Abstract. In the realm of healthcare, the challenges of copyright protection and unauthorized third-party misuse are increasingly significant. Traditional methods for data copyright protection are applied prior to data distribution, implying that models trained on these data become uncontrollable. This paper introduces a novel approach, named *DataCook*, designed to safeguard the copyright of healthcare data during the deployment phase. *DataCook* operates by “cooking” the raw data before distribution, enabling the development of models that perform normally on this processed data. However, during the deployment phase, the original test data must be also “cooked” through *DataCook* to ensure normal model performance. This process grants copyright holders control over authorization during the deployment phase. The mechanism behind *DataCook* is by crafting *anti-adversarial examples* (AntiAdv), which are designed to enhance model confidence, as opposed to standard adversarial examples (Adv) that aim to confuse models. Similar to Adv, AntiAdv introduces imperceptible perturbations, ensuring that the data processed by *DataCook* remains easily understandable. We conducted extensive experiments on MedMNIST datasets, encompassing both 2D/3D data and the high-resolution variants. The outcomes indicate that *DataCook* effectively meets its objectives, preventing models trained on AntiAdv from analyzing unauthorized data effectively, without compromising the validity and accuracy of the data in legitimate scenarios. Code and data are available at <https://github.com/MedMNIST/DataCook>.

Keywords: Data Security · Copyright Protection · Data-Centric ML.

1 Introduction

In the healthcare field, the rapid development and widespread application of deep learning technology have brought the issues of healthcare data misuse and copyright protection into sharp focus. Healthcare data sensitivity and confidentiality necessitate not only the protection of patients’ privacy rights but also the safeguarding of data providers’ and creators’ intellectual property rights [36,48,49]. Current data copyright protection mechanisms, such as data encryption[42,43], anonymization [37] and Digital Rights Management [38,41], although can prevent illegal copying and dissemination, yet they do not address the potential

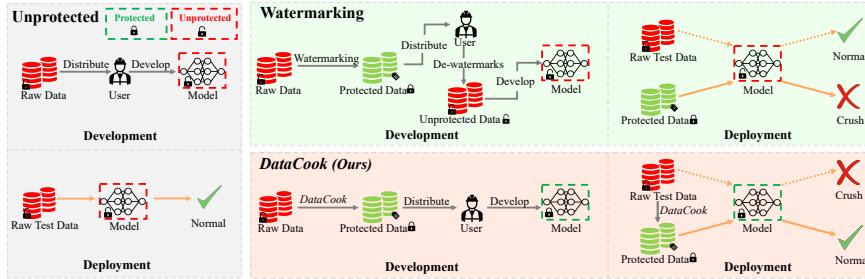

Fig. 1: **A Comparison of Data Copyright Protection.** **Unprotected:** Unprotected raw data can be directly utilized by unauthorized third parties for model development and deployment phases. **Watermarking:** Users receive watermarked data and authorized removal methods to obtain raw data for model development. yet post-removal, raw data remains at risk of breach and access by unauthorized third parties. **DataCook:** Users receive *DataCook*-processed data for model development. If data is breached, Models trained on this processed data are designed to work solely with datasets through *DataCook*-processed.

data extraction and generalization capabilities of deep learning models, making it difficult to effectively tackle the misuse of data in unauthorized training.

As illustrated in Fig. 1, watermarking is a widely adopted approach for copyright protection that embeds distinct watermarks into images to offer visual security. This method includes specific modifications designed to prevent unauthorized deep learning models from analyzing the images effectively [39]. However, this technique reduces the images' usability for legitimate training purposes which means the model trained on watermarking data has crush perform when deploying the model for original test data or watermarking test data. To restore data value for model deployment, it is necessary to remove the watermarks for model development. However, this leaves the data as vulnerable as those without any watermarking, exposing them to the risk of unauthorized use and data breaches. The challenge lies in protecting the data from misuse in unauthorized training scenarios without compromising its deployment utility. To tackle this issue, we introduce a novel setting *DataCook* aimed at resolving these challenges.

DataCook, leverages a novel strategy of generating anti-adversarial examples to safeguard healthcare data copyright during the model deployment. Essentially, *DataCook* operates by “cooking” the raw data before distribution, enabling the development of models that perform normally on this processed data. However, during the deployment phase, the original test data must be also “cooked” through *DataCook* to ensure normal model performance. This process grants copyright holders control over authorization during the deployment phase. The analogy inspiring *DataCook*’s name draws from the preference for cooked over raw food observed in daily life, symbolizing how processed data retains its value for authorized uses but becomes indigestible to models not adapted to its original form. Through experiments on the publicly available MedMNIST [9,10] medi-

cal image dataset, we have demonstrated that *DataCook* effectively prevents unauthorized deep learning models from accurately recognizing raw data, while preserving the original characteristics and utility of the data. This not only showcases the potential application of anti-adversarial examples in the copyright protection of healthcare data but also paves a new path for future work in the protection of healthcare data privacy.

2 Method

2.1 Background

To clearly present *DataCook*, we contrast it with unprotected data and watermarking [39] as shown in Fig. 1, highlighting *DataCook*'s difference and advantages. To better explain the comparison, We define a raw image dataset as $\mathcal{D}^r = \{(x_i^r, y_i)\}_{i=1}^N$, where the input space $\mathcal{X}^r = \{x_i^r\}_{i=1}^N \subset \mathbb{R}^d$ corresponds to the raw images and the label space $\mathcal{Y} = \{y_i\}_{i=1}^N = \{1, \dots, c\}$ represents their associated labels. Here, N denotes the number of samples, drawn from the distribution \mathcal{D}^r , covering the combined space of inputs and labels, $\mathcal{X}^r \times \mathcal{Y}$. A classification model $f^r = f_{\theta^r} : \mathcal{X}^r \rightarrow \mathbb{R}^c$ with logits output is parameterized by θ^r , optimized based on \mathcal{D}^r . This process is denoted as $\theta^r = \theta^r(\{\mathcal{X}^r, \mathcal{Y}\})$. Additionally, a protected image dataset, derived from the raw image dataset via specific processing steps, introduces a distribution \mathcal{D}^p . This protected image dataset maintains the same label space \mathcal{Y} but occupies a modified input space $\mathcal{X}^p = \{x_i^p\}_{i=1}^N \subset \mathbb{R}^d$, ensuring that the dataset spans the domain $\mathcal{X}^p \times \mathcal{Y}$. A corresponding classification model $f_{\theta^p}^p : \mathcal{X}^p \rightarrow \mathbb{R}^c$ with logits output, parameterized by $\theta^p = \theta^p(\{\mathcal{X}^p, \mathcal{Y}\})$, is trained on \mathcal{D}^p and denoted as f^p .

Unprotected: Raw data can be directly utilized by unauthorized third parties for model development and deployment phases.

Watermarking [39]: Users receive watermarked data along with authorized methods for watermark removal to access the raw data. In the deployment stage, if model f^p is trained on watermark-protected data, model f^p exhibits an inability to classify both watermark-test data and raw test data effectively (crush performance). To preserve the model's classification capability (normal performance), watermarks must be removed before model development. Once the watermark is removed and occurs data breaches, the data is vulnerable without any protective measures.

DataCook: The proposed *DataCook* transforms raw data into protected data before dataset distribution. In the deployment stage, models f^p trained on *DataCook*-protected data achieve normal performance on *DataCook*-test data but have crush performance on raw test data. Even occurs a data breach after distribution and unauthorized third-party use leaks data for model development, new data still need *DataCook* processed to ensure the model's classification capability in the model development stage where only data from authorized users can undergo *DataCook* processing. This process grants copyright holders control over authorization during the deployment phase and effectively mitigates data breach risks.

2.2 DataCook: Problem Setting

To achieve *DataCook*, the primary objective is to minimize the performance of model f^p when it is evaluated on the raw image dataset \mathcal{D}^r to prioritize data copyright protection. Concurrently, it is vital to ensure that the performance of model f^p on the protected image dataset \mathcal{D}^p closely matches the performance of model f^r on the raw image dataset \mathcal{D}^r to preserves model normal performance. Additionally, to ensure similarity, the distance between the raw image space \mathcal{X}^r and the protected image space \mathcal{X}^p must be minimized. we adopted the Structural Similarity (SSIM) index as a distance metric between the raw image space and the protected image space, aiming to minimize the intrusiveness of the transformation. Thus, The optimization task can be formalized as:

$$\underset{\mathcal{X}^p}{\text{minimize}} \quad \mathcal{E}(f^p, \mathcal{D}^r) \quad (1)$$

$$\text{w.r.t.} \quad |\mathcal{E}(f^p, \mathcal{D}^p) - \mathcal{E}(f^r, \mathcal{D}^r)| \leq \epsilon, \quad (2)$$

$$d(\mathcal{X}^r, \mathcal{X}^p) \leq \alpha \quad (3)$$

where $\mathcal{E}(f, \mathcal{D})$ denotes the evaluation metric for model f on dataset \mathcal{D} ; α is a threshold for the distance between \mathcal{X}^r and \mathcal{X}^p ; ϵ Represents an acceptable performance discrepancy, ideally zero; $f^p = f_{\theta^p}^p$ is parameterized by $\theta^p = \theta^p(\{\mathcal{X}^p, \mathcal{Y}\})$.

2.3 Crafting Anti-Adversarial Examples

Our strategy capitalizes on the potential of adversarial examples, which we have found to be particularly suited for resolving this optimization task. Adversarial examples are crafted by introducing a subtle perturbation ζ to the input raw image x_i^r as shown in Eq. 4, aimed at minimally yet significantly impacting the model’s prediction accuracy [47].

$$x_i^p = \arg \max_{\zeta} \mathcal{L}(f_{\theta}^r(x_i^r + \zeta), \hat{y}) \quad (4)$$

Perturbations are informed by data gradients, making them a targeted feature rather than mere noise [28]. Their subtlety and difficulty in detection ensure that adversarial examples satisfy the similarity criteria in Eq. 3 and adversarial examples serving in adversarial training to bolster model robustness [31,46,45,2] which align with Eq. 2 to maintain model performance. However, the potential of adversarial training to reduce model performance led us to develop the concept of anti-adversarial examples [40,44]. Contrary to traditional adversarial examples that aim to degrade performance, anti-adversarial examples are designed to improve it, directly addressing the criteria of Eq. 2. Our method confronts the complex challenge delineated by Eq. 1, with forthcoming experiments aimed at validating that our anti-adversarial examples not only adhere to the guidelines of Eq. 2 and Eq. 3 but also achieve the overarching goals of Eq. 1.

As illustrated in Fig. 2, we detail the process of generating anti-adversarial examples. Firstly, employing a pre-trained surrogate model f^r to predict the output of a raw image x_i^r and use the highest probability output as a pseudo-label

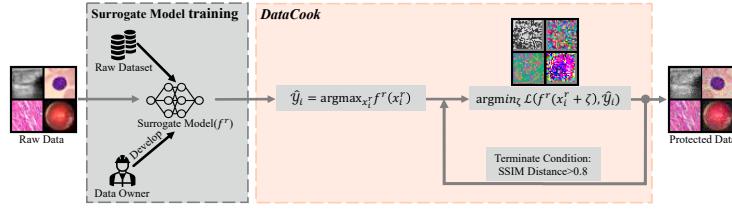

Fig. 2: **Generating Anti-Adversarial Examples in *DataCook*.** Utilizing the initial highest logic probability output from the surrogate model as a pseudo label \hat{y} serves as the direction for anti-adversarial attack iterations under the constraints of termination conditions.

\hat{y}_i , anti-adversarial examples are crafted by maximizing the logistic probability of the pseudo label as shown in Eq. 5, contrasting with adversarial examples that aim to minimize this probability in Eq. 4:

$$x_i^p = \arg \min_{\zeta} \mathcal{L}(f_\theta^r(x_i^r + \zeta), \hat{y}) \quad (5)$$

where \mathcal{L} is the loss function tailored to maximize the logistic probability of \hat{y}_i directly. We set SSIM threshold of 0.8 to maintain visual similarity.

3 Experiments

In this section, we evaluate our *DataCook* in 2D datasets(28×28) , 3D datasets($28 \times 28 \times 28$) and high-resolution datasets(224×224). Our experiment results show that the anti-adversarial examples crafted through *DataCook* fulfill the objectives of the optimization task. To assess the effectiveness of anti-adversarial examples, we designed comparative experiments using various optimization conditions.

3.1 Setup

Evaluation Metrics. Our evaluation of anti-adversarial examples hinges on two key metrics: Copyright Protection (*CP*) and Performance Preservation (*PP*). *CP* represent the definition of Eq.1. To facilitate effect comparison, *CP* is determined as $\mathcal{E}(f^p, \mathcal{D}^r) - \mathcal{E}(f^r, \mathcal{D}^r)$ and lower values indicate better protection. *PP* outlined in Eq. 2, we define $PP = -|\mathcal{E}(f^p, \mathcal{D}^p) - \mathcal{E}(f^r, \mathcal{D}^r)|$ and values nearing to zero denoting optimal model performance preservation. We use the Area Under the ROC Curve (AUC)[26] and accuracy (ACC) for quantitative analysis. Experiment results show alignment between AUC and ACC, but here we focus on ACC due to space limitations, with detailed AUC available in supplementary materials.

Method Comparison. To quantitatively evaluate *DataCook*'s performance, we utilize several benchmarking methods for comparison: *Random Noise*: Introducing random Gaussian noise as a basic benchmark; *Adversarial Target*: This theoretical benchmark, represented as an oracle state with provided true data labels,

aims to delineate the upper limits of performance, particularly infeasible during deployment; *Adv/AntiAdv*: Differentiating adversarial from anti-adversarial examples to clarify the practical implications of each strategy.

Datasets. To rigorously evaluate our method, we utilize the MedMNIST dataset, a comprehensive repository of pre-processed medical images available for public use, cited from both *medmnistv2* and *medmnistv1*. MedMNIST is tailored for benchmarking machine learning models on a wide array of medical image analysis tasks, encompassing diverse data types such as 2D, 3D, and high-resolution images. This diversity positions MedMNIST as an exemplary dataset for testing the efficacy and versatility of our approach across varied medical imaging contexts. Our evaluation strategy involves computing the average performance across all MedMNIST subsets, offering a detailed assessment of our method’s capability in the sophisticated domain of medical image analysis, ensuring both logical coherence and succinctness in our validation process.

Configuration. Our experiments leveraged PyTorch 2.0 [1] for evaluating wide applicability of *DataCook* across diverse model architectures, including ResNet18, ResNet50 [5], VGG16 [7] and ConvNet [6]. Training for 2D, 3D, and high-resolution datasets involved 200 epochs using Stochastic Gradient Descent [24], with batch size of 128, momentum of 0.9, and learning rate of 1×10^{-3} . For protected dataset generation, a uniform learning rate of 5×10^{-3} was applied. All protected data achieved an SSIM over 0.8 to the corresponding raw data.

3.2 Quantitative Experiments on 2D Data

Settings. The MedMNIST 2D dataset includes 12 subsets, ranging from 100 to over 100,000 images. We analyzed 11 of these datasets—excluding Chest [12] due to its multi-label focus, which our method doesn’t currently support. The datasets include Path [11], Derma [13,14], OCT [15], Pneumonia, Retina, Breast [16], Blood [17], Tissue [18], OrganA, OrganC, and OrganS. Despite the limitation, we foresee potential future adaptation to multi-label tasks. In addition to standard 2D datasets, MedMNIST also provides high-resolution versions 224×224 of 2D datasets. Given computational constraints, we particularly focused on Blood [17], Retina, OrganA, Breast [16], and Pneumonia for deeper investigation.

Results. As shown in Tab. 1, our analysis reveals three key insights. First, perturbations introduced by *DataCook* significantly outperform random noise in enhancing copyright protection, effectively demonstrating that Anti Adv examples can achieve the optimization objectives outlined in Eq. 1. Second, the Oracle state, despite offering better copyright protection, substantially impairs model performance as shown in data with *underline*, underscoring a crucial trade-off. This finding affirms that the use of pseudo-labels does not compromise model performance. Third, the juxtaposition of Adv and Anti Adv examples indicates that while Anti Adv examples may provide marginally less robust copyright protection, they excel in preserving model performance. This aligns with our main goal of copyright protection without impacting model performance.

Table 1: Protection Results on 2D datasets. We evaluate CP and PP on the 2D datasets comparing various models. The reported values represent the average percentage change in ACC of CP and PP across all 2D datasets; Underline data entries highlight key comparative findings.

		ResNet-18		ResNet-50		VGG-16		ConvNext-t	
Method		$CP\downarrow$	$PP\uparrow$	$CP\downarrow$	$PP\uparrow$	$CP\downarrow$	$PP\uparrow$	$CP\downarrow$	$PP\uparrow$
Random Noise		-2.65	-1.61	-4.43	-2.01	-3.43	-1.92	-1.05	-2.08
Adv	Oracle	-35.17	<u>-17.66</u>	-16.52	<u>-7.44</u>	-42.58	-12.79	-39.59	-32.21
	Pseudo	-27.02	<u>-1.58</u>	-11.99	<u>-4.51</u>	-24.95	<u>-2.41</u>	-18.37	<u>-3.54</u>
AntiAdv	Oracle	-13.15	<u>-22.14</u>	-7.68	<u>-16.45</u>	-12.27	-18.33	-7.91	-32.4
	Pseudo	-18.78	<u>-0.67</u>	-9.63	<u>-0.91</u>	-16.1	<u>-0.56</u>	-13.8	<u>-1.59</u>

Ablation on Optimization Procedure. Our study includes ablation experiments focusing on optimization procedures, which examine the impact of external adversarial targets, various loss functions, and optimizers. The results are depicted in supplementary materials. We show the current method to craft anti-adversarial examples by pseudo label is the best.

Generalize to High-Resolution Data. We also conducted tests on the *DataCook* using high-resolution data, with the results detailed in the supplementary materials. These outcomes are consistent with those obtained from 2D data, demonstrating the *DataCook* robustness and applicability across different data formats.

3.3 Quantitative Experiments on 3D Data

Settings. The MedMNIST 3D datasets include six subsets, ranging from 1,500 to 200 images. Given computational constraints, we focused on OrganMNIST3D [19], NoduleMNIST3D, and FractureMNIST3D.

Results. Tab. 2 presents the outcomes from the 3D datasets, revealing trends consistent with those found in the 2D counterparts, yet with distinct nuances. Notably, Anti Adv examples demonstrate superior performance in CP and PP over Adv examples in larger datasets as shown in data with *underline*, a phenomenon more evident that Anti Adv example can deepen its effects in the context of 3D data. However, this protective efficacy diminishes in deeper architectures like ResNet50, hinting that such networks might overlook perturbations in 3D data. This observation suggests an avenue for enhancement in future research. Intriguingly, pseudo labels yield better results than the Oracle in ResNet18 and ConvNet models, suggesting that providing data labels might lead to reduced performance with 3D datasets, highlighting the complexity of model-data interactions in 3D spaces.

Analysis on DataCook-Generated Perturbation As illustrated in Fig. 3. The selected model exhibits identical training and testing results across raw, protected,

Table 2: Protection Results on 3D data. We evaluate CP and PP on the 3D data datasets comparing various model. The reported values represent the average change in ACC of CP and PP across all 3D datasets. Underline data entries highlight key comparative findings.

		ResNet-18		ResNet-50		VGG-16		ConvNext-t	
	Method	$CP \downarrow$	$PP \uparrow$

	Pseudo	<u>-18.67</u>	<u>-1.75</u>	<u>-1.81</u>	<u>-1.35</u>	<u>-26.7</u>	<u>-0.91</u>	<u>-15.27</u>	<u>-1.01</u>

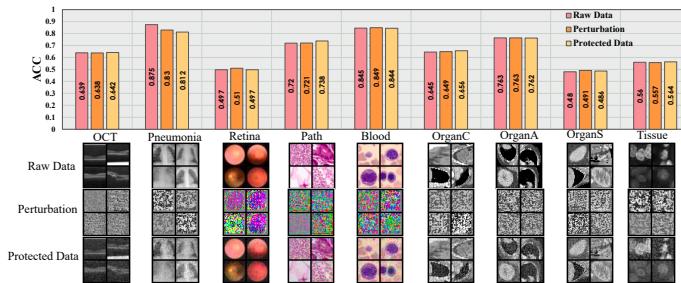

Fig. 3: Top: The figure presents a comparison among the performance outcomes raw data, protected data, and perturbation on convnet. **Bottom:** Raw data, Perturbation, and protected data comparison.

and perturbed data, and this effect persists across other models as well. Firstly, this indicates a stable capacity for performance perseverance. Secondly, it suggests that perturbation serves as an effective feature, impacting both model learning and performance. In comparison to protected data, raw data lacks the effective feature of perturbation, which is essential for validating Eq. 1. The bottom figure shows that despite the introduction of protective perturbations, the visual alterations to protected data are subtle to the human eye. This reveals that *DataCook*, through its integration of label information via classifiable perturbations, does not degrade model performance or visual perceptibly, contrasting with data compression methods[34,35] that might compromise the integrity of raw data. Our analysis demonstrates that *DataCook* is designed to offer complete confidentiality and obscurity, enabling its use without detection by others, thus significantly increasing its practical utility.

4 Conclusion

In conclusion, this study introduces *DataCook*, a pioneering approach for healthcare data copyright protection during the deployment phase, effectively addressing the challenges of unauthorized third-party misuse. Through the innovative use of *anti-adversarial examples*, *DataCook* ensures that data remains protected and only accessible by authorized users, without compromising data integrity and model performance.

Table A1: **Protection Results(ACC) on 2D data.** We evaluate *CP* and *PP* on the 2D datasets comparing various models. The reported values represent the average percentage change in ACC of *CP* and *PP* across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology.

Table A5: Original Results(ACC) on 2D data. We show original result of 2D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. The reported values represent the original value in ACC of our method across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology. *Dataset (D)* represent benign (original dataset) and protected dataset.

Table A6: Original Results(ACC) on 2D data. We show original result of 2D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. The reported values represent the original value in ACC of our method across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology. *Dataset (D)* represent benign (original dataset) and protected dataset.

Table A7: Original Results(ACC) on 2D data. We show original result of 2D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. The reported values represent the original value in ACC of our method across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology. *Dataset (D)* represent benign (original dataset) and protected dataset.

Table A9: Original Results(AUC) on 2D data. We show original result of 2D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. The reported values represent the original value in AUC of our method across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology. *Dataset (D)* represent benign (original dataset) and protected dataset.

Table A11: Original Results(AUC) on 2D data. We show original result of 2D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. The reported values represent the original value in AUC of our method across all 2D datasets. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions, "Probability (Max P)" indicates attacks steered by the maximum output probability of the model, and "Pseudo Labels" refers to using the initial prediction's highest probability to guide the attack direction. *Loss (L)* involves two approaches: using Logistic Probability (Logit) directly as the loss function and applying the logarithm of Logistic Probability ($\log P$) as the loss criterion. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Optimizer (O)* specifies the choice of optimizer for image updates, enhancing the clarity and logical flow of the evaluation methodology. *Dataset (D)* represent benign (original dataset) and protected dataset.

Table A12: **Original Results(ACC) on 3D data.** We show original result of 3D datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions and "Pseudo" refers to using the initial prediction's highest probability to guide the attack direction. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Dataset (D)* represent benign (original) dataset and protected dataset. Using Logistic Probability (Logit) directly as the loss function and Adam as optimizer.

Table A15: Raw Results(AUC) on High-Resolution data. We show original result of High-Resolution datasets comparing various models. *CP* is Protected model on Benign data and *PP* is on Protected model on Protected data. *Target (T)* delineates the adversarial attack aim: "Oracle" represents the ideal conditions and "Pseudo" refers to using the initial prediction's highest probability to guide the attack direction. *Adv/Anti-adv* indicates whether the strategy aims to minimize or maximize the loss function. *Dataset (D)* represent benign (original) dataset and protected dataset. Using Logistic Probability (Logit) directly as the loss function and Adam as optimizer.
