} \\
d w_{n-1}-d w_{n}+c_{n} w_{n} \geq 0
\end{array}\right.
$$

where $c_{i} \in \mathbb{R}$. If $\boldsymbol{w} \leq \mathbf{0}$, then either $\boldsymbol{w} \ll \mathbf{0}$ or $\boldsymbol{w}=\mathbf{0}$.

Proof: Set $\Sigma=\left\{i \in \mathcal{A}: w_{i}=0\right\}$. We need to show $\Sigma=\{1,2, \cdots, n\}$ if $\Sigma \neq \emptyset$. If $w_{1}=0$, then we may find from the first equation of (3.40) and $\boldsymbol{w} \leq \mathbf{0}$ that $w_{2}=0$. Furthermore, the second and the third equations of (3.40) imply that $w_{3}=\cdots=w_{n}=0$. Similarly, we arrive at $\boldsymbol{w}=\mathbf{0}$ provided that $w_{n}=0$. If now $w_{1}<0, w_{2}=0$, by $w_{3} \leq 0=w_{2}$, we then have from the second equation of (3.40) that

$$
\begin{equation*}
0 \leq d w_{1}+(-2 d-q) w_{2}+(d+q) w_{3}+c_{2} w_{2}=d\left(w_{1}-w_{2}\right)+(d+q)\left(w_{3}-w_{2}\right)<0 \tag{3.41}
\end{equation*}
$$

which is a contradiction. This implies that $w_{1}$ can not be negative if $w_{2}=0$. That is, $w_{2}=0$ yields that $w_{1}=w_{2}=0$. By the similar method, one can get that $\boldsymbol{w}=\mathbf{0}$ provided that there exists a $i_{0} \in \mathcal{A}$ such that $w_{i_{0}}=0$.

Lemma 3.5 (Strong maximum principle II). Let $c_{i} \in \mathbb{R}$, u satisfy

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) u_{j}+c_{i} u_{i} \leq 0, \quad i \in \mathcal{A} \tag{3.42}
\end{equation*}
$$

where the inequality above is strict for some $j_{0} \in \mathcal{A}$. Suppose that $\lambda_{1}(d, q, \boldsymbol{c})<0$. Then there holds $u \gg 0$.
Proof: Indeed, after setting $w_{i}=\left(\frac{d}{d+q}\right)^{i-1} u_{i},(3.42)$ is equivalent to

$$
\left\{\begin{array}{l}
-(d+q) w_{1}+(d+q) w_{2}+c_{1} w_{1} \leq 0  \tag{3.43}\\
d w_{j-1}+(-2 d-q) w_{j}+(d+q) w_{j+1}+c_{j} w_{j} \leq 0, j \in \mathcal{B} \\
d w_{n-1}-d w_{n}+c_{n} w_{n} \leq 0
\end{array}\right.
$$

We shall verify this lemma in several steps.
Step 1. Let $\boldsymbol{\phi}>\mathbf{0}$ be the non-negative eigenvector corresponding to $\lambda_{1}(d, q, \boldsymbol{c})$. Then $\boldsymbol{\phi} \gg 0$.
Clearly, it follows from (3.1) that $\bar{\phi}_{i}:=\left(\frac{d}{d+q}\right)^{i-1} \phi_{i}$ satisfies

$$
\left\{\begin{array}{l}
-(d+q) \bar{\phi}_{1}+(d+q) \bar{\phi}_{2}+c_{1} \bar{\phi}_{1}=\lambda_{1}(d, q, \boldsymbol{c}) \bar{\phi}_{1} \leq 0  \tag{3.44}\\
d \bar{\phi}_{j-1}+(-2 d-q) \bar{\phi}_{j}+(d+q) \bar{\phi}_{j+1}+c_{j} \bar{\phi}_{j}=\lambda_{1}(d, q, \boldsymbol{c}) \bar{\phi}_{j} \leq 0, j \in \mathcal{B} \\
d \bar{\phi}_{n-1}-d \bar{\phi}_{n}+c_{n} \bar{\phi}_{n}=\lambda_{1}(d, q, \boldsymbol{c}) \bar{\phi}_{n} \leq 0
\end{array}\right.
$$

and the inequality above is strict for some $j_{0} \in \mathcal{A}$. Furthermore, Lemma 3.4 yields that $\overline{\boldsymbol{\phi}} \gg \mathbf{0}$, and hence $\phi \gg \mathbf{0}$.

Step 2. $\boldsymbol{w} \gg \mathbf{0}$. Suppose that there exists a $i_{0} \in \mathcal{A}$ such that $w_{i_{0}}=\min _{i \in \mathcal{A}} w_{i}<0$. Then we can find some $\xi>0$ such that $\boldsymbol{w}+\xi \overline{\boldsymbol{\phi}} \geq \mathbf{0}$. In fact, we can define $\xi_{0}=\inf \left\{\xi>0: w_{i}+\xi \bar{\phi}_{i} \geq 0 \forall i \in \mathcal{A}\right\}>0$. Therefore $\boldsymbol{w}+\xi_{0} \overline{\boldsymbol{\phi}} \geq \mathbf{0}$. Note that $\boldsymbol{w}+\xi_{0} \overline{\boldsymbol{\phi}}$ satisfies

$$
\left\{\begin{array}{l}
-(d+q)\left(w_{1}+\xi_{0} \bar{\phi}_{1}\right)+(d+q)\left(w_{2}+\xi_{0} \bar{\phi}_{2}\right)+c_{1}\left(w_{1}+\xi_{0} \bar{\phi}_{1}\right) \leq 0  \tag{3.45}\\
d\left(w_{j-1}+\xi_{0} \bar{\phi}_{j-1}\right)+(-2 d-q)\left(w_{j}+\xi_{0} \bar{\phi}_{j}\right)+(d+q)\left(w_{j+1}+\xi_{0} \bar{\phi}_{j+1}\right)+c_{j}\left(w_{j}+\xi_{0} \bar{\phi}_{j}\right) \leq 0, j \in \mathcal{B} \\
d\left(w_{n-1}+\xi_{0} \bar{\phi}_{n-1}\right)-d\left(w_{n}+\xi_{0} \bar{\phi}_{n}\right)+c_{n}\left(w_{n}+\xi_{0} \bar{\phi}_{n}\right) \leq 0
\end{array}\right.
$$

and the inequality above is also strict for some $j_{0} \in \mathcal{A}$. This implies that $\boldsymbol{w}+\xi_{0} \overline{\boldsymbol{\phi}}=\mathbf{0}$ can not happen. We than conclude from Lemma 3.4 that $\boldsymbol{w}+\xi_{0} \overline{\boldsymbol{\phi}} \gg \mathbf{0}$, which contradicts the definition of $\xi_{0}$. Therefore, $\boldsymbol{w} \geq \mathbf{0}$. Combined with Lemma 3.4 again, we reach that $\boldsymbol{w} \gg \mathbf{0}$. That is, $\boldsymbol{u} \gg \mathbf{0}$.

Lemma 3.6 (Comparison principle). Let $\boldsymbol{w}(t)$ satisfy

$$
\left\{\begin{align*}
\frac{\mathrm{d} w_{1}}{\mathrm{~d} t} & \geq-(d+q) w_{1}+(d+q) w_{2}+c_{1} w_{1}, 0<t<T  \tag{3.46}\\
\frac{\mathrm{~d} w_{j}}{\mathrm{~d} t} & \geq d w_{j-1}+(-2 d-q) w_{j}+(d+q) w_{j+1}+c_{i} w_{i}, \quad j \in \mathcal{B}, 0<t<T \\
\frac{\mathrm{~d} w_{n}}{\mathrm{~d} t} & \geq d w_{n-1}-d w_{n}+c_{n} w_{n}, 0<t<T \\
\boldsymbol{w}(0) & >\mathbf{0}
\end{align*}\right.
$$

where $c_{i} \in \mathbb{R}$. Then $\boldsymbol{w}(t) \geq \mathbf{0}$.
Proof: Consider the case where $c_{i} \leq 0$ for every $i \in \mathcal{A}$, and the strict inequality

$$
\begin{equation*}
\frac{\mathrm{d} w_{i}}{\mathrm{~d} t}>\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) w_{j}+c_{i} w_{i} \tag{3.47}
\end{equation*}
$$

firstly. If there exists a point $\left(i_{0}, t_{0}\right) \in \mathcal{A} \times(0, T]$ such that $w_{i_{0}}\left(t_{0}\right)=\inf _{(i, t) \in \mathcal{A} \times(0, T)} w_{i}(t)<0,(3.47)$ then yields that

$$
\begin{equation*}
0 \geq \frac{\mathrm{d} w_{i_{0}}}{\mathrm{~d} t}>\sum_{j=1}^{n}\left(d D_{i_{0} j}+q Q_{i_{0} j}\right) w_{j}+c_{i_{0}} w_{i_{0}} \geq 0 \tag{3.48}
\end{equation*}
$$

which is a contradiction. This contradiction shows that $\boldsymbol{w}(t) \geq \mathbf{0}$.
For the case

$$
\begin{equation*}
\frac{\mathrm{d} w_{i}}{\mathrm{~d} t} \geq \sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) w_{j}+c_{i} w_{i} \tag{3.49}
\end{equation*}
$$

write $w_{i}^{\varepsilon}(t)=w_{i}(t)+\varepsilon t$ where $\varepsilon>0$. Then $\frac{\mathrm{d} w_{i}^{\varepsilon}}{\mathrm{d} t}>\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) w_{j}^{\varepsilon}+c_{i} w_{i}^{\varepsilon}$ and so $w_{i}^{\varepsilon} \geq 0$. Let $\varepsilon \rightarrow 0$ to find $w_{i} \geq 0$. This proves the theorem for the case $c_{i} \leq 0$. For arbitrary $c_{i}$, we choose $b_{i} \geq c_{i}$ and define $v_{i}(t)=e^{-b_{i} t} w_{i}(t)$. It is easy to see from (3.46) that $v_{i}(t)$ satisfies

$$
\left\{\begin{align*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t} & \geq-(d+q) v_{1}+(d+q) v_{2}+\left(c_{1}-b_{1}\right) v_{1}, 0<t<T  \tag{3.50}\\
\frac{\mathrm{~d} v_{j}}{\mathrm{~d} t} & \geq d v_{j-1}+(-2 d-q) v_{j}+(d+q) v_{j+1}+\left(c_{i}-b_{i}\right) v_{i}, j \in \mathcal{B}, 0<t<T \\
\frac{\mathrm{~d} v_{n}}{\mathrm{~d} t} & \geq d v_{n-1}-d v_{n}+\left(c_{n}-b_{n}\right) v_{n}, 0<t<T \\
\boldsymbol{v}(0) & >\mathbf{0}
\end{align*}\right.
$$

Since $c_{i}-b_{i} \leq 0$, the above conclusion for $c_{i} \leq 0$ implies that $\boldsymbol{v} \geq \mathbf{0}$. The conclusion $\boldsymbol{w}(t) \geq \mathbf{0}$ follows from $w_{i}(t)=e^{b_{i} t} v_{i}(t)$.

Lemma 3.7 (Strong maximum principle III). Let $\boldsymbol{w}(t)$ satisfy

$$
\left\{\begin{align*}
\frac{\mathrm{d} w_{1}}{\mathrm{~d} t} & \leq-(d+q) w_{1}+(d+q) w_{2}+c_{1} w_{1}, 0<t<T  \tag{3.51}\\
\frac{\mathrm{~d} w_{j}}{\mathrm{~d} t} & \leq d w_{j-1}+(-2 d-q) w_{j}+(d+q) w_{j+1}+c_{i} w_{i}, \quad j \in \mathcal{B}, 0<t<T \\
\frac{\mathrm{~d} w_{n}}{\mathrm{~d} t} & \leq d w_{n-1}-d w_{n}+c_{n} w_{n}, 0<t<T \\
\boldsymbol{w}(0) & <\mathbf{0}
\end{align*}\right.
$$

where $c_{i} \in \mathbb{R}$. If $w_{i_{0}}\left(t_{0}\right)=\max _{i \in \mathcal{A}, t>0} w_{i}(t)=M \geq 0$ for some $t_{0}>0, i_{0} \in \mathcal{A}$, then $w_{i}(t) \equiv M$ for all $t<t_{0}$.

Proof: Without loss of generality, we may assume that $c_{i} \leq 0$, otherwise one can set $v_{i}(t)=e^{-b_{i} t} w_{i}(t)$ for $b_{i} \geq c_{i}$ and consider $v_{i}(t)$. Suppose by contradiction that there exists $\left(i_{1}, t_{1}\right) \in \mathcal{A} \times\left(0, t_{0}\right)$ such that $w_{i_{1}}\left(t_{1}\right) \leq M_{1}<M$. Set $u_{i}(t)=M-w_{i}(t)-\left(M-M_{1}\right) h e^{-\alpha\left(t-t_{1}\right)}$, where $h$ is a small positive constant. We then have that

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) u_{j}+c_{i} u_{i}-\frac{\mathrm{d} u_{i}}{\mathrm{~d} t} \leq-e^{\alpha\left(t-t_{1}\right)}\left(M-M_{1}\right)\left(\alpha h+c_{i} h+\sum_{j=1}^{n}\left(d D_{i j}+q Q_{i j}\right) h\right)<0 \tag{3.52}
\end{equation*}
$$

provided $\alpha \gg 1$. Since $u_{i}\left(t_{1}\right)=M-w_{i}\left(t_{1}\right)-\left(M-M_{1}\right) h \geq(1-h)\left(M-M_{i}\right)>0$ for $0<h \ll 1$. It then follows from Lemma 3.6 that $\boldsymbol{u}(t) \geq \mathbf{0}$. Furthermore, $w_{i}(t) \leq M-\left(M-M_{1}\right) h e^{-\alpha\left(t-t_{1}\right)}<M$ for $t>t_{1}$. This implies that $w_{i_{0}}\left(t_{0}\right)<M$, which is a contradiction. The proof of this lemma is hence finished.

## 4 Proof of the main results

This section is devoted to the proofs of our main results.

### 4.1 Dynamic classification in the $q-\gamma$ plane

Clearly, the steady states of (1.6) consists of the trivial steady state ( $\mathbf{0}, \mathbf{0}$ ), the semi-trivial steady state $(\boldsymbol{\theta}, \mathbf{0})$ and the positive steady state $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$.

Lemma 4.1. Suppose that $(\mathbf{H})$ hold. The trivial steady state $(\mathbf{0}, \mathbf{0})$ of $(1.6)$ is always unstable.
Proof: The linearization eigenvalue problem of $(1.6)$ at $(\mathbf{0}, \mathbf{0})$ is

$$
\left\{\begin{array}{l}
\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) \phi_{j}+r_{i} \phi_{i}=\lambda \phi_{i}, i \in \mathcal{A}  \tag{4.1}\\
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \psi_{j}-\gamma \psi_{i}=\lambda \psi_{i} i \in \mathcal{A}
\end{array}\right.
$$

Note by $\boldsymbol{r} \gg \mathbf{0}$ that $\lambda_{1}\left(d_{1}, q, \boldsymbol{r}\right)>0$. We conclude that $(\mathbf{0}, \mathbf{0})$ is always unstable.

Lemma 4.2. Suppose that $(\mathbf{H})$ hold. There exists a unique continuous critical curve $\Gamma: \gamma=\gamma^{*}\left(q, d_{1}, d_{2}\right)$ such that $(\boldsymbol{\theta}, \mathbf{0})$ is locally asymptotically stable if $\gamma>\gamma^{*}\left(q, d_{1}, d_{2}\right)$ and unstable if $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$.
Proof: The linearization eigenvalue problem of (1.6) at $(\boldsymbol{\theta}, \mathbf{0})$ is

$$
\left\{\begin{array}{l}
\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) \phi_{j}+r_{i}\left(1-\frac{2 \theta_{i}}{k_{i}}\right) \phi_{i}-a \theta_{i} \psi_{i}=\mu \phi_{i}, \quad i \in \mathcal{A}  \tag{4.2}\\
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \psi_{j}+\left(\beta a \theta_{i}-\gamma\right) \psi_{i}=\mu \psi_{i} i \in \mathcal{A}
\end{array}\right.
$$

Clearly, the local stability of $(\boldsymbol{\theta}, \mathbf{0})$ is determined by the sign of the principal eigenvalue of $L \psi_{i}=$ $\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \psi_{j}+\left(\beta a \theta_{i}-\gamma\right) \psi_{i} ;$ namely, $(\boldsymbol{\theta}, \mathbf{0})$ is locally asymptotically stable if $\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)<0$ and unstable if $\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)>0$. Furthermore, we have

$$
\begin{equation*}
\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)=\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}\right)-\gamma \tag{4.3}
\end{equation*}
$$

Therefore, we let $\gamma^{*}\left(q, d_{1}, d_{2}\right)=\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}\right)$. Then it follows from Lemma 3.1(iv) that

$$
\left\{\begin{array}{l}
\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)>0 \text { if } 0<\gamma<\gamma^{*}  \tag{4.4}\\
\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)=0 \text { if } \gamma=\gamma^{*} \\
\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)<0 \text { if } \gamma>\gamma^{*}
\end{array}\right.
$$

Proof of Theorem 2.1: We shall split the proof into several steps.
Step 1. Let $U_{i}(t)=\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1} N_{i}(t)$ and $V_{i}(t)=\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{i-1} P_{i}(t)$, where $(\boldsymbol{N}(t), \boldsymbol{P}(t))$ is the solution of (1.6). Then $(\boldsymbol{U}(t), \boldsymbol{V}(t))$ satisfies

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} U_{1}}{\mathrm{~d} t}=-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-a U_{1} P_{1}  \tag{4.5}\\
\frac{\mathrm{~d} U_{j}}{\mathrm{~d} t}=d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-a U_{j} P_{j}, j \in \mathcal{B}, \\
\frac{\mathrm{~d} U_{n}}{\mathrm{~d} t}=d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{N_{n}}{k_{n}}\right)-a U_{n} P_{n} \\
\frac{\mathrm{~d} V_{1}}{\mathrm{~d} t}=-\left(d_{2}+\tau q\right) V_{1}+\left(d_{2}+\tau q\right) V_{2}+V_{1}\left(\beta a N_{1}-\gamma\right), \\
\frac{\mathrm{d} V_{j}}{\mathrm{~d} t}=d_{2} V_{j-1}+\left(-2 d_{2}-\tau q\right) V_{j}+\left(d_{2}+\tau q\right) V_{j+1}+V_{j}\left(\beta a N_{j}-\gamma\right), j \in \mathcal{B}, \\
\frac{\mathrm{~d} V_{n}}{\mathrm{~d} t}=d_{2} V_{n-1}-d_{2} V_{n}+V_{n}\left(\beta a N_{n}-\gamma\right) \\
\boldsymbol{U}(0)=\left(1, \frac{d_{1}}{d_{1}+q}, \cdots,\left(\frac{d_{1}}{d_{1}+q}\right)^{n-1}\right) \cdot \boldsymbol{N}(0)>\mathbf{0} \\
\boldsymbol{V}(0)=\left(1, \frac{d_{2}}{d_{2}+\tau q}, \cdots,\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{n-1}\right) \cdot \boldsymbol{P}(0)>\mathbf{0} .
\end{array}\right.
$$

Clearly, Lemma 3.7 leads to $\boldsymbol{U}, \boldsymbol{V} \gg \mathbf{0}$ since $\boldsymbol{U}(0), \boldsymbol{V}(0)>\mathbf{0}$, and then $\boldsymbol{N}, \boldsymbol{P} \gg \boldsymbol{0}$. Note that

$$
\left\{\begin{align*}
& \frac{\mathrm{d} U_{1}}{\mathrm{~d} t} \leq-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{U_{1}}{k_{1}}\right)  \tag{4.6}\\
& \frac{\mathrm{d} U_{j}}{\mathrm{~d} t} \leq d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{U_{j}}{k_{j}}\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1}\right), j \in \mathcal{B}, \\
& \frac{\mathrm{~d} U_{n}}{\mathrm{~d} t} \leq d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{U_{n}}{k_{n}}\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}\right)
\end{align*}\right.
$$

Let $C_{1}=\max _{i \in \mathcal{A}}\left\{k_{i}, U_{i}(0)\right\}$, and $\mathcal{U}_{i}=U_{i}-C_{1}$. It then follows that $\mathcal{U}_{i}$ satisfies $\mathcal{U}_{i}(0) \leq 0$ and

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} \mathcal{U}_{1}}{\mathrm{~d} t} \leq-\left(d_{1}+q\right) \mathcal{U}_{1}+\left(d_{1}+q\right) \mathcal{U}_{2}+r_{1} C_{1}\left(-\frac{\mathcal{U}_{1}}{k_{1}}\right)  \tag{4.7}\\
\frac{\mathrm{d} \mathcal{U}_{j}}{\mathrm{~d} t} \leq d_{1} \mathcal{U}_{j-1}+\left(-2 d_{1}-q\right) \mathcal{U}_{j}+\left(d_{1}+q\right) \mathcal{U}_{j+1}+r_{j} C_{1}\left(-\frac{\mathcal{U}_{j}}{k_{j}}\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1}\right), j \in \mathcal{B} \\
\frac{\mathrm{~d} \mathcal{U}_{n}}{\mathrm{~d} t} \leq d_{1} \mathcal{U}_{n-1}-d_{1} \mathcal{U}_{n}+r_{n} C_{1}\left(-\frac{\mathcal{U}_{n}}{k_{n}}\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}\right)
\end{array}\right.
$$

From the above inequalities, one can get that $\mathcal{U}_{i} \leq 0$ for $i \in \mathcal{A}$ and $t \geq 0$, and hence $U_{i} \leq C_{1}$, $0<N_{i} \leq C_{1}\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}$ for $t>0$.

Step 2. Next, we verify $V_{i}$ and $P_{i}$ are bounded uniformly for $i \in \mathcal{A}, t>0$. We rewrite system (4.5) as

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} U_{1}}{\mathrm{~d} t}=-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-a U_{1} P_{1},  \tag{4.8}\\
\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1} \frac{\mathrm{~d} U_{j}}{\mathrm{~d} t}=\left(d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-a U_{j} P_{j}\right)\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1}, j \in \mathcal{B}, \\
\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1} \frac{\mathrm{~d} U_{n}}{\mathrm{~d} t}=\left(d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{U_{n}}{k_{n}}\right)-a U_{n} P_{n}\right)\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}, \\
\frac{\mathrm{~d} V_{1}}{\mathrm{~d} t}=-\left(d_{2}+\tau q\right) V_{1}+\left(d_{2}+\tau q\right) V_{2}+V_{1}\left(\beta a N_{1}-\gamma\right), \\
\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{j-1} \frac{\mathrm{~d} V_{j}}{\mathrm{~d} t}=\left(d_{2} V_{j-1}+\left(-2 d_{2}-\tau q\right) V_{j}+\left(d_{2}+\tau q\right) V_{j+1}+V_{j}\left(\beta a N_{j}-\gamma\right)\right)\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{j-1}, j \in \mathcal{B}, \\
\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{n-1} \frac{\mathrm{~d} V_{n}}{\mathrm{~d} t}=\left(d_{2} V_{n-1}-d_{2} V_{n}+V_{n}\left(\beta a N_{n}-\gamma\right)\right)\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{n-1}, \\
\boldsymbol{U}(0)>\mathbf{0}, \\
\boldsymbol{V}(0)>\mathbf{0} .
\end{array}\right.
$$

Let $w(t)=\sum_{i=1}^{n}\left(\beta\left(\frac{d_{1}+q}{d_{1}}\right)^{i-1} U_{i}+\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{i-1} V_{i}\right)$. Adding all the equations in (4.8) up yields that

$$
\begin{equation*}
w^{\prime}(t)+\gamma w(x) \leq \beta\left(r_{\max }+\gamma\right) \sum_{i=1}^{n}\left(\frac{d_{1}+q}{d_{1}}\right)^{i-1} U_{i} \leq \beta\left(r_{\max }+\gamma\right) C_{1} n\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1} \tag{4.9}
\end{equation*}
$$

By Gronwall inequality, we have

$$
\begin{equation*}
w(t) \leq w(0) e^{-\gamma t}+\frac{\beta\left(r_{\max }+\gamma\right) C_{1} n\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}}{\gamma}\left(1-e^{-\gamma t}\right), \tag{4.10}
\end{equation*}
$$

which implies that $w(t)$ is bounded for all $t>0$. Then one can get that $0<V_{i} \leq\left(\frac{d_{2}+\tau q}{d_{2}}\right)^{i-1} V_{i}<w(t)$ is also bounded uniformly. Hence $P_{i}(t)$ is bounded uniformly and the statement (i) holds.

Step 3. Consider the case $\gamma>\gamma^{*}$.
Step 3.1. Let $\boldsymbol{f}(t)$ be the solution of

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} f_{1}}{\mathrm{~d} t}=-\left(d_{1}+q\right) f_{1}+\left(d_{1}+q\right) f_{2}+r_{1} f_{1}\left(1-\frac{f_{1}}{k_{1}}\right)  \tag{4.11}\\
\frac{\mathrm{d} f_{j}}{\mathrm{~d} t}=d_{1} f_{j-1}+\left(-2 d_{1}-q\right) f_{j}+\left(d_{1}+q\right) f_{j+1}+r_{j} f_{j}\left(1-\frac{f_{j}}{k_{j}}\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1}\right), j \in \mathcal{B} \\
\frac{\mathrm{~d} f_{n}}{\mathrm{~d} t}=d_{1} f_{n-1}-d_{1} f_{n}+r_{n} f_{n}\left(1-\frac{f_{n}}{k_{n}}\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1}\right) \\
\boldsymbol{f}(0)=\left(1, \frac{d_{1}}{d_{1}+q}, \cdots,\left(\frac{d_{1}}{d_{1}+q}\right)^{n-1}\right) \cdot \boldsymbol{N}(0)>\mathbf{0}
\end{array}\right.
$$

The comparison principle (Lemma 3.6) and (4.6) yield that $U_{i} \leq f_{i}$. Observe from [2, Lemma 2.2] that $\lim _{t \rightarrow+\infty} f_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1} \theta_{i}$. This implies that

$$
\begin{equation*}
\limsup _{t \rightarrow+\infty} U_{i} \leq\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1} \theta_{i} \text { for all } i \in \mathcal{A} \tag{4.12}
\end{equation*}
$$

Then for any $\varepsilon>0$, there exists $T_{1}>0$ such that $N_{i}(t)<\theta_{i}+\varepsilon$ for all $t \geq T_{1}$. Let $\boldsymbol{g}(t)$ be the solution of

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} g_{1}}{\mathrm{~d} t}=-\left(d_{2}+\tau q\right) g_{1}+\left(d_{2}+\tau q\right) g_{2}+g_{1}\left(\beta a\left(\theta_{1}+\varepsilon\right)-\gamma\right)  \tag{4.13}\\
\frac{\mathrm{d} g_{j}}{\mathrm{~d} t}=d_{2} g_{j-1}+\left(-2 d_{2}-\tau q\right) g_{j}+\left(d_{2}+\tau q\right) g_{j+1}+g_{j}\left(\beta a\left(\theta_{j}+\varepsilon\right)-\gamma\right), j \in \mathcal{B} \\
\frac{\mathrm{~d} g_{n}}{\mathrm{~d} t}=d_{2} g_{n-1}-d_{2} g_{n}+g_{n}\left(\beta a\left(\theta_{n}+\varepsilon\right)-\gamma\right) \\
\boldsymbol{g}\left(T_{1}\right)=\boldsymbol{V}\left(T_{1}\right)
\end{array}\right.
$$

Clearly, one can get that $V_{i}(t) \leq g_{i}(t)$ for all $t \geq T_{1}$ by using Lemma 3.6. Since $\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)<0$ when $\gamma>\gamma^{*}$, there exists $\varepsilon>0$ small enough such that $\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}+\boldsymbol{\varepsilon})-\gamma\right)<0$. Since it is easy to see that $C\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{i-1} e^{\lambda_{1}\left(d_{2}, \tau q, \beta a(\theta+\varepsilon)-\gamma\right)\left(t-T_{1}\right)} \phi$ is a super solution of (4.13) for $C$ large enough, where $\phi$ is the principal eigenfunction of the eigenvalue problem (3.2) with respect to $\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}+\boldsymbol{\varepsilon})-\gamma\right)$. Lemma 3.6 then yields that

$$
\begin{equation*}
0 \leq \limsup _{t \rightarrow+\infty} V_{i}(t) \leq \lim _{t \rightarrow+\infty} C \phi_{i} e^{\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}+\boldsymbol{\varepsilon})-\gamma\right)\left(t-T_{1}\right)}=0 \tag{4.14}
\end{equation*}
$$

Step 3.2. Since $\lim _{t \rightarrow+\infty} V_{i}(t)=0$, therefore, $\lim _{t \rightarrow+\infty} P_{i}(t)=0$ and for any $\varepsilon>0$, there exists $T_{2}>T_{1}$ such that $P_{i}(t) \leq \varepsilon$ for $t \geq T_{2}$, which leads to

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} U_{1}}{\mathrm{~d} t} \geq-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-a U_{1} \varepsilon  \tag{4.15}\\
\frac{\mathrm{~d} U_{j}}{\mathrm{~d} t} \geq d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-a U_{j} \varepsilon, j \in \mathcal{B} \\
\frac{\mathrm{~d} U_{n}}{\mathrm{~d} t} \geq d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{N_{n}}{k_{n}}\right)-a U_{n} \varepsilon
\end{array}\right.
$$

Let $\boldsymbol{f}^{\varepsilon}(t)$ be the solution of

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} f_{1}^{\varepsilon}}{\mathrm{d} t}=-\left(d_{1}+q\right) f_{1}^{\varepsilon}+\left(d_{1}+q\right) f_{2}^{\varepsilon}+r_{1} f_{1}^{\varepsilon}\left(1-\frac{f_{1}^{\varepsilon}}{k_{1}}\right)-a f_{1}^{\varepsilon} \varepsilon  \tag{4.16}\\
\left.\frac{\mathrm{d} f_{j}^{\varepsilon}}{\mathrm{d} t}=d_{1} f_{j-1}^{\varepsilon}+\left(-2 d_{1}-q\right) f_{j}^{\varepsilon}+\left(d_{1}+q\right) f_{j+1}^{\varepsilon}+r_{j} f_{j}^{\varepsilon}\left(1-\frac{N_{j}}{k_{j}} \frac{d_{1}+q}{d_{1}}\right)^{j-1}\right)-a f_{j}^{\varepsilon} \varepsilon, j \in \mathcal{B} \\
\left.\frac{\mathrm{~d} f_{n}^{\varepsilon}}{\mathrm{d} t}=d_{1} f_{n-1}^{\varepsilon}-d_{1} f_{n}^{\varepsilon}+r_{n} f_{n}^{\varepsilon}\left(1-\frac{N_{n}}{k_{n}} \frac{d_{1}+q}{d_{1}}\right)^{n-1}\right)-a f_{n}^{\varepsilon} \varepsilon \\
\boldsymbol{f}\left(T_{2}\right)=\boldsymbol{U}\left(T_{2}\right)
\end{array}\right.
$$

Lemma 3.6 implies that $U_{i}(t) \geq f_{i}^{\varepsilon}(t)$ for all $t \geq T_{2}$. By applying [2, Lemma 2.2] and choosing $\varepsilon>0$ sufficiently small, we have that $\lim _{t \rightarrow+\infty} f_{i}^{\varepsilon}(t)=\theta_{i}^{\varepsilon}\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1}$ uniformly for $i \in \mathcal{A}$, where $\theta_{i}^{\varepsilon}\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1}$ is the unique positive steady state solution of (4.16). Furthermore, by virtue of Lemma 3.3(i) and (4.16), we can obtain that $0 \leq \theta_{i}^{\varepsilon} \leq\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1} \max _{i \in \mathcal{A}} k_{i}\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1}$. Note that we can deduce that $\lim _{\varepsilon \rightarrow 0} \theta_{i}^{\varepsilon}=\theta_{i}$. That is

$$
\begin{equation*}
\liminf _{t \rightarrow+\infty} U_{i}(t) \geq \theta_{i}\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1} \tag{4.17}
\end{equation*}
$$

Combining with (4.12), we get that

$$
\begin{equation*}
\lim _{t \rightarrow+\infty} U_{i}(t)=\theta_{i}\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1}, \lim _{t \rightarrow+\infty} N_{i}(t)=\theta_{i} \tag{4.18}
\end{equation*}
$$

Hence the statement (ii) holds.
Step 4. Consider the case $\gamma<\gamma^{*}$.
Step 4.1. System (1.6) is uniformly persistent.
In order to prove the uniform persistence of system (1.6)(or the equivalent system (4.5)) in the case where $\gamma<\gamma^{*}$, let $\Theta(t)$ be the solution semiflow generated by system (4.5) on the state space $\mathbb{P}$, where

$$
\begin{equation*}
\mathbb{P}=\left\{(\boldsymbol{U}, \boldsymbol{V}) \in \mathbb{R}^{n} \times \mathbb{R}^{n}: \boldsymbol{U}>\mathbf{0}, \boldsymbol{V}>\mathbf{0}\right\} \tag{4.19}
\end{equation*}
$$

Define

$$
\begin{equation*}
\mathbb{P}_{0}=\{(\boldsymbol{U}, \boldsymbol{V}) \in \mathbb{P}: \boldsymbol{U} \neq \mathbf{0} \text { and } \boldsymbol{V} \neq \mathbf{0}\} \tag{4.20}
\end{equation*}
$$

and $\partial \mathbb{P}_{0}=\mathbb{P} \backslash \mathbb{P}_{0}$. Let

$$
\begin{equation*}
M_{\partial}=\left\{(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \partial \mathbb{P}_{0}: \Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \partial \mathbb{P}_{0}, \forall t \geq 0\right\} \tag{4.21}
\end{equation*}
$$

and $\omega((\boldsymbol{U}(0), \boldsymbol{V}(0)))$ be the omega limit set of the forward orbit $\delta^{+}((\boldsymbol{U}(0), \boldsymbol{V}(0)))=\{\Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0))$ : $t \geq 0\}$. By Lemma 3.7, we can conclude that $\mathbb{P}_{0}$ is open in $\mathbb{P}$ and forward invariant under the dynamics generated by system (4.5), and $\partial \mathbb{P}_{0}$ contains steady state points $(\mathbf{0}, \mathbf{0}),(\boldsymbol{\theta}, \mathbf{0})$. We claim that

$$
\begin{equation*}
\bigcup_{(0), \boldsymbol{V}(0)) \in M_{\partial}} \omega((\boldsymbol{U}(0), \boldsymbol{V}(0))) \in\{(\mathbf{0}, \mathbf{0}),(\boldsymbol{\theta}, \mathbf{0})\} . \tag{4.22}
\end{equation*}
$$

In fact, for any $(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in M_{\partial}$, we have $\Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \partial \mathbb{P}_{0}, \forall t \geq 0$. This implies that $\boldsymbol{U}(t ;(\boldsymbol{U}(0), \boldsymbol{V}(0)))=\mathbf{0}$ or $\boldsymbol{V}(t ;(\boldsymbol{U}(0), \boldsymbol{V}(0)))=\mathbf{0}$ for $t \geq 0$. If $\boldsymbol{U}(t ;(\boldsymbol{U}(0), \boldsymbol{V}(0)))=\mathbf{0}$ for $t \geq 0$, then $\boldsymbol{P}(t ;(\boldsymbol{N}(0), \boldsymbol{P}(0)))$ satisfies

$$
\left\{\begin{align*}
\frac{\mathrm{d} P_{1}}{\mathrm{~d} t} & =-\left(d_{2}+\tau q\right) P_{1}+d_{2} P_{2}-\gamma P_{1}  \tag{4.23}\\
\frac{\mathrm{~d} P_{j}}{\mathrm{~d} t} & =\left(d_{2}+\tau q\right) P_{j-1}+\left(-2 d_{2}-\tau q\right) P_{j}+d_{2} P_{j+1}-\gamma P_{j}, j \in \mathcal{B} \\
\frac{\mathrm{~d} P_{n}}{\mathrm{~d} t} & =\left(d_{2}+\tau q\right) P_{n-1}-d_{2} P_{n}-\gamma P_{n} \\
\boldsymbol{P}(0) & >\mathbf{0}
\end{align*}\right.
$$

It follows that $\frac{\mathrm{d}\left(e^{\gamma t} \sum_{i=1}^{n} P_{i}\right)}{\mathrm{d} t}=0$, which hence implies that $0 \leq \lim _{t \rightarrow+\infty} P_{i}=0$. In the case where $\boldsymbol{U}\left(\tau_{0} ;(\boldsymbol{U}(0), \boldsymbol{V}(0))\right) \neq \mathbf{0}$ for some $\tau_{0}>0$, we have $\boldsymbol{U}(t ;(\boldsymbol{U}(0), \boldsymbol{V}(0)))>\mathbf{0}$ for all $t>\tau_{0}$ by Lemma 3.7, which implies that $\boldsymbol{V}(t ;(\boldsymbol{U}(0), \boldsymbol{V}(0)))=\mathbf{0}$ for all $t>\tau_{0}$. Thus $\boldsymbol{N}(t ;(\boldsymbol{N}(0), \boldsymbol{P}(0)))$ is the solution of (2.1). Then we have that either $\lim _{t \rightarrow+\infty} N_{i}(t)=0$, or $\lim _{t \rightarrow+\infty} N_{i}(t)=\theta_{i}$. Hence, our claim holds.

We next claim that $(\mathbf{0}, \mathbf{0}),(\boldsymbol{\theta}, \mathbf{0})$ are uniform weak repellers in the sense that

$$
\begin{equation*}
\limsup _{t \rightarrow+\infty}\|\Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0))-(\mathbf{0}, \mathbf{0})\| \geq \delta_{1} \text { for all }(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \mathbb{P}_{0} \tag{4.24}
\end{equation*}
$$

and

$$
\begin{equation*}
\limsup _{t \rightarrow+\infty}\|\Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0))-(\boldsymbol{\theta}, \mathbf{0})\| \geq \delta_{2} \text { for all }(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \mathbb{P}_{0} \tag{4.25}
\end{equation*}
$$

Suppose by contradiction that (4.24) is not true. Then for any $\delta>0$, there exists $(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \mathbb{P}_{0}$ such that

$$
\begin{equation*}
\limsup _{t \rightarrow+\infty}\|\Theta(t)(\boldsymbol{U}(0), \boldsymbol{V}(0))-(\mathbf{0}, \mathbf{0})\|<\delta \tag{4.26}
\end{equation*}
$$

Therefore, there exists $t_{0}>0$ such that for $t \geq t_{0}$, we have that

$$
\begin{equation*}
\|\boldsymbol{N}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))\|<\delta,\|\boldsymbol{P}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))\|<\delta \tag{4.27}
\end{equation*}
$$

Consequently, it follows from the equation for $\boldsymbol{N}$ that

$$
\begin{equation*}
\frac{\mathrm{d} N_{i}}{\mathrm{~d} t} \geq \sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}+N_{i}\left(r_{i}-\frac{r_{i} \delta}{k_{i}}-a \delta\right), \quad i \in \mathcal{A}, t \geq t_{0} \tag{4.28}
\end{equation*}
$$

In view of $(\boldsymbol{U}(0), \boldsymbol{V}(0)) \in \mathbb{P}_{0}$, by Lemma 3.7, we have $U_{i}\left(t_{0}\right)>0$, and then $N_{i}\left(t_{0}\right)>0$. Thus there exists an $\alpha_{0}>0$ such that $N_{i}\left(t_{0}\right) \geq \alpha_{0} \phi_{1 i}^{\delta}$, where $\phi_{1}^{\delta}$ is the principal eigenfunction corresponding to the principal eigenvalue $\lambda_{1}\left(d_{1}, q, \boldsymbol{r}-\frac{\boldsymbol{r}}{\boldsymbol{k}} \delta-\boldsymbol{a} \delta\right)$ of (3.2). Let $\underline{N}_{i}(t)=\alpha_{0} e^{\lambda_{1}\left(d_{1}, q, \boldsymbol{r}-\frac{r}{k} \delta-\boldsymbol{a} \delta\right)\left(t-t_{0}\right)} \phi_{1 i}^{\delta}$. Then $\underline{N}_{i}(t)$ satisfies

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} \underline{N}_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) \underline{N}_{j}+\underline{N}_{i}\left(r_{i}-\frac{r_{i} \delta}{k_{i}}-a \delta\right), \quad i \in \mathcal{A}, t>0  \tag{4.29}\\
\underline{\mathbf{N}}\left(t_{0}\right)=\alpha_{0} \phi_{1}^{\delta}
\end{array}\right.
$$

The comparison principle(Lemma 3.6) yields that

$$
\begin{equation*}
N_{i}(t) \geq \underline{N}(t) \text { for all } t \geq t_{0} \tag{4.30}
\end{equation*}
$$

Since $\lambda_{1}\left(d_{1}, q, \boldsymbol{r}\right)>0$, by continuity, we can choose $\delta>0$ small enough such that $\lambda_{1}\left(d_{1}, q, \boldsymbol{r}-\frac{\boldsymbol{r}}{\boldsymbol{k}} \delta-\boldsymbol{a} \delta\right)>0$, which implies $\lim _{t \rightarrow+\infty} N_{i}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))=+\infty$. This is a contradiction to $\|\boldsymbol{N}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))\|<\delta$ for $t>t_{0}$. Hence, we conclude that $(\mathbf{0}, \mathbf{0})$ is a uniform weak repeller.

Suppose by contradiction that (4.25) is not true. Then for any $\delta>0$, there exists $(\boldsymbol{N}(0), \boldsymbol{P}(0)) \in \mathbb{P}_{0}$ such that $\limsup _{t \rightarrow+\infty}\|\Theta(t)(\boldsymbol{N}(0), \boldsymbol{P}(0))-(\boldsymbol{\theta}, \mathbf{0})\|<\delta$. Therefore, there exists $t_{1}>0$ such that for $t \geq t_{1}$, we have

$$
\begin{equation*}
\|\boldsymbol{N}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))-\boldsymbol{\theta}\|<\delta,\|\boldsymbol{P}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))\|<\delta . \tag{4.31}
\end{equation*}
$$

Therefore, it follows from the equation for $\boldsymbol{P}$ that

$$
\begin{equation*}
\frac{\mathrm{d} P_{i}}{\mathrm{~d} t} \geq \sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) P_{j}+P_{i}\left(\beta a\left(\theta_{i}-\delta\right)-\gamma\right), \quad i \in \mathcal{A}, t \geq t_{1} \tag{4.32}
\end{equation*}
$$

In view of $(\boldsymbol{N}(0), \boldsymbol{P}(0)) \in \mathbb{P}_{0}$, by Lemma 3.7, we have $P_{i}\left(t_{1}\right)>0$. Let $\boldsymbol{\psi}_{1}^{\delta}$ be the principal eigenfunction with respect to $\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}-\boldsymbol{\delta})-\boldsymbol{\gamma}\right)$. Thus there exists an $\alpha_{1}>0$ such that $P_{i}\left(t_{1}\right) \geq \alpha_{1} \psi_{1 i}^{\delta}$. Let $\underline{P}_{i}(t)=\alpha_{1} e^{\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}-\boldsymbol{\delta})-\gamma\right)\left(t-t_{1}\right)} \psi_{1 i}^{\delta}$. Then $\underline{P}_{i}(t)$ satisfies

$$
\left\{\begin{array}{l}
\frac{\mathrm{d} \underline{P}_{i}}{\mathrm{~d} t}=\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \underline{P}_{j}+\underline{P}_{i}\left(\beta a\left(\theta_{i}-\delta\right)-\gamma\right), \quad i \in \mathcal{A}, t \geq t_{1}  \tag{4.33}\\
\underline{P}_{i}\left(t_{1}\right)=\alpha_{1} \psi_{1 i}^{\delta}
\end{array}\right.
$$

It follows from Lemma 3.6 that $P_{i}(t) \geq \underline{P}_{i}(t)$ for all $t \geq t_{1}$. On the other hand, since $0<\gamma<\gamma^{*}$, we have that $\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}-\gamma\right)>0$ by (4.4). By continuity, we can choose $\delta>0$ small enough such that $\lambda_{1}\left(d_{2}, \tau q, \beta a(\boldsymbol{\theta}-\boldsymbol{\delta})-\boldsymbol{\gamma}\right)>0$, which implies $\lim _{t \rightarrow+\infty} P_{i}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))=+\infty$. This is a contradiction to $\|\boldsymbol{P}(t,(\boldsymbol{N}(0), \boldsymbol{P}(0)))\|<\delta$ for $t>t_{1}$. Hence, we conclude that $(\boldsymbol{\theta}, \mathbf{0})$ is a uniform weak repeller.

We define now a continuous function $\mathcal{D}: \mathbb{P} \rightarrow[0, \infty)$ by

$$
\begin{equation*}
\mathcal{D}((\boldsymbol{N}, \boldsymbol{P}))=\min \left\{\min _{i \in \mathcal{A}} N_{i}, \min _{i \in \mathcal{A}} P_{i}\right\} \text { for any }(\boldsymbol{N}, \boldsymbol{P}) \in \mathbb{P} \tag{4.34}
\end{equation*}
$$

It follows from Lemma 3.7 that $\mathcal{D}^{-1}(0, \infty) \subset \mathbb{P}_{0}$ and $D$ satisfies if $\mathcal{D}((\boldsymbol{N}, \boldsymbol{P}))>0$ or $(\boldsymbol{N}, \boldsymbol{P}) \in \mathbb{P}_{0}$ with $\mathcal{D}((\boldsymbol{N}, \boldsymbol{P}))=0$, then $D(\Theta(t)(\boldsymbol{N}, \boldsymbol{P}))>0, \forall t>0$. That is, $\mathcal{D}$ is a generalized distance function for the semiflow $\Theta(t): \mathbb{P} \rightarrow \mathbb{P}$ (see [28]). It follows from Step 2 that $\Theta(t)$ is point dissipative on $\mathbb{P}$. Moreover, it is easy to see from the Arzela-Ascoli theorem that $\Theta(t): \mathbb{P} \rightarrow \mathbb{P}$ is compact for any $t>0$. By [22, Theorem 2.6], $\Theta(t): \mathbb{P} \rightarrow \mathbb{P}, t \geq 0$ admits a global compact attractor that attracts each bounded set in $\mathbb{P}$. Since $(\mathbf{0}, \mathbf{0})$ and $(\boldsymbol{\theta}, 0)$ are uniform weak repellers, we conclude that $(\mathbf{0}, \mathbf{0})$ and $(\boldsymbol{\theta}, 0)$ are isolated invariant sets in $\mathbb{P}$, and

$$
\begin{equation*}
W^{S}\{(\mathbf{0}, \mathbf{0})\} \cap \mathcal{D}^{-1}(0, \infty)=\emptyset, W^{S}\{(\boldsymbol{\theta}, 0)\} \cap \mathcal{D}^{-1}(0, \infty)=\emptyset \tag{4.35}
\end{equation*}
$$

where $W^{S}\{(\mathbf{0}, \mathbf{0})\}, W^{S}\{(\boldsymbol{\theta}, 0)\}$ are the stable sets of $(\mathbf{0}, \mathbf{0}),(\boldsymbol{\theta}, 0)$, respectively (see [28]). Hence, there are no subsets of $\{(\mathbf{0}, \mathbf{0})\} \cup\{(\boldsymbol{\theta}, 0)\}$ form a cycle in $\partial \mathbb{P}_{0}$. By [28, Theorem 3], there exists $\eta>0$ such that for any $(\boldsymbol{N}(0), \boldsymbol{P}(0)) \in \mathbb{P}_{0}$,

$$
\begin{equation*}
\min _{(\boldsymbol{N}, \boldsymbol{P}) \in \omega((\boldsymbol{N}(0), \boldsymbol{P}(0)))} \mathcal{D}((\boldsymbol{N}, \boldsymbol{P}))>\eta . \tag{4.36}
\end{equation*}
$$

This implies that for any $(\boldsymbol{N}, \boldsymbol{P}) \in \mathbb{P}_{0}, \liminf _{t \rightarrow+\infty} N_{i}(t) \geq \eta$ and $\liminf _{t \rightarrow+\infty} P_{i}(t) \geq \eta$. That is, system (1.6) with initial conditions $(\boldsymbol{N}(0), \boldsymbol{P}(0)) \in \mathbb{P}_{0}$ is uniformly persistent.

Step 4.2. System (1.6) has a steady state solution. It follows from [22, Theorem 3.7 and Remark 3.10] that $\Theta(t): \mathbb{P}_{0} \rightarrow \mathbb{P}_{0}$ admits a global attractor $A_{0}$. Then [22, Theorem 4.7] yields that $\Theta(t)$ admits at least one steady-state solution $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right) \in \mathbb{P}_{0}$. Furthermore, we deduce that $\boldsymbol{N}^{*}, \boldsymbol{P}^{*} \gg \mathbf{0}$ by Lemma 3.4. Thus, system (1.6) admits at least one positive steady state solution $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$. That is, $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ satisfies

$$
\begin{cases}\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}^{*}+r_{i} N_{i}^{*}\left(1-\frac{N_{i}^{*}}{k_{i}}\right)-a N_{i}^{*} P_{i}^{*}=0, & i \in \mathcal{A}  \tag{4.37}\\ \sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) P_{j}^{*}+P_{i}^{*}\left(\beta a N_{i}^{*}-\gamma\right)=0, & i \in \mathcal{A}\end{cases}
$$

The proof of this Theorem is hence completed.
Proof of Theorem 2.2: (1) Note that $\gamma^{*}\left(q, d_{1}, d_{2}\right)=\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}\right)$. By means of Lemma 3.1(ii) and Lemma 3.3(iv), it follows that $\lim _{q \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\beta a k_{n}$.
(2) Since by Lemma 3.3(v), there holds $\lim _{d_{1} \rightarrow+\infty} \theta_{i}=\frac{\sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}}$, it then indicates from Lemma 3.2 that

$$
\begin{equation*}
\lim _{d_{1} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\beta a \sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}} \tag{4.38}
\end{equation*}
$$

(3) Note from Lemma 3.3(iv) that $\lim _{d_{1} \rightarrow 0^{+}}\left(\theta_{1}, \theta_{2}, \cdots, \theta_{n}\right)=\left(0, \cdots, 0, k_{n}\right)$. Hence one has $\lim _{d_{1} \rightarrow 0^{+}} \gamma^{*}\left(q, d_{1}, d_{2}\right)=$ $\mu\left(k_{n}\right)$, where $\mu\left(k_{n}\right)$ is the principal eigenvalue of (2.2). Clearly, $\mu(0)=0$ and $\mu\left(k_{n}\right)$ is strictly increasing with respect to $k_{n}$.
(4) Since $\gamma^{*}\left(0, d_{1}, d_{2}\right)=\lambda_{1}\left(d_{2}, 0,\left.\boldsymbol{\theta}\right|_{q=0}\right)$, by Lemma $3.3($ vi $)$, there holds

$$
\begin{equation*}
\lim _{d_{1} \rightarrow 0^{+}} \gamma^{*}\left(0, d_{1}, d_{2}\right)=\lambda_{1}\left(d_{2}, 0, \beta a \boldsymbol{k}\right) \tag{4.39}
\end{equation*}
$$

(5) If $q \geq 0$, by applying Lemma 3.1(iii), one can have that

$$
\begin{equation*}
\lim _{d_{2} \rightarrow 0^{+}} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\max \left\{\beta a \theta_{1}-\tau q, \cdots, \beta a \theta_{n-1}-\tau q, \beta a \theta_{n}\right\}, \text { and } \lim _{d_{2} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\sum_{i=1}^{n} \beta a \theta_{i}}{n} \tag{4.40}
\end{equation*}
$$

The proof of this Theorem is therefore completed.

### 4.2 Asymptotic profiles of positive steady states

This subsection is devoted to studying the influence of diffusion and advection on the asymptotic profiles of the positive steady state of system (1.6). Therefore, we focus on the steady states system (4.37). Let $U_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{i-1} N_{i}$ and $V_{i}=\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{i-1} P_{i}$. Then $(\boldsymbol{U}, \boldsymbol{V})$ satisfies

$$
\left\{\begin{array}{l}
-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-a U_{1} P_{1}=0  \tag{4.41}\\
d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-a U_{j} P_{j}=0, j \in \mathcal{B} \\
d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{N_{n}}{k_{n}}\right)-a U_{n} P_{n}=0 \\
-\left(d_{2}+\tau q\right) V_{1}+\left(d_{2}+\tau q\right) V_{2}+V_{1}\left(\beta a N_{1}-\gamma\right)=0 \\
d_{2} V_{j-1}+\left(-2 d_{2}-\tau q\right) V_{j}+\left(d_{2}+\tau q\right) V_{j+1}+V_{j}\left(\beta a N_{j}-\gamma\right)=0, j \in \mathcal{B} \\
d_{2} V_{n-1}-d_{2} V_{n}+V_{n}\left(\beta a N_{n}-\gamma\right)=0
\end{array}\right.
$$

Lemma 4.3. Suppose $(\mathbf{H})$ hold. Let $(\boldsymbol{N}, \boldsymbol{P})$ be a nonnegative solution of $(4.37)$ with $(\boldsymbol{N}, \boldsymbol{P}) \neq(\mathbf{0}, \mathbf{0})$. Then $\mathbf{0} \ll \boldsymbol{N} \ll \boldsymbol{\theta}$ and $\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$.
Proof: Note that, $(\boldsymbol{U}, \boldsymbol{V})$ is a nonnegative solution of (4.41) with $(\boldsymbol{U}, \boldsymbol{V}) \neq(\mathbf{0}, \mathbf{0})$. Lemma 3.4 yields that $\boldsymbol{U} \gg \mathbf{0}$ and $\boldsymbol{V} \gg \mathbf{0}$. Hence, $\boldsymbol{N} \gg \mathbf{0}$ and $\boldsymbol{P} \gg \mathbf{0}$. From the equations of $\boldsymbol{U}$ in (4.41), we have that

$$
\left\{\begin{array}{l}
0=-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-a U_{1} P_{1}<-\left(d_{1}+q\right) U_{1}+\left(d_{1}+q\right) U_{2}+r_{1} U_{1}\left(1-\frac{N_{1}}{k_{1}}\right)  \tag{4.42}\\
0=d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-a U_{j} P_{j} \\
<d_{1} U_{j-1}+\left(-2 d_{1}-q\right) U_{j}+\left(d_{1}+q\right) U_{j+1}+r_{j} U_{j}\left(1-\frac{N_{j}}{k_{j}}\right), j \in \mathcal{B} \\
0=d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{N_{n}}{k_{n}}\right)<d_{1} U_{n-1}-d_{1} U_{n}+r_{n} U_{n}\left(1-\frac{N_{n}}{k_{n}}\right)
\end{array}\right.
$$

Since $\boldsymbol{\theta}$ is the unique positive solution to (3.7), then $\boldsymbol{w}:=\left(\theta_{1},\left(\frac{d_{1}}{d_{1}+q}\right) \theta_{2}, \cdots,\left(\frac{d_{1}}{d_{1}+q}\right)^{n-1} \theta_{n}\right)$ is the unique positive solution to

$$
\left\{\begin{array}{l}
\left(d_{1}+q\right)\left(w_{2}-w_{1}\right)+r_{1}\left(1-\frac{w_{1}}{k_{1}}\right) w_{1}=0  \tag{4.43}\\
d_{1} w_{j-1}+\left(-2 d_{1}-q\right) w_{j}+\left(d_{1}+q\right) w_{j+1}+r_{j}\left(1-\left(\frac{d_{1}+q}{d_{1}}\right)^{j-1} \frac{w_{j}}{k_{j}}\right) w_{j}=0, j \in \mathcal{B} \\
d_{1}\left(w_{n-1}-w_{n}\right)+r_{n}\left(1-\left(\frac{d_{1}+q}{d_{1}}\right)^{n-1} \frac{w_{n}}{k_{n}}\right) w_{n}=0
\end{array}\right.
$$

By the similar arguments in the proof of [2, Lemma 2.2](see also [16]), one can conclude that $\mathbf{0} \ll \boldsymbol{U} \ll \boldsymbol{w}$, which implies $\mathbf{0} \ll \boldsymbol{N} \ll \boldsymbol{\theta}$. Furthermore, from the equations of $\boldsymbol{V}$ in (4.41) and Lemma 3.1(iv), we have

$$
\begin{equation*}
\gamma=\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{N}\right)<\lambda_{1}\left(d_{2}, \tau q, \beta a \boldsymbol{\theta}\right)=\gamma^{*}\left(q, d_{1}, d_{2}\right) \tag{4.44}
\end{equation*}
$$

This completes the proof.

Lemma 4.4. Suppose $(\mathbf{H})$ hold. Let $(\boldsymbol{N}, \boldsymbol{P})$ be a nonnegative solution of $(4.37)$ with $(\boldsymbol{N}, \boldsymbol{P}) \neq(\mathbf{0}, \mathbf{0})$. We have the following results:
(1) if $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$, there holds $0<N_{1}<\cdots<N_{n}$;
(2) if $q \geq \max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{\beta a N_{n}+2 \sqrt{\beta a d_{2} N_{n}}}{\tau}\right\}$, there holds $0<P_{1}<\cdots<P_{n}$.

Proof: (1) It follows from Lemma 4.3 that $\boldsymbol{N} \gg \mathbf{0}$ and $\boldsymbol{P} \gg \mathbf{0}$. Now set $\alpha_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{\frac{i-1}{2}}, \xi_{i}=\alpha_{i} N_{i}$ and $\zeta_{i}=\alpha_{i} P_{i}$. Direct calculations yield

$$
\left\{\begin{array}{l}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(\xi_{2}-\xi_{1}\right)+\left[r_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}-\frac{a \zeta_{1}}{\alpha_{1}}\right] \xi_{1}=0  \tag{4.45}\\
\sqrt{d_{1}\left(d_{1}+q\right)}\left(\xi_{j-1}-2 \xi_{j}+\xi_{j+1}\right)+\left[r_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}-\frac{a \zeta_{j}}{\alpha_{j}}\right] \xi_{j}=0, j \in \mathcal{B}
\end{array}\right.
$$

If $q \geq r_{\max }+2 \sqrt{d_{1} r_{\max }}$, then

$$
\left\{\begin{array}{l}
r_{1}\left(1-\frac{N_{1}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}-\frac{a \zeta_{1}}{\alpha_{1}}<0,  \tag{4.46}\\
r_{j}\left(1-\frac{N_{j}}{k_{j}}\right)-2 d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}-\frac{a \zeta_{j}}{\alpha_{j}}<0, j \in \mathcal{B}
\end{array}\right.
$$

Thus, we get from (4.45) that $0<\xi_{1}<\xi_{2}<\cdots<\xi_{n}$. This indicates that $0<N_{1}<\cdots<N_{n}$.
(2) Set $a_{i}=\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{\frac{i-1}{2}}, \xi_{i}=a_{i} N_{i}$ and $\zeta_{i}=a_{i} P_{i}$. Then we have

$$
\left\{\begin{array}{l}
\sqrt{d_{2}\left(d_{2}+\tau q\right)}\left(\zeta_{2}-\zeta_{1}\right)+\left[\beta a N_{1}-\gamma-d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)}\right] \zeta_{1}=0  \tag{4.47}\\
\sqrt{d_{2}\left(d_{2}+\tau q\right)}\left(\zeta_{j-1}-2 \zeta_{j}+\zeta_{j+1}\right)+\left[\beta a N_{j}-\gamma-2 d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)}\right] \zeta_{j}=0, j \in \mathcal{B}
\end{array}\right.
$$

By means of (1), we get that

$$
\left\{\begin{array}{l}
\beta a N_{1}-\gamma-d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)}<\beta a N_{n}-d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)} \leq 0  \tag{4.48}\\
\beta a N_{i}-\gamma-2 d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)}<\beta a N_{n}-2 d_{2}-\tau q+\sqrt{d_{2}\left(d_{2}+\tau q\right)} \leq 0, j \in \mathcal{B}
\end{array}\right.
$$

Here $q \geq \max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{\beta a N_{n}+2 \sqrt{\beta a d_{2} N_{n}}}{\tau}\right\}$ is used. Hence, we get from (4.47) that $0<\zeta_{1}<$ $\zeta_{2}<\cdots<\zeta_{n}$. This indicates that $0<P_{1}<\cdots<P_{n}$. The proof of this lemma is therefore completed.

Lemma 4.5. Suppose $(\mathbf{H})$ hold. Let $(\boldsymbol{N}, \boldsymbol{P})$ be a nonnegative solution of $(4.37)$ with $(\boldsymbol{N}, \boldsymbol{P}) \neq(\mathbf{0}, \mathbf{0})$. Then the following results hold:
(1) for fixed $d_{1}, d_{2}>0, P_{i}$ is uniformly bounded for $i \in \mathcal{A}$ as $q \rightarrow+\infty$;
(2) for fixed $d_{1}>0$ and $q>\max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{\beta a N_{n}}{\tau}\right\}, P_{i}$ is uniformly bounded for $i \in \mathcal{A}$ as $d_{2} \rightarrow 0^{+}$;
(3) for fixed $d_{2}>0$ and $q \geq 0, P_{i}$ is uniformly bounded for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$;
(4) for fixed $d_{1}>0$ and $q \geq 0, P_{i}$ is uniformly bounded for $i \in \mathcal{A}$ as $d_{2} \rightarrow+\infty$.

Proof: By a similar argument as in the proof of Lemma 4.3, we have $\boldsymbol{N} \gg \mathbf{0}$ and $\boldsymbol{P} \gg \mathbf{0}$.
(1) According to Lemma 4.4(2), we only need to show $P_{n}$ is uniformly bounded as $q \rightarrow+\infty$. If this is not true, then by passing to a sequence if necessary, we may assume $P_{n} \rightarrow+\infty$ as $q \rightarrow+\infty$. Set $\tilde{P}_{i}=\frac{P_{i}}{P_{n}}$. Then

$$
\begin{cases}\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}+r_{i} N_{i}\left(1-\frac{N_{i}}{k_{i}}\right)-a N_{i} \tilde{P}_{i} P_{n}=0, & i \in \mathcal{A}  \tag{4.49}\\ \sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \tilde{P}_{j}+\tilde{P}_{i}\left(\beta a N_{i}-\gamma\right)=0, & i \in \mathcal{A}\end{cases}
$$

Since $k_{i} \leq k_{\max }, 0<\tilde{P}_{i} \leq 1$ and $0<N_{i}<\theta_{i}$ is bounded uniformly for $q \rightarrow+\infty$ by lemma 3.3 and Lemma 4.3, passing to a sequence if necessary yields that $k_{i} \rightarrow k_{i}^{*} \geq 0, \tilde{P}_{i} \rightarrow P_{i}^{*} \leq 1$ and $N_{i} \rightarrow N_{i}^{*} \geq 0$. In particular, $P_{n}^{*}=1$, since $\tilde{P}_{n}=1$. By dividing the second equation of (4.49) by $q$, it follows that

$$
\left\{\begin{array}{l}
\left(-\frac{d_{2}}{q}-\tau\right) \tilde{P}_{1}+\frac{d_{2}}{q} \tilde{P}_{2}+\frac{\beta a N_{1}-\gamma}{q} \tilde{P}_{1}=0  \tag{4.50}\\
\left(\frac{d_{2}}{q}+\tau\right) \tilde{P}_{j-1}+\left(-\frac{2 d_{2}}{q}-\tau\right) \tilde{P}_{j}+\frac{d_{2}}{q} \tilde{P}_{j+1}+\frac{\beta a N_{j}-\gamma}{q} \tilde{P}_{j}=0, j \in \mathcal{B}
\end{array}\right.
$$

Consequently, as $q \rightarrow+\infty, \tilde{P}_{1}, \tilde{P}_{2}, \cdots, \tilde{P}_{n-1} \rightarrow 0$. Noting that $\sum_{i=1}^{n} \sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \tilde{P}_{j}=0$, we deduce that

$$
\begin{equation*}
\sum_{i=1}^{n} \tilde{P}_{i}\left(\beta a N_{i}-\gamma\right)=0 \tag{4.51}
\end{equation*}
$$

A simple calculation gives $\beta a N_{n}^{*}-\gamma=0$, which shows $N_{n}^{*}=\frac{\gamma}{\beta a}$.
Combining the first equation of (4.49) with $\sum_{i=1}^{n} \sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) N_{j}=0$ yields that

$$
\begin{equation*}
a P_{n} \sum_{i=1}^{n} N_{i} \tilde{P}_{i}=\sum_{i=1}^{n} N_{i} r_{i}\left(1-\frac{N_{i}}{k_{i}}\right) \tag{4.52}
\end{equation*}
$$

which implies that

$$
\begin{equation*}
+\infty \leftarrow a P_{n}=\frac{\sum_{i=1}^{n} N_{i} r_{i}\left(1-\frac{N_{i}}{k_{i}}\right)}{\sum_{i=1}^{n} N_{i} \tilde{P}_{i}} \tag{4.53}
\end{equation*}
$$

This is impossible. Hence $P_{n}$ is uniformly bounded as $q \rightarrow+\infty$.
(2) Given $q>\max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{\beta a N_{n}}{\tau}\right\}$, by the similar arguments as in the proof of Lemma 4.4, we can deduce that for $d_{2} \ll 1,0<P_{1}<\cdots<P_{n}$. Hence, we need only to show $P_{n}$ is bounded uniformly for $d_{2} \rightarrow 0^{+}$. Suppose that there exist a sequence $d_{2}^{m}$ and positive solutions $\left(\boldsymbol{N}^{m}, \boldsymbol{P}^{m}\right)$ to
(4.37) such that $\lim _{m \rightarrow+\infty} d_{2}^{m}=0$ and $P_{n}^{m} \rightarrow+\infty$ as $m \rightarrow+\infty$. Set $\tilde{P}_{i}^{m}=\frac{P_{i}^{m}}{P_{n}^{m}} \leq 1$. Then we reach that

$$
\left\{\begin{array}{l}
\left(-d_{2}^{m}-\tau q\right) \tilde{P}_{1}^{m}+d_{2} \tilde{P}_{2}^{m}+\left(\beta a N_{1}-\gamma\right) \tilde{P}_{1}^{m}=0  \tag{4.54}\\
\left(d_{2}^{m}+\tau q\right) \tilde{P}_{j-1}^{m}+\left(-2 d_{2}^{m}-\tau q\right) \tilde{P}_{j}^{m}+d_{2}^{m} \tilde{P}_{j+1}^{m}+\left(\beta a N_{j}-\gamma\right) \tilde{P}_{j}^{m}=0, j \in \mathcal{B} \\
\left(d_{2}^{m}+\tau q\right) \tilde{P}_{n-1}^{m}-d_{2}^{m} \tilde{P}_{n}^{m}+\left(\beta a N_{n}-\gamma\right) \tilde{P}_{n}^{m}=0
\end{array}\right.
$$

Since $N_{i}$ is bounded for all $d_{2}>0$, we may assume that $\tilde{P}_{i}^{m} \rightarrow P_{i}^{*} \in[0,1]$ and $N_{i}^{m} \rightarrow N_{i}^{*} \geq 0$ as $m \rightarrow+\infty$. Letting $m \rightarrow+\infty$ yields

$$
\left\{\begin{array}{l}
-\tau q P_{1}^{*}+\left(\beta a N_{1}^{*}-\gamma\right) P_{1}^{*}=0  \tag{4.55}\\
\tau q P_{j-1}^{*}-\tau q P_{j}^{*}+\left(\beta a N_{j}^{*}-\gamma\right) P_{j}^{*}=0, j \in \mathcal{B} \\
\tau q P_{n-1}^{*}+\left(\beta a N_{n}^{*}-\gamma\right) P_{n}^{*}=0
\end{array}\right.
$$

from which $P_{1}^{*}=0$ or $\beta a N_{1}^{*}=\gamma+\tau q>0$ follows. On the other hand, by dividing the equation of $N_{i}^{m}$ by $P_{n}^{m}$ and letting $m \rightarrow+\infty$, one can deduce that $N_{1}^{*} P_{1}^{*}=0$. Hence, $P_{1}^{*}=0$. By the similar methods above, it further follows that $P_{1}^{*}=\cdots=P_{n-1}^{*}=0, P_{n}^{*}=1$. Therefore, a contradiction happens according to the same arguments of deriving (4.53). Hence, $P_{n}$ is bounded for $d_{2} \rightarrow 0^{+}$.
(3) Note that $N_{i}$ is bounded uniformly for $d_{1} \rightarrow+\infty$. Suppose that $P_{i}$ is unbounded for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$. There exist a sequence $d_{1}^{m}$ and positive solutions $\left(\boldsymbol{N}^{m}, \boldsymbol{P}^{m}\right)$ to (4.37) such that $d_{1}^{m} \rightarrow+\infty$ and $P_{i_{0}}^{m}:=\max _{i \in \mathcal{A}} P_{i}^{m} \rightarrow+\infty$ as $m \rightarrow+\infty$. Let $\hat{P}_{i}^{m}=\frac{P_{i}^{m}}{P_{i_{0}}^{m}} \leq 1$. Then we can deduce that there exists a convergent subsequence of $\left(N_{i}^{m}, \hat{P}_{i}^{m}\right)\left(\right.$ still denoted by $\left.\left(N_{i}^{m}, \hat{P}_{i}^{m}\right)\right)$ such that $\hat{P}_{i}^{m} \rightarrow \hat{P}_{i} \in[0,1]$, $N_{i}^{m} \rightarrow N_{i} \geq 0$ as $m \rightarrow+\infty$. Clearly, $1=\hat{P}_{i_{0}}^{m} \rightarrow \hat{P}_{i_{0}}>0$ as $m \rightarrow+\infty$.

Similar to the proof of (2), we also have $\hat{\boldsymbol{P}}>\mathbf{0}$ and

$$
\begin{equation*}
\lambda_{1}\left(d_{1}^{m}, q, r_{i}\left(1-\frac{N_{i}^{m}}{k_{i}}\right)-a \hat{P}_{i}^{m} P_{i_{0}}^{m}\right)=0 \tag{4.56}
\end{equation*}
$$

By Lemma 3.1(iii) again, we have $\lambda_{1}\left(d_{1}^{m}, q, r_{i}\left(1-\frac{N_{i}^{m}}{k_{i}}\right)-a \hat{P}_{i}^{m} P_{i_{0}}^{m}\right)<0$ as $m \rightarrow+\infty$, a contradiction occurs. Therefore, $P_{i}$ is bounded for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$.
(4) Suppose now that $P_{i}$ is unbounded for $i \in \mathcal{A}$ as $d_{2} \rightarrow+\infty$. There exist a sequence $d_{2}^{m}$ and positive solutions $\left(\boldsymbol{N}^{m}, \boldsymbol{P}^{m}\right)$ to (4.37) such that $d_{2}^{m} \rightarrow+\infty$ and $P_{i_{0}}^{m}:=\max _{i \in \mathcal{A}} P_{i}^{m} \rightarrow+\infty$ as $m \rightarrow+\infty$. Let $\hat{P}_{i}^{m}=\frac{P_{i}^{m}}{P_{i_{0}}^{m}} \leq 1$. Then we can deduce that there exists a convergent subsequence of $\left(N_{i}^{m}, \hat{P}_{i}^{m}\right)$ (still denoted by $\left.\left(N_{i}^{m}, \hat{P}_{i}^{m}\right)\right)$ satisfying $\hat{P}_{i}^{m} \rightarrow \hat{P}_{i} \in[0,1], N_{i}^{m} \rightarrow N_{i} \geq 0$ as $m \rightarrow+\infty$. Clearly, $1=\hat{P}_{i_{0}}^{m} \rightarrow \hat{P}_{i_{0}}>0$ as $m \rightarrow+\infty$.

Dividing the equation of $\hat{P}_{i}^{m}$ by $d_{2}^{m}$ and letting $m \rightarrow+\infty$ yield that $\hat{P}_{1}=\cdots=\hat{P}_{n}=\hat{P}_{i_{0}}=1$. Therefore, a contradictions occurs according the same arguments of deriving (4.53). $P_{i}$ is hence bounded for $d_{2} \rightarrow+\infty$.

The proof of this lemma is thus complete.
It follows from Theorem $2.1(2)$ that (1.6) has a positive steady state $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$ when $0<\gamma<$ $\gamma^{*}\left(q, d_{1}, d_{2}\right)$. In the following, we shall investigate the positive steady state $\left(\boldsymbol{N}^{*}, \boldsymbol{P}^{*}\right)$.
Lemma 4.6. Suppose $(\mathbf{H})$ hold, $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$. Then for $i \in \mathcal{C}$,

$$
\left\{\begin{array}{l}
\left(\frac{d_{1}+q+2\left(a P_{n}^{*}+\max _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} N_{n}^{*}\right)}{d_{1}}\right)^{i-n} N_{n}^{*}<N_{i}^{*}<\left(\frac{d_{1}+q-2 r_{\max }}{d_{1}}\right)^{i-n} N_{n}^{*}  \tag{4.57}\\
\text { if } q \geq \max \left\{d_{1}+2 r_{\max }, r_{\max }+2 \sqrt{d_{1} r_{\max }}\right\} \\
\left(\frac{d_{2}+\tau q+2 \gamma}{d_{2}}\right)^{i-n} P_{n}^{*}<P_{i}^{*}<\left(\frac{d_{2}+\tau q-2 \beta a N_{n}^{*}}{d_{2}}\right)^{i-n} P_{n}^{*}, \text { if } q \geq \max \left\{\frac{d_{2}+2 \beta a N_{n}^{*}}{\tau}, \frac{\beta a N_{n}^{*}+2 \sqrt{\beta a N_{n}^{*} d_{2}}}{\tau}\right\}
\end{array}\right.
$$

Proof: Set $\alpha=\frac{d_{1}+q-2 r_{\max }}{d_{1}}, \delta=\frac{d_{1}+q+2\left(a P_{n}^{*}+\max _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} N_{n}^{*}\right)}{d_{1}}, A=\frac{d_{2}+\tau q-2 \beta a N_{n}^{*}}{d_{2}}, B=$ $\frac{d_{2}+\tau q+2 \gamma}{d_{2}}, \alpha_{i}=\alpha^{i-1}, \delta_{i}=\delta^{i-1}, A_{i}=A^{i-1}, B_{i}=B^{i-1}$. Let $\bar{N}_{i}^{*}=N_{n}^{*} \frac{\alpha_{i}}{\alpha_{n}}, \underline{N}_{i}^{*}=N_{n}^{*} \frac{\delta_{i}}{\delta_{n}}, \bar{P}_{i}^{*}=P_{n}^{*} \frac{A_{i}}{A_{n}}$, $\underline{P}_{i}^{*}=P_{n}^{*} \frac{B_{i}}{B_{n}}$. Letting $u_{i}=\left(\frac{d_{1}}{d_{1}+q}\right)^{\frac{i-1}{2}}\left(\bar{N}_{i}^{*}-N_{i}^{*}\right)$, it is obvious that

$$
\left\{\begin{array}{l}
\sqrt{d_{1}\left(d_{1}+q\right)}\left(u_{2}-u_{1}\right)+\left[r_{1}\left(1-\frac{N_{1}^{*}}{k_{1}}\right)-d_{1}-q+\sqrt{d_{1}\left(d_{1}+q\right)}-a P_{1}^{*}\right] u_{1}<0,  \tag{4.58}\\
\sqrt{d_{1}\left(d_{1}+q\right)}\left(u_{j-1}-2 u_{j}+u_{j+1}\right)+\left[r_{j}\left(1-\frac{N_{j}^{*}}{k_{j}}\right)-2 d_{1}-q+2 \sqrt{d_{1}\left(d_{1}+q\right)}-a P_{j}^{*}\right] u_{j}<0, j \in \mathcal{B}
\end{array}\right.
$$

for $q \geq \max \left\{d_{1}+2 r_{\max }, r_{\max }+2 \sqrt{d_{1} r_{\max }}\right\}$, some similar methods in obtaining (3.9) give rise to $u_{i}>0$ and thus $\bar{N}_{i}^{*}>N_{i}^{*}$ for $i \in \mathcal{C}$.

By means of the similar arguments above, combining the equations of $\underline{N}_{i}^{*}, \bar{P}_{i}^{*}, \underline{P}_{i}^{*}$ with

$$
\begin{equation*}
q \geq \max \left\{d_{1}, \frac{d_{2}+2 \beta a k_{n}}{\tau}, \frac{\beta a k_{n}+2 \sqrt{\beta a k_{n} d_{2}}}{\tau}, \frac{d_{2}-2 \gamma}{\tau}\right\} \tag{4.59}
\end{equation*}
$$

yields that $N_{i}^{*}>\underline{N}_{i}^{*}, \bar{P}_{i}^{*}>P_{i}^{*}>\underline{P}_{i}^{*}$ for $i \in \mathcal{C}$. Hence, we finish the proof of this lemma.
Proof of Theorem 2.3: Note that $0<\gamma<\beta a k_{n}$ and $\lim _{q \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\beta a k_{n}$ guarantee that there exists a sufficiently large positive constant $Q$ such that $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$ when $q>Q$. This implies that a positive steady state of system (1.6) exists for all large $q$ (see Theorem 2.1(2)).

Notice from Lemmas 4.3 and $4.5(1)$ that $N_{n}^{*}$ and $P_{n}^{*}$ are uniformly bounded as $q \rightarrow+\infty$. By choosing a subsequence if necessary, we may assume that $\left(N_{n}^{*}, P_{n}^{*}\right) \rightarrow\left(p_{1}, p_{2}\right)$ as $q \rightarrow+\infty$ for some constants $p_{1}$ and $p_{2}$. It follows from (4.57) that

$$
\begin{equation*}
\frac{N_{i}^{*}}{N_{n}^{*}} \rightarrow 0, \frac{P_{i}^{*}}{P_{n}^{*}} \rightarrow 0, \text { for } i \in \mathcal{C}, q \rightarrow+\infty \tag{4.60}
\end{equation*}
$$

Applying (4.37), we get

$$
\left\{\begin{array}{l}
\sum_{i=1}^{n} \frac{N_{i}^{*}}{N_{n}^{*}}\left(r_{i}-\frac{r_{i}}{k_{i}} \frac{N_{i}^{*}}{N_{n}^{*}} N_{n}^{*}-a \frac{P_{i}^{*}}{P_{n}^{*}} P_{n}^{*}\right)=0,  \tag{4.61}\\
\sum_{i=1}^{n} \frac{P_{i}^{*}}{P_{n}^{*}}\left(\beta a \frac{N_{i}^{*}}{N_{n}^{*}} N_{n}^{*}-\gamma\right)=0
\end{array}\right.
$$

Furthermore, we reach that

$$
\left\{\begin{array}{l}
0=r_{n}-\frac{r_{n}}{k_{n}} N_{n}^{*}-a P_{n}^{*}+\sum_{i=1}^{n-1} \frac{N_{i}^{*}}{N_{n}^{*}}\left(r_{i}-\frac{r_{i}}{k_{i}} \frac{N_{i}^{*}}{N_{n}^{*}} N_{n}^{*}-a \frac{P_{i}^{*}}{P_{n}^{*}} P_{n}^{*}\right) \rightarrow r_{n}-\frac{r_{n}}{k_{n}} p_{1}-a p_{2},  \tag{4.62}\\
0=\beta a N_{n}^{*}-\gamma+\sum_{i=1}^{n-1} \frac{P_{i}^{*}}{P_{n}^{*}}\left(\beta a \frac{N_{i}^{*}}{N_{n}^{*}} N_{n}^{*}-\gamma\right) \rightarrow \beta a p_{1}-\gamma,
\end{array}\right.
$$

by letting $q \rightarrow+\infty$. Therefore, we obtain that

$$
\begin{equation*}
\left(p_{1}, p_{2}\right)=\left(\frac{\gamma}{\beta a}, \frac{1}{a}\left(r_{n}-\frac{r_{n}}{k_{n}} \frac{\gamma}{\beta a}\right)\right) . \tag{4.63}
\end{equation*}
$$

According to (4.57), we have

$$
\begin{align*}
& {\left[\left(\frac{d_{1}}{d_{1}+q+2\left(a P_{n}^{*}+\max _{i \in \mathcal{A}} \frac{r_{i}}{k_{i}} N_{n}^{*}\right)}\right)^{n-i}-\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right] N_{n}^{*}<N_{i}^{*}-N_{n}^{*}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}}  \tag{4.64}\\
& <\left[\left(\frac{d_{1}}{d_{1}+q-2 r_{\max }}\right)^{n-i}-\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right] N_{n}^{*}
\end{align*}
$$

which implies

$$
\begin{equation*}
\max _{i \in \mathcal{A}}\left(N_{i}^{*}-N_{n}^{*}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right) \rightarrow 0 \text { as } q \rightarrow+\infty . \tag{4.65}
\end{equation*}
$$

Similarly, it can be proved by (4.57) that

$$
\begin{equation*}
\max _{i \in \mathcal{A}}\left(P_{i}^{*}-P_{n}^{*}\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{n-i}\right) \rightarrow 0 \text { as } q \rightarrow+\infty \tag{4.66}
\end{equation*}
$$

That is,

$$
\begin{equation*}
\max \left\{\max _{i \in \mathcal{A}}\left(N_{i}^{*}-N_{n}^{*}\left(\frac{d_{1}}{d_{1}+q}\right)^{n-i}\right), \max _{i \in \mathcal{A}}\left(P_{i}^{*}-P_{n}^{*}\left(\frac{d_{2}}{d_{2}+\tau q}\right)^{n-i}\right)\right\} \rightarrow 0 \text { as } q \rightarrow+\infty \tag{4.67}
\end{equation*}
$$

which implies that $\left(N_{i}^{*}, P_{i}^{*}\right) \rightarrow(0,0)$ uniformly for $i \in \mathcal{C}$ as $q \rightarrow+\infty$. In conclusion, we complete the proof of Theorem 2.3.

Proof of Theorem 2.4: Note that $0<\gamma<\beta a k_{\text {min }}$ and $\lim _{d_{1} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\beta a \sum_{i=1}^{n} r_{i}}{\sum_{i=1}^{n} \frac{r_{i}}{k_{i}}}>\beta a k_{\text {min }}$ guarantee that there exists a sufficiently large positive constant $D_{1}$ such that $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$ when $d_{1}>D_{1}$. This implies that a positive steady state of system (1.6) exists for all large $d_{1}$ (see Theorem 2.1(2)).

It follows from Lemmas 4.3, 3.3(v) and 4.5(3) that $N_{i}^{*}$ and $P_{i}^{*}$ are uniformly bounded for $i \in \mathcal{A}$ as $d_{1} \rightarrow+\infty$. We may assume by passing to a subsequence if necessary that $P_{i}^{*} \rightarrow \dot{P}_{i}$ as $d_{1} \rightarrow+\infty$. Dividing the equation of $N_{i}^{*}$ in (4.37) by $d_{1}$ and taking $d_{1} \rightarrow+\infty$ lead to $N_{i}^{*} \rightarrow s \geq 0$ for all $i$. Let $\max _{i \in \mathcal{A}} P_{i}^{*}=P_{i_{0}\left(d_{1}\right)}^{*}$ and $\tilde{P}_{i}:=\frac{P_{i}^{*}}{P_{i_{0}\left(d_{1}\right)}^{*}}$. Then it follows that $\tilde{P}_{i} \rightarrow \frac{\dot{P}_{i}}{P_{i_{0}(\infty)}^{*}} \geq 0$ for $d_{1} \rightarrow+\infty$. Clearly, $\tilde{P}_{i}$ satisfies

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \tilde{P}_{j}+\tilde{P}_{i}\left(\beta a N_{i}^{*}-\gamma\right)=0 \tag{4.68}
\end{equation*}
$$

After taking $d_{1} \rightarrow+\infty$, we arrive at

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \frac{\dot{P}_{j}}{P_{i_{0}(\infty)}^{*}}+\frac{\dot{P}_{i}}{P_{i_{0}(\infty)}^{*}}(\beta a s-\gamma)=0 \tag{4.69}
\end{equation*}
$$

Adding (4.69) up with respect to $i$ yields

$$
\begin{equation*}
\sum_{i=1}^{n} \frac{\dot{P}_{i}}{P_{i_{0}(\infty)}^{*}}(\beta a s-\gamma)=0 \tag{4.70}
\end{equation*}
$$

The above equality then implies that $s=\frac{\gamma}{\beta a}$. Letting $d_{1} \rightarrow+\infty$ in the equation of $P_{i}^{*}$ in (4.37), we see that

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \dot{P}_{j}=0 \tag{4.71}
\end{equation*}
$$

which implies that $\dot{P}_{i}=\left(1+\frac{\tau q}{d_{2}}\right)^{i-1} \dot{P}_{1}$.
After letting $d_{1} \rightarrow+\infty$ in the equation of $N_{i}^{*}$ in (4.37) and adding them up respect to $i$ from 1 to $n$, we can see that

$$
\begin{equation*}
\sum_{i=1}^{n} r_{i}\left(1-\frac{\gamma}{\beta a k_{i}}\right)=a \dot{P}_{1} \sum_{i=1}^{n}\left(1+\frac{\tau q}{d_{2}}\right)^{i-1} \tag{4.72}
\end{equation*}
$$

That is, $\left.\dot{P}_{1}=\left(1+\frac{\tau q}{d_{2}}\right)^{i-1} \frac{\sum_{j=1}^{n} r_{j}\left(1-\frac{\gamma}{\beta a k_{j}}\right)}{\frac{d_{2} a}{\tau q}\left[\left(1+\frac{\tau q}{d_{2}}\right)^{n}-1\right]}\right)$. Then (2.3) is obtained.

Proof of Theorem 2.5: Note that $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$. This implies that a positive steady state of system (1.6) exists(see Theorem 2.1(2)).

Note that $N_{i}^{*}$ is uniformly bounded as $d_{2} \rightarrow 0^{+}$(see Lemma 4.3). Since $q>\max \left\{r_{\max }+2 \sqrt{d_{1} r_{\max }}, \frac{2 \beta a N_{n}^{*}}{\tau}\right\}$, by Lemma $4.5(2)$ and (4.57), we have that $P_{n}^{*}$ is uniformly bounded and

$$
\begin{equation*}
\left(\frac{d_{2}+\tau q+2 \gamma}{d_{2}}\right)^{i-n} P_{n}^{*}<P_{i}^{*}<\left(\frac{d_{2}+\tau q-2 \beta a N_{n}^{*}}{d_{2}}\right)^{i-n} P_{n}^{*} \tag{4.73}
\end{equation*}
$$

for $d_{2} \rightarrow 0^{+}$. Therefore,

$$
\begin{equation*}
\max _{i}\left(P_{i}^{*}-P_{n}^{*}\left(\frac{d_{1}}{d_{2}+\tau q}\right)^{n-i}\right) \rightarrow 0 \text { as } d_{2} \rightarrow 0^{+} \tag{4.74}
\end{equation*}
$$

and we may suppose $\left(N_{i}^{*}, P_{n}^{*}\right) \rightarrow\left(N_{i}^{0}, l\right)$ as $d_{2} \rightarrow 0^{+}$by passing to a subsequence if necessary. Here $N_{i}^{0} \geq 0, l \geq 0$.

Set $\tilde{P}_{i}=\frac{P_{i}^{*}}{P_{n}^{*}}$. Then $\tilde{P}_{i}$ satisfies

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d_{2} D_{i j}+\tau q Q_{i j}\right) \tilde{P}_{j}+\tilde{P}_{i}\left(\beta a N_{i}^{*}-\gamma\right)=0 \tag{4.75}
\end{equation*}
$$

If $l>0$, then we must have $\tilde{P}_{i} \rightarrow 0(i \in \mathcal{C})$ as $d_{2} \rightarrow 0^{+}$. Combined with (4.75), we obtain that $l=0$. Setting $d_{2} \rightarrow 0^{+}$in the equation of $N_{i}^{*}$ yields $N_{i}^{0}=\theta_{i}$. The proof of Theorem 2.5 is thus complete.

At last, before giving the proof of Theorem 2.6, we introduce the following lemma.
Lemma 4.7. Suppose $(\mathbf{H})$ hold, $0<\gamma<\frac{\beta a \sum_{i}^{n} \theta_{i}}{n}$ and $y \geq 0$. The system

$$
\begin{cases}\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) Z_{j}+Z_{i}\left(r_{i}-\frac{r_{i}}{k_{i}} Z_{i}-a y\right)=0, & i \in \mathcal{A}  \tag{4.76}\\ \beta a \sum_{i=1}^{n} Z_{i}=\gamma n, & i \in \mathcal{A}\end{cases}
$$

admits a unique positive solution $\left(Z_{i}(\tilde{y}), \tilde{y}\right)$.
Proof: Let $y^{*}=\frac{\lambda_{1}\left(d_{1}, q, \boldsymbol{r}\right)}{a}>0$. Clearly, it follows from [2, Lemma 2.2](see also [16]) that for $y \geq y^{*}$, $\boldsymbol{Z}=\mathbf{0}$ is the unique solution of the first equation of (4.76), and for $0 \leq y<y^{*}$, the first equation of (4.76) admits a unique positive solution, denoted by $Z_{i}(y)$. Now choosing $0 \leq y^{1}<y^{2}<y^{*}$, we obtain

$$
\begin{equation*}
\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) Z_{j}+Z_{i}\left(r_{i}-\frac{r_{i}}{k_{i}} Z_{i}-a y^{2}\right)<\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) Z_{j}+Z_{i}\left(r_{i}-\frac{r_{i}}{k_{i}} Z_{i}-a y^{1}\right) \tag{4.77}
\end{equation*}
$$

By applying some similar arguments in the proof of [2, Lemma 2.2] (see also [16]), we have $0<Z_{i}\left(y^{2}\right)<$ $Z_{i}\left(y^{1}\right)$ which yields $Z_{i}(y)$ is strictly decreasing with respect to $y$ in $\left[0, y^{*}\right]$. Thus, $F(y)=\sum_{i=1}^{n} Z_{i}(y)-\frac{\gamma n}{\beta a}$ is strictly decreasing with respect to $y$ in $\left[0, y^{*}\right]$. Since $F(0)=\sum_{i=1}^{n} Z_{i}(0)-\frac{\gamma n}{\beta a}=\sum_{i=1}^{n} \theta_{i}-\frac{\gamma n}{\beta a}>0$, $F\left(y^{*}\right)=-\frac{\gamma n}{\beta a}<0$, we can deduce from the monotonicity of $F(y)$ that there exists a unique $\tilde{y} \in\left(0, y^{*}\right)$ such that $F(\tilde{y})=0$. After substituting $\tilde{y}$ into the first equation of (4.76), we deduce that (4.76) admits a unique positive solution $\left(Z_{i}(\tilde{y}), \tilde{y}\right)$.

Proof of Theorem 2.6: Note that $0<\gamma<\frac{\beta a \sum_{i}^{n} \theta_{i}}{n}$ and $\lim _{d_{2} \rightarrow+\infty} \gamma^{*}\left(q, d_{1}, d_{2}\right)=\frac{\beta a \sum_{i}^{n} \theta_{i}}{n}$ guarantee that there exists a sufficiently large positive constant $D_{2}$ such that $0<\gamma<\gamma^{*}\left(q, d_{1}, d_{2}\right)$ when $d_{2}>D_{2}$. This implies that a positive steady state of system (1.6) exists for all large $d_{2}$ (see Theorem $2.1(2)$ ).

It can be shown similarly to Lemma 4.3 and $4.5(4)$ that $N_{i}^{*}, P_{i}^{*}$ are uniformly bounded as $d_{2} \rightarrow+\infty$. By using similar arguments as in the proof of Theorem 2.4, we may assume that $\left(N_{i}^{*}, P_{i}^{*}\right) \rightarrow\left(\hat{\theta}_{i}, z\right)$ as $d_{2} \rightarrow+\infty$ by passing to a subsequence if necessary, where $\left(\hat{\theta}_{i}, z\right)$ satisfies

$$
\begin{cases}\sum_{j=1}^{n}\left(d_{1} D_{i j}+q Q_{i j}\right) \hat{\theta}_{j}+\hat{\theta}_{i}\left(r_{i}-\frac{r_{i}}{k_{i}} \hat{\theta}_{i}-a z\right)=0, & i \in \mathcal{A}  \tag{4.78}\\ \sum_{i=1}^{n}\left(\beta a \hat{\theta}_{i}-\gamma\right)=0, & i \in \mathcal{A}\end{cases}
$$

By Lemma 4.7, it follows that $\left(\hat{\theta}_{i}, z\right)$ exists and is unique.

## 5 Discussion

In this paper, we consider the specialist predator-prey model (1.6) in a closed advective patchy environment. We obtain threshold dynamics in terms of the mortality rate of the specialist predators. In Theorem 2.1, we prove that the specialist predators will die out if their mortality rate exceeds a critical value $\gamma^{*}$ and persist if the mortality rate is less than $\gamma^{*}$. In Theorem 2.1, we also prove that, no matter how large advection and diffusion rates are, the specialist predators can invade successfully as long as they maintain a small mortality rate.

We also investigate the influence of advection and diffusion on the asymptotic profiles of the positive steady state solutions of systems (1.6) and find that diffusion and advection can dramatically affect the spatial distribution of species. In Theorems 2.3, we demonstrate that two species will coexist and concentrate at the patch $n$ for a large positive advection. This implies that the advection does not eliminate coexistence of species but significantly affect the distribution of species. The intuitive biological explanation is that predators always keep pace with the prey, allowing them to successfully invade and coexist with the prey at the patch $n$ as flow speed increases. In Theorems 2.4 and 2.6 , we show that, if the diffusion rate of the prey (resp. the predator) is large, the species will coexist.

If the prey has a small diffusion rate, in Theorems 2.1 and 2.2 , we prove that the specialist predators can always invade successfully as long as the mortality rate is suitably small.

If the specialist predators have a small diffusion rate, they can successfully invade but with a small population density which tends to zero as the diffusion rate goes to zero. The biological explanation is that the specialist predators cannot catch up with the prey if they do not move fast (see Theorem 2.2(5) and 2.5).

We end this section by proposing several interesting problems that deserve further consideration. The first one is that whether there is the uniqueness of positive steady state solutions of system (1.6). Note that the arguments of deriving the uniqueness as in Step 3 of [26, Theorem 3.1] or the proof of [24, Lemma 3.3, Theorem 3.4] do not work in our model (4.37) here. For our model, a probable method to obtain the uniqueness is to verify the invertible of the coefficient matrix. However, due to the complexity of the coefficient matrix, it is difficult to calculate it's determinant. This requests us to further explore some new methods to calculate the determinant or to consider the uniqueness. Another problem concerns the dynamics of the specialist predator-prey model (1.6) in open advective patchy environments. Also, how does the dynamics change for the generalist predator-prey patchy system ? We leave these challenging problems for future investigation.
