1 Prognostics and Health Management

In the realm of modern manufacturing, significant emphasis is placed on improving the reliability, performance, and service life of complex engineering systems (ESs), which has catalyzed the emergence of Prognostics and Health Management (PHM) as an essential discipline in the past two decades [1, 2]. PHM includes a range of methods dedicated to the early detection, prognosis, and mitigation of impending faults or failures in ESs, thereby facilitating sophisticated maintenance strategies and enhancing operational efficiency [3].

Central to the efficacy of PHM methods is the acquisition and analysis of degradation data, which encapsulates the evolving health condition of ESs over time [3]. Degradation data serves as a rich source of information, offering invaluable insights into the underlying degradation processes, failure modes, and performance trends of ESs [2, 4]. Through the integration of advanced sensing technologies, data analytics, and machine learning algorithms, researchers

**Citation:* Hagemeyer, S.; Mauthe, F.; Zeiler, P. (2021): Creation of Publicly Available Data Sets for Prognostics and Diagnostics Addressing Data Scenarios Relevant to Industrial Applications. International Journal of Prognostics and Health Management, Volume 12, Issue 2, DOI: 10.36001/ijphm.2021.v12i2.3087.

and practitioners can harness degradation data to develop prognostic models, optimize maintenance schedules, and make informed operational decisions [1].

In the remainder of this paper, the tasks of diagnostics and prognostics are listed, and an overview of publicly available degradation data sets is presented as well as briefly described. The authors aim to update the overview regularly in the future, as new data sets are continually being published in the dynamic research field of PHM.

2 Tasks of Diagnostics and Prognostics

Extensive and representative degradation data enables addressing a specific task—prognosis—within PHM, with the subdivision of PHM into distinct tasks. Based on [1], [5], and [4], the tasks of diagnostics and prognostics within PHM can be subdivided as follows:

- **Fault detection/anomaly detection:** Detect a fault state or anomaly in an ES without considering its root cause. This results in a binary classification problem with the states fault or no fault.
- **Diagnosis:** Assign one or more causes to a detected fault state.
- **Health assessment:** Assess the state of degradation or the current risk of failure of an ES based on its current condition.
- **Prognosis:** Prediction of the future degradation behavior or the current Remaining Useful Life (RUL).

The prognosis task poses the greatest challenge in diagnostics and prognostics within PHM [6]. This difficulty stems from the intricate nature of failure mechanisms and the multitude of factors influencing degradation progression. Therefore, sufficient degradation data is of huge importance for this task and needs to be comprehensively available.

3 Data Sets for Diagnostics and Prognostics

Table 1 in the *Appendix: Overview of Publicly Available Data Sets* contains an overview of publicly available data sets for the tasks of diagnostics and prognostics within PHM, sorted alphabetically. This is the extended overview from [4], which already contains 70 data sets.

The designation of the data sets is divided into two parts, consisting of the source or platform and the title under which they were published. In addition, the overview contains the following columns:

- **Domain and Application:** The associated domain from which the data set originates and the respective application within this domain.
- **Task:** The corresponding task within PHM addressable with this data set.
- **URL:** The respective hyperlink to the source or platform hosting the data set.

4 Description of Data Sets

The overview of publicly available degradation data sets in Table 1 comprises a total of 79 data sets. These data sets originate from eleven different domains. The domains as well as the applications presented do not claim to be exhaustive and are based solely on the available data sets. With 17 assigned data sets, the *Mechanical component* domain is the most extensive, followed by the *Electrical component* domain with 13 assigned data sets. The two most frequently occurring applications, *Bearing* (ten) and *Battery* (six), also originate from these two domains. In total, the domains contain 36 different applications.

Except for the *Building* domain, which is sparsely represented in PHM, the data sets are evenly distributed for the remaining domains, with at least four and at most nine assignments per domain. With only one data set for each application, the *Mechatronic system* domain contains the greatest variation of applications. Moreover, there are five data sets with unknown applications and therefore, no domain can be assigned. Data sets with degradation data resulting from a simulated application are assigned to the corresponding domains but marked. With 32 assigned data sets for prognosis and 29 for diagnosis, these tasks are the most represented. For fault detection, 15 data sets are assigned, and for health assessment, 3 data sets are assigned. The *Electrical component* domain contains the most data sets (ten) for the task prognosis, followed by the *Drive technology* domain with six and the *Manufacturing process* as well as *Process technology* domains with four assigned data sets each.

Of the 17 assigned data sets in the *Mechanical component* domain, only two are for task prognosis. However, for the task diagnosis, the *Mechanical component* domain contains the most data sets with eleven assignments. Followed

by the *Mechatronic system* domain with five and the *Robotic* domain with four assigned data sets. Regarding fault detection, the domains *Mechanical component* and *Production system* contain the most data sets with four assignments each. With two data sets with an *Unknown* domain and one data set from the *Drive technology* domain, the overview contains the fewest data sets for the health assessment task.
