Motivated by recent experiments (Subero et. al. Nature Comm. **14**, 7924 (2023)) we analyze photonic heat transport through a Josephson junction in a dissipative environment. For this purpose we derive the general expressions for the heat current in terms of non-equilibrium Green functions for the junction coupled in series or in parallel with two environmental impedances at different temperatures. We show that even on the insulating side of the Schmid transition the heat current is sensitive to the Josephson coupling exhibiting an opposite behavior for the series and parallel connection and in qualitative agreement with experiments. We also predict that this device should exhibit heat rectification properties and provide simple expressions to account for them in terms of the system parameters.

Introduction.— The physics of Josephson junctions (JJs) has attracted great interest for many decades [1]. Even the apparently simple case of a single JJ in a resistive environment provides a rich playground to study the interplay of quantum tunneling and dissipation [2], which continues to be explored until today [3, 4]. For this system a transition between a superconducting and an insulating phase was predicted to appear as a function of the environmental resistance (R), regardless of the Josephson coupling energy (E_J). This is the so-called Schmid-Bulgadaev (SB) transition [5, 6], which has been the object of intense theoretical [7–11] and experimental debate in recent years [12–14].

In spite of this intense activity little is known regarding this system properties beyond dc charge transport. In this respect, heat transport [15] can provide additional insights. In a recent experiment, Subero *et al.* [16] explored heat transport through a JJ in the supposedly insulating regime ($R > R_Q = h/4e^2$). Even when charge transport could be well described by dynamical Coulomb blockade theory, it was found that heat transport was sensitive to the E_J value (tunable through a magnetic flux in a SQUID configuration) indicating inductive response at high frequencies. The experimental results were fitted using a phenomenological theory including an inductive term to the junction effective impedance.

In the present work we analyze this problem from a microscopic perspective. For this purpose we develop a non-equilibrium Green functions (GFs) approach which takes into account interaction effects due to finite E_J/E_C values, where

Figure 1. Schematics of the configurations considered, consisting in two resistors, R_L and R_R , connected in (a) parallel and (b) series to a Josephson junction (defined by a Josephson, E_J , and a charging energy E_C), and holding different temperatures, T_L and T_R , that lead to a heat current J .

E_C is the junction charging energy. We find that even for $R > R_Q$, heat transport is sensitive to the Josephson coupling, in qualitative agreement with experiments. Moreover, we find that the heat current response is radically different depending on whether the junction is connected in parallel or in series to the source and drain leads. We finally demonstrate that asymmetric devices exhibit heat rectification properties.

In Fig. 1 we schematically represent the two situations to be considered: in panel 1(a) the JJ is connected in parallel with the left and right resistors (R_L and R_R) which are held at temperatures T_L and T_R respectively, whereas in panel 1(b) these circuit elements are connected in series, corresponding to the experimental configuration in Ref. [16]. The aim of the theory is to determine the resulting heat current J as a function of the model parameters in these two situations, assuming that temperatures are low enough to neglect excited quasiparticles in the superconducting leads.

Parallel configuration.— Let us start with the parallel configuration [17]. This is modeled by the following Hamiltonian

$$H = E_C N^2 - E_J \cos \varphi - \sum_{j,k} \left[\lambda_{j,k} (a_{jk} + a_{jk}^\dagger) \varphi - \frac{\lambda_{j,k}^2}{\hbar \omega_{j,k}} \varphi^2 \right] + \sum_{j,k} \omega_{j,k} a_{j,k}^\dagger a_{j,k}, \quad (1)$$

where $j \equiv L, R$ and the dissipative terms satisfy

$$\frac{\pi}{2} \sum_k \lambda_{j,k}^2 \delta(\omega - \omega_{j,k}) = \frac{\hbar^2 \omega}{4e^2} \text{Re} \left[\frac{1}{Z_j(\omega)} \right],$$

$Z_j(\omega)$ being the leads impedances, which in our case correspond to pure resistances R_j . In this configuration only one superconducting phase variable, φ , conjugate to the charge which is transferred through the junction, N , plays a role.

Following Ref. [18], the heat current through lead j can then be computed as

$$J_j = \langle \dot{H}_j \rangle = -i \sum_k \lambda_{j,k} \omega_{Lk} \left[\langle a_{jk}(t) \varphi(t) \rangle - \text{h.c.} \right] = 2 \sum_k \lambda_{j,k} \omega_{j,k} \text{Re} G_{a_{j,k}^\pm}^{+-}(t, t), \quad (2)$$

where $G_{A,B}^{\alpha\beta}(t, t') = -i\langle T_C B(t')A(t) \rangle$ denotes the Keldysh $\alpha\beta$ GF associated with operators A, B . Using the equation of motion method and transforming it into frequency representation one can express $G_{a_{jk},N}^{+-}$ as

$$G_{a_{jk},\varphi}^{+-}(\omega) = \lambda_{jk} \left[D^r(\omega) g_{a_{jk}}^{+-}(\omega) + D^{+-}(\omega) g_{a_{jk}}^a(\omega) \right], \quad (3)$$

where the $g_{a_{jk}}^{+-a}$ correspond to the uncoupled leads and, for simplicity, we denote $D^{\alpha\beta,r,a} \equiv G_{\varphi\varphi}^{\alpha\beta,r,a}$ (the superscripts r, a indicate the retarded, advanced components). In this way we can express the heat current as

$$J_j = 2 \sum_k \lambda_{jk}^2 \omega_{jk} \int \frac{d\omega}{2\pi} \text{Re} \left[D^r(\omega) g_{a_{jk}}^{+-}(\omega) + D^{+-}(\omega) g_{a_{jk}}^a(\omega) \right]. \quad (4)$$

We can further use $g_{a_{jk}}^{+-}(\omega) = -2\pi i n_j(\omega_{jk}) \delta(\omega - \omega_{jk})$ and $g_{a_{jk}}^a(\omega) = 1/(\omega - \omega_{jk} - i0^+)$, where $n_j(\omega)$ denotes the Bose function for the modes in the j -lead. Then, replacing in Eq. (4) and taking the real part we obtain

$$J_j = \int \frac{d\omega}{2\pi} \frac{\hbar^2 \omega^2}{e^2} \text{Im} \left[D^r(\omega) \coth \left(\frac{\omega \beta_j}{2} \right) - \frac{D^K(\omega)}{2} \right] \text{Re} \left[\frac{1}{Z_j(\omega)} \right], \quad (5)$$

where we have introduced the Keldysh GFs $D^K = D^{+-} + D^{-+}$ in the triangular representation [19] and $\beta_j = 1/k_B T_j$. Further simplification is obtained if, as in our case, the lead admittances $1/Z_j(\omega) \equiv 1/R_j$ are frequency independent. Then, imposing heat current conservation $J_R = -J_L = J$ one gets [18]

$$J = -\frac{\hbar^2}{2\pi e^2} \int d\omega \frac{\omega^2 \text{Im} D^r(\omega)}{R_L + R_R} [n_L(\omega) - n_R(\omega)], \quad (6)$$

which is the heat transport analog of Meir-Wingreen formula for mesoscopic charge transport [20], allowing us to define an effective heat transmission coefficient for the parallel configuration

$$\tau_{\text{parallel}}^{\text{eff}}(\omega) = -\frac{4\eta_L \eta_R \omega \text{Im} D^r(\omega)}{\eta_L + \eta_R}, \quad (7)$$

where $\eta_j = R_Q/(2\pi R_j) \equiv \alpha_j/2\pi$. One can further check that for the perfect transmission case one obtains $J = J_{\text{max}} \equiv \pi k_B^2 (T_L^2 - T_R^2)/(12\hbar)$ as it corresponds to a ballistic channel [21].

Perturbation theory.— The problem is thus mapped into the evaluation of the Keldysh GFs $D^{r,a,K}(\omega)$. In the present work we focus on the regime $R_{L,R} \gtrsim R_Q$ and $E_J \ll E_c$ for which perturbation theory in E_J should be valid. To zero-th order in E_J the GFs are given by

$$\begin{aligned} D_0^{r,a}(\omega) &= \frac{1}{m\omega^2 \pm i\omega(\eta_L + \eta_R) - m\omega_c^2}, \\ D_0^K(\omega) &= \frac{-2i\omega(\eta_L(1 + 2n_L(\omega)) + \eta_R(1 + 2n_R(\omega)))}{(m(\omega^2 - \omega_c^2))^2 + (\omega(\eta_L + \eta_R))^2}, \end{aligned} \quad (8)$$

where $m = \hbar/E_c$ and ω_c is a small frequency cutoff which warrants convergence in the Fourier transforms. At zero-th

order in E_J and $\omega_c \rightarrow 0$, from (7) we obtain

$$\tau_{\text{parallel}}^0(\omega) = \frac{4\eta_L \eta_R}{(m\omega)^2 + (\eta_L + \eta_R)^2}, \quad (9)$$

which reaches a maximum value $4\eta_L \eta_R/(\eta_L + \eta_R)^2$ at zero frequency.

Higher order corrections can be introduced through the self-energies $\Sigma^{r,a,K}(\omega)$ associated to the E_J term in the Hamiltonian, which would allow us to evaluate the needed GFs as

$$\begin{aligned} D^{r,a}(\omega) &= \left[\left(D_0^{r,a}(\omega) \right)^{-1} - \Sigma^{r,a}(\omega) \right]^{-1} \\ D^K(\omega) &= [1 + D^r(\omega) \Sigma^r(\omega)] D_0^K(\omega) [1 + \Sigma^a(\omega) D_0^a(\omega)] \\ &\quad + D^r(\omega) \Sigma^K(\omega) D^a(\omega). \end{aligned} \quad (10)$$

To lowest order in E_J we have [22]

$$\Sigma^{r,a(1)}(\omega) = E_J \exp \left[-\frac{i}{4} D_0^K(t=0) \right] \rightarrow 0, \quad (11)$$

since $\text{Im} D_0^K(t=0) \rightarrow \infty$ for $\omega_c \rightarrow 0$. One also obtains $\Sigma^{K(1)}(\omega) = 0$ as it corresponds to an effective static potential. To obtain the frequency-dependent corrections it is then necessary to go to higher order. To second order in E_J one obtains [22]

$$\begin{aligned} \Sigma^{r(2)}(t) &= E_J^2 \sin \frac{D_0^r(t)}{2} \exp \left[\frac{i}{2} (D_0^K(t) - D_0^K(0)) \right] - B\delta(t) \\ \Sigma^{K(2)}(t) &= -iE_J^2 \cos \frac{D_0^r(t)}{2} \cos \frac{D_0^a(t)}{2} \exp \left[\frac{i}{2} (D_0^K(t) - D_0^K(0)) \right], \end{aligned} \quad (12)$$

where B is a constant such that $\Sigma^{r(2)}(\omega=0) = 0$.

From these expressions one can obtain numerical results for the self-energies [23]. In addition, fully analytical results for the Keldysh self-energies can be obtained in the limit $(R_L + R_R)/R_Q \rightarrow 1$ and $T_j \rightarrow 0$ [23] (see also comments below).

Replacing these results into Eq. (10), we obtain the results in Fig. 2(a) for the heat transmission coefficient, which exhibits a strong dependence on E_J , in spite of the full suppression of the dc Josephson effect that occurs in the insulating phase [24]. As shown in the inset of Fig. 2(a), the total heat current in this configuration decreases with increasing E_J , and, as illustrated by the dashed lines in this inset, the sensitivity of the total heat current with E_J exhibits a strong dependence on the lead resistances.

One gets more insight by analyzing the low frequency renormalization of the heat transmission coefficient $\tau_{\text{parallel}}(\omega)$. In fact, at low frequencies $\Sigma^{r(2)}(\omega) \sim -i\delta\eta\omega + \delta m\omega^2$, where $\delta\eta$ and δm provide renormalization of the damping and mass model parameters. An analytical expression for the temperature and resistance scaling of these effective parameters is presented in [23]. At low temperatures ($T_{L,R} \ll \gamma$) and for $\eta_{L,R} \sim 1/2\pi$ we obtain

$$\delta\eta \sim \left(\frac{E_J}{\gamma} \right)^2 \left(\frac{\eta_L T_L + \eta_R T_R}{m^2 \gamma^2} \right)^{-2} \prod_j \left(\frac{T_j}{\gamma} \right)^{\eta_j / \pi m^2 \gamma^2}, \quad (13)$$

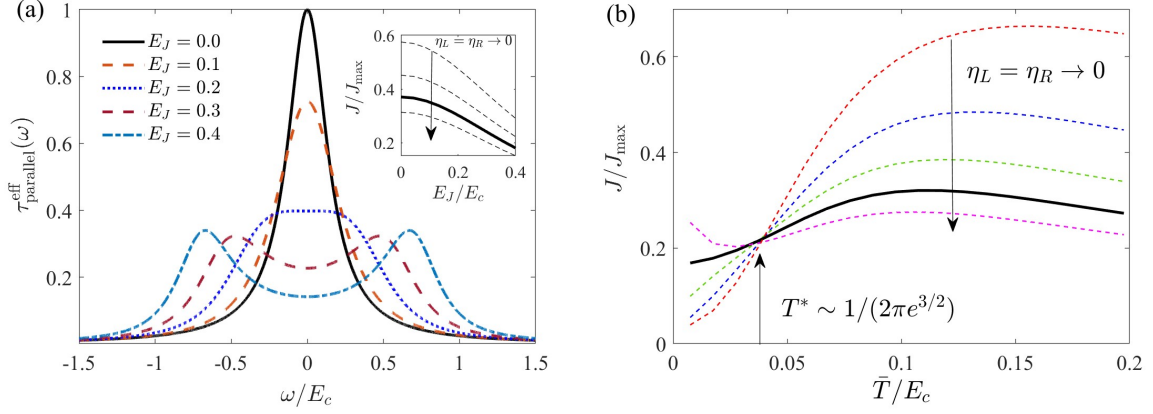

Figure 2. (a) Effective heat transmission coefficient in the parallel configuration for increasing E_J values (from 0 to 0.4) and $T_L = 0.2$, $T_R = 0.1$, $\omega_c = 2 \times 10^{-3}$ (in units of E_c) and $\eta_{L,R} = 1/4\pi$. The full lines in the insets correspond to the total heat current J , normalized to the maximum heat current for a ballistic channel J_{\max} , as a function of E_J , while the dashed lines illustrate its behavior with $\eta_L = \eta_R$ varying between $1/\pi$ to $1/5\pi$. (b) J/J_{\max} for $E_J = 0.2$ as a function of mean temperature $\bar{T} = (T_L + T_R)/2$ in the linear response regime for the same $\eta_L = \eta_R$ range.

where $\gamma = (\eta_L + \eta_R)/m$. Notice that for $T_L = T_R = T$ and $\alpha_L = \alpha_R = 2\alpha$, the SB transition at $\alpha = 1$ is encoded in the scaling law $\sim T^{2/\alpha-2}$, which results for the renormalization of the damping parameter [22, 25].

In terms of these renormalized parameters $\tau_{\text{parallel}}(\omega)$ can be written as

$$\tau_{\text{parallel}}^{\text{eff}}(\omega) = \frac{4\eta_L\eta_R}{\tilde{m}^2\omega^2 + \tilde{\eta}^2} \frac{\tilde{\eta}}{\eta_L + \eta_R}, \quad (14)$$

where $\tilde{\eta} = \eta_L + \eta_R + \delta\eta$ and $\tilde{m} = m - \delta m$. This expression accounts for the qualitative behavior of the heat transmission coefficient that can be observed in Fig. 2(a), i.e. a suppression and broadening of the $\omega \sim 0$ peak for increasing E_J .

On the other hand, lower temperatures are required to observe signatures of the SB transition in the heat transport properties. In Fig. 2(b) we show the heat current J as a function of $\bar{T} = (T_L + T_R)/2$ in the linear regime ($\delta T = T_L - T_R \rightarrow 0$) for different values of $\eta_L = \eta_R$, ranging from $1/\pi$ to $1/5\pi$, i.e. across the transition which for the parallel case should occur at $\eta_{L,R} = 1/4\pi$. While for $\bar{T} \gtrsim \gamma$, J decreases with increasing resistance due to the narrowing of the $\tau_{\text{parallel}}^{\text{eff}}(\omega)$ zero-frequency peak, the tendency is reversed at low temperatures ($\bar{T} \ll \gamma$) due to the divergence of $\delta\eta$ for $\alpha > 1$. The transition between these two opposite behaviors occurs around $\bar{T} = T^* \sim 1/(2\pi e^{3/2})$, where the damping renormalization is weakly dependent on the environment resistance [23]. This behavior is similar to the non-monotonous dependence of the mobility found for quantum Brownian motion in a periodic potential [26].

Series configuration.— In the actual setup in Ref. [16] left and right leads are placed in a loop for the heat current measurements, which actually corresponds to a *series* connection, as depicted in Fig. 1(b). One should describe this situation in terms of two phase variables φ_1 and φ_2 , each one coupled to the left and right reservoirs respectively, while the charge N through the junction is conjugate to $\varphi_1 - \varphi_2$. Thus, the bare

Figure 3. Same as Fig. 2(a) but for the series configuration.

GFs adopt a matrix form in the $\varphi_{1,2}$ space and can be obtained from the following equations

$$\begin{pmatrix} m(\omega^2 - \omega_c^2) \pm i\omega\eta_L & -m(\omega^2 - \omega_c^2) \\ -m(\omega^2 - \omega_c^2) & m(\omega^2 - \omega_c^2) \pm i\omega\eta_R \end{pmatrix} \hat{D}_0^{r,a} = \hat{I}, \quad (15)$$

and $\hat{D}_0^K = \hat{D}_0^r \hat{d}_0^K \hat{D}_0^a$, where

$$\hat{d}_0^K = -2i\omega \text{diag}(\eta_L \coth(\beta_L \omega/2); \eta_R \coth(\beta_R \omega/2)) .$$

To include the effect of finite E_J one should notice that the junction term in the Hamiltonian is now $-E_J \cos(\varphi_1 - \varphi_2)$, thus the corresponding self-energies in Eq. (12) have to be expressed in terms of $\tilde{D}_0(t) = \text{Tr}[\hat{D}_0(t)(\hat{I} - \sigma_x)]$, where σ_x is a Pauli matrix in $\varphi_{1,2}$ space. The resulting self-energies $\tilde{\Sigma}^{r,K}(\omega)$ exhibit a similar behavior as in the parallel configuration (see SM [23]).

On the other hand, the Dyson equations for the dressed GFs (10) acquire a matrix form in the $\varphi_{1,2}$ space and the cor-

responding self-energies are obtained from $\tilde{\Sigma}^{r,a,K}$ as $\hat{\Sigma}^{r,a,K} = \tilde{\Sigma}^{r,a,K}(\hat{I} - \sigma_x)$.

The heat current in the series connection cannot be expressed in the compact form (6). It is, in contrast, necessary to reproduce the steps leading to Eq. (5), in order to derive the corresponding expression for the heat current in the series connection

$$J_j = \int d\omega \omega^2 \eta_j \text{Im} \left[D_{l_j l_j}^r(\omega) (1 + 2n_j(\omega)) - \frac{D_{l_j l_j}^K(\omega)}{2} \right] \quad (16)$$

where $l_j = 1, 2$ for $j = L, R$ respectively. This expression can be decomposed [23] as $J_j = (-1)^{l_j} J_j^{\text{el}} + J_j^{\text{in}}$, where $J_j^{\text{el}} = \int d\omega \hbar \omega \tau_{\text{series}}^{\text{eff}}(\omega) [n_L(\omega) - n_R(\omega)]$ corresponds to the *elastic* contribution with

$$\tau_{\text{series}}^{\text{eff}}(\omega) = 4\eta_L \eta_R |D_{12}^r(\omega)|^2, \quad (17)$$

while the *inelastic* contribution is given by

$$J_j^{\text{in}} = \int d\omega \omega^2 \eta_j \text{Im} \left[\hat{D}^r \left\{ (\hat{\Sigma}^r - \hat{\Sigma}^a) (1 + 2n_j) - \hat{\Sigma}^K \right\} \hat{D}^a \right]_{l_j l_j}. \quad (18)$$

In the non-interacting case (i.e. $E_J = 0$) the inelastic term vanishes and the heat current can again be written in the usual Landauer form with a transmission coefficient at $\omega_c \rightarrow 0$

$$\tau_{\text{series}}^0(\omega) = \frac{4m^2 \omega^2 \eta_L \eta_R}{((\eta_L + \eta_R)m\omega)^2 + (\eta_L \eta_R)^2}, \quad (19)$$

which exhibits a zero frequency dip and tends to $4\eta_L \eta_R / (\eta_L + \eta_R)^2$ at large frequencies, as illustrated in Fig. 3.

The behavior of the effective transmission coefficient for finite E_J is illustrated in Fig. 3 for the same parameters as in Fig. 2(a). We observe that at finite E_J the zero frequency dip is progressively suppressed. On the other hand, the inelastic term provides an additional contribution to the heat current [23]. Thus, in contrast to the parallel configuration, there is a slight increase of the heat current with E_J , which is confirmed by the integrated results in the inset of Fig. 3. As can be observed, this increase is more pronounced as the leads resistances approach R_Q . This behavior is in qualitative agreement with the experimental results in Ref. [16].

Rectification properties.— Another interesting property of a JJ in a resistive environment is its possible behavior as a heat rectifier. The JJ anharmonicity has been used to define thermal diodes based on weakly coupled qubits [27], see also Ref. [18]. Though heat rectifiers using JJs have been measured in the absence of environmental effects (but additionally coupled to a phonon bath) [28] or in superconducting qubits [29, 30] (see also Ref. [31] for a review), their rectifying properties in the insulating side of the SB transition have not been considered. For simplicity we consider here only the parallel configuration with an asymmetry provided by $R_L \neq R_R$. We can then define a “forward” (J^+) and a “reverse” (J^-) heat current given by

$$J^\pm = \int \frac{d\omega}{\pi} \hbar \omega \tau^{\text{eff}(\pm)}(\omega) [n_L^\pm(\omega) - n_R^\pm(\omega)], \quad (20)$$

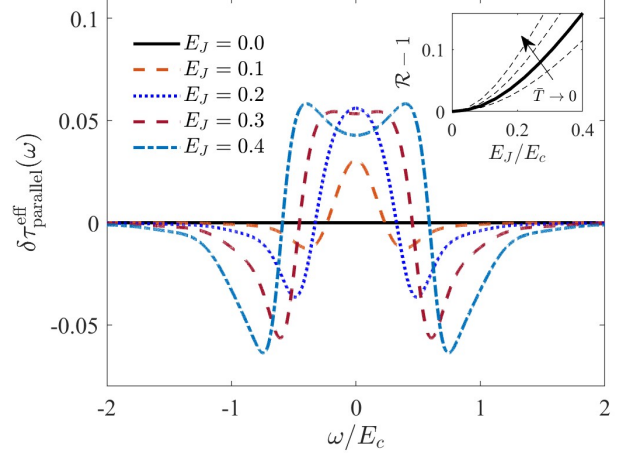

Figure 4. Asymmetry in the heat transmission coefficient $\delta\tau^{\text{eff}}(\omega) = \tau^{\text{eff}(+)}(\omega) - \tau^{\text{eff}(-)}(\omega)$ for the parallel configuration with $\eta_L = 1/\pi$, $\eta_R = 1/4\pi$, $\Delta T = 0.1$, $\bar{T} = (T_L + T_R)/2 = 0.15$, and increasing values of E_J from 0 to 0.4. The corresponding heat rectification ratio $\mathcal{R} = |J^+/J^-|$ as a function of E_J is shown as a full line in the inset. The dashed lines illustrate its variation with \bar{T} from 0.175 to 0.1.

which correspond to positive and negative temperature bias $\Delta T = T_L - T_R$. As is customary, we also define a heat rectification ratio $\mathcal{R} = |J^+/J^-|$ which, as can be seen from Eq. (20), would deviate from unity provided $\delta\tau^{\text{eff}} = \tau^{\text{eff}(+)} - \tau^{\text{eff}(-)} \neq 0$.

In Fig. 4 we show the behavior of $\delta\tau^{\text{eff}}(\omega)$ for increasing values of E_J in an asymmetric configuration with $\alpha_L = 2$ and $\alpha_R = 0.5$. We observe that, for finite E_J , heat transport in the forward direction is favored at low frequencies, while the opposite occurs at higher frequencies. There is not, however, a compensation in the total heat current and thus one obtains that $\mathcal{R} > 1$ as illustrated in the inset of Fig. 4. Rectification ratios of the order of 10% or larger are obtained for the set of parameters in this figure. These ratios can increase further by decreasing the mean temperature $\bar{T} = (T_L + T_R)/2$ (see inset in Fig. 4).

Further insight on these properties can be obtained from the analytical approximation to the system self-energies. As shown in [23] the rectification ratio in the parallel configuration can be expressed as

$$\mathcal{R} - 1 \sim (mE_J)^2 \frac{\eta_R - \eta_L}{\eta_L + \eta_R} \left(\frac{2}{\alpha} - 2 \right) \bar{T}^{\frac{\alpha}{2} - 2} \frac{\delta T}{\bar{T}} \quad (21)$$

in the limit $T_{L,R} \ll \gamma$ and $\alpha \gtrsim 1$ upon a small temperature difference $\delta T \ll \bar{T}$. This expression accounts for the main features of the numerical results, i.e. the quadratic increase with E_J and the increase of \mathcal{R} as the mean temperature is decreased. Eq. (21) also indicates that, as far as $\alpha > 1$, the heat current is larger when the colder reservoir corresponds to the one with larger resistance. This behavior is similar to the case of a two-level system with a nonseparable coupling to the heat baths [27, 32].

Conclusions.— In summary, we have presented non-equilibrium Green functions calculations for photonic heat

transport through a Josephson junction in a resistive environment. Our results are in qualitative agreement with the experimental ones from [16] and suggest how signatures of the SB transition can be detected in heat transport measurements at sufficiently low temperatures [33]. We further demonstrate rectification properties for this device that can be tested in future experiments.

Note added: While completing this manuscript we become aware of a related study [34] for the same system in the scaling regime, yielding results which are complementary to the ones in the present work.

The authors wish to thank M. Houzet and P. Joyez for enlightening discussions. ALY also acknowledges Prof. U. Weiss for useful comments on the validity of the perturbative approach adopted in this work. We acknowledge funding from the Spanish Ministerio de Ciencia e Innovación via grants No. PID2020-117671GB-I00, PID2019-110125GB-I00 and PID2022-142911NB-I00, and through the “María de Maeztu” Programme for Units of Excellence in R&D CEX2018-000805-M. SUPPLEMENTARY INFORMATION FOR “PHOTONIC HEAT TRANSPORT THROUGH A JOSEPHSON JUNCTION IN A RESISTIVE ENVIRONMENT”

DETAILS ON NUMERICAL CALCULATIONS

Self-energies

From Eq. (8) in the main text, the zero order GFs in time representation are given by

$$\begin{aligned} D_0^r(t) &= -\frac{\theta(t)}{m\omega_1} e^{-\gamma t/2} \sinh(\omega_1 t) \\ D_0^K(t) &= S_1(t) + S_2(t) \end{aligned} \quad (\text{S } 1)$$

where $\gamma = (\eta_L + \eta_R)/m$, $\omega_1 = \sqrt{\gamma^2/4 - \omega_c^2}$ and

$$\begin{aligned} S_1(t) &= -\sum_{\mu=L,R} \frac{\eta_\mu}{2m\omega_1\gamma} \left(\coth\left(\frac{\beta_\mu\lambda_1}{2}\right) e^{i\lambda_1|t|} - \coth\left(\frac{\beta_\mu\lambda_2}{2}\right) e^{i\lambda_2|t|} \right) \\ S_2(t) &= 4i \sum_{\mu=L,R} \frac{\eta_\mu}{m\beta_\mu} \sum_{n>0} \frac{\nu_n^\mu e^{-\nu_n^\mu|t|}}{(\omega_c^2 + (\nu_n^\mu)^2)^2 - \gamma^2(\nu_n^\mu)^2}, \end{aligned} \quad (\text{S } 2)$$

where $\lambda_{1,2} = i(\gamma/2 \pm \omega_1)$, and $\nu_n^\mu = 2n/\beta_\mu$ are the Matsubara frequencies.

By introducing these analytical expressions for the propagators in time representation into Eqs. (12) in the main text and performing their Fourier transform numerically, we obtain the results shown in Fig. 2 for the different self-energies in frequency space. For comparison we show the corresponding results for the series configuration.

In Fig. S2 we show the inelastic contribution to the heat current in the series configurations for the same parameters as in Fig. 3 in the main text. As can be observed, this contribution is positive so that it tends to increase the total heat current when added to the elastic contribution.

ANALYTICAL APPROXIMATIONS

Here we give details on the approximations used to obtain the analytic behaviour of the self-energies $\Sigma^{r(2)}(\omega)$ and $\Sigma^{K(2)}(\omega)$ in the parallel configuration.

Retarded self-energy

We start with the time-dependent retarded selfenergy as expressed in Eq. (12) in the main text:

$$\Sigma^{r(2)}(t) = E_J^2 \sin\left(\frac{D_0^r(t)}{2}\right) \exp\left[\frac{i}{2}(D_0^K(t) - D_0^K(0))\right] - B\delta(t), \quad (\text{S } 3)$$

Figure S1. Self-energies in frequency representation obtained numerically from Eqs. (12) in the main text. Energies in units of E_c . The corresponding parameters are indicated in the figure title. The dashed lines correspond to the self-energies in the series configuration for the same set of parameters.

of which we want to obtain the Fourier transform. For this, we consider the first term:

$$\tilde{\Sigma}(t) = E_J^2 \sin\left(\frac{D_0^r(t)}{2}\right) \exp\left[\frac{i}{2}(D_0^K(t) - D_0^K(0))\right]. \quad (\text{S } 4)$$

The second term, proportional to B will be cancelled out with $\tilde{\Sigma}(0)$. We can simplify it by writing $D_0^r(t) = D_0^r(-t) = -\theta(t)(1 - \exp[-\gamma t])/m\gamma$, and using the approximation

$$\text{Re}\left[\frac{i}{2}(D_0^K(t) - D_0^K(0))\right] \approx -\sum_{\mu} \frac{\eta_{\mu}}{\pi m^2 \gamma^2} \ln\left[\frac{\gamma\beta_{\mu}}{\pi} \sinh\left(\frac{\pi|t|}{\beta_{\mu}}\right)\right] \quad (\text{S } 5)$$

for $|\gamma t| \gg 1$ and $k_B T \ll \gamma$ [22]. Doing so, we get:

$$\tilde{\Sigma}(t) = \theta(t) E_J^2 \sin\left(\frac{e^{-\gamma t} - 1}{2m\gamma}\right) \prod_{\mu} \left[\frac{\gamma\beta_{\mu}}{\pi} \sinh\left(\frac{\pi|t|}{\beta_{\mu}}\right)\right]^{-\eta_{\mu}/\pi m^2 \gamma^2}, \quad (\text{S } 6)$$

where $\eta_{\mu} = R_Q/2\pi R_{\mu}$, $m = \hbar/E_C$ and $\gamma = \sum_{\mu} \eta_{\mu}/m$, as defined in the main text. We need to solve its Fourier transform:

$$\tilde{\Sigma}(\omega) = \mathcal{A}\gamma \int_0^{\infty} dt \sin\left(\frac{e^{-\gamma t} - 1}{2m\gamma}\right) \prod_{\mu} \left[2 \sinh\left(\frac{\pi|t|}{\beta_{\mu}}\right)\right]^{-\frac{\eta_{\mu}}{\pi m^2 \gamma^2}} e^{i\omega t}, \quad (\text{S } 7)$$

Figure S2. Inelastic contribution to the heat current in the series configuration for the same parameters as in Fig. 3 in the main text.

where we have defined the prefactor

$$\mathcal{A} \equiv \frac{E_J^2}{\gamma} \prod_{\mu} \left(\frac{\gamma \beta_{\mu}}{2\pi} \right)^{-\eta_{\mu}/\pi m^2 \gamma^2}. \quad (\text{S } 8)$$

To reach the low frequency limit $T_j \gg \omega$, we approximate $\sinh(\pi|t|/\beta_{\mu}) \approx e^{\pi|t|/\beta_{\mu}}/2$. Then, performing the change of variables $u = e^{-\gamma t}$ we get:

$$\tilde{\Sigma}(\omega) = \mathcal{A} \int_0^1 du \sin\left(\frac{u-1}{2m\gamma}\right) u^{c-1}, \quad (\text{S } 9)$$

with

$$c \equiv \frac{1}{m^2 \gamma^3} \left(\frac{\eta_L}{\beta_L} + \frac{\eta_R}{\beta_R} \right) - \frac{i\omega}{\gamma}. \quad (\text{S } 10)$$

The integral in Eq. (S 9) has an analytical solution if $\text{Re}(c) > 0$:

$$\int_0^1 du \sin[a(u-1)] u^{c-1} = g_1(a, c) + g_2(a, c), \quad (\text{S } 11)$$

with

$$g_1(a, c) = \frac{\cos(a)}{(1+c)/a} {}_1F_2\left(\frac{1+c}{2}; \frac{3}{2}, \frac{3+c}{2}; -\frac{a^2}{4}\right) \\ g_2(a, c) = -\frac{\sin(a)}{c} {}_1F_2\left(\frac{c}{2}; \frac{1}{2}, \frac{2+c}{2}; -\frac{a^2}{4}\right), \quad (\text{S } 12)$$

and where ${}_1F_2(a_1; b_1, b_2; z)$ is a ‘‘generalized hypergeometric function’’. Formally, this then gives an analytical solution:

$$\tilde{\Sigma}(\omega) = \mathcal{A} \left[g_1\left(\frac{1}{2m\gamma}, c\right) + g_2\left(\frac{1}{2m\gamma}, c\right) \right], \quad (\text{S } 13)$$

but it is not very informative until we plot its real and imaginary parts, which is done in Fig. S 3.

In a linear expansion, the constant term is real, giving the value of B in Eq. (S 3), and the linear term is pure imaginary, so the linear expansion simplifies to:

$$\tilde{\Sigma}(\omega) = i\mathcal{A}\text{Im}\left[(g'_1 + g'_2)|_{\omega=0}\right]\omega. \quad (\text{S } 14)$$

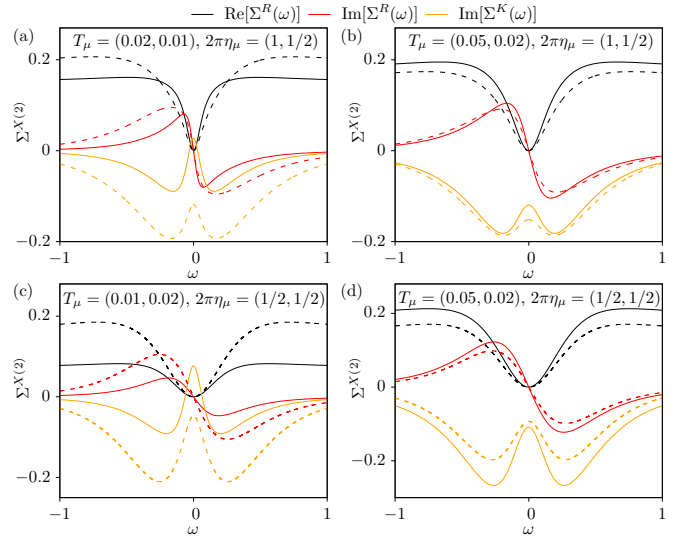

Figure S3. Self-energies for different temperatures $T_{\mu} = (T_L, T_R)$ and damping parameters $\eta_{\mu} = (\eta_L, \eta_R)$. (a) and (b): asymmetric case with $\eta_L = 1/2\pi$ and $\eta_R = 1/4\pi$. (c) and (d): symmetric case with $\eta_L = \eta_R = 1/4\pi$. Dashed lines show the numerical results. In all panels, $E_J = 0.2$, $m = 1$.

Figure S4. Comparison of numeric and analytic self-energies in the low impedance regime, $R_{\mu} = 0.5R_Q$, for increasing temperatures. Other parameters are as in Fig. S 3.

Keldysh self-energy

Now we consider the time-dependent Keldysh self-energy in Eq. (12) in the main text:

$$\Sigma^{K(2)}(t) = \frac{E_J^2}{i} \cos\left(\frac{D_0^K(t)}{2}\right) \cos\left(\frac{D_0^K(t)}{2}\right) \exp\left[\frac{i}{2} (D_0^K(t) - D_0^K(0))\right]. \quad (\text{S } 15)$$

We separate the time integral in the Fourier transform in two terms, with $D_0^r(t < 0) = 0$ and $D_0^a(t > 0) = 0$:

$$\begin{aligned} \Sigma^{K(2)}(\omega) = & -i\mathcal{A}\gamma \left\{ \int_{-\infty}^0 dt \cos\left(\frac{e^{\gamma t}-1}{2m\gamma}\right) \prod_{\mu} \left[2 \sinh\left(\frac{-\pi t}{\beta_{\mu}}\right) \right]^{\frac{-\eta_{\mu}}{\pi m^2 \gamma^2}} e^{i\omega t} \right. \\ & \left. + \int_0^{\infty} dt \cos\left(\frac{e^{-\gamma t}-1}{2m\gamma}\right) \prod_{\mu} \left[2 \sinh\left(\frac{\pi t}{\beta_{\mu}}\right) \right]^{\frac{-\eta_{\mu}}{\pi m^2 \gamma^2}} e^{i\omega t} \right\}, \end{aligned} \quad (\text{S } 16)$$

where we have again used the approximation in Eq. (S 5) [22]. Doing a change $t \rightarrow -t$ in the first integral of Eq. (S 16), we can write

$$\Sigma^{K(2)}(t) = -i\mathcal{A}\gamma(I^+ + I^-), \quad (\text{S } 17)$$

with

$$I^{\pm} = \int_0^{\infty} dt \cos\left(\frac{e^{-\gamma t}-1}{2m\gamma}\right) \prod_{\mu} \left[2 \sinh\left(\frac{\pi t}{\beta_{\mu}}\right) \right]^{\frac{-\eta_{\mu}}{\pi m^2 \gamma^2}} e^{\pm i\omega t}. \quad (\text{S } 18)$$

Following the same steps as for the retarded case ($u = e^{-\gamma t}$), we arrive to:

$$\Sigma^{K(2)} = -i\mathcal{A} \int_0^1 du \cos\left(\frac{u-1}{2m\gamma}\right) (u^{c-1} + u^{c^*-1}) \quad (\text{S } 19)$$

In this case, we can use the integral:

$$\int_0^1 du \cos[a(u-1)]u^{c-1} = g_3(a, c) + g_4(a, c), \quad (\text{S } 20)$$

with

$$\begin{aligned} g_3(a, c) &= \frac{\cos(a)}{c} {}_1F_2\left(\frac{c}{2}; \frac{1}{2}, \frac{2+c}{2}; -\frac{a^2}{4}\right) \\ g_4(a, c) &= a \frac{\sin(a)}{1+c} {}_1F_2\left(\frac{1+c}{2}; \frac{3}{2}, \frac{3+c}{2}; -\frac{a^2}{4}\right), \end{aligned} \quad (\text{S } 21)$$

provided $\text{Re}(c) > 0$. We note that $g_3(1/2m\gamma, c^*) = g_3^*(1/2m\gamma, c)$ and $g_4(1/2m\gamma, c^*) = g_4^*(1/2m\gamma, c)$. Hence, the Keldysh self-energy is purely imaginary:

$$\Sigma^{K(2)} = -i2\mathcal{A}\text{Re} \left[g_3\left(\frac{1}{2m\gamma}, c\right) + g_4\left(\frac{1}{2m\gamma}, c\right) \right]. \quad (\text{S } 22)$$

The result is plotted in orange lines in Fig. S 3.

Frequency expansion

We can expand on the integrand of Eqs. (S 9) and (S 19) for low frequencies, getting:

$$\Sigma^{\alpha(2)} \approx \Sigma_0^{\alpha(2)} + \omega \Sigma_1^{\alpha(2)} + \omega^2 \Sigma_2^{\alpha(2)}, \quad (\text{S } 23)$$

with

$$\Sigma_k^{r(2)} = -\frac{1}{k!} \left(\frac{i}{\gamma}\right)^k \mathcal{A} \mathcal{I}_k(c_0) \quad (\text{S } 24)$$

$$\Sigma_0^{K(2)} = -2i\mathcal{A} \int_0^1 du \cos\left(\frac{u-1}{2m\gamma}\right) u^{c_0-1} \quad (\text{S } 25)$$

$$\Sigma_1^{K(2)} = 0 \quad (\text{S } 26)$$

$$\Sigma_2^{K(2)} = \frac{i}{\gamma^2} \mathcal{A} \int_0^1 du \cos\left(\frac{u-1}{2m\gamma}\right) u^{c_0-1} \ln^2 u, \quad (\text{S } 27)$$

where

$$c_0 \equiv c(\omega = 0) = \frac{1}{m^2 \gamma^3} \left(\frac{\eta_L}{\beta_L} + \frac{\eta_R}{\beta_R} \right) \quad (\text{S } 28)$$

and

$$\mathcal{I}_k(c_0) = \int_0^1 du \sin\left(\frac{u-1}{2m\gamma}\right) u^{c_0-1} \ln^k u. \quad (\text{S } 29)$$

These integrals again have analytical solutions in terms of hypergeometric functions of higher order. For this, we define:

$$\mathcal{G}_{pqs}^{(n)} = {}_nF_{n+1} \left(\frac{p+c_0}{2} 1_n; \frac{q}{2}, \frac{s+c_0}{2} 1_n; -\frac{1}{16m^2\gamma^2} \right), \quad (\text{S } 30)$$

where 1_n is a list of n units. With these, we write:

$$\begin{aligned} \mathcal{I}_0(c_0) &= \frac{\cos\left(\frac{1}{2m\gamma}\right)}{2m\gamma(1+c_0)} \mathcal{G}_{1,3,3}^{(1)} - \frac{\sin\left(\frac{1}{2m\gamma}\right)}{c_0} \mathcal{G}_{0,1,2}^{(1)} \\ \mathcal{I}_1(c_0) &= -\frac{2m\gamma(1+2c_0) \cos\left(\frac{1}{2m\gamma}\right) \sin\left(\frac{1}{2m\gamma}\right)}{c_0^2(1+c_0)^2} \\ &+ \frac{\cos\left(\frac{1}{2m\gamma}\right)}{12m^2\gamma^2(1+c_0)(3+c_0)} \left[\frac{\mathcal{G}_{3,5,5}^{(1)}}{1+c_0} + \frac{\mathcal{G}_{3,5,5}^{(2)}}{3+c_0} \right] \\ &- \frac{\sin\left(\frac{1}{2m\gamma}\right)}{2m\gamma c_0^2(2+c_0)^2} \left[(2+c_0) \mathcal{G}_{2,3,4}^{(1)} + c_0 \mathcal{G}_{2,3,4}^{(2)} \right] \\ \mathcal{I}_2(c_0) &= 2 \left[\frac{\cos\left(\frac{1}{2m\gamma}\right)}{2m\gamma(1+c_0)^3} \mathcal{G}_{2,3,3}^{(3)} - \frac{\sin\left(\frac{1}{2m\gamma}\right)}{c_0^3} \mathcal{G}_{0,1,2}^{(3)} \right]. \end{aligned} \quad (\text{S } 31)$$

For the Keldysh self-energy, it is sufficient to look at the value at the origin, $\Sigma^{K(2)}(\omega) = \Sigma_0^{K(2)} + \mathcal{O}(\omega^2)$:

$$\Sigma_0^{K(2)} = -2i\mathcal{A} \left[\frac{\cos\left(\frac{1}{2m\gamma}\right)}{c_0} \mathcal{G}_{0,1,2}^{(1)} + \frac{\sin\left(\frac{1}{2m\gamma}\right)}{2m\gamma(1+c_0)} \mathcal{G}_{1,3,3}^{(1)} \right]. \quad (\text{S } 32)$$

Low temperature scaling

The linear coefficient of the retarded self-energy corresponds to the damping parameter correction, $\delta\eta$, defined in the main text. Taking the low temperature limit in the above expressions it is straightforward to show that for $T_{L,R} \ll \gamma$ and $m\gamma \sim 1/(2\pi)$

Figure S5. Rectification effect as a function of the temperature difference using the approximation of Eq. (S36), for different temperatures. Thin solid lines correspond to the linear expansion of Eq. (S38). Parameters: $E_J = 0.2$, $m = 1$, $\eta_L = 1/\pi$, $\eta_R = 1/4\pi$.

$$\delta\eta \sim \mathcal{A} \frac{\gamma}{c_0^2} \equiv \left(\frac{E_J}{\gamma}\right)^2 \frac{\left(\frac{T_L}{\gamma}\right)^{\frac{\eta_L}{\pi m^2 \gamma^2}} \left(\frac{T_R}{\gamma}\right)^{\frac{\eta_R}{\pi m^2 \gamma^2}}}{\left(\frac{\eta_L T_L + \eta_R T_R}{m^2 \gamma^2}\right)^2}. \quad (\text{S33})$$

In the limit $T_L = T_R = T$ the scaling reduces to $\delta\eta \sim T^{2/\alpha-2}$, where $\alpha = 2\pi(\eta_L + \eta_R)$ is the inverse of the total resistance in units of R_Q , which signals the SB transition at $\alpha = 1$ [22].

Based on this scaling it is possible to determine the transition point T^* for heat transport indicated in Fig. 3(b) of the main text. For that purpose remind that at low frequency the heat transmission coefficient scales as $\eta/\bar{\eta}$ for a symmetric case with $\eta_L = \eta_R = \eta$ (see Eq. (14) in main text). Thus, in order to get the same heat current for two cases with different resistances at the same mean temperature we need

$$\frac{\bar{\eta}_1}{\eta_1} = \frac{\bar{\eta}_2}{\eta_2} \rightarrow \frac{T^{2/\alpha_1-2}}{\gamma_1^{2/\alpha_1+1}} = \frac{T^{2/\alpha_2-2}}{\gamma_2^{2/\alpha_2+1}}. \quad (\text{S34})$$

Setting $\alpha_1 = 1$ in the limit $\alpha_2 \rightarrow 1$ we obtain $T = T^* =$

$1/(2\pi e^{3/2}) \simeq 0.036$, in agreement with the numerical results in Fig. 3(b) of the main text.

RECTIFICATION

The term $\Sigma_1^{r(2)}$ modifies the damping parameter $\Sigma_1^{r(2)} = -i\delta\eta$, which affects the transmission probability. If the resistances are different, the response is different depending on their temperature. Linearizing Eq. (14) in the main text at $\omega = 0$:

$$\tau_{\text{eff}}^{\pm} \approx \frac{4\eta_L\eta_R}{(\eta_L + \eta_R)^2} \left(1 - \frac{\delta\eta^{\pm}}{\eta_L + \eta_R}\right). \quad (\text{S35})$$

A rectification effect appears when $\delta\tau_{\text{parallel}}^{\text{eff}} = \tau_{\text{eff}}^+ - \tau_{\text{eff}}^- \neq 0$:

$$\delta\tau_{\text{parallel}}^{\text{eff}} \approx \frac{4\eta_L\eta_R}{(\eta_L + \eta_R)^3} (\delta\eta^- - \delta\eta^+). \quad (\text{S36})$$

We hence need

$$\delta\eta^- - \delta\eta^+ = i \left[\Sigma_{1,L}^{r(2)} - \Sigma_{1,R}^{r(2)} \right] \quad (\text{S37})$$

to be finite, where $\Sigma_{1,\mu}^{r(2)}$ is defined as the linear coefficient $\Sigma_1^{r(2)}$ when terminal μ is at temperature $T + \delta T$ and the other one is at T . They are obtained using Eqs. (S24) and (S31). The result is plotted in Fig. S5 as a function of the temperature difference δT .

We gain further insight by assuming a small temperature difference δT , so we can linearize use the scaling of Eq. (S33), getting

$$\delta\eta^- - \delta\eta^+ \approx (mE_J)^2 \frac{\eta_R - \eta_L}{\eta_L + \eta_R} \left(\frac{2}{\alpha} - 2\right) T^{\frac{2}{\alpha}-2} \frac{\delta T}{T}, \quad (\text{S38})$$

see Fig. S5. This expression gives the scaling of the rectification coefficient:

$$\mathcal{R} - 1 \sim (mE_J)^2 \frac{\eta_R - \eta_L}{\eta_L + \eta_R} \left(\frac{2}{\alpha} - 2\right) T^{\frac{2}{\alpha}-2} \frac{\delta T}{T} \quad (\text{S39})$$

given in the main text.
