The spectral flow is ubiquitous in the physics of soliton-fermion interacting systems. We study the spectral flows related to a continuous deformation of background soliton solutions, which enable us to develop insight into the emergence of fermionic zero modes and the localization mechanism of fermion densities. We investigate a \mathbb{CP}^2 nonlinear sigma model in which there are the (anti-)instantons and also the sphalerons with vanishing topological charge. The standard Yukawa coupling of the fermion successfully generates infinite towers of the spectra and the spectral flow is observed when increasing the size of such solitons. At that moment, the localization of the fermions on the solitons emerges. The avoided crossings are also observed in several stages of the exchange of the flows, they are indicating a manifestation of the fermion exchange of the localizing nature.

Keywords: Topological soliton, Dirac fermion, Spectral flow

I. INTRODUCTION

Fermion-soliton interacting systems have been extensively investigated in a vast range of physics, including condensed matter physics, particle physics, planetary science and also cosmology. The normalizable modes with zero eigenenergy, the zero modes, certainly develop when fermions interact with soliton solutions [1, 2]¹, as indicated by the Atiyah-Singer index theorem [4–8].

The study of the topological solitons has been activated in the context of the fermion-soliton systems. In the ϕ^4 kink, localized zero energy fermions and their fractionalization occur [1, 9–11]. There are the normalizable zero modes in the vortex-fermion system [2, 12], and the 't Hooft-Polyakov magnetic monopoles [1, 13–18]. Another non-trivial effect is the nonconservation of the fermion numbers. The instanton in the Yang-Mills theory on four-dimensional Euclidean space [19] has the nontrivial vacuum structure and gives rise to an anomalous phenomenon i.e., the fractionalization of the fermion number and the electric charge [20]. The sphalerons [21, 22] in the Weinberg-Salam theory play a similar role to the instantons, leading to the nontrivial consequence [23].

In the case of the broken time reversal invariance, positive/negative energy eigenvalues of the fermions is asymmetric, which characterizes the spectral asymmetry N_{as} [6, 24–26]

$$N_{\text{as}} := \sum_{\varepsilon_\mu < 0} 1 - \sum_{\varepsilon_\mu > 0} 1,$$

where ε_μ are a tower of energy eigenvalues of fermions. The fermion number N_f in the fermion-soliton system is related to the spectral asymmetry as $N_f := \frac{1}{2}N_{\text{as}}$. The index theorem tells that the fermion number is equal to the topological charge Q up to the sign, i.e., $N_f \propto Q$ [6, 26]. The spectral flow of the fermion energy eigenvalues originates from the coincidence.

Numerous details about the number of fermionic zero modes are provided by the index theorem, but it offers less information about the spectral flow, which is a transition in the spectrum with a changing parameter of the soliton in the background. In the instanton or the sphaleron background, rearrangements of energy spectra occur, e.g. one negative energy level undergoes the transition to a positive energy level concerning the imaginary time evolution [23]. Such behavior is commonly referred to as the spectral flow [27–29], which is a manifestation of the anomaly [27, 30, 31]. In addition to gauge theories, nonlinear sigma models have also been studied [32–36]. The spectral flow argument is a direct tool for elucidating the connection between topology and flow of the fermions [25, 30, 31, 37, 38].

The bulk-edge correspondences in 2D topological insulators and 3D Weyl semimetals have been extensively studied in a vast number of literature [39–42]. The spectral flow argument arises at some stages in the research. A more astounding application can be found in the shallow water dynamics of the ocean sea [43, 44].

In this paper, we examine the spectral flow analysis with the \mathbb{CP}^2 nonlinear sigma model. The model possesses two types of analytical solutions: the (anti-)instanton solutions [45], and also the sphalerons, which are non-interacting mixtures of instanton and anti-instanton [46–48]. There are several possibilities to incorporate the fermionic degrees of freedom into the model, e.g., the minimal coupling [49] and the supersymmetric coupling [50]. In the present paper, we investigate a Yukawa coupling of the Dirac fermions with the instanton and also the sphaleron solutions. These solutions allow us to look at two significant issues. As we mentioned, the normalizable zero-mode solutions are caused by the finite charged topological solitons. Now, we shall study the spectral

¹ It depends on the coupling scheme between fermions and solitons. In the fermion-vortex system, for example, the zero mode does not appear in the gauge coupling [3] while it does in the Yukawa coupling [2].

flow of Dirac fermions interacting with the net-zero topological charged solutions. Another topic is that we shall study *the full* spectral flow analysis using the moduli parameters of the solutions. In Refs.[51, 52], a size parameter was introduced for realizing the flow of the fermions, which has nothing to do with the solution itself. Another way is that one can employ an interpolating field between the soliton and the vacuum configuration $\phi_{\text{int}} = (1 - \lambda)\phi_{\text{vac}} + \lambda\phi_{\text{sol}}$, $0 \leq \lambda \leq 1$, where the ϕ_{sol} and ϕ_{vac} denotes the soliton and the vacuum configuration [30, 32]. One successfully obtains the normalizable modes, but ϕ_{int} is only the exact solution at $\lambda = 1$. In terms of the whole range of the moduli parameters of the solutions, we obtain the spectral flow with the true background soliton solutions. As a result, we investigate the sequences of the flows as growing the parameters. At the moment, we ignore any back-reactions from the fermions to the soliton solutions, although the effects could be crucial for the structure of the solitons and also the spectral flows [36, 53–55].

This paper is organized as follows: In Sec. II, we introduce the solutions of the (anti-)instantons and the sphalerons. The topological charge is defined in this section. Their moduli parameters are described in Sec. II B. Sec. III is the fermionic model and the details of our numerical method. In Sec. IV, we present the results of the spectral flows for the anti-instanton and the mixture. In Sec. V, we are concentrating on the localization of the fermion density through the avoided crossing. Sec. VI is devoted to our conclusions.

II. \mathbb{CP}^2 NONLINEAR SIGMA MODEL

A nonlinear sigma model (NLSM) with a target space which is the complex projective space \mathbb{CP}^{N-1} is an important class of quantum field theories [45]. In any $N \geq 2$, the \mathbb{CP}^{N-1} NLSM has 2D mimic of (anti-) instanton solutions in Yang–Mills gauge theory. Moreover, there are further solutions in $N > 2$ that are a non-interacting mixture of instantons and anti-instantons [46–48], that we simply refer to it as the mixture.

Instantons in d -dimensional Euclidean space can be regarded as static topological solitons in $(d + 1)$ dimensions. A model consisting of fermions and instantons can have two different prescriptions. One is that, as utilized in Refs.[25, 31, 37, 56], fermions couple with instantons in a region of space where the instantons localize. Another involves embedding solutions in $(d + 1)$ dimensional spacetime. In this paper, we follow the latter. In the following, we concentrate on the case of the $N = 3$, but the extensions of $N \geq 3$ are straightforward.

A. The model and the formal solutions

In this subsection, we provide a formal introduction of the model and its solution. The static energy of the \mathbb{CP}^2 NLSM in $(2 + 1)$ -dimensional space-time is given by

$$E = \int d^2x (D_j Z)^\dagger \cdot (D_j Z), \quad j = 1, 2 \quad (1)$$

where $Z = (Z_1, Z_2, Z_3)^T$ is a three dimensional complex unit vector $Z^\dagger \cdot Z = 1$, and $D_j = \partial_j - Z^\dagger \cdot \partial_j Z$ defines a covariant derivative. Since soliton solutions should be of finite energy,

the field Z at the spatial infinity must be a constant vector up to $U(1)$ phase. Due to the boundary condition and the identification of \mathbb{CP}^2 : $Z \sim Z' = e^{i\alpha(x)}Z$, \mathbb{R}^2 is compactified to 2-sphere S^2 , and then $\pi_2(\mathbb{CP}^2) = \mathbb{Z}$. The solutions of \mathbb{CP}^2 NLSM are classified by an integer, so-called topological charge Q , which is defined as

$$Q = -\frac{i}{2\pi} \int d^2x \epsilon_{jk} (D_j Z)^\dagger \cdot (D_k Z), \quad j, k = 1, 2 \quad (2)$$

where ϵ_{jk} is an antisymmetric tensor: $\epsilon_{12} = -\epsilon_{21} = 1$, $\epsilon_{11} = \epsilon_{22} = 0$. In terms of the complex coordinates $x_\pm = x_1 \pm ix_2$ for convenience, the energy and the topological charge can be rewritten as

$$E = \int d^2x 2[|D_+ Z|^2 + |D_- Z|^2], \quad (3)$$

$$Q = \frac{1}{2\pi} \int d^2x 2[|D_+ Z|^2 - |D_- Z|^2] \quad (4)$$

with $D_\pm = \partial_\pm - Z^\dagger \cdot \partial_\pm Z$. The equation of motion (EOM) is

$$D_- D_+ Z + |D_+ Z|^2 Z = 0. \quad (5)$$

From Eq. (3) and Eq. (4), we get

$$E = 2\pi|Q| + 4 \int d^2x |D_\mp Z|^2 \geq 2\pi|Q|. \quad (6)$$

The equality is realized when the solution satisfies the Bogomol'nyi-Prasad-Sommerfield (BPS) equation

$$D_\mp Z = 0. \quad (7)$$

The solutions of the equation are referred to as the (anti-)instantons. Their forms can be written in terms of holomorphic vectors

$$Z^\pm = \frac{f(x_\pm)}{|f(x_\pm)|} \quad (8)$$

where $f(x_\pm)$ is 3-dimensional non-zero holomorphic vectors ($+$: instanton, $-$: anti-instanton). The solutions automatically satisfy the BPS equation (7) and also the EOM, and can thus minimize the energy, i.e., $E = 2\pi|Q|$. Eqs. (4), (7) tell us that the (anti-)instantons possess a positive (negative) topological charge. Furthermore, a more general class of solutions has been discovered by Din and Zakrzewski, that we refer to it as Din–Zakrzewski (DZ) solutions [46–48]. Using the Bäcklund transformation

$$P_+ g = \partial_+ g - \frac{g^\dagger \cdot \partial_+ g}{|g|^2} g, \quad (9)$$

with $g \in \mathbb{C}^3 \setminus \{0\}$, the DZ solutions are obtained as

$$Z_{(k)} = \frac{P_+^k f}{|P_+^k f|} \quad (k = 0, \dots, 2). \quad (10)$$

Note that $Z_{(k)}$ s are independent solutions of the EOM (5) for each k . One can verify that only $Z_{(0)}$ and $Z_{(2)}$ satisfy the BPS equation, i.e., $D_- Z_{(0)} = 0$ and $D_+ Z_{(2)} = 0$. This means that $Z_{(0)}$ has positive, and $Z_{(2)}$ has negative topological charge. Therefore, they are *instanton* and *anti-instanton* solutions respectively. Generally, the other solution, $k = 1$, does not satisfy the BPS equation. From Eq. (6), we can see that if

Fig. 1. The a dependences of \mathcal{Q}_I , \mathcal{Q}_A and \mathcal{Q}_M with $b = 1$. Although \mathcal{Q}_A and \mathcal{Q}_M have a blue curve ($a = 0.3$) that appears to be divergent, they are actually finite at the origin, i.e., $\mathcal{Q}_A(0) \sim -88$ and $\mathcal{Q}_M(0) \sim 88$, respectively.

Z satisfies the BPS equation (7), the energy is minimized, whereas if it does not, the energy is higher. Therefore, such a non-BPS solution is a saddle point for the energy. As we see later, it can be interpreted as a mixture solution of instantons and anti-instantons.

Since there are three types of the solutions ($Z_{(0)}, Z_{(1)}, Z_{(2)}$) in the $\mathbb{C}P^2$ NLSM. For all solutions, we give formal forms of the energy, the topological charge, and their densities

$$E_{(k)} = \int d^2x \mathcal{E}_{(k)},$$

$$\mathcal{E}_{(k)} := 2 \left[|D_+ Z_{(k)}|^2 + |D_- Z_{(k)}|^2 \right]; \quad (11)$$

$$Q_{(k)} = \frac{1}{2\pi} \int d^2x \mathcal{Q}_{(k)},$$

$$\mathcal{Q}_{(k)} := 2 \left[|D_+ Z_{(k)}|^2 - |D_- Z_{(k)}|^2 \right], \quad k = 0, 1, 2. \quad (12)$$

The $Z_{(0)}$ and $Z_{(2)}$ are the solutions of the BPS equation, but the $Z_{(1)}$ is not. More explicit form of the energy densities and the topological charge densities are given as

$$\mathcal{E}_{(0)} = 2|D_+ Z_{(0)}|^2, \quad \mathcal{E}_{(2)} = 2|D_- Z_{(2)}|^2,$$

$$\mathcal{E}_{(1)} = 2 \left[|D_+ Z_{(1)}|^2 + |D_- Z_{(1)}|^2 \right]; \quad (13)$$

$$\mathcal{Q}_{(0)} = 2|D_+ Z_{(0)}|^2, \quad \mathcal{Q}_{(2)} = -2|D_- Z_{(2)}|^2,$$

$$\mathcal{Q}_{(1)} = 2 \left[|D_+ Z_{(1)}|^2 - |D_- Z_{(1)}|^2 \right]. \quad (14)$$

From these, one directly checks that the energy and the topological charge of the instanton and the anti-instanton have the connection $E_{(0)} = 2\pi Q_{(0)}$ and $E_{(2)} = 2\pi |Q_{(2)}|$. Also, after some algebra (see the Appendix A), we can confirm that the components of $\mathcal{Q}_{(1)}$ and $\mathcal{E}_{(1)}$ can be written as

$$|D_+ Z_{(1)}|^2 = |D_- Z_{(2)}|^2, \quad |D_- Z_{(1)}|^2 = |D_+ Z_{(0)}|^2. \quad (15)$$

As a result, the energy $E_{(1)}$ and the topological charge $Q_{(1)}$ have the form below:

$$E_{(1)} = E_{(0)} + E_{(2)}; \quad (16)$$

$$Q_{(1)} = |Q_{(2)}| + (-Q_{(0)}). \quad (17)$$

From these, $Z_{(1)}$ can be interpreted as a non-interacting composite of the $Q_{(0)}$ instantons and the $Q_{(2)}$ anti-instantons.

Therefore, we call the solution $Z_{(1)}$ as the mixture. Since $|Q_{(2)}|$ and $(-Q_{(0)})$ are the positive and negative part of the topological charge of the mixture, then the anti-instanton $Z_{(2)}$ and the instanton $Z_{(0)}$ are the instanton and anti-instanton part of the mixture, respectively. To make the meaning more clear, we rewrite $(Z_{(0)}, Z_{(1)}, Z_{(2)})$ to (Z_I, Z_M, Z_A) which stand for the instanton, the mixture, and the anti-instanton solutions, respectively. Accordingly, the energy, the topological charges and the densities are now (E_I, E_M, E_A) , (Q_I, Q_M, Q_A) , $(\mathcal{E}_I, \mathcal{E}_M, \mathcal{E}_A)$ and $(\mathcal{Q}_I, \mathcal{Q}_M, \mathcal{Q}_A)$.

B. The explicit solutions

In this subsection, we construct the explicit DZ solutions in the $\mathbb{C}P^2$ NLSM, with introducing the parameters which govern the deformation of solutions. We employ a simple holomorphic vector $f(x_+) \in \mathbb{C}^3 \setminus \{0\}$

$$f = \begin{pmatrix} 1 \\ a\rho \exp[i\phi] \\ b\rho^2 \exp[2i\phi] \end{pmatrix} \quad (18)$$

where (ρ, ϕ) denote polar coordinates defined through $x_{\pm} = x_1 \pm ix_2 = \rho \exp[\pm i\phi]$ and (a, b) are generally complex constants. Here we note that thanks to $U(3)$ global symmetry of the model (3), they are set to be non-negative real numbers without loss of generality. For the boundary conditions imposed on the soliton solutions, the finiteness of (a, b) is required.

By the nonlinear operator P_+ acting on f , we obtain the DZ solutions (Z_I, Z_M, Z_A) as followings:

$$Z_I = \frac{f}{|f|} = \frac{1}{\sqrt{\Delta_1}} \begin{pmatrix} 1 \\ a\rho \exp[i\phi] \\ b\rho^2 \exp[2i\phi] \end{pmatrix}, \quad (19)$$

$$Z_M = \frac{P_+ f}{|P_+ f|} = \frac{1}{\sqrt{\Delta_1 \Delta_2}} \begin{pmatrix} -(a^2 + 2b^2 \rho^2) \rho \exp[-i\phi] \\ a(1 - b^2 \rho^4) \\ b(2 + a^2 \rho^2) \rho \exp[i\phi] \end{pmatrix}, \quad (20)$$

$$Z_A = \frac{P_+^2 f}{|P_+^2 f|} = \frac{1}{\sqrt{\Delta_2}} \begin{pmatrix} ab\rho^2 \exp[-2i\phi] \\ -2b\rho \exp[-i\phi] \\ a \end{pmatrix}. \quad (21)$$

Fig. 2. The b dependences of Q_I , Q_A and Q_M with $a = 1$.

where (Δ_1, Δ_2) are defined by

$$\begin{aligned}\Delta_1 &\equiv |f|^2 = 1 + a^2\rho^2 + b^2\rho^4, \\ \Delta_2 &\equiv |f|^2|P_+f|^2 = a^2 + 4b^2\rho^2 + a^2b^2\rho^4.\end{aligned}$$

Here we emphasize that, for arbitrary parameters $(a, b) \in (0, \infty)$, Z_I , Z_M and Z_A are exact solutions of EOM (5). We designate Eq.(19)–Eq.(21) as axially symmetric solutions because the topological charge densities and energy densities evaluated by (19)–(21) are the function of the radial coordinate ρ .

Table. 1. Values of the topological charges at the boundaries of the parameter limits.

The parameters	Q_I	Q_M	Q_A
$a = 0, b = \text{finite}$	2	-2	0
$\frac{1}{a} = 0, b = \text{finite}$	0	2	-2
$a = \text{finite}, b = 0$	1	-1	0
$a = \text{finite}, \frac{1}{b} = 0$	0	1	-1

The topological charge densities can be written as

$$Q_I = 2 \frac{\Delta_2}{(\Delta_1)^2}, \quad (22)$$

$$Q_M = 2 \left(4a^2b^2 \frac{\Delta_1}{(\Delta_2)^2} - \frac{\Delta_2}{(\Delta_1)^2} \right), \quad (23)$$

$$Q_A = -2 \cdot 4a^2b^2 \frac{\Delta_1}{(\Delta_2)^2}. \quad (24)$$

After the integration, we obtain the topological charges

$$Q_I = 2, \quad Q_M = 0, \quad Q_A = -2. \quad (25)$$

which is supported for all the parameters choice $(a, b) \in (0, \infty)$. It should be emphasized that we obtain completely

different values for the topological charges when we use the limiting values of the parameters, such as $\frac{1}{a} = 0$. The results are summarized in Table. 1. As a result, the deformations of the solutions successfully induce the spectral flow since the DZ solutions (19)–(21) are the function of the parameters. For example, a parameter sequence $a : 0 \rightarrow \text{finite} \rightarrow \infty$ with finite b of the anti-instanton corresponds to a transition of the anti-instanton charge $Q_A : 0 \rightarrow -2 \rightarrow -2$, that certainly causes the two levels to cross the zero energy line as a grows.

III. FERMIONIC SIGMA MODEL

We consider the fermions coupled with the DZ solutions that are embedded into $(2 + 1)$ dimensional spacetime.

A. The Effective Action and the NLSM

For the construction of the model, we begin with a partition function \mathcal{Z} defined in three dimensional Euclidean space

$$\mathcal{Z} = \int \mathcal{D}Z \mathcal{D}\Psi \mathcal{D}\bar{\Psi} \exp \left[- \int d^3x \bar{\Psi} i \mathcal{D} \Psi \right]. \quad (26)$$

where $i \mathcal{D} \equiv i \gamma_\mu \partial_\mu + m X$ is called a Dirac operator. Here $m \in \mathbb{R}$ is a coupling constant and the gamma matrices γ_μ are given by the standard Clifford algebra

$$\{\gamma_\mu, \gamma_\nu\} = -2\delta_{\mu\nu} I_2. \quad (27)$$

In the two space dimensions, the matrices are given by $\gamma_1 = i\sigma_1$, $\gamma_2 = i\sigma_2$, and $\gamma_3 = -i\sigma_3$ where σ_j are the standard Pauli matrices. For the spectral flow analysis of the DZ solutions, we provide an efficient Yukawa-type coupling with a nice parametrization of $\mathbb{C}P^2$ in terms of a matrix-valued field X , i.e., the principal variable. [57, 58]. Formally, it is defined by

$$X(g) = g\sigma(g)^{-1}, \quad g \in \text{SU}(3). \quad (28)$$

It parametrizes the coset space $\mathbb{C}P^2 = \text{SU}(3)/\text{SU}(2) \otimes \text{U}(1)$ with the subgroup $\text{SU}(2) \otimes \text{U}(1)$ being invariant under the involutive automorphism ($\sigma^2 = 1$). It follows that $X(gk) =$

$X(g)$ for $\sigma(k) = k$, $k \in \text{SU}(2) \otimes \text{U}(1)$. The \mathbb{CP}^2 model possesses some symmetries. With the definition (28), one finds that the principal variable possesses the following property

$$X^\dagger = X^{-1} = X, \quad X^2 = I_3. \quad (29)$$

The low-energy effective action of this theory includes the aforementioned \mathbb{CP}^2 NLSM, which can be derived using a perturbative method. Here, we give a brief outline of the derivation using a normal derivative expansion [59, 60]. Integrating out the fermion fields in the partition function \mathcal{Z} , we obtain so-called a Dirac determinant

$$\int \mathcal{D}\Psi \mathcal{D}\bar{\Psi} \exp \left[- \int d^3x \bar{\Psi} i\mathcal{D}\Psi \right] = \det [i\mathcal{D}]. \quad (30)$$

Therefore, \mathcal{Z} is now

$$\mathcal{Z} \propto \int \mathcal{D}Z \exp [-S[X]], \quad S[X] = -\ln \det [i\mathcal{D}], \quad (31)$$

where S is called the effective action. $i\mathcal{D}$ is not Hermitian in Euclidean space, so we separate S into the real part and the imaginary part, $S = \text{Re } S + i \text{Im } S$ and each component becomes

$$\text{Re } S = -\frac{1}{2} \text{Sp} \ln \mathcal{D}^\dagger \mathcal{D}, \quad (32)$$

$$\text{Im } S = -\frac{1}{2i} \text{Sp} \ln \frac{i\mathcal{D}}{(i\mathcal{D})^\dagger} \quad (33)$$

where Sp means a functional trace taking all trace, i.e. matrices, states, and Euclidean space. Using a derivative expansion, we can evaluate the regularized real part of the action leaving only the first nonzero orders in $\frac{1}{m}$ as

$$\text{Re } S = \frac{m}{16\pi} \int d^3x \text{Tr}(\partial_\mu X \partial_\mu X) + \mathcal{O}(m^0). \quad (34)$$

Note that the principal variable has directly related to Z ,² such as

$$X = I_3 - 2Z \otimes Z^\dagger, \quad I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (35)$$

From this, we confirm that the action (34) becomes

$$\text{Re } S = \frac{m}{2\pi} \int dx_3 E[Z] + \mathcal{O}(m^0) \quad (36)$$

where $E(Z)$ is exactly the energy functional in the \mathbb{CP}^2 NLSM. Since the background field Z is independent of x_3 , the terms with imaginary time derivatives vanish. We can evaluate the imaginary part of the action in a similar fashion, which often contains the imaginary time derivative, and always vanishes in our model.

² Through this representation, the principal variable X has another direct connection with the $\text{SU}(3)$ color field \mathfrak{n} , such that $\mathfrak{n} = \frac{1}{3}I_3 - X$. For more general case of \mathbb{CP}^{N-1} , this kind of connection holds.

B. The Dirac Hamiltonian and Method for the Computation

For the spectral flow analysis, we numerically solve an eigenequation of the Dirac Hamiltonian \mathcal{H}

$$\mathcal{H}\psi(\mathbf{x}) = \varepsilon\psi(\mathbf{x}). \quad (37)$$

The Hamiltonian is derived from the Dirac operator

$$i\mathcal{D} = i\gamma_3(\partial_3 + \mathcal{H}). \quad (38)$$

The explicit form of the Hamiltonian is

$$\begin{aligned} \mathcal{H} &= i\gamma_3(i\gamma_k\partial_k + mX) \\ &= \begin{pmatrix} mX & \exp[-i\phi]\left(-\partial_\rho + \frac{i\partial_\phi}{\rho}\right) \\ \exp[i\phi]\left(\partial_\rho + \frac{i\partial_\phi}{\rho}\right) & -mX \end{pmatrix}. \end{aligned} \quad (39)$$

The Hamiltonian is commuted with an extended spin operator \mathcal{K} , so-called grand-spin operator [32], which is defined by

$$\mathcal{K} = l_3 + \frac{1}{2}\sigma_3 + \frac{1}{2}\lambda_3 + \frac{\sqrt{3}}{2}\lambda_8 \quad (40)$$

where l_3 , λ_3 and λ_8 represent an angular momentum operator, the third and eighth components of Gell-Mann matrices respectively. This operator satisfies $\mathcal{K}\mathcal{H}\mathcal{K}^{-1} = \mathcal{H}$. Therefore, the eigenvalue κ is conserved and labels the energy levels and the fermion densities. Also, irrespective of details of the background fields (19)–(21), when the fields are axially symmetric, the operator (40) always commutes with the Dirac Hamiltonian.

We solve the Dirac eigenequation (37) corresponding to the Hamiltonian (39) numerically. Since the Hamiltonian depends on the parameters (a, b) through the X , we can analyze the spectral flow of the fermions as a function of (a, b) .

Here we provide a quick overview of the procedure that is being developed in Ref.[61]. The secular equation for the energy eigenvalue ε is given by

$$\det(H - \varepsilon\tilde{I}) = 0, \quad (41)$$

where the matrix element of H and \tilde{I} is given by

$$H_{k^{(p)}, k^{(q)}} \equiv \int d^2x \Phi_\kappa^{(p)}(k^{(p)}, x)^\dagger \mathcal{H} \Phi_\kappa^{(q)}(k^{(q)}, x), \quad (42)$$

$$\tilde{I}_{k^{(p)}, k^{(q)}} \equiv \int d^2x \Phi_\kappa^{(p)}(k^{(p)}, x)^\dagger \Phi_\kappa^{(q)}(k^{(q)}, x). \quad (43)$$

To obtain these matrix representations, we construct plane-wave spinor bases $\Phi_\kappa^{(p)}$ which are the eigenvectors of the Hamiltonian of the massive free fermions $\mathcal{H}^0 =$

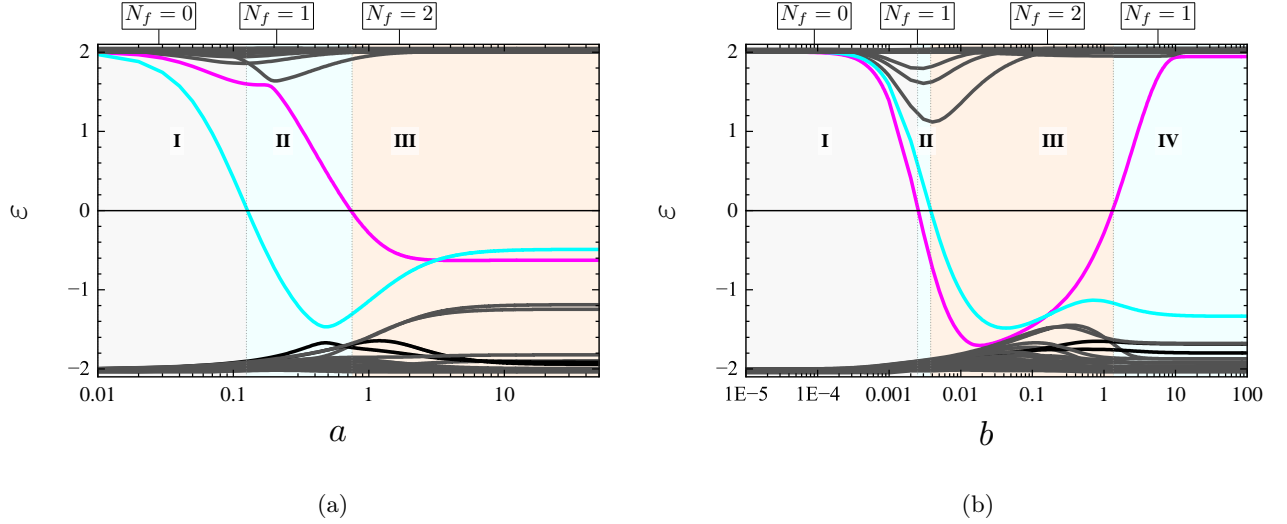

Fig. 3. The spectral flow of the anti-instanton solution. We illustrate the colored cyan and magenta lines as the crossing levels. (a) The flow with change of the parameter a with fixed $b = 1.0$, and (b) of the parameter b with $a = 1.0$.

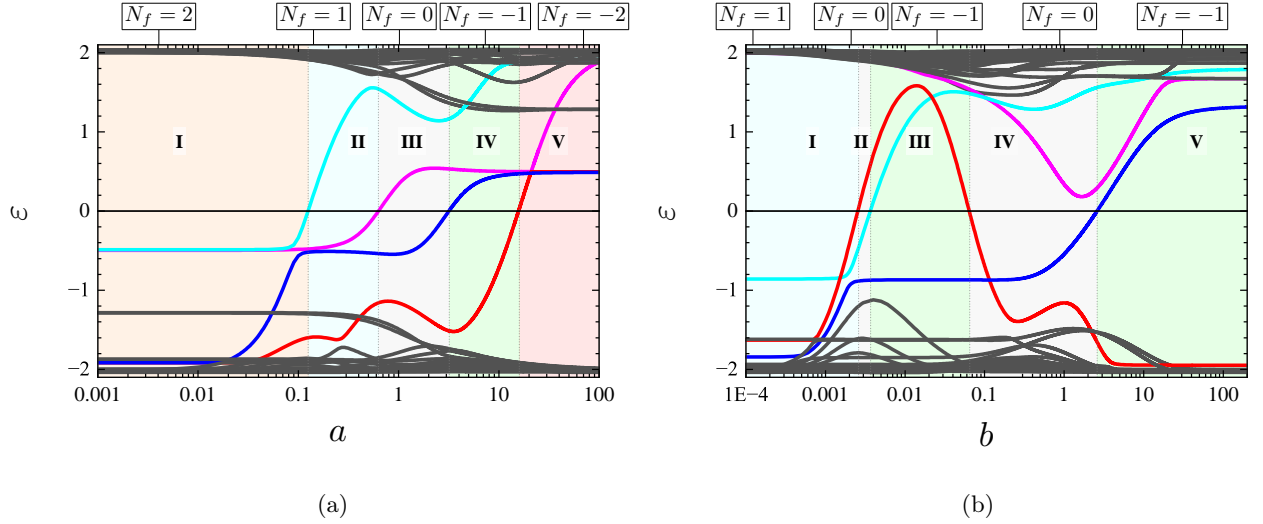

Fig. 4. The spectral flow of the mixture solution. We illustrate the colored red, blue, cyan and magenta lines as the crossing levels. (a) The flow with change of the parameter a with fixed $b = 1.0$, and (b) of the parameter b with $a = 1.0$.

$i\gamma_3(i\gamma_k\partial_k \pm m)$. They are given by

$$\Phi_\kappa^{(u)} = \mathcal{N}_i^{(u)} \begin{pmatrix} \zeta_+^{(u)} J_{\kappa-\frac{3}{2}}(k_i^{(u)}\rho) \exp[i(\kappa-\frac{3}{2})\phi] \\ \zeta_-^{(u)} J_{\kappa-\frac{1}{2}}(k_i^{(u)}\rho) \exp[i(\kappa-\frac{1}{2})\phi] \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad (44)$$

$$\Phi_\kappa^{(d)} = \mathcal{N}_i^{(d)} \begin{pmatrix} \zeta_-^{(d)} J_{\kappa-\frac{1}{2}}(k_i^{(d)}\rho) \exp[i(\kappa-\frac{1}{2})\phi] \\ \zeta_+^{(d)} J_{\kappa+\frac{1}{2}}(k_i^{(d)}\rho) \exp[i(\kappa+\frac{1}{2})\phi] \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad (45)$$

$$\Phi_\kappa^{(s)} = \mathcal{N}_i^{(s)} \begin{pmatrix} \zeta_+^{(s)} J_{\kappa+\frac{1}{2}}(k_i^{(s)}\rho) \exp[i(\kappa+\frac{1}{2})\phi] \\ \zeta_-^{(s)} J_{\kappa+\frac{3}{2}}(k_i^{(s)}\rho) \exp[i(\kappa+\frac{3}{2})\phi] \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \quad (46)$$

where $J_{l^{(p)}}(k_i^{(p)}\rho)$ are standard Bessel functions with the integer order $l^{(p)}$. The coefficients ζ are given by

$$\zeta_+^{(p)} = \begin{cases} 1 & (\omega_i^{(p)} > 0) \\ \frac{k_i^{(p)}}{|\omega_i^{(p)}|+m} & (\omega_i^{(p)} < 0) \end{cases}$$

$$\zeta_-^{(p)} = \begin{cases} -\frac{k_i^{(p)}}{\omega_i^{(p)}+m} & (\omega_i^{(p)} > 0) \\ 1 & (\omega_i^{(p)} < 0) \end{cases}$$

where $\omega_i^{(p)} = \pm\sqrt{(k_i^{(p)})^2 + m^2}$ are the vacuum energy eigenvalues.

We can construct the bases in a cylinder of radius R . This radius is ideally infinite, however, for numerical computation, it must take a finite value. Imposing boundary conditions

$$J_{l^{(p)}}(k_i^{(p)}R) = 0 \quad (47)$$

for $l^{(p)} = \kappa - \frac{3}{2}$, $\kappa - \frac{1}{2}$, or $\kappa + \frac{1}{2}$, we obtain some sets of discretized wave numbers $k_i^{(p)}$, $p = (u, d, s)$. The orthogonality conditions are given by

$$\begin{aligned} & \int_0^R d\rho \rho J_{l^{(p)}}(k_i^{(p)}\rho) J_{l^{(p)}}(k_j^{(p)}\rho) \\ &= \int_0^R d\rho \rho J_{l^{(p)}\pm 1}(k_i^{(p)}\rho) J_{l^{(p)}\pm 1}(k_j^{(p)}\rho) \\ &= \delta_{ij} \frac{R^2}{2} \left[J_{l^{(p)}\pm 1}(k_i^{(p)}R) \right]^2. \end{aligned} \quad (48)$$

Then, the normalization constants $\mathcal{N}_i^{(p)}$ are determined as

$$\mathcal{N}_i^{(p)} = \left[\frac{2\pi R^2 |\omega_i^{(p)}|}{|\omega_i^{(p)}| + m} \left(J_{l^{(p)}}(k_i^{(p)}R) \right)^2 \right]^{-\frac{1}{2}}. \quad (49)$$

In this setup, the plane waves form orthonormal bases.

By solving the secular equation (41) numerically for each parameter (a, b) , we can obtain some energy spectra $\{\varepsilon\}$ and corresponding wave functions $\{\psi\}$ for each κ . The eigenproblem (41) is solved by a standard matrix diagonalization solver 'dsyev' in the LAPACK, Math Kernel Library. Note that to study the localization of wave functions to the background soliton in real space, we calculate the fermion density which is defined by

$$\chi_\kappa(\rho) \equiv \frac{1}{2\pi} \int_0^{2\pi} d\phi \psi_\kappa^\dagger \psi_\kappa. \quad (50)$$

In Sec. V, we shall see property of the localization of χ is strongly linked to the spectral flow. For our numerical computations, we set $m = 2.0$, $R = 25.0$ and the number of discrete wavenumbers is chosen as 128, which gives a sufficient convergence.

IV. RESULTS: THE SPECTRAL FLOW

Many previous studies on spectral flow analysis have shown the level crossings in which the background fields do not represent the solution of the model [30, 32, 51, 52]. One of the characteristic features of this study is that the background field is always the solution of the equation of motion, because of the spectral flow with the moduli parameters (a, b) . Since changing (a, b) causes expansions or deformations of the solutions (see Fig. 1 and Fig. 2), it is possible to derive the spectral flow as a function of these moduli parameters. As the spectral flow analysis with the instanton solutions was previously discussed in Ref.[33], here we concentrate on the results of the anti-instanton and the mixture solution.

Fig.3 plots the behavior of the energy spectra for the anti-instantons with the parameters (a, b) change. First, we begin by analyzing the result of varying a shown in Fig.3(a). The topological charge $Q_A = 0$ at $a = 0$ and the background field is a vacuum solution; The number of positive and negative energy levels is strictly equal, as indicating the fermion number $N_f = 0$. The topological charge switches on $Q_A = -2$

for $a \neq 0$. As gradually increasing the parameter a , the two energy levels (colored in magenta and cyan) move from the positive continuum to the negative. As a result, the number of positive levels decreases and negative rises by 2 respectively, which corresponds to $N_{as} = 4$, and then $N_f = 2$. Note that N_f and Q_A are not necessarily correlated with each other. We see the local behavior of the energy levels of the regions I – V in Fig.3(a). From region I to II, the positive level decreases and the negative increases by 1 which corresponds to the change of $N_f : 0 \rightarrow 1$. From region II to III, the additional level comes from positive to negative, that is N_f is now 2. As a result, the number of zero modes (= the number of crossing zero energy lines) between regions I and III equals to 2. For larger a , since the topological charge Q_A continues to be -2 as shown in Table. 1, it is expected that no further net crossing can appear. Actually, in Fig. 3(a), one can confirm that the sign flip of the energy levels does not occur at large a .

It is worth discussing the behavior of the soliton at the vicinity of $a \sim 0$. As it was already utilized in previous analysis [51, 52, 62], the solitons with tiny size do not induce the fermion number at all. The situation is comparable to the bound state problem in the quantum mechanical potential well [63], when a bound state is absent below a certain threshold for the potential's size or depth. Therefore, the solution with sufficiently small a has the same effect as the vacuum configuration.

In the case with the parameter b (Fig.3(b)), more complex behavior emerges. Given that the series passes over $Q_A = 0 \rightarrow -2 \rightarrow -1$, there needs to be one more crossing zero energy. The magenta level descends and after that, it returns to the positive continuum. The transition of the topological charge appropriately results in this swing- back behavior, and the spectral flow appropriately connects the fermion number $N_f : 0 \rightarrow 2 \rightarrow 1$.

Next, we discuss the spectral flow for the mixture, sphaleron solution Z_M . This solution has zero net topological charge $Q_M = 0$ since it appears to composite two instantons and two anti-instantons. As we showed in Table 1, it behaves as (anti-) instantons at some parameter limits. Therefore, the spectral flow connects three different states: the anti-instanton, the mixture, and the instanton. As you can see in Fig.4, four zero modes manifest in the process of the spectral flows. We begin with the change of a in Fig.4(a). With $a = 0$ the topological charge Q_M is -2 , meaning that there are two more negative energy levels than there are in the vacuum state. As increasing a , the magenta levels and the cyan cross the zero-energy line from negative to positive, corresponding to the change of $N_f : 2 \rightarrow 0$. In region III, the number of negative levels and the positive levels are equal, i.e., $N_f = 0$, and the energy gap between them significantly decreases, there is a nontrivial modulation to the vacuum. Further increasing a , additional two levels, the red and the blue move from negative to positive, which corresponds to the change of $N_f : 0 \rightarrow -2$. In region V, the charge finally arrives $Q_M = 2$ at $a = \infty$. Since the topological charge changes from -2 to 2 , the four zero modes manifest in the process of the spectral flow.

As one can see in Fig.4(b), again the behavior for the change of the parameter b is a little more complex. The red level crosses the zero-energy line once and then crosses it again and goes back to the negative as growing b . In region I, the number of negative levels has increased by one. As increasing b , the red and cyan levels move from negative to positive, with the change of $N_f : -1 \rightarrow 0 \rightarrow 1$. A larger b ,

the red level crosses the zero-energy line again, and the blue level moves from negative to positive, corresponding to $N_f: 1 \rightarrow 0 \rightarrow 1$. In this process, the energy spectra cross the zero-energy line a total of four times, indicating the existence of four zero modes. However, the red level undergoes an even number of crossings, resulting in net two crossings over the entire spectral flow.

In conclusion, we obtain a firm result regarding the complete correlation among the number of zero modes in all ranges of the parameters (a, b) , the number of crossings of the zero energy line, and the change of Q or N_f . The net number of crossings equals the difference in topological charges at the parameter limits. On the other hand, the number of zero modes is not necessarily equivalent to them as seen in Fig.3(b) and Fig.4(b). To fix the exact number of the zero modes, we just count the number of times the fermion number changes. The spectral flow analysis is the best way to do this.

V. RESULTS: THE LOCALIZING FERMIONS

The localizing Dirac fermions coupled with the texture-type topological soliton (i.e., the skyrmion) were first addressed in Refs.[51, 52]. The zero modes of fermions are localized on a linear profile function: $f(r) \sim \pi - \pi r/\xi$, $0 \leq r \leq \xi$ of sufficiently large size ξ . We stress once more that they do not represent the solutions on the genuine background profile. In this section, we present the true localizing solutions on the genuine solitons.

First, we consider the case of the anti-instanton. At the vacuum, $Q_A = 0$ occurs with $a = 0$ or $b = 0$ (see Table. 1), and the fermions are not localized. As increasing the parameters a, b , the localization emerges. It is an intricate process that is often triggered by the energy level junction, which is also referred to as an energy level repulsion or an avoided crossing (AC). Fig. 5 shows the spectral flow and the fermion densities of varying a for the anti-instanton. The levels concerning the avoided crossing are $L_i, L'_i, i = 1, 2$, and they are situated at AC_1 and AC_2 . On the junctions, the localization property is exchanged with each other. For example, at around the AC_1 , below $a \sim 0.4$ the density of L'_1 is localized, while the L_1 is not. The L'_1 density starts to delocalize and the L_1 density localizes at $a \geq 0.4$. The same has happened at the AC_2 .

In Fig. 6, the spectral flow for the change of b is plotted and, one can see some ACs. The L_1, L_2 are the delocalized mode at $b \lesssim 10^{-4}$. They transition into localized modes via the AC_1 at $b \sim 0.01$. It is a almost similar behavior as the previous one, but now the level L_1 again encounters the next ACs, interaction between levels L_1 and L'_1 occurs at $b \sim 10$. Now the localization of the L_1 transitions to the counterpart L'_1 . The L'_1 is to be a continuous mode in the limit of $b \rightarrow \infty$, by the additional AC with the other continuous levels. Since the L_2 remains a discrete level for the whole b . Consequently, only the density of L_2 remains as the localizing mode for b large, that is, $b \sim 100$.

Our new insights into the fermion density localization are effective for understanding the case of the mixture solution. Fig. 7 shows the spectral flow of the mixture and the corresponding fermion density as a is varied. The four levels move from negative to positive as a grows, and the five ACs switch their localization and delocalization. This results in the localization of L_1 and L_2 densities in the region where a is small, and of L_3 and L_4 densities in the region where a is large. Re-

calling that the mixture behaves as the anti-instanton where a is sufficiently small and as the instanton where a is sufficiently large, one can see that the L_1 and L_2 densities are modes localized in the anti-instanton part of the mixture, and the L_3 and L_4 densities in the instanton part. Here, the behavior of the fermion density around $a = 1$ gives us a deep understanding of the mixture solution. In the region, the four fermion densities are localized as shown in Fig. 8. Consequently, the modes localized in the anti-instanton component and the instanton part coexist in this region. This means that the mixture with $Q_M = 0$ topological charge is not just a topologically trivial field, but has the function of trapping fermions and closing the energy gap as discussed in the previous section. Moreover, we can interpret fermions can detect the instantons and anti-instantons inside the mixture.

The (de)localization of fermion densities occur by the same mechanism in the spectral flow when b is varied, as shown in Fig. 9 and Fig. 10. Since the level L_3 crosses the zero-energy line an even number of times, the switching between localized and delocalized state occurs more than once (totally three times), as explained in the anti-instanton case.

VI. CONCLUSIONS

In this paper, we developed a novel approach to the realization of spectral flows pertaining to solitons' parameters in the CP^2 NLSM. We elucidated the connection between fermion density localization and the emergence of the fermion zero mode. Since the (anti-)instantons and the mixtures are the exact solutions with the two moduli parameters, our spectral flow analysis meaningful for the whole parameter space. At the spectral flow, some energy levels cross zero and the net number of the crossings coincides with the difference of topological charge of both ends of the flow. In the previous studies concerning the spectral flow, they claimed that the number of crossings should be equivalent to the number of zero modes. In this paper, we examined the flows between the solutions with the several charges, so the number of zero modes reflect how many times the topological charge changes its value.

The solutions consist of the anti-instanton ($Q_M < 0$), the mixture ($Q_M = 0$) and the instanton ($Q_M > 0$). The spectral flow analysis for the mixture is one of the most intriguing results. The energy gap closes in the $Q_M = 0$ region, indicating that the mixture realizes an instanton + anti-instanton composite with an interior structure rather than just being a topologically trivial one.

For the localization property of the fermions, generally, a large soliton solution induces the localizing fermion mode. It is also essential that the transition between localizing and delocalizing fermion density is observed. The avoided crossings between relevant energy levels play a role in such transition of the fermion density. In other words, it is concluded that the localization of the fermion density depends not only on the soliton size but also on the presence of AC in the spectral flow. The localization also occurs in the spectral flow of the mixture solution. Of particular interest is the fact that the four fermion densities are localized in the region $Q_M = 0$, containing both the instanton-localized and the anti-instanton-localized densities. This result implies that the fermions can successfully detect the (anti-) instanton inside the mixture.

Our spectral flow analysis, utilizing parameters of the solutions, has provided two crucial outcomes:

1. The spectral asymmetry,
2. The (de)localization of density of the fermions.

Both are deeply intertwined with the topology through the index theorem. The former emerges as a manifestation of the global change of the topology, represented by the difference in topological charges at the outside of the parameter space. (see Sec.V). On another hand, the latter has a more geometrical origin; it often arises through the avoided crossings in the spectral flow process. It is worth repeating that we were able to discuss the second property since the spectral flow was treated exactly. Since topology signifies a solitonic symmetry, the avoided crossings indicate signs of subtle modulation of the symmetry. Therefore, it is envisaged that the avoided crossings arising in the spectrum flow will serve as a harbor for new physics in the fermion-soliton system. As case studies, the avoided crossings could be explored in systems such as the flag manifold sigma model [64–67], an extension of the $\mathbb{C}P^{N-1}$ NLSM to large homotopy group, or composite soliton systems such as domain-wall skyrmion chain [68]. We will report on these issues in our subsequent papers.

Appendix A: Derivation of the mixed charge or energy density

In this appendix, we derive the topological charge or energy density of a $\mathbb{C}P^2$ mixture in terms of the (anti-) instanton charge density \mathcal{Q}_I and \mathcal{Q}_A or energy density \mathcal{E}_I and \mathcal{E}_A . We use the following properties without proof:

$$P_+^k f \perp P_+^{k'} f, \quad k \neq k', \quad (\text{A1})$$

$$P_+^0 f = f, \quad P_+^3 f = 0. \quad (\text{A2})$$

The first one can be verified recursively, and one can directly see that the second one is automatically satisfied for an arbitrary $f \in \mathbb{C}^3 \setminus \{0\}$.

Let us define a Bäcklund transformation:

$$P_{\pm} f = \partial_{\pm} f - \frac{f^{\dagger} \cdot \partial_{\pm} f}{|f|^2} f, \quad (\text{A3})$$

$$P_{\pm}^k f = \partial_{\pm} P_{\pm}^{k-1} f - \frac{(P_{\pm}^{k-1} f)^{\dagger} \cdot \partial_{\pm} P_{\pm}^{k-1} f}{|P_{\pm}^{k-1} f|^2} P_{\pm}^{k-1} f. \quad (\text{A4})$$

This definition leads a relation, $D_{\pm} \frac{g}{|g|} = \frac{1}{|g|} P_{\pm} g$ for an arbitrary $g \in \mathbb{C}^3 \setminus \{0\}$. Therefore, the topological charge densities

have the form below:

$$\begin{aligned} \mathcal{Q}_I(x) &= \mathcal{Q}_{(0)}(x) = 2 \left[|D_+ Z_{(0)}|^2 - |D_- Z_{(0)}|^2 \right] \\ &= \frac{2}{|f|^2} (|P_+ f|^2 - |P_- f|^2) = 2 \frac{|P_+ f|^2}{|f|^2}, \end{aligned} \quad (\text{A5})$$

$$\begin{aligned} \mathcal{Q}_M(x) &= \mathcal{Q}_{(1)}(x) = 2 \left[|D_+ Z_{(1)}|^2 - |D_- Z_{(1)}|^2 \right] \\ &= \frac{2}{|P_+ f|^2} (|P_+^2 f|^2 - |P_- P_+ f|^2), \end{aligned} \quad (\text{A6})$$

$$\begin{aligned} \mathcal{Q}_A(x) &= \mathcal{Q}_{(2)}(x) = 2 \left[|D_+ Z_{(2)}|^2 - |D_- Z_{(2)}|^2 \right] \\ &= \frac{2}{|P_+^2 f|^2} (|P_+^3 f|^2 - |P_- P_+^2 f|^2) \\ &= -2 \frac{|P_- P_+^2 f|^2}{|P_+^2 f|^2}. \end{aligned} \quad (\text{A7})$$

In the same way, the energy densities have the form below:

$$\mathcal{E}_I(x) = \mathcal{E}_{(0)}(x) = 2 \frac{|P_+ f|^2}{|f|^2}, \quad (\text{A8})$$

$$\mathcal{E}_M(x) = \mathcal{E}_{(1)}(x) = \frac{2}{|P_+ f|^2} (|P_+^2 f|^2 + |P_- P_+ f|^2), \quad (\text{A9})$$

$$\mathcal{E}_A(x) = \mathcal{E}_{(2)}(x) = 2 \frac{|P_- P_+^2 f|^2}{|P_+^2 f|^2}. \quad (\text{A10})$$

Our goal is to derive two relations:

$$\frac{|P_- P_+ f|^2}{|P_+ f|^2} = \frac{|P_+ f|^2}{|f|^2}, \quad (\text{A11})$$

$$\frac{|P_- P_+^2 f|^2}{|P_+^2 f|^2} = \frac{|P_+^2 f|^2}{|P_+ f|^2}. \quad (\text{A12})$$

These relations lead $\mathcal{Q}_M = |\mathcal{Q}_A| - \mathcal{Q}_I$ and $\mathcal{E}_M = |\mathcal{E}_A| + \mathcal{E}_I$.

1. Instanton part

In this subsection, we show

$$\frac{|P_- P_+ f|^2}{|P_+ f|^2} = \frac{|P_+ f|^2}{|f|^2}. \quad (\text{A13})$$

In order to see this, we calculate

$$P_- P_+ f = \partial_- P_+ f - \frac{(P_+ f)^{\dagger} \cdot \partial_- P_+ f}{|P_+ f|^2} P_+ f. \quad (\text{A14})$$

The second term of Eq. (A14) vanishes because of $P_+ f \perp f$,

$$\begin{aligned} &(P_+ f)^{\dagger} \cdot \partial_- P_+ f \\ &= \frac{1}{|f|^2} \left(-|\partial_+ f|^2 + \frac{|f^{\dagger} \cdot \partial_+ f|^2}{|f|^2} \right) (P_+ f)^{\dagger} \cdot f \\ &= 0. \end{aligned} \quad (\text{A15})$$

Thus we obtain

$$P_- P_+ f = \partial_- P_+ f = \frac{1}{|f|^2} \left(-|\partial_+ f|^2 + \frac{|f^{\dagger} \cdot \partial_+ f|^2}{|f|^2} \right) f. \quad (\text{A16})$$

Here we consider $|P_+f|^2 = |\partial_+f|^2 - \frac{|f^\dagger \cdot \partial_+f|^2}{|f|^2}$. Then, P_-P_+f has the form

$$P_-P_+f = -\frac{|P_+f|^2}{|f|^2}f, \quad (\text{A17})$$

and we have

$$|P_-P_+f|^2 = \frac{|P_+f|^4}{|f|^2}. \quad (\text{A18})$$

Therefore, we obtain

$$\frac{|P_-P_+f|^2}{|P_+f|^2} = \frac{|P_+f|^2}{|f|^2}. \quad (\text{A19})$$

2. Anti-instanton part

In this subsection, we show

$$\frac{|P_-P_+^2f|^2}{|P_+^2f|^2} = \frac{|P_+^2f|^2}{|P_+f|^2}. \quad (\text{A20})$$

The method is the same as for the instanton part. We calculate

$$P_-P_+^2f = \partial_-P_+^2f - \frac{(P_+^2f)^\dagger \cdot \partial_-P_+^2f}{|P_+^2f|}P_+^2f. \quad (\text{A21})$$

The second term of Eq. (A21) vanishes because of $P_+^2f \perp P_+f$, $P_+^2f \perp f$. First, we show this fact. The main component can be reduced into

$$\begin{aligned} \partial_-P_+^2f &= \partial_+\partial_-P_+f - \frac{|\partial_+P_+f|^2}{|P_+f|^2}P_+f \\ &\quad - \frac{(P_+f)^\dagger \cdot \partial_+\partial_-P_+f}{|P_+f|^2}P_+f \\ &\quad + \frac{(P_+f)^\dagger \cdot \partial_+P_+f}{|P_+f|^4}\partial_-|P_+f|^2P_+f \\ &\quad - \frac{(P_+f)^\dagger \cdot \partial_+P_+f}{|P_+f|^2}\partial_-P_+f. \end{aligned} \quad (\text{A22})$$

Since we have

$$\partial_-P_+f = P_-P_+f = -\frac{|P_+f|^2}{|f|^2}f \quad (\text{A23})$$

from Eq. (A16), the component of the third term of Eq. (A22) has the form

$$\begin{aligned} &(P_+f)^\dagger \cdot \partial_+\partial_-P_+f \\ &= -\frac{\partial_+|P_+f|^2}{|f|^2}(P_+f)^\dagger \cdot f \\ &\quad + \frac{|P_+f|^2}{|f|^4}\partial_+|f|^2(P_+f)^\dagger \cdot f \\ &\quad - \frac{|P_+f|^2}{|f|^2}(P_+f)^\dagger \cdot \partial_+f \\ &= -\frac{|P_+f|^4}{|f|^2}. \end{aligned} \quad (\text{A24})$$

And the component of the second term of Eq. (A22) is

$$|\partial_+P_+f|^2 = |P_+^2f|^2 + \frac{|(P_+f)^\dagger \cdot \partial_+P_+f|^2}{|P_+f|^2}. \quad (\text{A25})$$

As a result, Eq. (A22) can be written as follows:

$$\begin{aligned} \partial_-P_+^2f &= \partial_+\partial_-P_+f - \frac{|P_+^2f|^2}{|P_+f|^2}P_+f \\ &\quad - \frac{|(P_+f)^\dagger \cdot \partial_+P_+f|^2}{|P_+f|^4}P_+f + \frac{|P_+f|^2}{|f|^2}P_+f \\ &\quad + \frac{(P_+f)^\dagger \cdot \partial_+P_+f}{|P_+f|^4}\partial_-|P_+f|^2P_+f \\ &\quad - \frac{|(P_+f)^\dagger \cdot \partial_+P_+f|^2}{|P_+f|^2}\partial_-P_+f. \end{aligned} \quad (\text{A26})$$

Here using a relation

$$\partial_-|P_+f|^2 = (\partial_+P_+f)^\dagger \cdot P_+f, \quad (\text{A27})$$

Eq. (A26) has a more simple form,

$$\begin{aligned} \partial_-P_+^2f &= \partial_+\partial_-P_+f + \left(-\frac{|P_+^2f|^2}{|P_+f|^2} + \frac{|P_+f|^2}{|f|^2} \right) P_+f \\ &\quad + \frac{|(P_+f)^\dagger \cdot \partial_+P_+f|^2}{|f|^2}f. \end{aligned} \quad (\text{A28})$$

Recalling that $\partial_+\partial_-P_+f$ does not contain P_+^2f (see Eq. (A24)) and $\partial_+f = P_+f + \frac{f^\dagger \cdot \partial_+f}{|f|^2}f$, the second term of Eq. (A21) vanishes, i.e.

$$(P_+^2f)^\dagger \cdot \partial_-P_+^2f = 0. \quad (\text{A29})$$

Therefore we obtain

$$\begin{aligned} P_-P_+^2f &= \partial_-P_+^2f \\ &= \partial_+\partial_-P_+f + \left(-\frac{|P_+^2f|^2}{|P_+f|^2} + \frac{|P_+f|^2}{|f|^2} \right) P_+f \\ &\quad + \frac{(P_+f)^\dagger \cdot \partial_+P_+f}{|f|^2}f. \end{aligned} \quad (\text{A30})$$

From Eq. (A24), the first term of Eq. (A30) is

$$\begin{aligned} &\partial_+\partial_-P_+f \\ &= -\frac{\partial_+|P_+f|^2}{|f|^2}f + \frac{|P_+f|^2}{|f|^4}\partial_+|f|^2f - \frac{|P_+f|^2}{|f|^2}\partial_+f. \end{aligned} \quad (\text{A31})$$

Considering

$$\partial_+|P_+f|^2 = (P_+f)^\dagger \cdot \partial_+P_+f, \quad (\text{A32})$$

Eq. (A30) can be written as

$$P_-P_+^2f = -\frac{|P_+^2f|^2}{|P_+f|^2}P_+f, \quad (\text{A33})$$

and then we have

$$|P_- P_+^2 f|^2 = \frac{|P_+^2 f|^4}{|P_+ f|^2}. \quad (\text{A34})$$

Therefore, we obtain the relation

$$\frac{|P_- P_+^2 f|^2}{|P_+^2 f|^2} = \frac{|P_+^2 f|^2}{|P_+ f|^2}. \quad (\text{A35})$$

Then, from Eq. (A19) and Eq. (A35), we find $|D_+ Z_{(1)}|^2 = |D_- Z_{(2)}|^2$ and $|D_- Z_{(1)}|^2 = |D_+ Z_{(0)}|^2$.

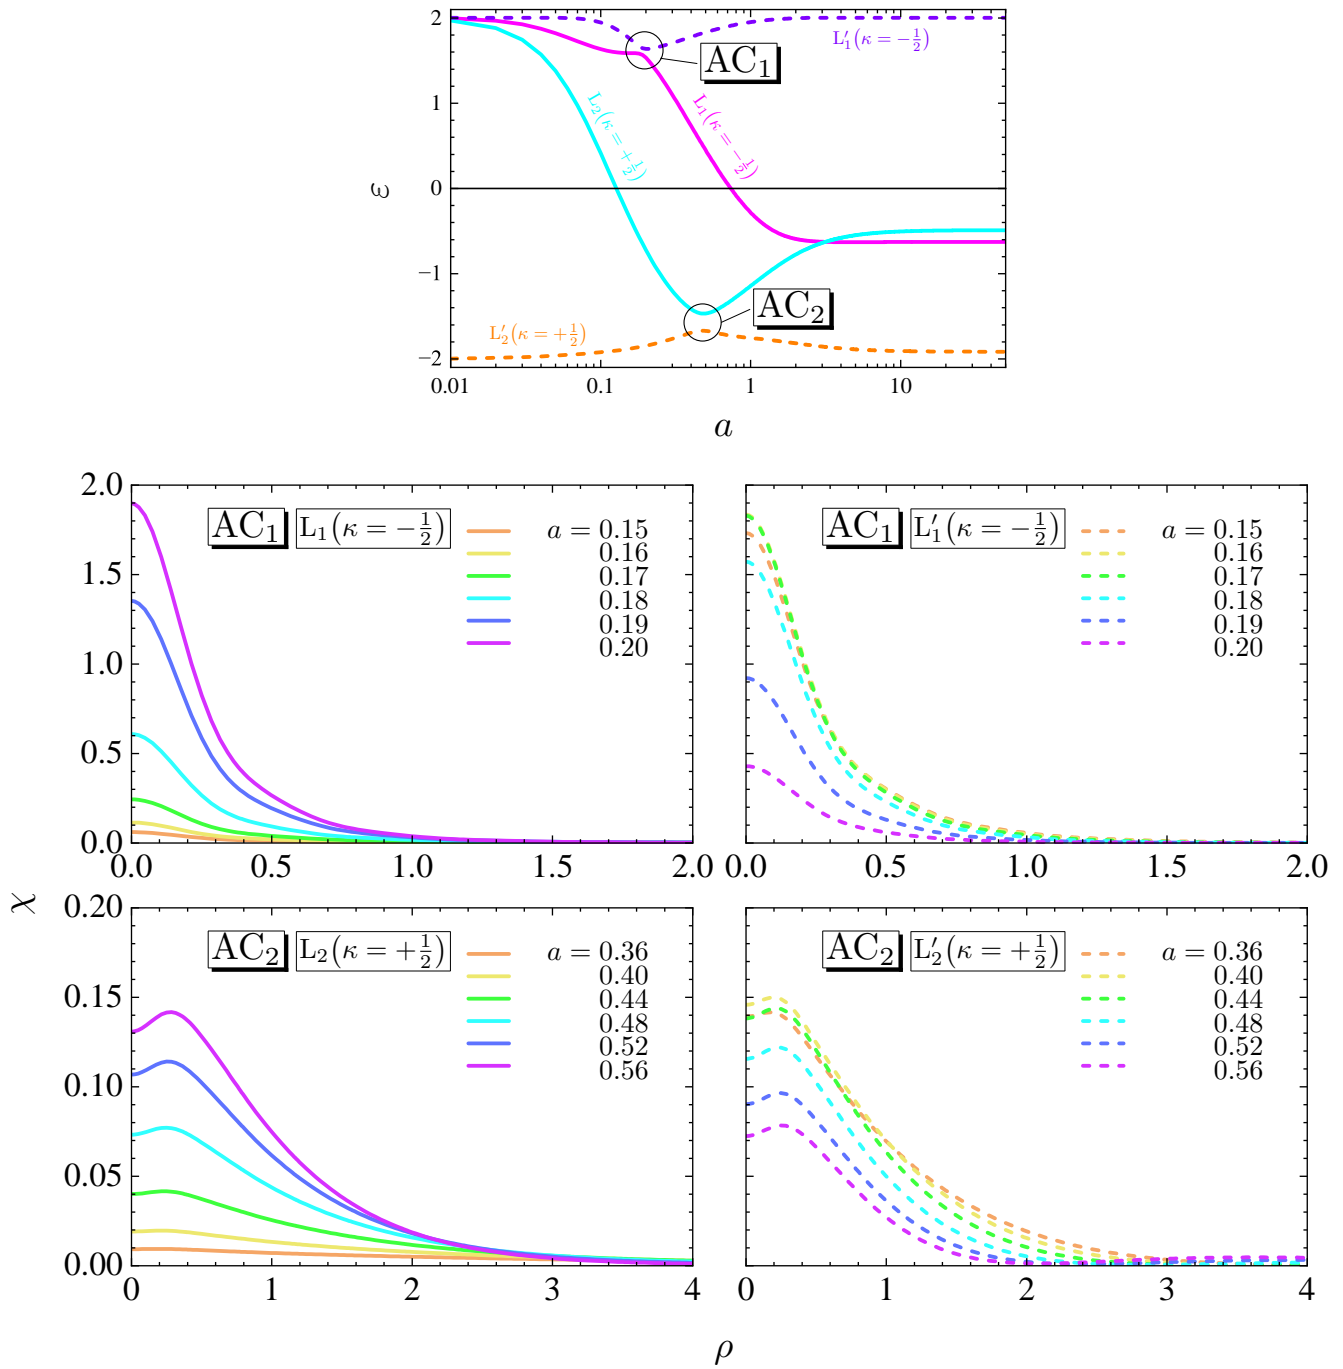

Fig. 5. The spectral flow of the anti-instanton by changing a and corresponding fermion densities concerning the ACs, the avoided crossings, which are the specific level repulsions with the exchange of the localization property. In the figure of the spectral flow, only the levels crossing the zero-energy line and the partner of the avoided crossing are shown. The figures of fermion densities shows the fermion densities with their quantum number related to the AC.

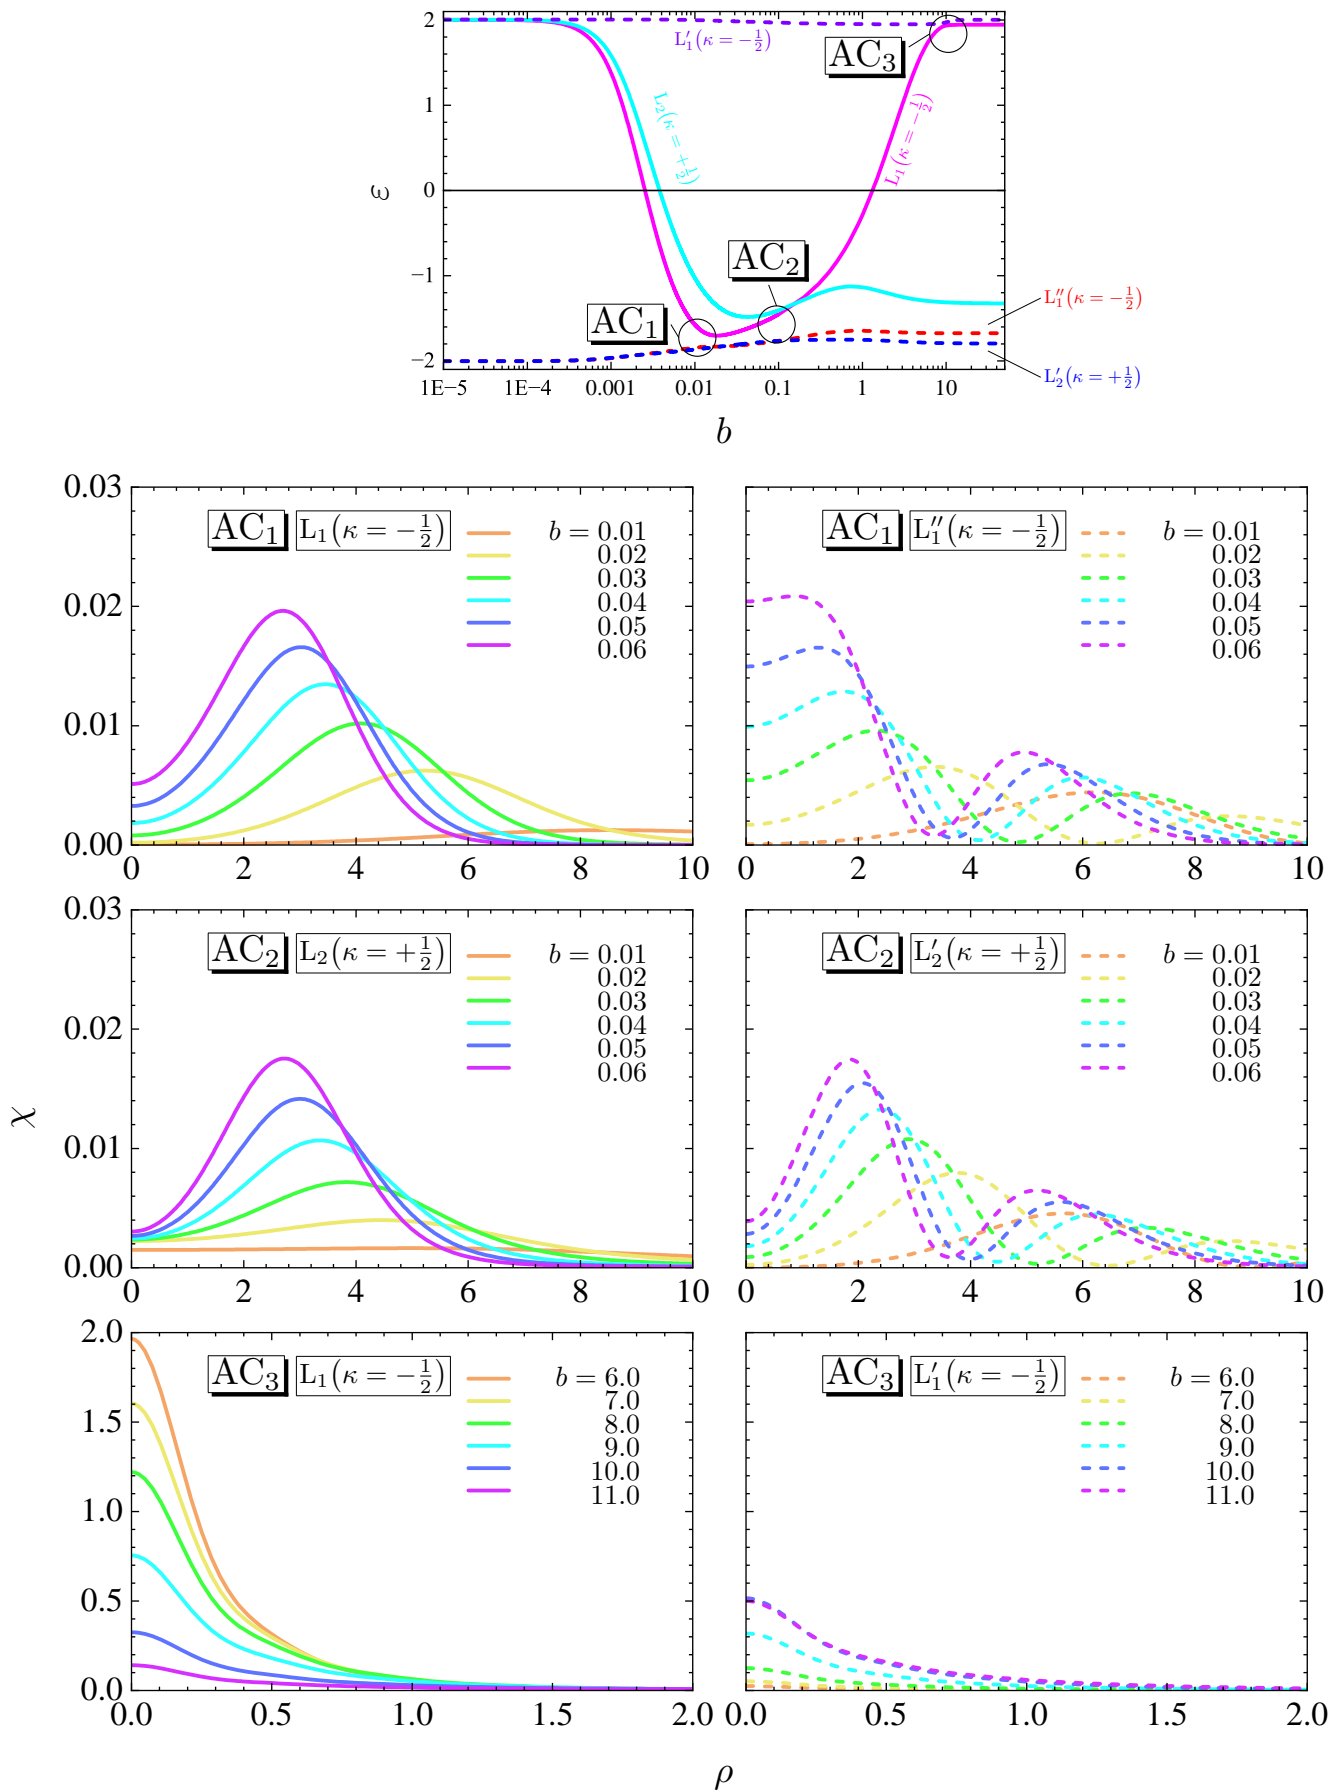

Fig. 6. The spectral flow of the anti-instanton by changing b and corresponding fermion densities around the ACs, the avoided crossings. In the figure of the spectral flow, only the levels crossing the zero-energy line and the partner of the avoided crossing are shown. The figures of fermion densities shows the fermion densities with their quantum number related to the AC. It should be noted that L_1'' and L_2' oscillate because of their respective delocalizations. AC_2 : (left,right)=(cyan,blue), AC_3 : (left,right)=(magenta,violet)

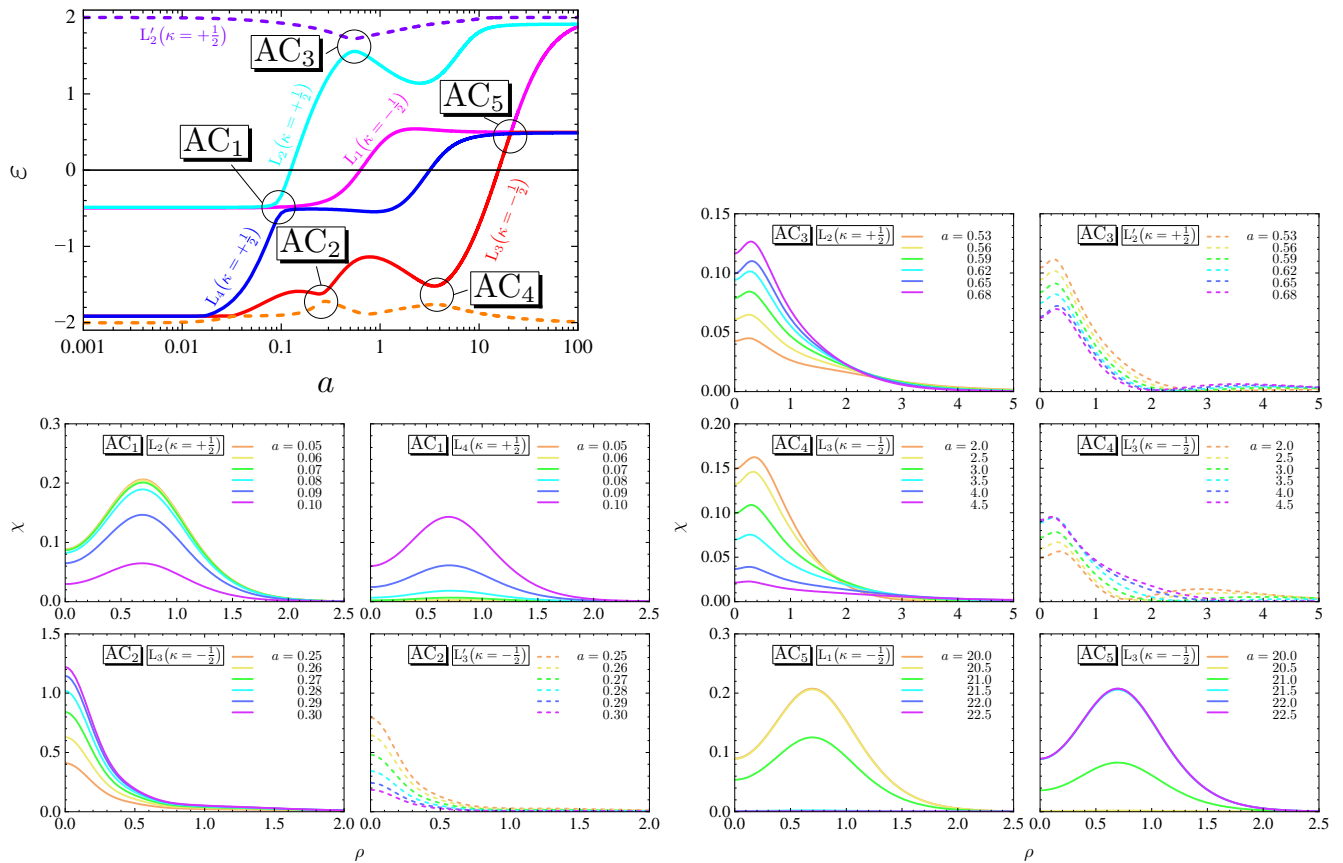

Fig. 7. The spectral flow of the mixture by changing a and corresponding fermion densities around the ACs, the avoided crossings. In the figure of the spectral flow, only the levels crossing the zero-energy line and the partner of the avoided crossing are shown. The figures of fermion densities shows the fermion densities with their quantum number related to the AC.

Fig. 8. The typical behaviors of fermion densities in terms of L_1 , L_2 , L_3 and L_4 , concerning the five types of the avoided crossings. For small a , below the AC₁, the densities of L_1 and L_2 are localized. In intermediate regions, between the AC₃ and AC₄, all of the densities are localized. For large a , above the AC₅, the densities of L_3 and L_4 are localized.

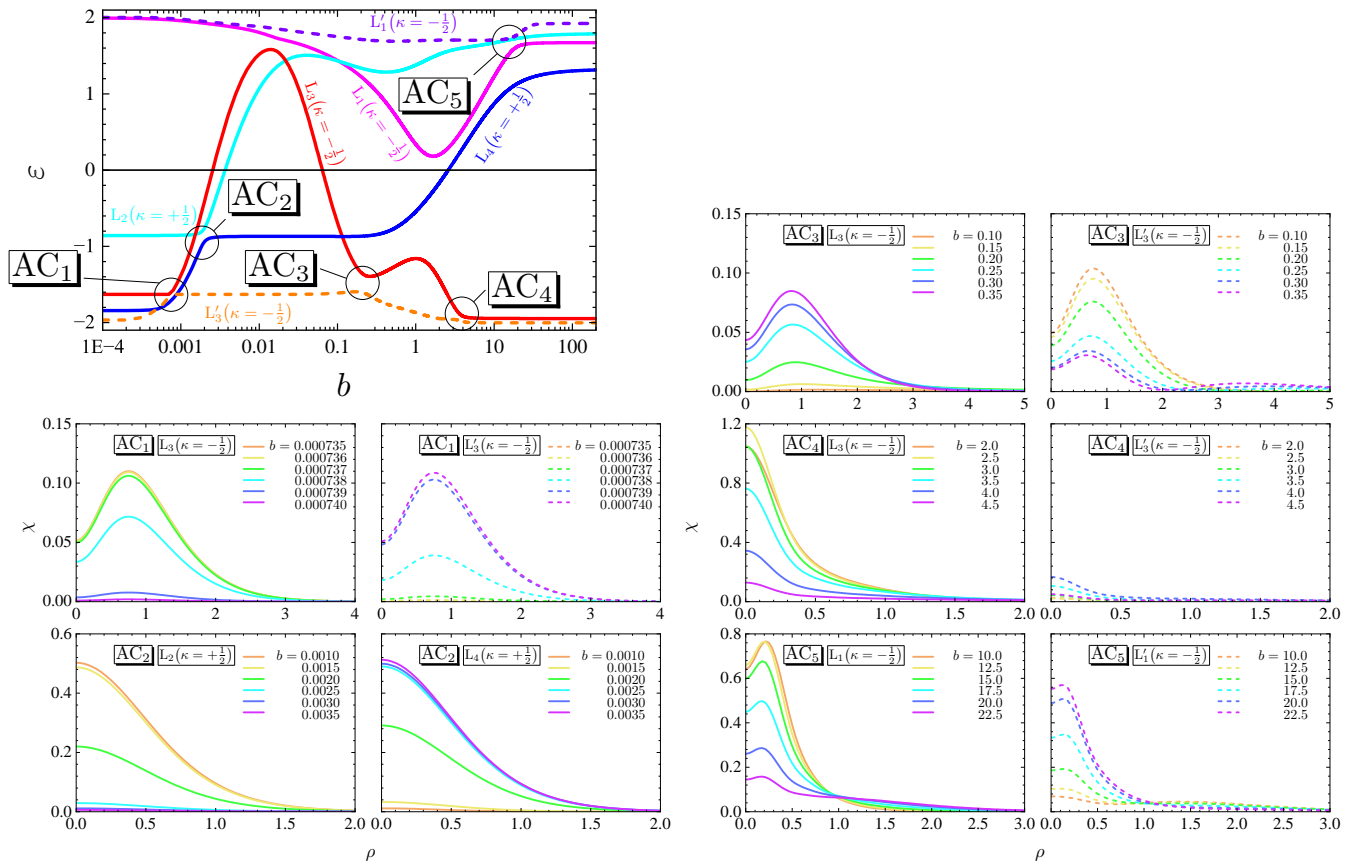

Fig. 9. The spectral flow of the mixture by changing b and corresponding fermion densities around the ACs, the avoided crossings. In the figure of the spectral flow, only the levels crossing the zero-energy line and the partner of the avoided crossing are shown. The figures of fermion densities shows the fermion densities with their quantum number related to the AC.

Fig. 10. The typical behaviors of fermion densities in terms of L_1 , L_2 , L_3 and L_4 concerning the five types of the avoided crossings. For small b , below the AC_1 , the densities of L_2 and L_3 are localized. In intermediate regions, between the AC_3 and AC_4 , all of the densities are localized. For large b , above the AC_5 , the densities of L_1 and L_4 are localized.
