### Abstract

A subset A of a topological space X is called *relatively functionally countable* (*RFC*) in X, if for each continuous function  $f : X \to \mathbb{R}$  the set f[A] is countable. We prove that all RFC subsets of a product  $\prod_{n \in \omega} X_n$  are countable, assuming that spaces  $X_n$  are Tychonoff and all RFC subsets of every  $X_n$  are

countable. In particular, in a metrizable space every RFC subset is countable. The main tool in the proof is the following result: for every Tychonoff

space X and any countable set  $Q \subseteq X$  there is a continuous function  $f : X^{\omega} \to \mathbb{R}^2$  such that the restriction of f to  $Q^{\omega}$  is injective.

*Keywords:* functionally countable subsets, countable products, metrizable spaces, Hilbert cube 2020 MSC: 54A25, 54B10, 54C05, 54C30

#### 1. Introduction

This paper comes from the following

Question 1.1 (A.V. Osipov). Is there an uncountable set  $A \subseteq [0, 1]^{\omega}$  such that for every continuous function  $f : [0, 1]^{\omega} \to \mathbb{R}$  the set f[A] is countable?

The author knows this problem from private communication with A.V. Osipov. In 2016 Osipov and A. Miller proved that the answer is no under  $\mathfrak{b} > \omega_1$ or cov(meager) >  $\omega_1$ , but they did not publish these results. Apparently, no one ever raised Question 1.1 in literature, although one can find some discussion at this problem on mathoverflow [5], where user fedja and T. Banakh

*Email address:* tony.lipin@yandex.ru (Anton E. Lipin)

proved the negative answer under  $\neg$ CH. In this paper we prove the negative answer in ZFC.

Instead of the term *projectively countable* as in [5], let us use the following notion.

**Definition 1.2.** A subset A of a topological space X is called *relatively* functionally countable (*RFC*) in X, if for every continuous function  $f: X \to \mathbb{R}$  the set f[A] is countable.

Note that being an RFC subset is not the same as being a functionally countable subspace. For instance, if A is an uncountable discrete and X is one-point compactification of A, then A is an RFC subset and is not a functionally countable subspace. However, every functionally countable subspace is an RFC subset. A nice criterion of functional countability for perfectly normal spaces can be found in [4].

Let us describe the structure of this paper. The most complicated result here is (rather technical) Theorem 3.7. Section 3 is devoted entirely to its proof. Corollaries of Theorem 3.7 in terms of functional countability and, in particular, the negative answer to Question 1.1 can be found in Section 4.

#### 2. Preliminaries

We assume the following notation and conventions.

- We use the term *tree* and associated notation as in [3, Definition III.5.1] or [2, Definition 9.10] with the following amendments:
  - instead of "immediate successor" we say *son*;
  - the set of all leaves of a tree T is denoted by L(T);
  - we write  $T \leq P$  to say that T is a subtree of P.
- if a function  $f: X \to \mathbb{R}^2$  is bounded, then we denote ||f|| the uniform norm of f in any norm of the plane  $\mathbb{R}^2$ .
- the restriction of a function  $f: X \to Y$  to a set  $A \subseteq X$  is denoted by  $f|_A$ .
- *countable* means not greater than countable.

The following obvious proposition plays a significant role in our argumentation.

**Proposition 2.1.** Denote  $\Box = [-1, 1] \times [0, 1]$  and  $\bot = \{(x, y) \in [-1, 1] \times [0, 1] : x = 0 \text{ or } y = 0\}$ . Suppose we are given a countable set  $Q \subseteq [-1, 1] \times (0, 1]$ . Then there is a continuous function  $\varphi : \Box \to \bot$  such that (whenever  $x \in [-1, 1]$  and  $a \in Q$ ):

- (1)  $\varphi(x,0) = (x,0);$
- (2)  $\varphi(x,1) = (0,1);$
- (3)  $\varphi(a) \neq (0,0).$

Also let us note a trivial fact on RFC sets.

**Proposition 2.2.** If a subset A of a topological space X is RFC, then for every natural n and any continuous  $f : X \to \mathbb{R}^n$  the set f[A] is countable.

## 3. Constructing maps into the plane $\mathbb{R}^2$

In this section we use functions, whose codomains are sets of some special form in the plane  $\mathbb{R}^2$ . To define this special form we need the following two definitions.

**Definition 3.1.** We say that a triple (p, I, U) is a *sprig*, if all the following conditions are satisfied:

- (a) p is a point in  $\mathbb{R}^2$ ;
- (b) I is a line segment in  $\mathbb{R}^2$  and p is an end-point for I;
- (c) U is a neighborhood of  $I \setminus \{p\}$ .

**Definition 3.2.** We say that a rooted tree (T, <) of finite height is an *oak*, if all its elements are sprigs and every  $t = (p, I, U) \in T$  satisfies the following conditions:

- (A) if (q, J, V) is a son of t, then  $q \in I \setminus \{p\}, J \cap I = \{q\}, \overline{V} \subseteq U$  and  $\overline{V} \cap I = \{q\};$
- (B) if  $(q_1, J_1, V_1)$  and  $(q_2, J_2, V_2)$  are different sons of t, then  $\overline{V_1} \cap \overline{V_2} = \emptyset$ .
  - If (T, <) is an oak and  $T = \{(p_t, I_t, U_t) : t \in T\}$ , then we denote:
  - $Y(T) = \bigcup_{t \in T} I_t;$

- $K(T) = \{p_t : t \in T\}$  (from <u>K</u>nots);
- $C(T) = \bigcup_{t \in L(T)} (I_t \setminus \{p_t\})$  (from <u>C</u>rown);
- $R(T) = Y(T) \setminus C(T)$ .

Note that the order < of an oak (T, <) is determined by the family T, so we lose no information writing T instead of (T, <).

**Definition 3.3.** Suppose  $T \leq P$  are oaks and X is a space. We say that a function  $g: X \to Y(P)$  is a *T*-evolution of a function  $f: X \to Y(T)$ , if for all  $a \in X$  such that  $f(a) \in R(T)$  we have g(a) = f(a).

**Definition 3.4.** Suppose T is an oak, X is a space and  $Q \subseteq X$ . We say that a continuous function  $f: X \to Y(T)$  is a (T, X, Q)-lifting, if  $f[Q] \subseteq C(T)$ .

**Definition 3.5.** Suppose T is an oak, X is a space,  $Q \subseteq X$  and  $\mathcal{W}$  is a cover of the set Q. We say that a (T, X, Q)-lifting f is  $(T, X, Q, \mathcal{W})$ -splitting, if for every leaf  $(p, I, U) \in L(T)$  there is  $W \in \mathcal{W}$  such that  $f^{-1}[I] \cap Q \subseteq W$ .

**Lemma 3.6.** Suppose T is an oak, X is a Tychonoff space, a set  $Q \subseteq X$  is countable, f is a (T, X, Q)-lifting, W is an open cover of the set Q and  $\varepsilon > 0$ . Then there is an oak  $P \succeq T$  and a (P, X, Q, W)-splitting T-evolution g of the function f such that  $||f - g|| < \varepsilon$ .

*Proof.* Fix any indexing  $Q = \{a_n : n \in \omega\}$ . Denote  $f_0 = f$  and  $T_0 = T$ . Now let us presume that for some  $n \in \omega$  we have an oak  $T_n \succeq T$  and a continuous function  $f_n : X \to Y(T_n)$  with the following properties:

- (A1) the set  $T_n \setminus T$  is finite;
- (A2)  $f_n[Q] \cap (R(T) \cup K(T_n)) = \emptyset;$
- (A3) for every  $(p, I, U) \in T_n \setminus T$  there is  $W \in \mathcal{W}$  such that  $f_n^{-1}[I] \subseteq W$ .

Let us take  $t_n = (p_n, I_n, U_n) \in T_n$  such that  $f_n(a_n) \in I_n$ . If  $t_n \notin T$ , define  $T_{n+1} = T_n$  and  $f_{n+1} = f_n$ . Otherwise choose any interval  $H_n \subseteq I_n$  which contains the point  $f_n(a_n)$  and is small enough to satisfy the following two properties:

(H1) the length of  $H_n$  is less than  $\varepsilon/2^{n+2}$ ; (H2)  $\overline{H_n} \cap K(T_n) = \emptyset$ .

Take any sprig  $s_n = (q_n, J_n, V_n)$  such that

- (S1)  $q_n \in H_n \setminus f_n[Q];$
- (S2)  $T_{n+1} = T_n \cup \{s_n\}$  is an oak;
- (S3) the length of  $J_n$  is less than  $\varepsilon/2^{n+2}$ .

Suppose  $a_n \in W_n \in \mathcal{W}$ . Denote  $O_n = W_n \cap f_n^{-1}[H_n]$ ; note that it is an open set. Choose any continuous function  $h_n : X \to [0,1]$  such that  $h_n(a_n) = 1$  and  $h_n[X \setminus O_n] = \{0\}$ .

Now let us take any continuous function  $\varphi_n : \overline{H_n} \times [0,1] \to \overline{H_n} \cup J_n$  with the properties as in Proposition 2.1, namely that, whenever  $x \in \overline{H_n}$  and  $a \in Q \cap O_n$ :

- (F1)  $\varphi_n(x,0) = x;$
- (F2)  $\varphi_n(x,1) \in J_n \setminus \{q_n\};$
- (F3)  $\varphi_n(f_n(a), h_n(a)) \neq q_n$ .

Define the function  $f_{n+1}: X \to Y(T_{n+1})$  in the following way:

$$f_{n+1}(a) = \begin{cases} \varphi_n(f_n(a), h_n(a)), & a \in O_n; \\ f_n(a), & a \in X \setminus O_n. \end{cases}$$

It is easy to see that  $T_{n+1}$  and  $f_{n+1}$  satisfy the recursion assumption and  $||f_{n+1} - f_n|| < \varepsilon/2^{n+1}$ .

Thus, the sequence  $(f_n)_{n \in \omega}$  uniformly converges to some continuous function  $g: X \to \mathbb{R}^2$  such that  $||f - g|| < \varepsilon$ . The tree  $P = \bigcup_{n \in \omega} T_n \succeq T$  is an oak (and its height is not greater than height of T plus 1). It is also not difficult to see that g is a  $(P, X, Q, \mathcal{W})$ -splitting T-evolution of the function f.  $\Box$ 

**Theorem 3.7.** Suppose X is a Tychonoff space and a set  $Q \subseteq X$  is countable. Then there is a continuous function  $f: X^{\omega} \to \mathbb{R}^2$  such that its restriction to  $Q^{\omega}$  is injective.

*Proof.* For every  $n \in \mathbb{N}$  choose some open cover  $\mathcal{W}_n$  of the set  $Q^n$  in the space  $X^n$  in such a way that for any different points  $a, b \in Q^{\omega}$  there is  $n \in \mathbb{N}$  such that no element of  $\mathcal{W}_n$  contains both  $a|_n$  and  $b|_n$ .

Take a sprig t = (p, I, U), where  $p = \{0, 0\}$ ,  $I = [0, 1] \times \{0\}$  and  $U = \mathbb{R}^2$ . Denote  $T_1 = \{t\}$  and denote  $f_1(x) = (1, 0)$  for all  $x \in X$ .

Now suppose that for some  $n \in \mathbb{N}$  we have an oak  $T_n$  and a  $(T_n, X^n, Q^n)$ lifting  $f_n : X^n \to Y(T_n)$ .

By Lemma 3.6 there is an oak  $T_{n+1} \succeq T_n$  and a  $(T_{n+1}, X^n, Q^n, \mathcal{W}_n)$ splitting  $T_n$ -evolution  $g_n$  of the function  $f_n$  such that  $||f_n - g_n|| < 1/2^n$ . Define

the function  $f_{n+1}: X^{n+1} \to Y(T_{n+1})$  in such way that  $f_{n+1}(x_1, \ldots, x_{n+1}) = g_n(x_1, \ldots, x_n)$ , so the pair  $f_{n+1}, T_{n+1}$  satisfies the recursion assumption.

Now for all  $n \in \mathbb{N}$  define the functions  $h_n : X^{\omega} \to Y(T_n)$  as follows:  $h_n(x_1, x_2, \ldots) = f_n(x_1, \ldots, x_n)$ . We have  $||h_{n+1} - h_n|| = ||g_n - f_n|| < 1/2^n$ , so the sequence  $(h_n)_{n \in \mathbb{N}}$  uniformly converges to some continuous function  $f : X^{\omega} \to \mathbb{R}^2$ . It remains to note that f is as required.  $\square$ 

Of course, Theorem 3.7 may be extended to products of different spaces.

**Corollary 3.8.** Suppose we are given Tychonoff spaces  $X_n$  for all  $n \in \omega$  and countable sets  $Q_n \subseteq X_n$ . Then there is a continuous function  $f : \prod_{n \in \omega} X_n \to \mathbb{R}^2$  such that its restriction to  $\prod_{n \in \omega} Q_n$  is injective.

*Proof.* We can suppose that all  $X_n$  are pairwise disjoint subsets of some space X. Applying Theorem 3.7 to X and  $Q = \bigcup_{n \in \omega} Q_n$ , we obtain this corollary.  $\Box$ 

**Remark 3.9.** The plane  $\mathbb{R}^2$  in Theorem 3.7 can not be replaced by  $\mathbb{R}$ .

*Proof.* Suppose a function  $f : \mathbb{R}^{\omega} \to \mathbb{R}$  is continuous. Let us show that the restriction of f to  $\mathbb{Q}^{\omega}$  is not injective.

For all  $x_1, \ldots, x_n \in \mathbb{Q}$  let us denote  $H(x_1, \ldots, x_n) = \{s \in \mathbb{R}^{\omega} : s|_n = (x_1, \ldots, x_n)\}$ . Clearly, every set  $f[H(x_1, \ldots, x_n)]$  is connected. If some one of sets f[H(x)] is singleton, then  $f|_{\mathbb{Q}^{\omega}}$  is not injective. Otherwise, since f is continuous, we can choose rational numbers  $a_1 \neq b_1$  such that  $|f[H(a_1)] \cap f[H(b_1)]| > 1$ . Reasoning similarly, we get rational numbers  $a_2, a_3, \ldots$  and  $b_2, b_3, \ldots$  such that  $|f[H(a_1, \ldots, a_n)] \cap f[H(b_1, \ldots, b_n)]| > 1$  whenever  $n \in \mathbb{N}$ . It follows that  $f(a_1, a_2, \ldots) = f(b_1, b_2, \ldots)$ .

#### 4. Relatively functionally countable subsets of products

**Theorem 4.1.** Suppose we are given Tychonoff spaces  $X_n$  for all  $n \in \omega$  and all RFC subsets of every  $X_n$  are countable. Then all RFC subsets of  $\prod_{n \in \omega} X_n$  are countable.

*Proof.* Suppose a set  $A \subseteq \prod_{n \in \omega} X_n = Y$  is RFC. In particular, for every projection  $\pi_n : Y \to X_n$ , defined as  $\pi_n(x_1, x_2, \ldots) = x_n$ , the set  $Q_n = \pi_n[A]$  is countable.

By Corollary 3.8 there is a continuous function  $f: Y \to \mathbb{R}^2$  such that its restriction to  $\prod_{n \in \omega} Q_n$  (and hence to A) is injective. By Proposition 2.2 the set f[A] is countable, so A is countable too.

In particular, the answer to Question 1.1 is no.

**Corollary 4.2.** Every RFC subset of a metrizable space is countable.

*Proof.* It follows from Theorem 4.1 and the fact that every metrizable space can be embedded into  $\omega$ -th power of a metrizable hedgehog [1, Theorem 4.4.9].

Clearly, there is no possibility to replace  $\omega$  by  $\omega_1$  in Theorem 4.1, since the uncountable functionally countable space  $\omega_1$  can be embedded into  $X^{\omega_1}$ whenever X is Hausdorff and |X| > 1.

Question 4.3 ( $\neg CH$ ). Is there a set  $A \subseteq [0,1]^{\omega}$  such that  $|A| = \mathfrak{c}$  and for every continuous function  $f: [0,1]^{\omega} \to \mathbb{R}$  we have  $|f[A]| < \mathfrak{c}$ ?

More generally,

Question 4.4 ( $\neg CH$ ). Is there a metrizable space X and its subset A such that for every continuous  $f: X \to \mathbb{R}$  we have  $|f[A]| < |A| \le \mathfrak{c}$ ?

Acknowledgements. The author is grateful to Alexander V. Osipov for constant attention to this work.
