A short proof of the Dvoretzky–Kiefer–Wolfowitz–Massart inequality

Henry W J Reeve University of Bristol henry.reeve@bristol.ac.uk

Abstract

The Dvoretzky–Kiefer–Wolfowitz–Massart inequality gives a sub-Gaussian tail bound on the supremum norm distance between the empirical distribution function of a random sample and its population counterpart. We provide a short proof of a result that improves the existing bound in two respects. First, our one-sided bound holds without any restrictions on the failure probability, thereby verifying a conjecture of [Birnbaum and McCarty](#page-9-0) [\(1958](#page-9-0)). Second, it is local in the sense that it holds uniformly over sub-intervals of the real line with an error rate that adapts to the behaviour of the population distribution function on the interval. ¹

Let X_1, \ldots, X_n be independent random variables with distribution function $F : \mathbb{R} \to$ [0, 1]. Let \hat{F}_n denote the empirical distribution function,

$$
\hat{F}_n(t) := \frac{1}{n} \sum_{i=1}^n \mathbb{1}_{\{X_i \le t\}},
$$

for $t \in \mathbb{R}$. Understanding the deviation of the empirical distribution function from its population counterpart is a longstanding goal within probability theory with a multitude of applications to statistics. The Glivenko–Cantelli theorem [\(Glivenko,](#page-10-0) [1933;](#page-10-0) [Cantelli](#page-9-1), [1933](#page-9-1)) gives almost sure convergence of the empirical distribution function to the population distribution function with respect to the supremum norm, initiating a line of work towards understanding the rate of convergence. Classical results of [Bernstein](#page-9-2) [\(1924\)](#page-9-2), and subsequent work by [Bennett](#page-9-3) [\(1962](#page-9-3)) and [Hoeffding](#page-10-1) [\(1963](#page-10-1)), may be viewed as giving finite-sample pointwise guarantees for specific value of $t \in \mathbb{R}$. [Dvoretzky et al.](#page-10-2) [\(1956\)](#page-10-2) proved a sub-Gaussian bound on the supremum norm distance between the empirical and population distribution functions. Subsequent work of [\(Devroye and Wise,](#page-9-4) [1979;](#page-9-4) [Hu](#page-10-3), [1985](#page-10-3); [Shorack and Wellner](#page-10-4), [1986](#page-10-4)) led to improvements in the bound. Motivated by an asymptotic analysis due to [Smirnov](#page-10-5) [\(1944](#page-10-5)), and further numerical computations, [Birnbaum and McCarty](#page-9-0) [\(1958\)](#page-9-0) gave a conjecture on the optimal leading constant. A breakthrough result of [Massart](#page-10-6) [\(1990](#page-10-6)) achieved the optimal constant, settling the conjecture of [Birnbaum and McCarty](#page-9-0) [\(1958\)](#page-9-0), subject to a mild constraint on the failure probability. It follows from [Smirnov](#page-10-5) [\(1944](#page-10-5)) that the leading term

¹I would like to express my gratitude to Richard J. Samworth for encouragement and useful feedback which substantially improved the quality of the exposition.

in [Massart](#page-10-6) [\(1990](#page-10-6)) cannot be improved. We recommend [Dudley](#page-10-7) [\(2014\)](#page-10-7) for an exposition of the proof of [Massart](#page-10-6) [\(1990](#page-10-6)[\), and its connections to](#page-10-8) [Bretagnolle and Massart](#page-9-5) [\(1989](#page-9-5)). Maillard [\(2021\)](#page-10-8) derived an integral expression for the probability that the empirical distribution function exceeds a given distance from their population counterpart, uniformly over a given interval. Recently, [Bartl and Mendelson](#page-9-6) [\(2023\)](#page-9-7) and Blanchard and Voráček (2023) give more interpretable local bounds.

Let's first introduce some notation. Given $a, b \in [0, 1]$ we let

$$
kl(a||b) := a \log \left(\frac{a}{b}\right) + (1-a) \log \left(\frac{1-a}{1-b}\right),
$$

where we adopt the convention that $0 \log 0 = 0 \log(0/0) = 0$ and $z \log(z/0) = \infty$ for $z >$ 0. Thus, $\mathbf{k}[(a||b)$ denotes the Kullback-Leibler divergence between two Bernoulli random variables with respective success probabilities a and b. For each $p \in (0, e^{-\varepsilon}]$ there is a unique value of $\eta \in [0, 1-p]$ with $kl(p+\eta||p) = \varepsilon$ (Lemma [5\)](#page-5-0) and we denote this unique value by $\omega(p,\varepsilon)$. We extend ω to $[0,1] \times [0,\infty)$ by letting $\omega(p,\varepsilon) := 1-p$ if $p \in (e^{-\varepsilon},1]$; we also let $\omega(p,\varepsilon) := 0$ whenever $p = 0$, so that $p \mapsto \omega(p,\varepsilon)$ is continuous (Lemma [6\)](#page-5-1). Given $\delta \in (0,1)$ we let $\varepsilon(n, \delta) := \log(1/\delta)/n$.

Our main result is the following.

Theorem 1. *Given any interval* $\mathcal{I} \subseteq \mathbb{R}$ *and* $\delta \in (0,1)$ *we have*

$$
\mathbb{P}\bigg\{\sup_{t\in\mathcal{I}}\{\hat{F}_n(t)-F(t)\}\bigg\}\geq \sup_{t\in\mathcal{I}}\,\omega\big(F(t),\varepsilon(n,\delta)\big)\bigg\}\leq \delta.
$$

In order to give a more interpretable bound we write $\sigma(p) := \sqrt{p(1-p)}$ for $p \in [0, 1]$ and introduce the function $\varphi_0 : [0, 1] \times (0, \infty) \to (0, 1]$ defined by

$$
\varphi_0(p,\varepsilon) := \sqrt{4\sigma^2(p)\rho_\varepsilon^2 + \sigma^2(\rho_\varepsilon)} + \sigma(\rho_\varepsilon)(1-2p)
$$

= $\sqrt{4\sigma^2(p)\rho_\varepsilon^2 + \sigma^2(\rho_\varepsilon)} + \sigma(\rho_\varepsilon)\operatorname{sign}(1-2p)\sqrt{1-4\sigma^2(p)},$ (1)

where $\rho_{\varepsilon} := 9/(9 + 2\varepsilon) \in (0, 1)$. Note that $\varphi_0(p, \varepsilon) \leq 1$ for all $p \in [0, 1]$. Indeed, the map $p \mapsto \varphi_0(p,\varepsilon)$ is concave with a unique maximum of $\sup_{p\in[0,1]} \varphi_0(p,\varepsilon) = 1$ attained when $1 - 2p = \sigma(\rho_{\varepsilon})/\rho_{\varepsilon}$. Moreover, we have $\lim_{\varepsilon \searrow 0} \rho_{\varepsilon} = 1$, so $\lim_{\varepsilon \searrow 0} \sigma(\rho_{\varepsilon}) = 0$, and hence $\lim_{\varepsilon \searrow 0} \varphi_0(p, \varepsilon) = 2\sigma(p)$ for all $p \in [0, 1]$. Given an interval $\mathcal{I} \subseteq \mathbb{R}$, let $p_{\min} := \inf_{t \in \mathcal{I}} F(t)$ and $p_{\text{max}} := \sup_{t \in \mathcal{I}} F(t)$, and set

$$
\varphi(\mathcal{I}, \varepsilon) := \begin{cases}\n\varphi_0(p_{\max}, \varepsilon) & \text{if } 2p_{\max} < 1 - \sigma(\rho_{\varepsilon})/\rho_{\varepsilon} \\
1 & \text{if } 2p_{\min} \le 1 - \sigma(\rho_{\varepsilon})/\rho_{\varepsilon} \le 2p_{\max} \\
\varphi_0(p_{\min}, \varepsilon) & \text{if } 2p_{\min} > 1 - \sigma(\rho_{\varepsilon})/\rho_{\varepsilon}.\n\end{cases}
$$

Our first corollary is designed to highlight the role played by variance in the local bound as well as the mild asymmetry in deviations around one half.

Corollary 1. *Given any interval* $\mathcal{I} \subseteq \mathbb{R}$ *and* $\delta \in (0,1)$ *we have*

$$
\mathbb{P}\bigg\{\sup_{t\in\mathcal{I}}\{\hat{F}_n(t)-F(t)\}>\varphi\big(\mathcal{I},\varepsilon(n,\delta)\big)\sqrt{\frac{\varepsilon(n,\delta)}{2}}\bigg\}\leq\delta.
$$

Our next corollary is a refinement of the celebrated Dvoretzky–Kiefer–Wolfowitz–Massart inequality [\(Dvoretzky et al.](#page-10-2), [1956;](#page-10-2) [Massart,](#page-10-6) [1990](#page-10-6)).

Corollary 2. *Given any* $\xi \geq 0$ *and* $\zeta := 2\xi^2/3$ *we have*

$$
\mathbb{P}\left\{\sup_{t\in\mathbb{R}}\sqrt{n}\left\{\hat{F}_n(t) - F(t)\right\} > \xi\right\} \le \exp\left(-2\xi^2 - \frac{\zeta^2}{n}\left\{1 + \frac{4\zeta}{5n} + \frac{425\zeta^2}{525n^2}\right\}\right).
$$

In comparison, [Massart](#page-10-6) [\(1990](#page-10-6), Theorem 1) gives a slightly larger bound of $\exp(-2\xi^2)$ for $\xi \ge \min\{\sqrt{\log(2)/2}, 1.0841n^{-1/6}\}\.$ [Massart](#page-10-6) [\(1990](#page-10-6)) remarks that whilst this captures the regime of interest for statistical purposes, the proof therein does not extend to smaller values of ξ . Corollary [1](#page-1-0) verifies the conjecture of [Birnbaum and McCarty](#page-9-0) [\(1958](#page-9-0)) for all values of $\xi > 0$ and Corollary [2](#page-2-0) proves a slightly stronger result.

Our final corollary is a variance-adaptive bound for the entire real line, at the expense of an extra logarithmic factor.

Corollary 3. Suppose that $\delta \in (0,1)$, $\beta > 1$ and let $\varepsilon_{\beta}(n, \delta) := \log(2\lceil \log_{\beta}(n) \rceil / \delta) / n$. Then,

$$
\mathbb{P}\bigg\{\hat{F}_n(t) - F(t) > \left(\beta\varphi_0\big(F(t), \varepsilon_\beta(n, \delta)\big)\sqrt{\varepsilon_\beta(n, \delta)/2}\right) \vee \left(\frac{1}{n}\right) \text{ for some } t \in \mathbb{R}\bigg\} \le \delta.
$$

Corollary [3](#page-2-1) is a slight improvement on recent results from [Bartl and Mendelson](#page-9-6) [\(2023,](#page-9-6) Theorem 1.2) and Blanchard and Voráček $(2023,$ Theorem 5) where similar bounds are given but the universal constants are left unspecified. We remark that Corollary [3](#page-2-1) can be restated as a simultaneous lower-confidence bound by taking

$$
\mathcal{U}(q,\varepsilon):=\frac{3\beta\big((2q-1)(3\beta-1)\varepsilon+\sqrt{\varepsilon\{18\sigma^2(q)+\varepsilon(3\beta-1)^2\}}\big)}{9+2\varepsilon(3\beta-1)^2}.
$$

Indeed, Corollary [3](#page-2-1) may be restated as follows

$$
\mathbb{P}\bigg\{F(t) > \hat{F}_n(t) - \mathcal{U}\big(\hat{F}_n(t), \varepsilon_\beta(n, \delta)\big) \vee \bigg(\frac{1}{n}\bigg) \text{ for all } t \in \mathbb{R}\bigg\} \ge 1 - \delta.
$$

The proof of Theorem [1](#page-2-2) is given in Section [1,](#page-2-2) with the proof a technical lemma and the corrollaries given in Section [2.](#page-4-0)

1 Proof of Theorem [1](#page-1-1)

To begin the proof we first introduce a reverse filtration $(\mathcal{G}_t)_{t\in\mathbb{R}}$ (a collection of sigma algebras such that $\mathcal{G}_{t_1} \subseteq \mathcal{G}_{t_0}$ whenever $t_0 \leq t_1$. For each $t \in \mathbb{R}$ we let \mathcal{G}_t denote the sigma-algebra by all events of the form $\{X_i \leq s\}$ with $s \geq t$ and $i \in [n]$ are measurable.

Given $\lambda \geq 0$ let $(M_{\lambda}(t))_{t>t_0}$ denote the non-negative stochastic process defined by

$$
M_{\lambda}(t) := \frac{1}{(1+\lambda)^n} \left(1 + \frac{\lambda}{F(t)}\right)^{n\hat{F}_n(t)}.
$$

Lemma 1. Suppose $t_0 \in \mathbb{R}$ satisfies $F(t_0) > 0$. Then $(M_\lambda(t))_{t \geq t_0}$ is a reverse martingale *with respect to* $(\mathcal{G}_t)_{t \geq t_0}$ *. Moreover,* $\mathbb{E}\{M_\lambda(t)\} = 1$ *for all* $t \geq t_0$ *.*

Proof. Take $s_0 \in [t_0, \infty)$ and $s_1 \in (s_0, \infty)$. Observe that, conditionally on \mathcal{G}_{s_1} , the random variable $W := n \hat{F}_n(s_0)$ has the distribution of a Binomial random variable with $m := n \hat{F}_n(s_1)$ trials and success probability $p := F(s_0)/F(s_1)$. Thus, for each $\lambda \geq 0$ we have

$$
\mathbb{E}\left\{\left(1+\frac{\lambda}{F(s_0)}\right)^{n\hat{F}_n(s_0)}\ \bigg|\ \mathcal{G}_{s_1}\right\} = \mathbb{E}\left\{\left(1+\frac{\lambda}{pF(s_1)}\right)^W\ \bigg|\ \mathcal{G}_{s_1}\right\}
$$

$$
= \left\{p\left(1+\frac{\lambda}{pF(s_1)}\right) + (1-p)\right\}^m = \left(1+\frac{\lambda}{F(s_1)}\right)^{n\hat{F}_n(s_1)}.
$$

which entails the reverse martingale property. Applying the dominated convergence theorem with the bound $(1 + \lambda/F(s_0))^n$ yields that for all $t \geq t_0$,

$$
\mathbb{E}\{M_{\lambda}(t)\}=\lim_{s\nearrow\infty}\mathbb{E}\{M_{\lambda}(s)\}=\mathbb{E}\left\{\lim_{s\nearrow\infty}M_{\lambda}(s)\right\}=1.
$$

Next, for each $\varepsilon > 0$, we define a function $\Delta \equiv \Delta_{\varepsilon} : (0,1] \times (0,\infty) \to [0,\infty)$ by

$$
\Delta(r,\lambda) \equiv \Delta_{\varepsilon}(r,\lambda) := \frac{\log(1+\lambda) + \varepsilon}{\log(1+\lambda/r)} - r.
$$

Note that the inequality $(1 + \lambda/r)^r \le (1 + \lambda)$ for $r \in [0, 1]$ ensures that Δ is non-negative. Given $\lambda > 0$ and $\delta \in (0,1)$ we define

$$
\mathcal{E}(\lambda,\delta) := \bigcap_{t \in \mathbb{R}: F(t) > 0} \{ \hat{F}_n(t) - F(t) \leq \Delta_{\varepsilon(n,\delta)}(F(t),\lambda) \}.
$$

Lemma 2. For all $\lambda > 0$ and $\delta \in (0,1)$ we have $\mathbb{P}\{\mathcal{E}(\lambda,\delta)\} \geq 1-\delta$.

Proof. Given $k \in \mathbb{N}$ we let $\mathbb{T}_k := \{t \in [-2^k, 2^k] : t = 2^{-k} \lfloor 2^k t \rfloor \text{ and } F(t) > 0\}$. By Lemma [1](#page-2-3) the process $\{M_\lambda(t)\}_{t\in\mathbb{T}_k}$ is a reverse martingale with $\mathbb{E}(M_\lambda(t)) = 1$ for all $k \in \mathbb{N}$ and $t \in \mathbb{T}_k$. Hence, by Doob's maximal inequality [\(Dudley](#page-10-9), [2018,](#page-10-9) Theorem 10.4.2) we have $\mathbb{P}\{\mathcal{E}_k(\lambda,\delta)\}\geq 1-\delta$ where

$$
\mathcal{E}_k(\lambda,\delta) := \left\{ \max_{t \in \mathbb{T}_k} M_{\lambda}(t) < 1/\delta \right\} = \bigcap_{t \in \mathbb{T}_k} \left\{ \hat{F}_n(t) < F(t) + \Delta_{\varepsilon(n,\delta)} \big(F(t), \lambda \big) \right\},
$$

where the equality between the events follows by taking logarithms. In addition, since $t \mapsto M_\lambda(t)$ is almost surely right-continuous and $\bigcup_{k\in\mathbb{N}} \mathbb{T}_k$ is dense in $\{t \in \mathbb{R} : F(t) > 0\}$ we have $\mathcal{E}(\lambda, \delta) = \bigcap_{k \in \mathbb{N}} \mathcal{E}_k(\lambda, \delta)$. Thus, since the events $\{\mathcal{E}_k(\lambda, \delta)\}_{k \in \mathbb{N}}$ form a decreasing sequence we have $\mathbb{P}\{\mathcal{E}(\lambda,\delta)\}\geq 1-\delta$.

Lemma 3. *Given any non-empty closed interval* $P \subseteq (0, e^{-\varepsilon})$ *there exists* $(p_{\star}, \lambda_{\star}) \in \mathcal{P} \times$ $(0, \infty)$ *with* $\Delta(p_\star, \lambda_\star) = \inf_{\lambda \in (0, \infty)} \Delta(p_\star, \lambda) = \sup_{p \in \mathcal{P}} \Delta(p, \lambda_\star) = \omega(p_\star, \varepsilon).$

The proof of Lemma [3](#page-3-0) is somewhat technical and is given in Section [2.](#page-4-0)

Proof of Theorem [1.](#page-1-1) Choose $\zeta \in (0,1)$ and suppose that the closed interval $\mathcal{P}_{\zeta} := \text{cl}(\lbrace F(t) :$ $t \in \mathcal{I}$) \cap $[\zeta, e^{-\varepsilon} - \zeta]$ is non-empty. By applying Lemma [3](#page-3-0) with $\varepsilon = \varepsilon(n, \delta)$ we obtain $(p_{\star}, \lambda_{\star}) \in \mathcal{P} \times (0, \infty)$ so that $\Delta(p_{\star}, \lambda_{\star}) = \sup_{p \in \mathcal{P}_{\zeta}} \Delta(p, \lambda_{\star}) = \omega(p_{\star}, \varepsilon) > 0$. Moreover, by Lemma [2](#page-3-1) we have $\mathbb{P}\{\mathcal{E}(\lambda_{\star},\delta)\}\geq 1-\delta$. On the event $\mathcal{E}(\lambda_{\star},\delta)$, for each $t \in \mathcal{I}$ with $F(t) \in [\zeta, e^{-\varepsilon} - \zeta]$ we have

$$
\hat{F}_n(t) - F(t) < \Delta(F(t), \lambda) \le \sup_{p \in \mathcal{P}_\zeta} \Delta(p, \lambda_\star) = \Delta(p_\star, \lambda_\star) = \omega(p_\star, \varepsilon)
$$
\n
$$
\le \sup_{p \in cl(\{F(t): t \in \mathcal{I}\})} \omega(p, \varepsilon) = \sup_{p \in \{F(t): t \in \mathcal{I}\}} \omega(p, \varepsilon) = \sup_{t \in \mathcal{I}} \omega(F(t), \varepsilon),
$$

where we applied the continuity of $p \mapsto \omega(p, \varepsilon)$ (Lemma [6\)](#page-5-1) for the penulitmate equality. Note that the bound holds vacuously if $\mathcal{P}_{\zeta} = \emptyset$. Moreover, if $t \in \mathcal{I}$ satisfies $F(t) \in \{0\} \cup [e^{-\varepsilon}, 1]$ then we have $\hat{F}_n(t) - F(t) \le \omega(F(t), \varepsilon) \le \sup_{t \in \mathcal{I}} \omega(F(t), \varepsilon)$ almost surely (Lemma [7\)](#page-6-0). Hence,

$$
\mathbb{P}\bigg\{\hat{F}_n(t) - F(t) > \sup_{t \in \mathcal{I}} \omega\big(F(t), \varepsilon(n, \delta)\big) \text{ for some } t \in \mathcal{I} \text{ with } F(t) \notin (0, \zeta) \cup (e^{-\varepsilon} - \zeta)\bigg\} \le \delta.
$$

Since this bound holds for all sufficiently small ζ , the conclusion of the theorem follows by continuity of probability. \Box

2 Proofs of technical lemmas

Throughout we shall consider $[-\infty,\infty]:=\mathbb{R}\cup\{-\infty,\infty\}$ with the usual topology, generated by the topological basis consisting of all intervals of the form (a, b) , (a, ∞) or $[-\infty, b)$ where $a, b \in \mathbb{R}$. We shall use the following elementary form of the implicit function theorem (Lemma [4\)](#page-4-1). Given a Borel set $\mathcal{Y} \subseteq [-\infty, \infty]$ we shall say that a function $g: \mathcal{Y} \to [-\infty, \infty]$ is *sign-monotonic* if

$$
(g(y_a), g(y_b)) \in ([-\infty, 0) \times [-\infty, \infty]) \cup ([-\infty, \infty] \times (0, \infty]),
$$
 (2)

for all $y_a, y_b \in \mathcal{Y}$ with $y_a < y_b$. Note that a sufficient condition for $g: \mathcal{Y} \to [-\infty, \infty]$ to be sign-monotonic is that g is both non-decreasing and $|\{y \in \mathcal{Y} : g(y) = 0\}| \leq 1$.

Lemma 4. Let $\mathcal{X} \subseteq \mathbb{R}^d$ be a Borel set, $\mathcal{Y} \subseteq [-\infty, \infty]$ is a non-empty interval which is *bounded from below and let* $\Gamma : \mathcal{X} \times \mathcal{Y} \to [-\infty, \infty]$ *be a function. Suppose that for each* $x \in \mathcal{X}$ the function $y \mapsto \Gamma(x, y)$ is sign-monotonic. Suppose further that for each $y \in \mathcal{Y}$, the *function* $x \mapsto \Gamma(x, y)$ *is continuous and define a function* $\gamma : \mathcal{X} \to cl(\mathcal{Y})$ *by*

$$
\gamma(x) := \begin{cases} \sup \mathcal{Y} & \text{if } \Gamma(x, y) < 0 \text{ for all } y \in \mathcal{Y} \\ \inf \{ y \in \mathcal{Y} : \Gamma(x, y) \ge 0 \} & \text{otherwise.} \end{cases}
$$

Then γ *is continuous and* $\Gamma(x, y)(y - \gamma(x)) > 0$ *for all* $x \in \mathcal{X}$ *and* $y \in \mathcal{Y} \setminus {\gamma(x)}$ *.*

Whilst we expect that Lemma [4](#page-9-8) is known, we include a proof in Section 4 for the convenience of the reader.

Lemma 5. For each $p \in (0,1)$, the function $\eta \mapsto k(p+\eta||p)$ is strictly increasing and *continuous bijection from* $[0, 1-p]$ *to* $[0, \log(1/p)]$ *. Hence, for* $p \in (0, e^{-\varepsilon}]$ *, there is a unique value of* $\eta \in [0, 1-p]$ *with* $\text{kl}(p+\eta||p) = \varepsilon$ *and if* $p \in (e^{-\varepsilon}, 1]$ *then* $\text{kl}(p+\eta||p) < \varepsilon$ *for all* $\eta \in [0, 1-p]$.

Proof. Given $p \in (0, 1)$ and $\eta_0 \in [0, 1 - p)$, we have $p + \eta_0 < 1$ so the map $\eta \mapsto \text{kl}(p + \eta || p)$ is differentiable at η_0 , with derivative

$$
\log\left(\frac{\eta_0+p}{p}\right)+\log\left(\frac{1-p}{1-p-\eta_0}\right)>0.
$$

Hence, $\eta \mapsto k\vert (p + \eta \vert p)$ is also strictly increasing and continuous function on $[0, 1 - p)$. Moreover, since $p \in (0,1)$ we have $\lim_{a \nearrow 1}$ kl $(a||p) = \log(1/p) =$ kl $(1||p)$ so that $\eta \mapsto$ kl $(p+$ $\eta||p)$ is strictly increasing and continuous bijection from $[0, 1 - p]$ to $[0, \log(1/p)]$. Finally, note that $\varepsilon \in [0, \log(1/p)] = \{kl(p+n||p) : n \in [0, 1 - p]\}$ if and only if $p \in (0, e^{-\varepsilon})$. note that $\varepsilon \in [0, \log(1/p)] = {\mathbf{kl}(p + \eta || p) : \eta \in [0, 1 - p]}$ if and only if $p \in (0, e^{-\varepsilon})$.

Lemma 6. *Given* $\varepsilon > 0$ *the function* $p \mapsto \omega(p, \varepsilon)$ *is continuous.*

Proof. Let's define a function $\Gamma_{kl} : [0, 1]^2 \to [0, \infty]$ by

$$
\Gamma_{\text{kl}}(x, y) := \begin{cases}\n-\varepsilon & \text{if } y \leq x \\
\text{kl}(y||x) - \varepsilon & \text{otherwise.}\n\end{cases}
$$

For each $x \in (0,1)$, it follows from Lemma [5](#page-5-0) that $y \mapsto \Gamma_{\text{kl}}(x, y)$ is sign-monotonic. Furthermore, if $x \in \{0,1\}$ then $y \mapsto \Gamma_{kl}(x, y)$ is a non-decreasing and piecewise constant with $\{y \in [0,1]: \Gamma_{\text{kl}}(x,y) = 0\} = \emptyset$. As such, $y \mapsto \Gamma_{\text{kl}}(x,y)$ is sign-monotonic for all $x \in [0,1]$. Note also that for each $y \in [0, 1]$, the map $x \mapsto kl(y||x)$ is continuous; and consequently so is $x \mapsto \Gamma_{\text{kl}}(x, y)$. Thus, by Lemma [4](#page-4-1) the function $\gamma_{\text{kl}} : [0, 1] \to [0, 1]$ by

$$
\gamma_{kl}(x) := \begin{cases} 1 & \text{if } kl(y||x) < \varepsilon \text{ for all } y \in [0,1] \\ \inf\{y \in [0,1] : kl(y||x) \ge \varepsilon\} & \text{otherwise.} \end{cases}
$$

is also continuous. Finally note that for all $p \in [0, 1]$ we have $\omega(p, \varepsilon) = \gamma_{kl}(p) - p$, so that $p \mapsto \omega(p, \varepsilon)$ is also continuous. $p \mapsto \omega(p, \varepsilon)$ is also continuous.

Proof of Lemma [3.](#page-3-0) Observe that Δ is twice differentiable on $(0, 1] \times (0, \infty)$ with

$$
\partial_r \Delta(r,\lambda) = \frac{\lambda \left\{ \varepsilon + \log \left(1 + \lambda \right) \right\}}{r \left(\lambda + r \right) \log^2 \left(1 + \lambda / r \right)} - 1,
$$

$$
\partial_{r,r} \Delta(r,\lambda) = \frac{\lambda^2 \left\{ \varepsilon + \log \left(1 + \lambda \right) \right\} \left\{ 2 - \left(1 + 2r/\lambda \right) \log \left(1 + \lambda / r \right) \right\}}{r^2 \left(r + \lambda \right)^2 \log^3 \left(1 + \lambda / r \right)}.
$$

By applying the inequality $\log(1+z) > 2z/(2+z)$ for $z > 0$ we deduce $\partial_{r,r}\Delta(r,\lambda) < 0$ for $r >$ 0, so $r \mapsto \Delta(r, \lambda)$ is strictly concave. Now consider the function $\Gamma_0 : (0, \infty) \times \mathcal{P} \to [-\infty, \infty]$ defined by $\Gamma_0(\lambda, r) := -\partial_r \Delta(r, \lambda)$. For each $\lambda \in (0, \infty)$, the strict concavity of $r \mapsto \Delta(r, \lambda)$ implies that $r \mapsto \Gamma_0(\lambda, r)$ is strictly increasing and as such $|\{r \in \mathcal{P} : \Gamma_0(\lambda, r) = 0\}| \leq 1$. Moreover, for each $r \in \mathcal{P}$ the function $\lambda \mapsto \Gamma_0(\lambda, r)$ is continuous. Hence, by Lemma [4](#page-4-1) there exists a continuous function $\bar{p}: (0,\infty) \to \mathcal{P}$ such that $(\bar{p}(\lambda) - r)\partial_r\Delta(r,\lambda) < 0$ for all $\lambda \in (0,\infty)$ and $p \in \mathcal{P}\setminus \{\overline{p}(\lambda)\}\.$ Hence, we have $\Delta(r,\lambda) \leq \Delta(\overline{p}(\lambda),\lambda)$ for all $(r,\lambda) \in \mathcal{P}\times(0,\infty)$. Next, we define a function $\Gamma_1 : \mathcal{P} \times (0, \infty) \to \mathbb{R}$ by

 $\Gamma_1(p,\lambda) := (p+\lambda)\log(1+\lambda/p) - (1+\lambda)\left\{\varepsilon + \log(\lambda+1)\right\},$

so that $\partial_{\lambda}\Delta(p,\lambda) = \Gamma_1(p,\lambda)/\{(1+\lambda)(p+\lambda)\log^2(1+\lambda/p)\}\.$ Note that for each $\lambda \in (0,\infty)$ the map $p \mapsto \Gamma_1(p, \lambda)$ is continuous on P with

$$
\partial_{\lambda}\Gamma_1(p,\lambda)=\log\left(1+\lambda/p\right)-\{\varepsilon+\log\left(1+\lambda\right)\},\
$$

so $\Gamma_1(p,\lambda) = 0$ implies $\partial_\lambda \Gamma_1(p,\lambda) > 0$. Thus, $\lambda \mapsto \Gamma_1(p,\lambda)$ is sign-monotonic for all $p \in \mathcal{P}$. Consequently, there exists a continuous function $\lambda : \mathcal{P} \to [0, \infty]$ such that $\Gamma_1(p, \lambda)(\underline{\lambda}(p) \lambda$) > 0, and consequently, $\partial_{\lambda}\Delta(p,\lambda)(\underline{\lambda}(p)-\lambda)$ > 0 for all $p \in \mathcal{P}$ and $\lambda \in (0,\infty)\setminus\{\underline{\lambda}(p)\}\$. Note also that for each $p \in \mathcal{P} \subseteq (0, e^{-\varepsilon})$ we have $\lim_{\lambda \searrow 0} \Gamma_0(p, \lambda) = -\varepsilon < 0$ and $\lim_{\lambda \nearrow \infty} \Gamma(p, \lambda) =$ ∞ so by by the continuity of $\lambda \mapsto \Gamma(p, \lambda)$ there must be at least one root in $(0, \infty)$, which must coincide with $\Delta(p)$ i.e. $\Gamma(p, \Delta(p)) = 0$. Hence, $\Delta(p) \in (0, \infty)$ and $\Delta(p, \Delta(p)) \leq \Delta(p, \lambda)$ for all $\lambda \in (0, \infty)$.

Next, we define a function $\Phi : \mathcal{P} \to \mathbb{R}$ by $\Phi(\rho) = \overline{p}(\underline{\lambda}(\rho)) - \rho$ and choose $p_{\min}, p_{\max} \in$ $(0, e^{-\varepsilon})$ so that $\mathcal{P} = [p_{\min}, p_{\max}]$. Notice that Φ is continuous with $\Phi(p_{\min}) \ge 0$ and $\Phi(p_{\max}) \le$ 0 so by the intermediate value theorem there must exist some $p_{\star} \in \mathcal{P}$ with $\Phi(p_{\star}) = 0$. Letting $\lambda_\star := \underline{\lambda}(p_\star)$ we obtain a pair $(p_\star, \lambda_\star) \in \mathcal{P} \times (0, \infty)$ satisfying $\Delta(p_\star, \lambda_\star) = \inf_{\lambda \in (0, \infty)} \Delta(p_\star, \lambda) =$ $\sup_{p \in \mathcal{P}} \Delta(p, \lambda_\star).$

In addition, given any $p \in (0, e^{-\varepsilon})$ we have $\Gamma_1(p, \underline{\lambda}(p)) = 0$ which yields $p + \Delta\{p, \underline{\lambda}(p)\} =$ $(p + \underline{\lambda}(p))/(1 + \underline{\lambda}(p)) \in (p, 1)$ and kl $(p + \Delta\{p, \underline{\lambda}(p)\}||p) = \varepsilon$ upon rearranging. Hence,
 $\omega(p, \lambda(p)) = \Delta(p, \varepsilon) > 0$. Since $\lambda_{\star} = \lambda(p_{\star})$ this completes the proof of the lemma. $\omega(p, \underline{\lambda}(p)) = \Delta(p, \varepsilon) > 0$. Since $\lambda_{\star} = \underline{\lambda}(p_{\star})$ this completes the proof of the lemma.

For the next lemma we define an event \mathcal{E}_0 by

$$
\mathcal{E}_0 := \bigcap_{t \in \mathbb{R}: F(t) \in \{0\} \cup [e^{-\varepsilon}, 1]} \left\{ \hat{F}_n(t) - F(t) \le \omega(F(t), \varepsilon) \right\}.
$$

Lemma 7. We have $\mathbb{P}(\mathcal{E}_0) = 1$.

Proof. Let's introduce $J_0 := \{t \in \mathbb{R} : F(t) = 0\}$ and $\tilde{\mathcal{E}}_0 := \{\sup_{t \in \mathbb{R}} \hat{F}_n(t) \leq 1\} \cap \bigcap_{i=1}^n \{X_i \notin$ J_0 , so that $\mathbb{P}(\tilde{\mathcal{E}}_0) = 1$. Now suppose the event $\tilde{\mathcal{E}}_0$ holds. If $F(t) = 0$ then $(0, t] \subseteq J_0$ so that $\hat{F}_n(t) = 0$, and so $\hat{F}_n(t) - F(t) = 0 = \omega(F(t), \varepsilon)$. On the other hand, if $F(t) \ge e^{-\varepsilon}$ then $\hat{F}_n(t) - F(t) \leq 1 - F(t) = \omega(F(t), \varepsilon)$, where we have used the definition of $\omega(p, \varepsilon)$ for $log(1/p) < \varepsilon$ and the continuity of $p \mapsto \omega(p, \varepsilon)$ at $p = e^{-\varepsilon}$ (Lemma [6\)](#page-5-1).

Given $(p, \eta) \in (0, 1)$ and $\eta \in [0, 1-p]$ we let

$$
h_m(p,\eta) := \frac{\eta^2}{2(p+\eta/3)(1-p-\eta/3)}.
$$

Lemma 8. For all $p \in (0,1)$ and $\eta \in [0,1-p]$ we have $h_m(p,\eta) \leq \text{kl}(p+\eta||p)$.

Proof. Given $z \in (0,1]$ let's write $f_z : (0, z] \to \mathbb{R}$ for the function

$$
f_z(\eta) := \mathrm{kl}(z||z - \eta) - h_m(z - \eta, \eta).
$$

Observe that $f_z(0) = 0$ and for $\eta < z \leq 1$ we have

$$
\partial_{\eta} f_z(\eta) = \frac{\eta^3 (16\eta^2 - 42\eta z + 21\eta + 27z^2 - 27z + 9)}{(3z - 2\eta)^2 (3 + 2\eta - 3z)^2 (z - \eta)(1 + \eta - z)} > 0.
$$

Hence, $\text{kl}(p + \eta || p) = h_m(p, \eta) + f_{p+\eta}(\eta) \ge h_m(p, \eta)$, which establishes the first part of the lemma. lemma.

3 Proofs of the corollaries

Proof of Corollary [1.](#page-1-0) Let $p_{\min} := \inf_{t \in \mathcal{I}} F(t)$, $p_{\max} := \sup_{t \in \mathcal{I}} F(t)$ and take $\varepsilon = \varepsilon(n, \delta)$. Given $t \in \mathcal{I}$ we have $p = F(t) \in [p_{\min}, p_{\max}]$ we have $\text{kl}(p + \eta | p) < \varepsilon$ for any $\eta \in (0, \omega(p, \varepsilon))$. Thus, by Lemma [8](#page-6-1) we have $h_m(p, \eta) < \varepsilon$. By rearranging this bound with $\rho_{\varepsilon} = 9/(9 + 2\varepsilon)$, so $\sigma^2(\rho_{\varepsilon})/\rho_{\varepsilon}^2 = 2\varepsilon/9$ we deduce that

$$
\eta < \frac{3(\sqrt{\varepsilon\{\varepsilon + 18p(1-p)\}} + \varepsilon\{1-2p\})}{2\varepsilon + 9} = \rho_{\varepsilon} \left\{ \sqrt{4p(1-p) + \frac{2\varepsilon}{9}} + (1-2p)\sqrt{\frac{2\varepsilon}{9}} \right\} \sqrt{\frac{\varepsilon}{2}}
$$

$$
= \left\{ \sqrt{4\sigma^2(p)\rho_{\varepsilon}^2 + \sigma^2(\rho_{\varepsilon})} + (1-2p)\sigma(\rho_{\varepsilon}) \right\} \sqrt{\frac{\varepsilon}{2}} = \varphi_0(p,\varepsilon) \sqrt{\frac{\varepsilon}{2}}.
$$

Since this result for all $t \in \mathcal{I}$ and $\eta \in (0, \omega(p, \varepsilon))$ we deduce that

$$
\sup_{t\in\mathcal{I}}\,\omega\big(F(t),\varepsilon\big)\leq \sup_{p\in[p_{\min},p_{\max}]}\varphi_0(p,\varepsilon)\sqrt{\frac{\varepsilon}{2}}.
$$

Moreover, the function $p \mapsto \varphi_0(p, \varepsilon)$ is unimodal, strictly increasing on $[0, 1/2 - \sqrt{\varepsilon/3}]$ and strictly decreasing on $[1/2 - \sqrt{\varepsilon/3}, 1]$. Thus, we have

$$
\varphi(\mathcal{I}, \varepsilon) = \sup_{p \in [p_{\min}, p_{\max}]} \varphi_0(p, \varepsilon) \ge \sup_{t \in \mathcal{I}} \omega(F(t), \varepsilon) \sqrt{\frac{2}{\varepsilon}},
$$

and the conclusion of Corollary [1](#page-1-0) follows from Theorem [1.](#page-1-1)

Proof of Corollary [2.](#page-2-0) Given $\xi \geq 0$, $\zeta := 2\xi^2/3$, $\eta = \xi/\sqrt{n}$ and $p \in [0, 1 - \eta]$ it follows from [Fedotov et al.](#page-10-10) [\(2003](#page-10-10), Theorem 7) that

$$
kl(p+\eta||p) \ge 2\eta^2 + \frac{4\eta^4}{9} + \frac{32\eta^6}{135} + \frac{7072\eta^8}{42525} > n\left(2\xi^2 + \frac{\zeta^2}{n}\left\{1 + \frac{4\zeta}{5n} + \frac{425\zeta^2}{525n^2}\right\}\right) =: \log(1/\delta).
$$

Thus, $\omega(p, \varepsilon(n, \delta)) \leq \eta$ for all $p \in [0, 1]$ $p \in [0, 1]$ $p \in [0, 1]$. By Theorem 1 we deduce that

$$
\mathbb{P}\bigg\{\sup_{t\in\mathcal{I}}\{\hat{F}_n(t)-F(t)\}>\eta\bigg\}\leq\delta.
$$

Rearranging yields the conclusion of Corollary [2.](#page-2-0)

 \Box

 \Box

Proof of Corollary [3.](#page-2-1) By computing first and second derivatives we note that the map $p \mapsto$ $\varphi_0(p,\varepsilon)\sqrt{\varepsilon/2}$ is concave with a unique maximum attained at $p_\star := \{1-\sigma(\rho_\varepsilon)/\rho_\varepsilon\}/2$. Hence, we may construct a sequence of closed intervals $\{A_r\}_{r=1}^{\lceil \log_\beta(n) \rceil-1}$ and $\{B_r\}_{r=1}^{\lceil \log_\beta(n) \rceil-1}$ such that $A_r \subseteq [0, p_\star], B_r \subseteq [p_\star, 1]$ and

$$
\inf_{p \in A_r} \varphi_0 \{ F(t), \varepsilon_\beta(n, \delta) \} = \inf_{p \in B_r} \varphi_0 \{ F(t), \varepsilon_\beta(n, \delta) \} = \sqrt{\frac{2\beta^{-2(r+1)}}{\varepsilon_\beta(n, \delta)}},
$$

\n
$$
\sup_{p \in A_r} \varphi_0 \{ F(t), \varepsilon_\beta(n, \delta) \} = \sup_{p \in B_r} \varphi_0 \{ F(t), \varepsilon_\beta(n, \delta) \} = \sqrt{\frac{2\beta^{-2r}}{\varepsilon_\beta(n, \delta)}}.
$$

By Corollary [1,](#page-1-0) for each $r = 1, \ldots, \lceil \log_{\beta}(n) \rceil - 1$ we have

$$
\mathbb{P}\left\{\hat{F}_n(t) - F(t) > \beta\varphi_0\{F(t), \varepsilon_\beta(n, \delta)\}\sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}} \text{ for some } t \in \mathbb{R} \text{ with } F(t) \in A_r\right\}
$$
\n
$$
\leq \mathbb{P}\left\{\sup_{t \in \mathbb{R} \,:\, F(t) \in A_r} \{\hat{F}_n(t) - F(t)\} > \inf_{p \in A_r} \beta\varphi_0\{p, \varepsilon_\beta(n, \delta)\}\sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}}\right\}
$$
\n
$$
\leq \mathbb{P}\left\{\sup_{t \in \mathbb{R} \,:\, F(t) \in A_r} \{\hat{F}_n(t) - F(t)\} > \sup_{p \in A_r} \varphi_0\{p, \varepsilon_\beta(n, \delta)\}\sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}}\right\}
$$
\n
$$
= \mathbb{P}\left\{\sup_{t \in \mathbb{R} \,:\, F(t) \in A_r} \{\hat{F}_n(t) - F(t)\} > \varphi\{A_r, \varepsilon_\beta(n, \delta)\}\sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}}\right\} \leq \frac{\delta}{2\lceil\log_\beta(n)\rceil},
$$

and similarly with B_r in place of A_r . We also let $A_{\lceil \log_\beta(n) \rceil} := [0, \inf A_{\lceil \log_\beta(n) \rceil-1}]$ and $B_{\lceil \log_\beta(n) \rceil} := \left[\sup B_{\lceil \log_\beta(n) \rceil-1}, 1 \right]$ so that

$$
\sup_{p \in A_{\lceil \log_\beta(n) \rceil} \cup B_{\lceil \log_\beta(n) \rceil}} \varphi_0\big\{F(t), \varepsilon_\beta(n, \delta)\big\} \le \sqrt{\frac{2\beta^{-2\lceil \log_\beta(n) \rceil}}{\varepsilon_\beta(n, \delta)}} \le \frac{1}{n} \sqrt{\frac{2}{\varepsilon_\beta(n, \delta)}}
$$

Thus, applying Corollary [1](#page-1-0) once more yields

$$
\mathbb{P}\bigg\{\hat{F}_n(t) - F(t) > \frac{1}{n} \text{ for some } t \in \mathbb{R} \text{ with } F(t) \in A_{\lceil \log_\beta(n) \rceil} \bigg\}
$$
\n
$$
\leq \mathbb{P}\bigg\{\sup_{t \in \mathbb{R} \,:\, F(t) \in A_{\lceil \log_\beta(n) \rceil}} \left\{\hat{F}_n(t) - F(t)\right\} > \varphi\big\{A_{\lceil \log_\beta(n) \rceil}, \varepsilon_\beta(n, \delta)\big\}\sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}}\bigg\} \leq \frac{\delta}{2\lceil \log_\beta(n) \rceil},
$$

and similarly with $B_{\lceil \log_\beta(n) \rceil}$ in place of $A_{\lceil \log_\beta(n) \rceil}$. Finally, letting C_0 denote the (possibly empty) closed open interval $C_0 := [0,1] \setminus \{ \bigcup_{r=1}^{\lceil \log_\beta(n) \rceil} (A_r \cup B_r) \}$ we have

$$
\mathbb{P}\left\{\hat{F}_n(t) - F(t) > \beta\varphi_0\{F(t), \varepsilon_\beta(n, \delta)\} \sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}} \text{ for some } t \in \mathbb{R} \text{ with } F(t) \in C_0\right\}
$$
\n
$$
= \mathbb{P}\left\{\sup_{t \in \mathbb{R} \,:\, F(t) \in C_0} \{\hat{F}_n(t) - F(t)\} > \inf_{p \in C_0} \beta\varphi_0\{p, \varepsilon_\beta(n, \delta)\} \sqrt{\frac{\varepsilon_\beta(n, \delta)}{2}}\right\}
$$
\n
$$
= \mathbb{P}\left\{\sup_{t \in \mathbb{R} \,:\, F(t) \in C_0} \{\hat{F}_n(t) - F(t)\} > 1\right\} = 0.
$$

Hence, the conclusion of Corollary [3](#page-2-1) follows by a union bound.

 \Box

.

4 Proof of the topological implicit function theorem

Proof of Lemma [4.](#page-4-1) First let's show that $\Gamma(x_0, y_0)(y_0 - \gamma(x_0)) > 0$ for all $x_0 \in \mathcal{X}$ and $y_0 \in \mathcal{Y}$ $\mathcal{Y}\setminus\{\gamma(x)\}\.$ If $y_0 \in \mathcal{Y}$ and $y_0 < \gamma(x)$ then $\Gamma(x_0, y_0) < 0$ and so $\Gamma(x_0, y_0)(y_0 - \gamma(x_0)) > 0$. On the other hand, if $y_0 \in \mathcal{Y}$ and $y_0 > \gamma(x_0)$ then $\gamma(x_0) = \inf \{y \in \mathcal{Y} : \Gamma(x_0, y) \geq 0\} \in \text{cl}(\mathcal{Y})$. Since Y is an interval we can choose $y_1 \in (\gamma(x_0), y_0) \subseteq Y$, so that $\Gamma(x_0, y_1) \geq 0$ and hence $\Gamma(x_0, y_0) > 0$ since $y \mapsto \Gamma(x_0, y)$ is sign-monotonic.

We begin by showing that γ is upper semi-continuous. Fix some $x_0 \in \mathcal{X}$ and $\epsilon > 0$. If $\gamma(x_0) = \sup \mathcal{Y}$, then $\gamma(x_1) \leq \gamma(x_0)$ for all $x_1 \in \mathcal{X}$. Suppose then that $\gamma(x_0) = \inf \{y \in \mathcal{Y}$: $\Gamma(x_0, y) < 0$ < sup $\mathcal Y$ and we can choose $y_0 \in (\gamma(x_0), \gamma(x_0) + \epsilon) \cap \mathcal Y$. Since $y_0 > \gamma(x_0)$ we have $\Gamma(x_0, y_0) > 0$. By the continuity of $x \mapsto \Gamma(x, y_0)$ we deduce that there exists an open set $U \subseteq \mathbb{R}^d$ with $x_0 \in U \cap \mathcal{X}$ and for all $x_1 \in U \cap \mathcal{X}$ we have $\Gamma(x_1, y_0) > 0$. As such, we have $\gamma(x_1) \leq y_0 < \gamma(x_0) + \epsilon$. Thus, γ is upper semi-continuous.

Next, we show that γ is lower semi-continuous. Again, we begin by choosing $x_0 \in \mathcal{X}$ and $\epsilon > 0$. If $\gamma(x_0) = \inf \mathcal{Y}$, then $\gamma(x_1) \geq \gamma(x_0)$ for all $x_1 \in \mathcal{X}$. Suppose that $\gamma(x_0) > \inf \mathcal{Y}$ so that we can choose $y_0 \in (\gamma(x_0) - \epsilon, \gamma(x_0)) \cap (\inf \mathcal{Y}, \gamma(x_0)) \subseteq (\inf \mathcal{Y}, \sup \mathcal{Y}) \subseteq \mathcal{Y}$, where we have used the fact that $\mathcal Y$ is an interval. Since $y_0 < \gamma(x_0)$ we have $\Gamma(x_0, y_0) < 0$. Hence, by the continuity of $x \mapsto \Gamma(x, y_0)$, there exists an open set $U \subseteq \mathbb{R}^d$ with $x_0 \in U \cap \mathcal{X}$ and for all $x_1 \in U \cap \mathcal{X}$ we have $\Gamma(x_1, y_0) < 0$. Thus, applying the sign-monotonicity of $y \mapsto \Gamma(x_0, y)$, we have $\gamma(x_0) - \epsilon < y_0 \le \inf\{y \in \mathcal{Y} : \Gamma(x_1, y) \ge 0\} \le \sup \mathcal{Y}$. Hence, $\gamma(x_1) > \gamma(x_0) - \epsilon$, and we have shown that γ is also lower semi-continuous. we have shown that γ is also lower semi-continuous.
