TWO PROVER PERFECT ZERO KNOWLEDGE FOR MIP*

 $\rm KIERAN~MASTEL^{1,2}$ AND WILLIAM $\rm SLOFSTAR^{1,2}$

ABSTRACT. The recent $MIP^* = RE$ theorem of Ji, Natarajan, Vidick, Wright, and Yuen shows that the complexity class MIP^{*} of multiprover proof systems with entangled provers contains all recursively enumerable languages. Prior work of Grilo, Slofstra, and Yuen [FOCS '19] further shows (via a technique called simulatable codes) that every language in MIP^{*} has a perfect zero knowledge (PZK) MIP^{*} protocol. The MIP^{*} = RE theorem uses two-prover one-round proof systems, and hence such systems are complete for MIP˚ . However, the construction in Grilo, Slofstra, and Yuen uses six provers, and there is no obvious way to get perfect zero knowledge with two provers via simulatable codes. This leads to a natural question: are there two-prover PZK-MIP˚ protocols for all of MIP˚ ?

In this paper, we show that every language in MIP^{*} has a two-prover oneround PZK-MIP˚ protocol, answering the question in the affirmative. For the proof, we use a new method based on a key consequence of the $MIP^* = RE$ theorem, which is that every MIP^{*} protocol can be turned into a family of boolean constraint system (BCS) nonlocal games. This makes it possible to work with MIP˚ protocols as boolean constraint systems, and in particular allows us to use a variant of a construction due to Dwork, Feige, Kilian, Naor, and Safra [Crypto '92] which gives a classical MIP protocol for 3SAT with perfect zero knowledge. To show quantum soundness of this classical construction, we develop a toolkit for analyzing quantum soundness of reductions between BCS games, which we expect to be useful more broadly. This toolkit also applies to commuting operator strategies, and our argument shows that every language with a commuting operator BCS protocol has a two prover PZK commuting operator protocol.

1. INTRODUCTION

In an interactive proof protocol, a prover tries to convince a verifier that a string x belongs to \mathcal{L} . Interactive proof systems can be more powerful than non-interactive systems; famously, the class IP of interactive proofs with a polynomial time verifier and a single prover is equal to PSPACE [\[Sha92\]](#page-43-0), and the class MIP with a polynomial time verifier and multiple provers is equal to NEXP [\[BFL90\]](#page-41-0). In this latter class, the provers can communicate with the verifier, but are assumed not to be able to communicate with each other. The proof systems used in [\[BFL90\]](#page-41-0) are very efficient, and require only two provers and one-round of communication. Interactive proof systems also allow zero knowledge protocols, in which the prover demonstrates that $x \in \mathcal{L}$ without revealing any other information to the verifier. As a result, interactive proof systems are important to both complexity theory and cryptography. The first zero knowledge proof systems go back to the invention of interactive proof systems by Goldwasser, Micali, and Rackoff [\[GMR85\]](#page-42-0), and every language in MIP

admits a two-prover one-round perfect zero knowledge proof system by a result of Ben-Or, Goldwasser, Kilian, and Wigderson [\[BOGKW88\]](#page-41-1). Perfect means that absolutely no information is revealed to the verifier, in contrast to statistical zero knowledge (in which the amount of knowledge gained by the verifier is small but bounded), or computational zero knowledge (in which zero knowledge relies on some computational intractability assumption).

Since the provers in a MIP protocol are not allowed to communicate, it is natural to ask what happens if they are allowed to share entanglement. This leads to the complexity class MIP˚ , first introduced by Cleve, Hoyer, Toner, and Watrous [\[CHTW04\]](#page-42-1). Entanglement allows the provers to break some classical proof systems by coordinating their answers, but the improved ability of the provers also allows the verifier to set harder tasks. As a result, figuring out the power of MIP˚ has been difficult, and there have been successive lower bounds in $[KKM^+11, KMO9, IV12,$ $[KKM^+11, KMO9, IV12,$ [Vid16,](#page-43-2) [Vid20,](#page-43-3) [Ji16,](#page-42-4) [NV18b,](#page-43-4) [Ji17,](#page-42-5) [NV18a,](#page-43-5) [FJVY19\]](#page-42-6). Most recently (and spectacularly), Ji, Natarajan, Vidick, Wright, and Yuen showed that $MIP^* = RE$, the class of languages equivalent to the halting problem JNV^+22b . Reichardt, Unger, and Vazirani also showed that MIP^{*} is equal to the class QMIP^{*}, in which the verifier is quantum, and can communicate with the provers via quantum channels [\[RUV13\]](#page-43-7). On the perfect zero knowledge front, Chiesa, Forbes, Gur, and Spooner showed that every language in NEXP (and hence in classical MIP) has a perfect zero knowledge MIP˚ proof system, or in other words belongs to PZK-MIP˚ [\[CFGS22\]](#page-41-2). Grilo, Slofstra, and Yuen show that all of MIP^{*} belongs to PZK-MIP^{*} [\[GSY19\]](#page-42-7).

Combining $PZK-MIP^* = MIP^*$ with $MIP^* = RE$ shows that there are one-round perfect zero-knowledge MIP˚ proof systems for all languages that can be reduced to the halting problem, a very large class. However, the construction in [\[GSY19\]](#page-42-7) is involved. The idea behind the proof is to encode a circuit for an arbitrary MIP verifier in a "simulatable" quantum error correcting code, and then hide information from the verifier by splitting the physical qubits of this code between different provers. The resulting proof systems in [\[GSY19\]](#page-42-7) require 6 provers, and because the core concept of the proof is to split information between provers, bringing this down to 2 provers (as can be done with perfect zero-knowledge for MIP) seems to require new ideas.

The purpose of this paper is to show that all languages in MIP˚ do indeed have two-prover one-round perfect zero knowledge proof systems. Specifically, we show that:

Theorem 1.1. Every language in MIP^* (and hence in RE) admits a two-prover one-round perfect zero knowledge MIP^{*} protocol with completeness probability $c = 1$ and soundness probability $s = 1/2$, in which the verifier chooses questions uniformly at random.

The idea behind the proof is to use the output of the $MIP^* = RE$ theorem, rather than encoding arbitrary MIP^{*}-protocols. The proof that $MIP^* = RE$ in JNV^+22b is very difficult, but requires only two-prover one-round proof systems. Natarajan and Zhang have sharpened the proof to show that these proof systems require only a constant number of questions, and polylog length answers from the provers [\[NZ23\]](#page-43-8). This shows that $MIP^* = AM^*(2)$, the complexity class of languages with two-prover MIP˚ -protocols in which the verifier chooses their messages to the prover uniformly at random. A one-round MIP or MIP˚ proof system is equivalent to a family of nonlocal games, in which the provers (now also called players) are given questions and return answers to a verifier (now also called a referee), who decides whether to accept (in which case the players are said to win) or reject (the players lose). In both $|JNV^+22b|$ and $[NZ23]$, the games are synchronous, meaning that if the players receive the same question then they must reply with the same answer, and admit what are called oracularizable strategies. As we observe in this paper, one-round MIP˚ proof systems in which the games are synchronous and oracularizable are equivalent to the class of BCS-MIP˚ proof systems, which are one-round two-prover proof systems in which the nonlocal games are boolean constraint system (BCS) games. In a boolean constraint system, two provers try to convince the verifier that a given BCS is satisfiable. BCS games were introduced by Cleve and Mittal [\[CM14\]](#page-42-8), and include famous examples of nonlocal games such as the Mermin-Peres magic square [\[Mer90,](#page-43-9) [Per90\]](#page-43-10). Boolean constraint systems are much easier to work with than general MIP˚ protocols, so rather than showing that every MIP˚ protocol can be transformed to a perfect zero knowledge protocol, we prove Theorem [1.1](#page-1-0) by showing that every BCS-MIP˚ protocol can be transformed to a perfect zero knowledge protocol. As we explain at the end of Section [3,](#page-6-0) when combined with the $MIP^* = RE$ theorem this gives an effective way to transform any MIP^* -protocol (including protocols with many provers and rounds) into a perfect zero knowledge BCS-MIP˚ protocol.

One way to transform a BCS-MIP˚ protocol to a perfect zero-knowledge protocol is to use graph colouring games, which are famous examples of perfect zero knowledge games. Classically, every BCS instance can be transformed to a graph such that the graph is 3-colourable if and only if the BCS is satisfiable. Ji has shown that every BCS can be transformed to a graph such that the original BCS game has a perfect quantum strategy if and only if the 3-colouring game for the graph has a perfect quantum strategy [\[Ji13\]](#page-42-9) (see also [\[Har23\]](#page-42-10)). Using the techniques in this paper, it is also possible to show that this transformation preserves soundness of BCS-MIP˚ protocols, and hence that every BCS-MIP˚ protocol can be transformed to a MIP˚ protocol based on graph colouring games. Unfortunately graph colouring games are only perfect zero knowledge against honest verifiers, so this construction does not give a perfect zero knowledge protocol for dishonest verifiers. Instead, we use another classical transformation due to Dwork, Feige, Kilian, Naor, and Safra $[DFK^+92]$, which takes every 3SAT instance to a perfect zero-knowledge MIP protocol. We show that a modest variant of this construction remains perfect zero knowledge in the quantum setting, and preserves soundness of BCS-MIP˚ protocols. In both the original argument and our argument, it is necessary for soundness to work with BCS-MIP protocols with small (meaning log or polylog) question length. In the classical setting, BCS-MIP with log question length is equal to NP, so the construction in $[DFK^+92]$ only shows that NP is contained in PZK-MIP, rather than all of NEXP. In the quantum setting, BCS-MIP˚ with polylog question length is equal to MIP^{*} and this construction suffices to prove perfect zero knowledge for any MIP^* protocol — an interesting difference in what techniques can be used between the classical and quantum setting.

In general, it's a difficult question to figure out if a classical transformation of constraint systems (of which there are many) remains sound (meaning that it preserves soundness of protocols) in the quantum setting. For instance, one of the key parts of the $MIP^* = RE$ theorem is the construction of PCP of proximity which is quantum sound. On the other hand, there are some transformations which lift fairly easily to the quantum setting. We identify two such classes of transformations, "classical transformations" which are applied constraint by constraint, and "context subdivision transformations", in which each constraint is split into a number of subclauses. Both types of transformations are used implicitly throughout the literature on nonlocal games, including in [\[Ji13\]](#page-42-9), which was the first paper to consider reductions between quantum strategies in BCS games. In this paper, we systematically investigate the quantum soundness of these transformations. It's relatively easy to show that classical transformations preserve soundness, and this is shown in Section [6.](#page-15-0) In subdivision, each subclause becomes a different question in the associated BCS game, and thus a strategy for the subdivided game has many more observables than the original game. Since these new observables don't need to commute with each other, subdivision is more difficult to work with. Nonetheless, we show that if the subclauses have a bounded number of variables, then subdivision preserves soundness with a polynomial dropoff. This is shown in Section [7.](#page-18-0) The construction in $[DFK^+92]$ can be described as a composition of classical transformations and context subdivision transformations, so quantum soundness (with polynomial dropoff) of this construction follows from combining the soundness of these two transformations. We recover a constant soundness gap by using parallel repetition, which preserves the class of BCS games.

While reductions between nonlocal games have been important in previous work, they are difficult to reason about, since it's necessary to keep track of how strategies for one game map to strategies for the other game. One advantage of working with constraint systems in the classical setting is that it's more convenient to work with assignments (and think about the fraction of constraints in the system that can be satisfied) than it is to work with strategies and winning probabilities. In the quantum setting, it isn't possible to work with assignments, because strategies involve observables that don't necessarily commute with each other. However, we can achieve a similar conceptual simplification by replacing assignments with representations of the BCS algebra of the constraint system. This algebra is the same as the synchronous algebra of the BCS game introduced in [\[HMPS19,](#page-42-12) [KPS18\]](#page-43-11); we refer to [\[PS23\]](#page-43-12) for more background. With this approach, reductions between BCS games can be expressed as homomorphisms between BCS algebras, and these are much easier to describe and work with than mappings between strategies. For soundness arguments, we need to work with near-perfect strategies, and these correspond to approximate representations of the BCS algebra [\[Pad22\]](#page-43-13). Previous work using this idea (see e.g. [\[Pad22,](#page-43-13) [Har23\]](#page-42-10)) has focused on reductions between single games, and the definitions are not suitable for working with protocols, as they do not incorporate question distributions. To solve this problem, we introduce a notion of weighted algebras and weighted homomorphisms, which allows us to keep track of soundness of reductions between games using completely algebraic arguments involving sums of squares.

Another advantage of the weighted algebras framework is that arguments can be made simultaneously for both quantum and commuting operator strategies. Our proof methods extend to commuting operator strategies as a result. However, our results here are not as conclusive, as the exact characterization of the corresponding complexity class MIP^{co} is not known. There is a conjecture that $MIP^{co} = \text{coRE}$, and with that conjecture and a parallel repetition theorem for commuting operator strategies, we expect that it would be possible to extend Theorem [1.1](#page-1-0) to show that all languages in MIP^{co} have a perfect zero knowledge commuting operator protocol. Without these ingredients, we are limited to showing that $BCS-MIP^{co} = PZK-BCS-$ MIPco. Previous work on perfect zero knowledge for commuting operator protocols does not preserve soundness gaps [\[CS19\]](#page-42-13).

Our results also have applications for the membership problem for quantum correlations. For exact membership, the cohalting problem is many-one reducible to membership in the set of quantum-approximable correlations C_{qa} , and to membership in the set of commuting operator correlations C_{qc} [\[Slo19,](#page-43-14) [CS19,](#page-42-13) [FMS21\]](#page-42-14). It follows from $MIP^* = RE$ that the halting problem is Turing reducible to approximate membership in C_q , the set of quantum correlations, but this is not a many-one reduction. The proof of Theorem [1.1](#page-1-0) immediately implies that there is a many-one reduction from the halting problem to approximate membership in C_q .

Because we use parallel repetition to reduce an inverse-polynomial soundness gap to a constant soundness gap, the protocols in Theorem [1.1](#page-1-0) use polynomial length questions and answers. If an inverse-polynomial soundness gap is allowed, we get perfect zero-knowledge protocols with polylog question length and constant answer length. Whether it is possible to get perfect zero-knowledge protocols with polylog question length, constant answer length, and constant soundness gap is an interesting open question. This would be possible with an improved analysis or construction for subdivision such as appears in the low degree test JNV^+22a used in the $MIP^* = RE$ theorem.

2. BACKGROUND ON *-ALGEBRAS

We recall some of the key concepts in the theory of *-algebras. See [\[Oza13,](#page-43-16) [Sch20\]](#page-43-17) for a more complete background. A complex $*$ -algebra A is a unital algebra over $\mathbb C$ with an antilinear involution $a \mapsto a^*$, such that and $(ab)^* = b^*a^*$. We let $\mathbb{C}^*\langle X \rangle$ denote the free complex *-algebra generated by the set X. If $R \subseteq \mathbb{C}^*\langle X\rangle$, we let $\mathbb{C}^*\langle X : R \rangle$ denote the quotient of $\mathbb{C}^*\langle X \rangle$ by the two-sided ideal generated by R. If X and R are finite then we call $\mathbb{C}^*\langle X : R \rangle$ a **finitely presented** *-algebra.

A *-homomorphism $\phi : A \rightarrow B$ between *-algebras is an algebra homomorphism such that $\phi(x^*) = \phi(x)^*$ for all $x \in A$. A *-representation of A is a *-homomorphism $\rho : A \to \mathcal{B}(\mathcal{H})$ from A to the *-algebra of bounded operators on the Hilbert space H. If A and B are *-algebras, and $\mathbb{C}^*\langle X : R \rangle$ is a presentation of A, then *-homomorphisms $\mathcal{A} \to \mathcal{B}$ correspond to homomorphisms $\phi : \mathcal{C}\langle X \rangle \to \mathcal{B}$ such that $\phi(r) = 0$ for all $r \in R$. Thus, a *-representation is an assignment of operators to the elements of X that satisfies the defining relations R .

If A is a $*$ -algebra, then $a \ge b$ if $a - b$ is a sum of hermitian squares, i.e. there is $k \geq 0$ and $c_1, \ldots, c_k \in \mathcal{A}$ such that $a - b = \sum_{i=1}^k c_i^* c_i$. A finitely presented $*$ algebra A is called **archimedean** if for all $a \in \overline{A}$ there exists a $\lambda > 0$ such that $a^*a \leq \lambda$ 1. The algebras we consider in this work are all archimedean. If $f : A \to \mathbb{C}$ is a linear functional then f is **positive** if $f(a) \geq 0$ whenever $a \geq 0$. A state on A is a positive linear functional $\tau : A \to \mathbb{C}$ with $\tau(a^*a) \geq 0$ for all $a \in A$, $\tau(1) = 1$ and $\tau(a^*) = \overline{\tau(a)}$ for all $a \in \mathcal{A}$. A state is **tracial** if $\tau(ab) = \tau(ba)$ for all $a, b \in \mathcal{A}$, and **faithful** if $\tau(a^*a) > 0$ for all $a \neq 0$. A tracial state τ induces the **trace norm** $||a||_{\tau} := \sqrt{\tau(a^*a)}$, also called the τ -norm. Trace norms are unitarily invariant, meaning that $||uav||_{\tau} = ||a||_{\tau}$ for all $a \in \mathcal{A}$, and all unitaries u and v. An element $u \in \mathcal{A}$ is called **unitary** if $u^*u = 1 = uu^*$.

If $\rho : A \to \mathcal{B}(\mathcal{H})$ is a *-algebra representation, then a vector $|v\rangle \in \mathcal{H}$ is cyclic for ρ if the closure of $\rho(\mathcal{A})|v\rangle$ with respect to the Hilbert space norm is equal to H. A cyclic representation of A is a tuple $(\rho, \mathcal{H}, |v\rangle)$, where ρ is a representation of A on H and $|v\rangle$ is a cyclic vector for ρ . If $\tau : A \to \mathbb{C}$ is a positive linear functional on A, then there is a cyclic representation ρ_{τ} of A, called the **GNS representation** of τ , such that $\tau(a) = \langle \xi_{\tau} | \rho_{\tau} | \xi_{\tau} \rangle$ for all $a \in \mathcal{A}$. Two representations $\rho : \mathcal{A} \to \mathcal{B}(\mathcal{H})$ and $\pi : A \to \mathcal{B}(\mathcal{K})$ of A are unitarily equivalent if there is a unitary operator $U: \mathcal{H} \to \mathcal{K}$ such that $U \rho(a) U^* = \pi(a)$ for all $a \in \mathcal{A}$. If τ is the state defined by $\tau(a) = \langle \xi | \rho(a) | \xi \rangle$ for all $a \in \mathcal{A}$ and some cyclic representation $(\rho, \mathcal{H}, |\xi \rangle)$, then $(\rho, \mathcal{H}, \langle \xi \rangle)$ is unitarily equivalent to the GNS representation. A state τ is finite**dimensional** if the Hilbert space \mathcal{H}_{τ} in the GNS representation $(\rho_{\tau}, \mathcal{H}_{\tau}, |\xi_{\tau})$ is finite-dimensional. A state τ on A is called **Connes-embeddable** if there is a trace-preserving embedding of $\mathcal A$ into the ultrapower of the hyperfinite II_1 factor.

If A is a *-algebra then two elements $a, b \in \mathcal{A}$ are said to be **cyclically equivalent** if there is $k \geq 0$ and $f_1, \ldots, f_k, g_1, \ldots, g_k \in \mathcal{A}$ such that $a - b = \sum_{i=1}^k [f_i, g_i]$, where $[f, g] = fg - gf$. We say that $a \geq b$ if $a - b$ is cyclically equivalent to a sum of squares. If τ is a tracial state on A then $\tau(c_i^*c_i) \geq 0$ and $\tau([f_j, g_j]) = 0$. Thus if $a \geq b$ then $\tau(a) \geq \tau(b)$, and if a and b are cyclically equivalent then $\tau(a - b) = 0$.

The *-algebras we use in this work are built out of the group algebras of the finitely presented groups

$$
\mathbb{Z}_q^{*V} = \langle V : x^q = 1 \rangle \text{ and } \mathbb{Z}_q^V = \langle V : x^q = 1, xy = yx \text{ for all } x, y \in V \rangle.
$$

The group algebra $\mathbb{C} \mathbb{Z}_q^{*V}$ is the *-algebra generated by variables $x \in V$ with the defining relations from \mathbb{Z}_q^{*V} , along with the relations $x^*x = xx^* = 1$ for all $x \in V$. Similarly $\mathbb{C}\mathbb{Z}_q^V$ is the *-algebra generated by variables $x \in V$ with the defining relations of \mathbb{Z}_q^V , along with the relations $x^q = x^*x = xx^* = 1$ for all $x \in V$. Notice

that $\mathbb{C}\mathbb{Z}_q^V$ is the quotient of $\mathbb{C}\mathbb{Z}_q^{*V}$ by the relations $xy = yx$ for all $x, y \in V$. If A and B are complex *-algebras, then we let $A * B$ denote their free product, and $A \otimes B$ denote their tensor product. Both are again complex $*$ -algebras.

When working with $\mathbb{C}\mathbb{Z}_q^V$, a **monomial** in V is an element of the form $\prod_{x\in V} x^{a_x}$, where $0 \leq a_x < q$. We say that the monomial contains a variable $y \in V$ if $a_y > 0$. The degree of a monomial is $\sum_{x} a_x$. If \mathcal{A}_1 and \mathcal{A}_2 are *-algebras for which we have a defined notion of monomial, then a monomial in $A_1 \otimes A_2$ is an element of the form v_1v_2 , where v_i is a monomial in \mathcal{A}_i . The degree of v_1v_2 is the sum of the degrees of v_1 and v_2 , and a variable y is contained in v_1v_2 if y is contained in v_1 or v_2 . For instance, a monomial in $\mathbb{C}\mathbb{Z}_{q_1}^{V_1}\otimes \mathbb{C}\mathbb{Z}_{q_2}^{V_2}$ is an element of the form $\prod_{x\in V_1} x^{a_x} \cdot \prod_{y\in V_2} y^{b_y}$, where $0 \le a_x < q_1$ and $0 \le b_y < q_2$. Similarly, a monomial in $\mathcal{A}_1 * \tilde{\mathcal{A}}_2$ is an element of the form $v_1 \cdots v_k$, where v_j is a monomial in \mathcal{A}_{i_j} for all $1 \leq j \leq k$, and $i_j \neq i_{j+1}$ for all $1 \leq j \leq k$. In this case, the degree of $v_1 \cdots v_k$ is the sum of the degrees of v_1, \ldots, v_k , and a variable y is contained in $v_1 \cdots v_k$ if y is contained in one of the monomials v_1, \ldots, v_k . In any $*$ -algebra where we have a defined notion of monomial, a polynomial is a linear combination of monomials.

A C^* -algebra A is a complex $*$ -algebra with a submultiplicative Banach norm that satisfies the C^{*} identity $\|aa^*\| = \|a\|^2$ for all $a \in \mathcal{A}$. Every C^{*}-algebra can be realized as a norm-closed *-subalgebra of the algebra of bounded operators $\mathcal{B}(\mathcal{H})$ on some Hilbert space H . A C^* -algebra is a von Neumann algebra if it can be realized as a \ast -subalgebra of $\mathcal{B}(\mathcal{H})$ which is closed in the weak operator topology. More background on C^* -algebras and von Neumann algebras can be found in [\[Bla06\]](#page-41-3).

3. Nonlocal games and MIP*

A two-player nonlocal (or Bell) scenario consists of a finite set of questions I, and a collection of finite answer sets $(O_i)_{i\in I}$. Often in this definition there are separate question and answer sets for each player, but it's convenient for us to assume that both players have the same question and answer sets, and we don't lose any generality by assuming this. We often think of the question and answer sets as being subsets of $\{0, 1\}^n$ and $\{0, 1\}^{m_i}$, $i \in I$ respectively, in which case we say that the questions have length n and the answers have length $\max_{i \in I} m_i$. A nonlocal game consists of a nonlocal scenario $(I,(O_i)_{i\in I})$, along with a probability distribution π on $I \times I$ and a family of functions $V(\cdot, \cdot | i, j): O_i \times O_j \to \{0, 1\}$ for $(i, j) \in I \times I$. In the game, the players (commonly called Alice and Bob) receive questions i and j from I with probability $\pi(i, j)$, and reply with answers $a \in O_i$ and $b \in O_j$ respectively. They win if $V(a, b|i, j) = 1$, and lose otherwise.

A correlation for scenario $(I, \{O_i\}_{i \in I})$ is a family p of probability distributions $p(\cdot, \cdot|i, j)$ on $O_i \times O_j$ for all $(i, j) \in I \times I$. Correlations are used to describe the players' behaviour in a nonlocal scenario. The probability $p(a, b|i, j)$ is interpreted as the probability that the players answer (a, b) on questions (i, j) . A correlation p is quantum if there are

- (a) finite-dimensional Hilbert spaces H_A and H_B ,
- (b) a projective measurement $\{M_a^i\}_{a \in O_i}$ on H_A for every $i \in I$,
- (c) a projective measurement $\{N_a^i\}_{a \in O_i}$ on H_B for every $i \in I$, and
- (d) a state $|v\rangle \in H_A \otimes H_B$

such that $p(a, b|i, j) = \langle v|M_a^i \otimes N_b^j$ $b_i^j|v\rangle$ for all $i, j \in I$, $a \in O_i$, $b \in O_j$. A collection $(H_A, H_B, \{M_a^i\}, \{N_a^i\}, |v\rangle)$ as in (a)-(d) is called a **quantum strategy**. A correlation p is commuting operator if there is

- (i) a Hilbert space H ,
- (ii) projective measurements $\{M_a^i\}_{a\in O_i}$ and $\{N_a^i\}_{a\in O_i}$ on H for every $i \in I$, and
- (iii) a state $|v\rangle \in H$

such that $M_a^i N_b^j = N_b^j M_a^i$ and $p(a, b|i, j) = \langle v | M_a^i N_b^j$ $b_i^{\jmath}|v\rangle$ for all $i, j \in I$ and $a \in O_i$, $b \in O_j$. A collection $(H, \{M_a^i\}, \{N_a^i\}, |v\rangle)$ as in (i)-(iii) is called a **commuting** operator strategy. The set of quantum correlations for a scenario $(I, \{O_i\})$ is denoted by $C_q(I, \{O_i\})$, and the set of commuting operator correlations is denoted by $C_{qc}(I, \{O_i\})$. If the scenario is clear from context, then we denote these sets by C_q and C_{qc} . Any quantum correlation is also a commuting operator correlation, so $C_q \subseteq C_{qc}$. If a commuting operator correlation has a commuting operator strategy on a finite-dimensional Hilbert space H , then it is also a quantum correlation, but in general C_{qc} is strictly larger than C_q .

The winning probability of a correlation p in a nonlocal game $\mathcal{G} = (I, \{O_i\}, \pi, V)$ is

$$
\omega(\mathcal{G};p) := \sum_{i,j\in I} \sum_{a\in O_i,b\in O_j} \pi(i,j) V(a,b|i,j) p(a,b|i,j).
$$

The quantum value of $\mathcal G$ is

$$
\omega_q(\mathcal{G}):=\sup_{p\in C_q}\omega(\mathcal{G};p)
$$

and the commuting operator value is

$$
\omega_{qc}(\mathcal{G}):=\sup_{p\in C_{qc}}\omega(\mathcal{G};p).
$$

A correlation p is perfect for G if $\omega(G; p) = 1$, and ϵ -perfect if $\omega(G; p) \geq 1 - \epsilon$. A strategy is ϵ -perfect if its corresponding correlation is ϵ -perfect. The set C_{qc} is closed and compact, so G has a perfect commuting operator correlation if and only if $\omega_{qc}(\mathcal{G}) = 1$. However, C_q is not necessarily closed, and there are games $\mathcal G$ with $\omega_q(\mathcal{G}) = 1$ which do not have a perfect quantum correlation. A correlation p is quantum approximable if it belongs to the closure $C_{qa} := C_q$, and a game G has a perfect quantum approximable correlation if and only if $\omega_q(\mathcal{G}) = 1$.

A nonlocal game $\mathcal{G} = (I, \{O_i\}, \pi, V)$ is synchronous if $V(a, b|i, i) = 0$ for all $i \in I$ and $a \neq b \in O_i$. A correlation p is **synchronous** if $p(a, b|i, i) = 0$ for all $i \in I$ and $a \neq b \in O_i$. The set of synchronous quantum (resp. commuting operator) correlations is denoted by C_q^s (resp. C_{qc}^s). A correlation p belongs to C_{qc}^s (resp. C_q^s) if and only if there is

- (A) a Hilbert space H (resp. finite-dimensional Hilbert space H),
- (B) a projective measurement $\{M_a^i\}_{a \in O_i}$ on H for all $i \in I$, and
- (C) a state $|v\rangle \in H$

such that $|v\rangle$ is tracial, in the sense that $\langle v|\alpha\beta|v\rangle = \langle v|\beta\alpha|v\rangle$ for all α and β in the *algebra generated by the operators M_a^i , $i \in I$, $a \in O_i$, and $p(a, b|i, j) = \langle v | M_a^i M_b^j | v \rangle$ for all $i, j \in I$, $a \in O_i$, $b \in O_j$. A collection $(H, {M_a^i}, |v\rangle)$ as in (A) -(C) is called a synchronous commuting operator strategy. If, in addition, H is finitedimensional, then $(H, \{M_a^i\}, |\nu\rangle)$ is also called a **synchronous quantum strategy**. The synchronous quantum and commuting operator values $\omega_q^s(\mathcal{G})$ and $\omega_{qc}^s(\mathcal{G})$ of a game G are defined equivalently to $\omega_q(\mathcal{G})$ and $\omega_{qc}(\mathcal{G})$, but with C_q and C_{qc} replaced by C_q^s and C_{qc}^s . A synchronous strategy $(H, \{M_a^i\}, |v\rangle)$ for a game $\mathcal{G} = (I, \{O_i\}, \pi, V)$ is **oracularizable** if $M_a^i M_b^j = M_b^j M_a^i$ for all $i, j \in I$, $a \in O_i$, $b \in O_j$ with $\pi(i, j) > 0$.

A theorem of Vidick [\[Vid22\]](#page-43-18) (see also [\[Pad22\]](#page-43-13)) states that every quantum correlation which is close to being synchronous, in the sense that $p(a, b|i, i) \approx 0$ for all $i \in I$ and $a \neq b \in O_i$, is close to a synchronous quantum correlation. This theorem has been extended to commuting operator correlations by [\[Lin23\]](#page-43-19). As a result, the synchronous quantum and commuting values of a game are polynomially related to the non-synchronous quantum and commuting values. We use a version of this result due to Marrakchi and de la Salle [\[MdlS23\]](#page-43-20). Following [\[MdlS23\]](#page-43-20), say that a probability distribution on $I \times I$ is C-diagonally dominant if $\pi(i, i) \geq C \sum_{j \in I} \pi(i, j)$ and $\pi(i, i) \geqslant C \sum_{j \in I} \pi(j, i)$ for all $i \in I$. Then:

Theorem 3.1 ([\[MdlS23\]](#page-43-20)). Suppose G is a synchronous game with a C-diagonally dominant question distribution. If $\omega_q(G)$ (resp. $\omega_{qc}(G)$) is $\geq 1-\epsilon$, then $\omega_q^s(G)$ (resp. $\omega_{qc}^s(\mathcal{G})$) is $\geq 1 - O((\epsilon/C)^{1/4})$.

A two-prover one-round MIP protocol is a family of nonlocal games $G_x =$ $(I_x, \{O_{xi}\}_{i\in I_x}, \pi_x, V_x)$ for $x \in \{0, 1\}^*$, along with a probabilistic Turing machine S and another Turing machine V , such that

- for all $x \in \{0, 1\}^*$ and $i \in I_x$, there are integers n_x and m_{xi} such that $I_x = \{0, 1\}^{n_x}$ and $O_{xi} = \{0, 1\}^{m_{xi}},$
- on input x, the Turing machine S outputs $(i, j) \in I \times I$ with probability $\pi_x(i,j)$, and
- on input (x, a, b, i, j) , the Turing machine V outputs $V_x(a, b|i, j)$.

Let $c, s : \{0,1\}^* \to \mathbb{Q}$ be computable functions with $c(x) > s(x)$ for all $x \in \{0,1\}^*$. A language $\mathcal{L} \subset \{0, 1\}^*$ belongs MIP^{*} $(2, 1, c, s)$ if there is a MIP protocol $(\{\mathcal{G}_x\}, S, V)$ such that n_x and m_{xi} are polynomial in |x|, S and V run in polynomial time in |x|, if $x \in \mathcal{L}$ then $\omega_q(\mathcal{G}_x) \geq c$, and if $x \notin \mathcal{L}$ then $\omega_q(\mathcal{G}_x) \leq s$. The function c is called the completeness probability, and s is called the soundness probability. The functions n_x and m_{xi} are called the **question length** and **answer length** respectively. The class $MIP^{co}(2, 1, c, s)$ is defined equivalently to $MIP^*(2, 1, c, s)$,

but with ω_q replaced by ω_{qc} . The protocols in these cases are called MIP^{*} and MIP^{co} protocols. A language belongs to $AM^*(2)$ (resp. $AM^{qc}(2)$) if it has a MIP^{*}protocol (resp. MIP^{qc}-protocol) in which π_x is the uniform distribution on $I_x \times I_x$. Such a protocol is called an $AM^*(2)$ protocol. We can also define classes SynMIP^{*} and SynMIP^{co} by replacing the quantum and commuting operator values by ω_q^s and ω_{qc}^s .

Any language in $\text{MIP}^*(2,1,c,s)$ is contained in RE, and this remains true even if we add more provers and rounds of communication. The $MIP^* = RE$ theorem of Ji, Natarajan, Vidick, Wright, and Yuen states that $MIP^*(2,1,1,1/2) = RE$ [\[JNV](#page-43-6)⁺22b]. In this paper, we use the following strong version of MIP^{*} = RE due to Natarajan and Zhang [\[NZ23\]](#page-43-8).

Theorem 3.2 (MIP^{*} = RE). There is a two-prover one round $AM^*(2)$ protocol $(\{G_x\}, S, V)$ for the halting problem with completeness $c = 1$ and soundness $s = 1/2$, such that \mathcal{G}_x is a synchronous game with constant length questions, and $\text{polylog}(|x|)$ length answers. Furthermore, if G_x has a perfect strategy, then it has a perfect oracularizable synchronous quantum strategy.

Proof. [\[NZ23\]](#page-43-8) shows that there is MIP^* protocol for the halting problem meeting this description. As they observe, any MIP˚ protocol with a constant number of questions can be turned into an $AM^*(2)$ protocol with completeness $c = 1$ and soundness $s < 1$, and then parallel repetition (see Section [8\)](#page-25-0) can be used to lower the soundness back to $1/2$.

One corollary of Theorem [3.2](#page-9-0) is that it is possible to transform any MIP˚ protocol into an equivalent $AM^*(2)$ protocol $(\{\mathcal{G}_x\}, S, V)$ as in the theorem. Indeed, suppose P is a polynomial-time probabilistic interactive Turing machine which on input x acts as the verifier in a MIP^{*} protocol with k rounds, p provers, completeness c, and soundness s, where k, p, c, and s are computable functions of |x|. Let $\mathcal T$ be the Turing machine which on input x, searches through k-round p-prover quantum strategies, uses P to calculate the success probability, and halts if it finds a strategy with success probability $\geq s$. Let $\mathcal{T}(x)$ be the Turing machine which on empty input writes x to the input tape and then runs T. Finally, let (\mathcal{G}_M, S, V) be the one-round protocol for the language $HALT = \{M : M$ is a Turing machine that halts on empty input. The Turing machines S and V run in polynomial time in the size $|M|$ of the input Turing machine M, and $\mathcal{T}(x)$ has size linear in |x|, so the one-round protocol which runs game $\mathcal{G}_{\mathcal{T}(x)}$ on input x is a polynomial-time $AM^*(2)$ protocol which recognizes the same language as P . Strikingly, this works for any computable k, p, and s, not just polynomial functions of $|x|$, since the only requirement is that $\mathcal{T}(x)$ have polynomial description size.

Remark 3.3. The underlying statement of Theorem [1.1](#page-1-0) (see Theorem [9.15\)](#page-40-0) is that there is a two-prover perfect-zero knowledge MIP˚ protocol for the halting problem. Hence the same argument as above shows that there is an effective procedure for transforming any MIP^{*} protocol into a two-prover perfect zero knowledge MIP^{*} protocol.

4. BCS games

We now introduce boolean constraint system games. If V is a set of variables, a constraint on V is a subset C of \mathbb{Z}_2^V . We think of \mathbb{Z}_2 as $\{\pm 1\}$ rather than $\{0, 1\}$, since this is more convenient when working with observables and measurements. In particular, we use -1 and 1 to represent true and false respectively, rather than 1 and 0. An **assignment to** V is an element $\phi \in \mathbb{Z}_2^V$, and we refer to the elements of C as satisfying assignments for C . For convenience, we assume every constraint is non-empty, i.e. has a satisfying assignment. A boolean constraint system (BCS) B is a pair $(X, \{(V_i, C_i)\}_{i=1}^m)$, where X is an ordered set of variables, V_i is a nonempty subset of X for all $1 \leq i \leq m$, and C_i is a constraint on the variables V_i . When working with nonlocal games, the sets V_i are sometimes called the **contexts** of the system. The order on X induces an order on the contexts V_i , and this will be used for some specific models of the weighted BCS algebra in Section [7.](#page-18-0) This is the only thing we use the order on X for, so it can be ignored otherwise. A **satisfying assignment for** B is an assignment ϕ to X such that $\phi|_{V_i} \in C_i$ for all $1 \leq i \leq m$. Although we won't use it until later, we define the **connectivity** of a BCS B to be the maximum over i of $|\{(x, j) \in V_i \times [m] : x \in V_j\}|$, where $[m] := \{1, \ldots, m\}.$ In other words, the connectivity is the maximum over i of the number of times the variables in constraint i appear in the constraints of B. Also, if $V = \bigcup_{i=1}^{k} V_i$ and C_i is a constraint on V_i , then the **conjunction** $\wedge_{i=1}^k C_i$ is the constraint C on variables V such that $\phi \in C$ if and only if $\phi|_{V_i} \in C_i$ for all $1 \leq i \leq k$.

Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let π be a probability distribution on $[m] \times [m]$. The **BCS game** $\mathcal{G}(B,\pi)$ is the nonlocal game $([m], C_{i \in m}, \pi, V)$, where $V(\phi_i, \phi_j|i, j) = 1$ if $\phi_i|_{V_i \cap V_j} = \phi_j|_{V_i \cap V_j}$, and is 0 otherwise. In other words, in $\mathcal{G}(B,\pi)$, the players are given integers $i, j \in [m]$ according to the distribution π , and must reply with satisfying assignments $\phi_i \in C_i$ and $\phi_j \in C_j$ respectively. They win if their assignments agree on the variables in $V_i \cap V_j$. With this definition, $\mathcal{G}(B, \pi)$ has questions of length $\lceil \log m \rceil$, and answer sets of length $|V_i|$.

A BCS-MIP protocol is a family of BCS games $\mathcal{G}(B_x, \pi_x)$, where $B_x = (X_x, \{(V_i^x, C_i^x)\}_{i=1}^{m_x}),$ along with a probabilistic Turing machine S and another Turing machine C , such that

- (1) on input x, S outputs $(i, j) \in [m_x] \times [m_x]$ with probability $\pi_x(i, j)$, and
- (2) on input (x, ϕ, i) , C outputs true if $\phi \in C_i^x$ and false otherwise.

Technically, this definition should also include some way of computing the sets X_x and V_i^x . For instance, we might say that the integers $|N_x|$ and $|V_i^x|$ are all computable, and there are computable order-preserving injections $[|V_i^x|] \to [|X_x|]$. However, for simplicity we ignore this aspect of the definition going forward, and just assume that in any BCS-MIP˚ protocol, we have some efficient way of working with the sets X_x and V_i^x , the intersections $V_i^x \cap V_j^x$, and assignments $\phi \in \mathbb{Z}_2^{V_i^x}$. A language $\mathcal L$ belongs to the complexity class BCS-MIP^{*}(s) if there is a BCS-MIP protocol as above such that $\lceil \log m_x \rceil$ and $|V_i^x|$ are polynomial in $|x|$, S and C run in polynomial time, if $x \in \mathcal{L}$ then $\omega_q^s(\mathcal{G}_x) = 1$, and if $x \notin \mathcal{L}$ then $\omega_q^s(\mathcal{G}_x) \leq s$. The parameter

s is called the soundness. Any BCS-MIP^{*} protocol for $\mathcal L$ can be transformed into a SynMIP^{*} protocol by playing the game \mathcal{G}_x with the answer sets C_i replaced by $\mathbb{Z}_2^{V_i^{\tilde{x}}}$, and on input (x, ϕ, ψ, i, j) , asking the verifier V to first check that $\phi \in C_i$ and $\psi \in C_j$ using C, and then checking that $\phi|_{V_i \cap V_j} = \psi|_{V_i \cap V_j}$. Hence BCS-MIP^{*}(s) is contained in SynMIP^{*} $(2, 1, 1, s)$. Notice that in this modified version of the BCS game, the players are allowed to answer with non-satisfying assignments, but they always lose if they do so. Thus any strategy for the modified game can be converted into a strategy for the original game with the same winning probability, and perfect strategies for both types of games (ignoring questions that aren't in the support of π) are identical, so the SynMIP^{*} protocol has the same completeness and soundness as the BCS-MIP^{*} protocol. The class BCS-MIP^{co}(s) can be defined similarly by replacing ω_q with ω_{qc} , and is contained in SynMIP^{co}(2, 1, 1, s). We can also define subclasses of BCS-MIP^{*} and BCS-MIP^{co}. For instance, we let $3SAT-MIP^*$ be the class of languages with a BCS-MIP^{*} protocol $(\{\mathcal{G}(B_x, \pi_x)\}, S, C)$, in which every constraint of B_x is a 3SAT clause, i.e. a disjunction $x \vee y \vee z$, where x, y, z are either variables from B_x , or negations of said variables, or constants.

If the players receive the same question $i \in [m]$, then they must reply with the same assignment ϕ to win. Consequently, if $\pi(i, i) > 0$ for all i then $\mathcal{G}(B, \pi)$ is a synchronous game. This version of BCS games is sometimes called the constraintconstraint version of the game. There is are other variants of BCS games, sometimes called constraint-variable BCS games, in which one player receives a constraint and another receives a variable (see [\[CM14\]](#page-42-8)). In this paper, we work with constraintconstraint games exclusively, but the two types of BCS games are closely related, and can often be used interchangeably. As per the previous section, a synchronous strategy for $\mathcal{G}(B,\pi)$ consists of projective measurements $\{M_{\phi}^{i}\}_{\phi \in \mathbb{Z}_{2}^{V_{i}}}, i \in [m]$, on a Hilbert space H, along with a state $|v\rangle \in \mathcal{H}$ which is tracial on the algebra generated by M^i_{ϕ} .

Conversely, it is well-known that every synchronous game $\mathcal{G} = (I, \{O_i\}, \pi, V)$ can be turned into a BCS game. One way to do this (see, e.g. [\[PS23,](#page-43-12) [Pad22\]](#page-43-13)) is to make a constraint system with variables x_{ia} for $i \in I$ and $a \in \mathcal{O}_i$, and constraints $\vee_{a \in \mathcal{O}_i} x_{ia} =$ true for all $i \in [m]$ and $x_{ia} \wedge x_{jb} =$ false whenever $V(a, b|i, j) = 0$. The variable x_{ia} represents whether the player answers a on input i , and the constraints express the idea that the players must choose an answer for every question, and that they should reply with winning answers (the synchronous condition on V implies that $x_{ia} \wedge x_{ib} =$ false is a constraint for all i and $a \neq b$, which means that the players should choose a single answer for question i). The BCS game \mathcal{G}' associated to this constraint system has a perfect quantum (resp. quantum approximable, commuting operator) strategy if and only if $\mathcal G$ has a perfect quantum (resp. quantum approximable, commuting operator) strategy. Unfortunately, this construction results in a game with answer sets $\{\pm 1\}^{O_i}$, which means that the bit-length of the answers increases exponentially from G. If $\omega_q(\mathcal{G}) = 1 - \epsilon$, then $\omega_q(\mathcal{G}) = 1 - O(\epsilon/|O_i|)$, meaning that if this construction is used in a MIP˚ -protocol, soundness can drop of exponentially.

To fix this, we look at the oracularization \mathcal{G}^{orac} of \mathcal{G} . There are several versions of \mathcal{G}^{orac} in the literature, all closely related. We use the version from [\[NW19\]](#page-43-21), in

which the verifier picks a question pair $(i_1, i_2) \in I$ according to π . The verifier then picks $a, b, c \in \{1, 2\}$ uniformly at random. When $a = 1$, they send player b both questions (i_1, i_2) , and the other player question (i_c) . Player b must respond with $a_j \in O_j$ such that $V(a_1, a_2|i_1, i_2) = 1$, and the other player responds with $b \in O_{i_c}$. The players win if $a_c = b$. If $a = 2$, both players are sent (i_1, i_2) and must respond with (a_1, a_2) and (b_1, b_2) in $O_{i_1} \times O_{i_2}$. They win if $(a_1, a_2) = (b_1, b_2)$. If G has questions of length q and answers of length a , then \mathcal{G}^{orac} has questions of length $2q$ and answers of length $2a$, so this construction only increases the question and answer length polynomially. The following lemma shows that this construction is sound, in the sense that $\omega_q(\mathcal{G}^{orac})$ cannot be much larger than $\omega_q(\mathcal{G})$.

Lemma 4.1 ([\[NW19,](#page-43-21) [JNV](#page-43-6)⁺22b]). Let G be a synchronous game. If G has an perfect oracularizable synchronous strategy, then \mathcal{G}^{orac} has a perfect synchronous strategy. Conversely, if $\omega_q(\mathcal{G}^{orac}) = 1 - \epsilon$, then $\omega_q(\mathcal{G}) \geq 1 - \text{poly}(\epsilon)$.

Proof. This is asserted in Definition 17.1 of [\[NW19\]](#page-43-21). Although a proof isn't supplied, the proof follows the same lines as Theorem 9.3 of JNV^+22b .

Given a synchronous game $G = (I, \{O_i\}, \pi, V)$ where $I \subseteq \{0, 1\}^n$ and $O_i \subseteq$ $\{0,1\}^{m_i}$, construct a constraint system B as follows. Take X to be the set of variables x_{ij} , where $i \in I$ and $1 \leq j \leq m_i$. Let $V_i = \{x_{ij}, 1 \leq j \leq m_i\}$, and identify $\mathbb{Z}_2^{V_i}$ with bit strings $\{0, 1\}^{m_i}$, where the assignment to x_{ij} corresponds to the jth bit, and let $C_i \subseteq \mathbb{Z}_2^{V_i}$ be the subset corresponding to O_i . Let $P = \{(i, j) \in I \times I : \pi(i, j) > 0\}.$ For $(i, j) \in P$, let $V_{ij} = V_i \cup V_j$, and let $C_{ij} \subset \mathbb{Z}_2^{V_{ij}} = \mathbb{Z}_2^{V_i} \times \mathbb{Z}_2^{V_j}$ 2^{\prime} be the set of pairs of strings (a, b) such that $a \in O_i$, $b \in O_j$, and $V(a, b|i, j) = 1$. Then B is the constraint system with variables X and constraints $\{(V_i, C_i)\}_{i \in I}$ and $\{(V_{ij}, C_{ij})\}_{(i,j) \in P}$. Let $I' = I \cup P$ and π^{orac} be the probability distribution on $I' \times I'$ such that

$$
\pi^{orac}(i',j') = \begin{cases}\n\frac{1}{8}\pi(i,j) & i' = (i,j), j' = i \\
\frac{1}{8}\pi(i,j) & i' = (i,j), j' = j \\
\frac{1}{8}\pi(i,j) & i' = i, j' = (i,j) \\
\frac{1}{8}\pi(i,j) & i' = j, j' = (i,j) \\
\frac{1}{2}\pi(i,j) & i' = j' = (i,j) \\
0 & \text{otherwise}\n\end{cases}
$$

Then $\mathcal{G}(B, \pi^{orac}) = \mathcal{G}^{orac}$, so the oracularization of a synchronous game is a BCS game. As a result, Theorem [3.2](#page-9-0) has the following corollary:

Corollary 4.2. There is a BCS-MIP^{*} protocol $(\{\mathcal{G}(B_x, \pi_x)\}, S, V)$ for the halting problem with constant soundness $s < 1$, in which B_x has a constant number of contexts and contexts of size polylog(|x|), and π_x is the uniform distribution on pairs of contexts.

Proof. Let $(\{\mathcal{G}_x\}, S, V)$ be the protocol from Theorem [3.2.](#page-9-0) Then \mathcal{G}_x^{orac} is a BCS game in which the underlying BCS has a constant number of contexts, and the contexts have size polylog(|x|). The probability distribution π^{orac} and the constraints of \mathcal{G}^{orac} can be computed in polynomial time from S and V, so by Lemma [4.1](#page-12-0) there

is a BCS-MIP^{*} protocol for the halting problem with constant soundness $s' < 1$. The probability distribution π_x in the oracularization construction is not uniform. However, it is not hard to see that changing the distribution π_x in the oracularization game does not change completeness, and since there are only a constant number of contexts, replacing π_x with the uniform distribution yields only a constant dropoff in soundness.

5. BCS algebras and approximate representations

It is often worth thinking about synchronous strategies more abstractly. Recall that $\mathbb{C}\mathbb{Z}_2^{*V}$ is the *-algebra generated by variables $x \in V$, satisfying the relations $x^2 = x^*x = xx^* = 1$ for all $x \in V$, and $\mathbb{C} \mathbb{Z}_2^V$ is the quotient of $\mathbb{C} \mathbb{Z}_2^{*V}$ by the relations $xy = yx$ for all $x, y \in V$. Given an assignment ϕ to an ordered set of variables V, we let

$$
\Phi_{V,\phi}:=\prod_{x\in V}\tfrac{1}{2}(1+\phi(x)x)
$$

considered as a polynomial in $\mathbb{C}\mathbb{Z}_2^{*V}$, where the product is taken with respect to the order on V . Given a constraint C on V , we let

$$
\mathcal{A}(V,C) = \mathbb{C}\mathbb{Z}_2^V/\langle \Phi_{V,\phi} = 0 \text{ for } \phi \notin C \rangle.
$$

Since $\mathbb{C}\mathbb{Z}_2^V$ is commutative, the image of $\Phi_{V,\phi}$ in $\mathbb{C}\mathbb{Z}_2^V$ is independent of the order of V; however, we will work with $\mathbb{C}\mathbb{Z}_2^{*V}$ in Section [7.](#page-18-0) The algebra $\mathcal{A}(V,C)$ is isomorphic to the algebra

$$
\mathbb{C}^*\langle m_{\phi}, \phi \in C : m_{\phi}^* = m_{\phi} = m_{\phi}^2 \text{ for all } \phi \in C \text{ and } \sum_{\phi \in C} m_{\phi} = 1 \rangle,
$$

where the isomorphism identifies m_{ϕ} with $\Phi_{V,\phi}$. In particular, $\mathbb{CZ}_2^V = \mathcal{A}(V, \mathbb{Z}_2^V)$ is generated by $\Phi_{V,\phi}$ for $\phi \in \mathbb{Z}_2^V$. Consequently if $\sigma : \mathcal{A}(V,C) \to \mathcal{B}(\mathcal{H})$ is a $*$ representation, then $\{\sigma(\Phi_{V,\phi})\}_{\phi\in C}$ is a projective measurement on H, and conversely if $\{M_{\phi}\}_{{\phi}\in C}$ is a projective measurement on H, then there is a *-representation $\sigma : \mathcal{A}(V, C) \to \mathcal{B}(\mathcal{H})$ with $\sigma(\Phi_{V, \phi}) = M_{\phi}$.

If $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS, then we let $\mathcal{A}(B)$ denote the free product $\mathcal{A}(B) := *_{i \in [m]} \mathcal{A}(V_i, C_i)$. We let $\sigma_i : \mathcal{A}(V_i, C_i) \to \mathcal{A}(B)$ denote the natural inclusion of the ith factor, so $\mathcal{A}(B)$ is generated by the involutions $\sigma_i(x)$ for $i \in [m]$ and $x \in V_i$. Equivalently, $\mathcal{A}(B)$ is generated by the projections $\sigma_i(\Phi_{V_i,\phi})$ for $i \in [m]$ and $\phi \in C_i$. To avoid clogging up formulas with symbols, we'll often write $\Phi_{V_i, \phi}$ instead of $\sigma_i(\Phi_{V_i,\phi})$ when it's clear what subalgebra $\mathcal{A}(V_i, C_i)$ the element belongs to. As with $\mathcal{A}(V, C)$, representations α of $\mathcal{A}(B)$ are in bijective correspondence with families of projective measurements $\{M_{\phi}^{i}\}_{\phi \in C_{i}}$, $i \in [m]$ via the relation $M_{\phi}^{i} = \alpha(\Phi_{V_{i},\phi})$. If $(\{M_\phi^i\}, |v\rangle, \mathcal{H})$ is a synchronous commuting operator strategy for $\mathcal{G}(B, \pi)$, and $\alpha : \mathcal{A}(B) \to \mathcal{B}(\mathcal{H})$ is the representation with $\alpha(\Phi_{V_i, \phi}) = M_{\phi}^i$, then $a \mapsto \langle v | \alpha(a) | v \rangle$ is a tracial state on $A(B)$. Conversely, if τ is a tracial state on $A(B)$, then the GNS representation theorem implies that there is a synchronous commuting operator strategy $S = (\{M^i_\phi\}, |v\rangle, \mathcal{H})$ such that $\tau(a) = \langle v | \alpha(a) | v \rangle$ where α is the representation corresponding to $\{M_{\phi}^{i}\}$. Note that the trace is faithful on the image of the GNS

representation. As a result, synchronous commuting operator strategies for $\mathcal{G}(B,\pi)$ and tracial states on $\mathcal{A}(B)$ can be used interchangeably, and in particular $p \in C_{qc}$ if and only if there is a tracial state τ with $p(\phi, \psi|i, j) = \tau(\Phi_{V_i, \phi} \Phi_{V_i, \psi})$ for all i, j , ϕ , and ψ . Finite-dimensional tracial states on $\mathcal{A}(B)$ can be used interchangeably with synchronous quantum strategies for $\mathcal{G}(B,\pi)$, and $p \in C_q$ if and only if there is a finite-dimensional tracial state τ with $p(\phi, \psi|i, j) = \tau(\Phi_{V_i, \phi} \Phi_{V_i, \psi})$ for all i, j, ϕ , and ψ . Similarly, $p \in C_{qa}$ if and only if there is a Connes-embbedable tracial state τ such that $p(\phi, \psi|i, j) = \tau(\Phi_{V_i, \phi} \Phi_{V_j, \psi})$ for all i, j, ϕ , and ψ [\[KPS18\]](#page-43-11).

A correlation p is perfect for a BCS game $\mathcal{G}(B,\pi)$ if $p(\phi, \psi|i, j) = 0$ whenever $\pi(i, j) > 0$ and (ϕ, ψ) is a losing answer to questions (i, j) . As a result, a tracial state τ on $\mathcal{A}(B)$ is **perfect** (aka. corresponds to a perfect correlation) if and only if $\tau(\Phi_{V_i,\phi}\Phi_{V_j,\psi})=0$ whenever $\phi|_{V_i\cap V_j}\neq \psi|_{V_i\cap V_j}$. Consequently a tracial state on $\mathcal{A}(B)$ is perfect for $\mathcal{G}(B, \pi)$ if and only if it is the pullback of a tracial state on the synchronous algebra of $\mathcal{G}(B,\pi)$, which is the quotient

$$
\text{SynAlg}(B,\pi) = \mathcal{A}(B) / \langle \Phi_{V_i,\phi} \Phi_{V_j,\psi} = 0 \text{ for all } i,j \in [m] \text{ with } \pi(i,j) > 0
$$

and $\phi \in C_i, \psi \in C_j \text{ with } \phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j} \rangle.$

For BCS games, this result about perfect strategies is due to Kim, Paulsen, and Schafhauser [\[KPS18\]](#page-43-11). The general notion of a synchronous algebra is due to [\[HMPS19\]](#page-42-12). In [\[Gol21,](#page-42-15) [PS23\]](#page-43-12), it is shown that the synchronous algebra of a BCS game is isomorphic to the so-called BCS algebra of the game. In working with MIP˚ protocols, we also need to keep track of ϵ -perfect strategies. In [\[Pad22\]](#page-43-13), it is shown that ϵ -perfect strategies for a BCS game correspond to ϵ -representations of the BCS algebra, where an ϵ -representation is a representation of $\mathcal{A}(B)$ such that all the defining relations of $\text{SynAlg}(B, \pi)$ are bounded by ϵ in the normalized Frobenius norm. In this prior work, the focus was on the behaviour of ϵ -perfect strategies for a fixed game, so the number of questions and answers was constant. For MIP˚ protocols, the game size is not constant, and we need to work with approximate representations where the average, rather than the maximum, of the norms of the defining relations is bounded. For this, we introduce the following algebraic structure:

Definition 5.1. A *(finitely-supported)* weight function on a set X is a function $\mu : X \to [0, +\infty)$ such that $\text{supp}(\mu) := \mu^{-1}((0, +\infty))$ is finite. A weighted *algebra is a pair (A, μ) where A is a \ast -algebra and μ is a weight function on A.

If τ is a tracial state on A, then the **defect** of τ is

$$
\operatorname{def}(\tau;\mu) := \sum_{a \in \mathcal{A}} \mu(a) \|a\|_{\tau}^2,
$$

where $||a||_{\tau} := \sqrt{\tau(a^*a)}$ is the τ -norm. When the weight function is clear, we just write def (τ) .

Since μ is finitely supported, the sum in the definition of the defect is finite, and hence is well-defined. Note that traces τ on a weighted algebra (\mathcal{A}, μ) with $\det(\tau) = 0$ correspond to traces on the algebra $A/\langle \text{supp}(\mu) \rangle$. In general, $\det(\tau)$ is a measure of how far τ is from being a trace on A. Thus we can think of a weighted algebra (\mathcal{A}, μ) as a presentation or model for the algebra $\mathcal{A}/\langle \text{supp}(\mu) \rangle$ that allows us to talk about approximate traces on this algebra.

Definition 5.2. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let π be a probability distribution on $[m] \times [m]$. The (weighted) BCS algebra $A(B, \pi)$ is the *-algebra $\mathcal{A}(B)$, with weight function μ_{π} defined by

$$
\mu_{\pi}(\Phi_{V_i,\phi}\Phi_{V_j,\psi})=\pi(i,j)
$$

for all $i, j \in [m]$ and $\phi \in C_i$, $\psi \in C_j$ with $\phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}$, and $\mu_{\pi}(r) = 0$ for all other $r \in \mathcal{A}(B)$.

Note that $A(B)/\langle \text{supp}(\mu_{\pi})\rangle$ is the synchronous algebra $\text{SynAlg}(B, \pi)$ defined above, so $\mathcal{A}(B, \pi)$ is a model of this synchronous algebra, and perfect strategies for $\mathcal{G}(B, \pi)$ correspond to tracial states τ on $\mathcal{A}(B, \pi)$ with def(τ) = 0. The following lemma is an immediate consequence of the definitions:

Lemma 5.3. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let π be a probability distribution on $[m] \times [m]$. A tracial state τ on $\mathcal{A}(B)$ is an e-perfect strategy for $\mathcal{G}(B, \pi)$ if and only if $\text{def}(\tau) \leq \epsilon$.

Proof. Let p be the correlation corresponding to τ , so $p(\phi, \psi|i, j) = \tau(\Phi_{V_i, \phi} \Phi_{V_i, \psi})$. Then

$$
\det(\tau) = \sum \pi(i,j)\tau(\Phi_{V_i,\phi}\Phi_{V_j,\psi}),
$$

where the sum is across $i, j \in [m]$ and $\phi \in C_i$, $\psi \in C_j$ with $\phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}$. So $\text{def}(\tau) = 1 - \omega(\mathcal{G}(B,\pi); p).$

6. Homomorphisms between BCS algebras

In addition to looking at BCS games, we also want to consider transformations between constraint systems and the corresponding games. To keep track of how near-perfect strategies change, we introduce a notion of homomorphism for weighted algebras.

Definition 6.1. Let (A, μ) and (B, ν) be weighted *-algebras, and let $C > 0$. A C-homomorphism $\alpha : (A, \mu) \to (B, \nu)$ is a *-homomorphism $\alpha : A \to B$ such that

$$
\alpha(\sum_{a\in \mathcal{A}} \mu(a)a^*a) \lesssim C \sum_{b\in \mathcal{B}} \nu(b)b^*b.
$$

The point of this definition is the following:

Lemma 6.2. Suppose $\alpha : (\mathcal{A}, \mu) \to (\mathcal{B}, \nu)$ is a C-homomorphism. If τ is a trace on (\mathcal{B}, ν) , then def $(\tau \circ \alpha) \leq C \det(\tau)$.

Proof. Let
$$
A = \alpha(\sum_{a \in A} \mu(a)a^*a)
$$
 and $B = \sum_{b \in B} \nu(b)b^*b$. Note that

$$
\operatorname{def}(\tau \circ \alpha) = \sum_{a \in \mathcal{A}} \mu(a) \|a\|_{\tau \circ \alpha} = \sum_{a \in \mathcal{A}} \mu(a) \tau(\alpha(a^*a)) = \tau(A),
$$

By the definition of \leq , there are c_1, \ldots, c_k and $f_1, \ldots, f_\ell, g_1, \ldots, g_\ell \in \mathcal{B}$ such that

$$
CB - A = \sum_{i=1}^{k} c_i^* c_i + \sum_{j=1}^{\ell} [f_j, g_j].
$$

Since τ is a tracial state, $\tau(c_i^* c_i) \geq 0$ and $\tau([f_j, g_j]) = 0$ for all i and j. Hence $C\tau(B) \geq \tau(A)$ as required.

One of the first things we can apply this idea to is changing between different presentations of the BCS algebra. For instance:

Proposition 6.3. Suppose $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS, and π is a probability distribution on $[m] \times [m]$. Let μ_{inter} be the weight function on $\mathcal{A}(B)$ defined by

$$
\mu_{inter}(\sigma_i(x) - \sigma_j(x)) = \pi(i, j)
$$

for all $i \neq j \in [m]$ and $x \in V_i \cap V_j$, and $\mu_{inter}(r) = 0$ for other $r \in \mathcal{A}(B)$. Then the identity map $A(B) \to A(B)$ gives a $O(1)$ -homomorphism $(A(B), \mu_{\pi}) \to$ $(A(B), \mu_{inter})$, and a $O(L)$ -homomorphism $(A(B), \mu_{inter}) \rightarrow (A(B), \mu_{\pi})$, where $L =$ $\max_{i,j} |V_i \cap V_j|.$

Recall that $\sigma_i : \mathcal{A}(V_i, C_i) \to \mathcal{A}(B)$ is the natural inclusion of the *i*th factor.

Proof. Fix $1 \leq i, j \leq m$. Since $\Phi_{V_i, \phi}$ is a projection in $\mathcal{A}(V_i, C_i)$, $(\Phi_{V_i, \phi} \Phi_{V_j, \psi})^*(\Phi_{V_i, \phi} \Phi_{V_j, \psi})$ is cyclically equivalent to $\Phi_{V_i,\phi}\Phi_{V_j,\psi}$ for all $\phi \in C_i$, $\psi \in C_j$. For $x \in V_i \cap V_j$, let R_x be the pairs $(\phi, \psi) \in C_i \times C_j$ such that $\phi(x) \neq \psi(x)$. Then

$$
\sum_{\phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}} \Phi_{V_i, \phi} \Phi_{V_j, \psi} \lesssim \sum_{x \in V_i \cap V_j} \sum_{(\phi, \psi) \in R_x} \Phi_{V_i, \phi} \Phi_{V_j, \psi},
$$

and since $\phi|_{V_i \cap V_j}$ and $\psi|_{V_i \cap V_j}$ can disagree in at most $|V_i \cap V_j|$ places,

$$
\sum_{x\in V_i\cap V_j}\sum_{(\phi,\psi)\in R_x}\Phi_{V_i,\phi}\Phi_{V_j,\psi}\lesssim |V_i\cap V_j|\sum_{\phi|_{V_i\cap V_j}\neq \psi_{V_i\cap V_j}}\Phi_{V_i,\phi}\Phi_{V_j,\psi}.
$$

Fix $x \in V_i \cap V_j$, and let $V'_i = V_i \setminus \{x\}, V'_j = V_j \setminus \{x\}.$

$$
\sum_{(\phi,\psi)\in R_x} \Phi_{V_i,\phi} \Phi_{V_j,\psi} = \sum_{\phi\in \mathbb{Z}_2^{V_i'},\psi\in \mathbb{Z}_2^{V_j'}} \Phi_{V_i',\phi} \frac{1}{4} \left[(1+\sigma_i(x))(1-\sigma_j(x)) + (1-\sigma_i(x))(1+\sigma_j(x)) \right] \Phi_{V_j',\psi}
$$

$$
= (1+\sigma_i(x))(1-\sigma_j(x)) + (1-\sigma_i(x))(1+\sigma_j(x)),
$$

where the last equality holds because $\sum_{\phi \in \mathbb{Z}_2^{V_i'}} \Phi_{V_i',\phi}$ and $\sum_{\psi \in \mathbb{Z}_2^{V_j'}} \Phi_{V_i',\psi}$ are both equal to 1.

Finally $(\sigma_i(x) - \sigma_j(x))^*(\sigma_i(x) - \sigma_j(x))$ is cyclically equivalent to

$$
2 - 2\sigma_i(x)\sigma_j(x) = (1 + \sigma_i(x))(1 - \sigma_j(x)) + (1 - \sigma_i(x))(1 + \sigma_j(x)),
$$

so the result follows. \Box

Definition 6.4. If $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS and π is a probability distribution on $[m] \times [m]$, define $A_{inter}(B, \pi)$ to be the weighted algebra $(A(B), \mu_{inter})$, where μ_{inter} is defined from π as in Proposition [6.3.](#page-16-0)

It is not hard to see that $A(B)/\langle \text{supp}(\mu_{inter}) \rangle \cong A(B)/\langle \text{supp}(\mu_{\pi}) \rangle$, so both $\mathcal{A}(B, \pi)$ and $\mathcal{A}_{inter}(B, \pi)$ are weighted algebra models of SynAlg (B, π) .

We can also easily handle transformations of constraint systems which apply a homomorphism to each context. Note that a homomorphism $\sigma : \mathcal{A}(V, C) \to$ $\mathcal{A}(W, D)$ between finite abelian C^{*}-algebras is equivalent to a function $f : D \to C$. Indeed, given a function $f: D \to C$, we can define a homomorphism σ by $\sigma(\Phi_{V,\phi}) =$ $\sum_{W,\psi \in f^{-1}(\phi)} \Phi_{W,\psi}$, and it is not hard to see that all homomorphisms have this form. We extend this notion to BCS algebras in the following way.

Definition 6.5. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ and $B' = (X', \{(W_i, D_i)\}_{i=1}^m)$ be constraint systems. A homomorphism $\sigma : \mathcal{A}(B) \to \mathcal{A}(B')$ is a **classical homomor**phism if

- $(1) \sigma(\mathcal{A}(V_i, C_i)) \subseteq \mathcal{A}(W_i, D_i)$ for all $1 \leq i \leq m$, and
- (2) if $\sigma(\Phi_{V_i,\phi_i}) = \sum_k \Phi_{W_i,\psi_{ik}}, \sigma(\Phi_{V_j,\phi_j}) = \sum_k \Phi_{W_j,\psi_{jl}}, \text{ and } \phi_i|_{V_i \cap V_j} \neq \phi_j|_{V_i \cap V_j}$ then $\psi_{ik}|_{W_i \cap W_j} \neq \psi_{jl}|_{W_i \cap W_j}$ for all k, l.

To explain this definition, note that condition (1) implies that σ restricts to a homomorphism $\mathcal{A}(V_i, C_i) \to \mathcal{A}(W_i, D_i)$, and hence gives a collection of functions $f_i: D_i \to C_i$ for all $1 \leq i \leq m$. Condition (2) states that if $f_i(\phi)|_{V_i \cap V_j} \neq f_j(\psi)|_{V_i \cap V_j}$ for some $\phi \in D_i$, $\psi \in D_j$, then $\phi|_{W_i \cap W_j} \neq \psi|_{W_i \cap W_j}$. Conversely, any collection of functions $f_i: D_i \to C_i$ satisfying this condition can be turned into a classical homomorphism $\sigma : \mathcal{A}(B) \to \mathcal{A}(B')$.

Lemma 6.6. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ and $B' = (Y, \{(W_i, D_i)\}_{i=1}^m)$ be constraint systems, and let π be a probability distribution on $[m] \times [m]$. If $\sigma : A(B) \to A(B')$ is a classical homomorphism, then σ is a 1-homomorphism $\mathcal{A}(B,\pi) \to \mathcal{A}(B',\pi)$.

Proof. Suppose σ arises from a family of functions $f_i : D_i \to C_i$ as above. For any $1 \leq i, j \leq m$, let $R_{ij} = \{(\phi, \psi) \in C_i \times C_j : \phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}\},\$ and let $T_{ij} = \{(\phi, \psi) \in D_i \times D_j : \phi|_{W_i \cap W_j} \neq \psi|_{W_i \cap W_j}$. Then

$$
\sigma \left(\sum_{i,j} \sum_{(\phi,\psi) \in R_{ij}} \pi(i,j) \Phi_{V_i,\phi} \Phi_{V_j,\psi} \right) = \sum_{i,j} \sum_{\phi' \in f_i^{-1}(\phi), \psi' \in f_i^{-1}(\psi)} \pi(i,j) \Phi_{W_i,\phi'} \Phi_{W_j,\psi'}
$$

$$
\leq \sum_{i,j} \sum_{(\phi,\psi) \in T_{ij}} \pi(i,j) \Phi_{W_i,\phi} \Phi_{W_j,\psi}.
$$

 \Box

One situation where we get a classical homomorphism is the following:

Corollary 6.7. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let $B' = (X', \{(W_i, D_i)\}_{i=1}^m)$ be a BCS with $X \subset X'$, $V_i \subseteq W_i$ for all $1 \leq i \leq m$, and $W_i \cap W_j = V_i \cap V_j$ for all $1 \le i, j \le m$. Suppose that for all $i \in [m]$, $\phi \in V_i$ if and only if there exists $\psi \in W_i$ with $\psi|_{V_i} = \phi$. Then for any probability distribution π on $[m] \times [m]$, the homomorphism

$$
\sigma: \mathcal{A}(B) \to \mathcal{A}(B'): \sigma_i(x) \mapsto \sigma_i(x) \text{ for } i \in [m], x \in V_i
$$

defined by the inclusions $V_i \subseteq W_i$ is a 1-homomorphism $\mathcal{A}(B,\pi) \to \mathcal{A}(B',\pi)$, and there is another 1-homomorphism $\sigma' : A(B', \pi) \to A(B, \pi)$. Furthermore, B' has the same connectivity as B.

Proof. The homomorphism σ is the classical homomorphism defined by the functions $D_i \to C_i : \psi \mapsto \psi|_{V_i}.$

For the homomorphism σ' , define $f_i : V_i \to W_i$ by choosing an element $f_i(\phi) \in W_i$ such that $f_i(\phi)|_{V_i} = \phi$ for all $\phi \in V_i$. Since $W_i \cap W_j = V_i \cap V_j$, if $f_i(\phi)|_{W_i \cap W_j} \neq$ $f_j(\psi)|_{W_i \cap W_j}$, then $\phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}$, so this collection of functions defines a classical homomorphism $A(B') \to A(B)$.

In other words, Corollary [6.7](#page-17-0) implies that any tracial state τ on $\mathcal{A}(B')$ (resp. $\mathcal{A}(B)$) with def $(\tau) \leq \epsilon$ pulls back to a tracial state on $\mathcal{A}(B)$ (resp. $\mathcal{A}(B')$) with defect also bounded by ϵ .

Remark 6.8. Let $(\{\mathcal{G}(B_x, \pi_x)\}, S, C)$ be a BCS-MIP^{*} protocol for a language \mathcal{L} with soundness s, where $B_x = (X_x, \{(V_i^x, C_i^x)\}_{i=1}^{m_x})$. Since $|V_i^x|$ is polynomial in $|x|$, and C runs in polynomial time, the Cook-Levin theorem implies that we can find sets W_i^x and constraints D_i^x on W_i^x as in Corollary [6.7](#page-17-0) in which $|W_i^x|$ is polynomial in |x|, and D_i^x is a 3SAT instance with number of clauses polynomial in |x|. By Lemma [6.2,](#page-15-1) we get a BCS-MIP^{*} protocol $(\mathcal{G}(B_x', \pi_x)), S, \widetilde{C})$ for $\mathcal L$ with the same soundness, such that $B'_x = (X'_x, \{(W^x_i, D^x_i)\})$ is a constraint system where all the clauses D_i^x are 3SAT instances, and the connectivity of B'_x is the same as B_x .

7. BCS algebras, subdivision and stability

Suppose we have a BCS where each constraint is made up of subconstraints on subsets of the variables (for instance, a 3SAT instance made up of 3SAT clauses). In this section, we look at what happens when we split up the contexts and constraints so that each subconstraint is in its own contex. In the weighted BCS algebra, splitting up a context changes the commutative subalgebra corresponding to the context to a non-commutative subalgebra. To deal with this, we use a tool from the approximate representation theory of groups, namely the stability of \mathbb{Z}_2^k .

Lemma 7.1 ([\[CVY23\]](#page-42-16)). Let (M, τ) be a tracial von Neumann algebra, and suppose $f : [k] \to \mathcal{M}$ is a function such that $f(i)^2 = 1$ for all $i \in [k]$ and $\Vert [f(i), f(j)] \Vert^2_{\tau} \leq \epsilon$ for all $i, j \in [k]$, where $k \geq 1$ and $\epsilon \geq 0$. Then there is a homomorphism $\psi : \mathbb{Z}_2^k \to$ $\mathcal{U}(\mathcal{M})$ such that $\|\psi(x_i) - f(i)\|_{\tau}^2 \leqslant \mathrm{poly}(k)\epsilon$ for all $i \in [k]$, where the x_i generate \mathbb{Z}_2^k .

Here a tracial von Neumann algebra is a von Neumann algebra $\mathcal M$ equipped with a faithful normal tracial state τ , and $\mathcal{U}(\mathcal{M})$ is the unitary group of M. If τ is a tracial state on a *-algebra A, and $(\rho : A \to B(H), |v\rangle)$ is the GNS representation, then the closure $\mathcal{M} = \rho(\mathcal{A})$ of $\rho(\mathcal{A})$ in the weak operator topology is a von Neumann algebra, and $\tau_0(a) = \langle v | a | v \rangle$ is a faithful normal tracial state on M. A function f satisfying the conditions of Lemma [7.1](#page-18-1) is called an ϵ -homomorphism from \mathbb{Z}_2^k to $U(\mathcal{M})$. The following lemma is useful for the proofs in this section:

Lemma 7.2. Suppose A is a $*$ -algebra, and let $h(a) := a^*a$ denote the hermitian square of $a \in \mathcal{A}$. Then $h(\sum_{i=1}^n a_i) \leq k \sum_i h(a_i)$, where $k = 2^{\lceil \log_2 n \rceil}$.

Proof. Since $h(a+b)+h(a-b)=2h(a)+2h(b)$, we see that $h(a+b)\leq 2h(a)+2h(b)$. Thus $h(\sum_{i=1}^n a_i) \leq 2h(\sum_{i=1}^{\lfloor n/2 \rfloor} a_i) + 2h(\sum_{i=\lfloor n/2 \rfloor+1}^n a_i)$, and repeated applications gives the desired inequality. \Box

We now formally define a subdivision of a BCS.

Definition 7.3. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS. Suppose that for all $1 \le i \le m$ there exists a constant $m_i \geq 1$ and a set of constraints $\{D_{ij}\}_{j=1}^{m_i}$ on variables $\{V_{ij}\}_{j=1}^{m_i}$ respectively, such that

- (1) $V_{ij} \subseteq V_i$ for all $i \in [m]$ and $j \in [m_i]$,
- (2) for every $x, y \in V_i$ and $i \in [m]$, there is a $j \in [m_i]$ such that $x, y \in V_i$, and
- (3) $C_i = \wedge_{j=1}^{m_i} D_{ij}$ for all $i \in [m]$, where \wedge is conjunction.

The BCS $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ is called a **subdivision** of B. When working with subdivisions, we refer to D_{ij} as the **clauses** of constraint C_i , and m_i as the **number** of clauses in constraint i. A subdivision is uniform if $m_i = m_j$ for all i, j.

Given a subdivision of B as in the definition, let $M = \sum_{i=1}^{m} m_i$, and pick a bijection between [M] and the set of pairs (i, j) with $1 \leq i \leq m$ and $1 \leq j \leq m_i$. If π is a probability distribution on $[m] \times [m]$, let π_{sub} be the probability distribution on $[M] \times [M]$ with $\pi_{sub}(ij, k\ell) = \pi(i, k)/m_i m_k$. Note that if π is uniform and the subdivision is uniform, then π_{sub} is uniform. Any subdivision can be turned into a uniform subdivision by repeating pairs (V_{ij}, D_{ij}) to increase m_i . Note that subdivision can increase connectivity.

One of the first things we notice about subdivision is that strategies for $\mathcal{G}(B,\pi)$ can be lifted to strategies for the subdivided game.

Proposition 7.4. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ be a subdivision. Let π be a probability distribution on $[m] \times [m]$, and let π_{sub} be the probability distribution defined from π as above. The homomorphism α : $\mathcal{A}(B') \to \mathcal{A}(B)$ defined by $\sigma_{ij}(x) \mapsto \sigma_i(x)$ is a 1-homomorphism $\mathcal{A}_{inter}(B', \pi_{sub}) \to$ $\mathcal{A}_{inter}(B,\pi)$, and also induces an isomorphism $\text{SynAlg}(B', \pi_{sub}) \cong \text{SynAlg}(B,\pi)$.

Here $\sigma_{ij}(x)$ denotes the copy of x in $\mathcal{A}(W_{ij}, D_{ij}) \subseteq \mathcal{A}(B')$.

Proof. Let $h(a) = a^*a$ denote the hermitian square of a as in Lemma [7.2.](#page-18-2) By definition, $\alpha(\sigma_{ij}(x) - \sigma_{kl}(x)) = \sigma_i(x) - \sigma_k(x)$. Hence

$$
\alpha \Big(\sum_{\substack{ij \neq kl \\ x \in V_{ij} \cap V_{kl}}} \pi_{sub}(ij, kl) h(\sigma_{ij}(x) - \sigma_{kl}(x)) \Big) = \sum_{\substack{ij \neq kl \\ x \in V_{ij} \cap V_{kl}}} \frac{\pi(i, k)}{m_i m_k} h(\sigma_i(x) - \sigma_k(x))
$$

$$
\leq \sum_{\substack{ij \neq k \\ x \in V_{i} \cap V_k}} \pi(i, k) h(\sigma_i(x) - \sigma_k(x)),
$$

since each variable $x \in V_i$ appears in at most m_i subclauses V_{ij} . Hence α : $\mathcal{A}_{inter}(B', \pi_{sub}) \rightarrow \mathcal{A}_{inter}(B, \pi)$ is a 1-homomorphism.

To show that the synchronous algebras are isomorphic, observe that since every pair of elements $x, y \in V_i$ belongs to some V_{ij} , there is an isomorphism

$$
\text{SynAlg}(B', \pi_{sub}) \cong \ast_{i=1}^m \mathbb{Z}_2^{V_i} / \langle R \rangle,
$$

where R is the set of relations $\sigma_i(\Phi_{V_{ii},\phi})\sigma_i(\Phi_{V_{k\ell},\psi})=0$ for all ϕ and ψ which do not agree on $V_{ij} \cap V_{k\ell}$, and $\sigma_i(\Phi_{V_{ij},\phi}) = 0$ for all $\phi \notin D_{ij}$. From these latter relations, it is possible to recover the relations $\Phi_{V_i, \phi} = 0$ for $\phi \notin C_i$, and then to recover all the relations of $\text{SynAlg}(B, \pi)$.

Proposition [7.4](#page-19-0) implies that $\mathcal{G}(B,\pi)$ has a perfect quantum (resp. commuting operator) strategy if and only if $\mathcal{G}(B', \pi_{sub})$ has a perfect quantum (resp. commuting operator) strategy. The main result of this section is that near perfect strategies for $\mathcal{G}(B', \pi_{sub})$ can be pulled back to near perfect strategies for $\mathcal{G}(B, \pi)$. For the theorem, we say that π is **maximized on the diagonal** if $\pi(i, i) \geq \pi(i, j)$ and $\pi(i, i) \geq \pi(j, i)$ for all $i, j \in [m]$.

Theorem 7.5. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ be a subdivision of B with m_i clauses in constraint C_i . Let π be a probability distribution on $[m] \times [m]$ that is maximized on the diagonal, and let π_{sub} be the probability distribution defined from π as above. If there is a trace τ on $\mathcal{A}(B', \pi_{sub})$, then there is a trace $\tilde{\tau}$ on $\mathcal{A}(B,\pi)$ with def $(\tilde{\tau}) \leq \text{poly}(m, 2^C, M, K) \det(\tau)$, where $C = \max_{i,j} |V_{ij}|, K = \max_i |V_i|, and M = \max_i m_i.$

For the proof of the theorem we consider several other versions of the weighted BCS algebra, where $\mathcal{A}(V_i, C_i)$ is replaced by $\mathbb{C} \mathbb{Z}_2^{*V_i}$, and the defining relations of $\mathcal{A}(V_i, C_i)$ are moved into the weight function.

Definition 7.6. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS with a probability distribution π on $[m] \times [m]$, and let $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ be a subdivision, with m_i clauses in constraint C_i and probability distribution π_{sub} induced by π . Let $\sigma_i : \mathbb{C} \mathbb{Z}_2^{*V_i} \to$ $\ast_{i=1}^{m} \mathbb{C} \mathbb{Z}_{2}^{\ast V_{i}}$ denote the inclusion of the ith factor. Let $\mathcal{A}_{free}(B) := \ast_{i=1}^{m} \mathbb{C} \mathbb{Z}_{2}^{\ast V_{i}}$, and define weight functions μ_{inter} , μ_{sat} , μ_{clause} , and μ_{comm} on $\mathcal{A}_{free}(B)$ by

 $\mu_{inter}(\sigma_i(x) - \sigma_j(x)) = \pi(i, j)$ for all $i \neq j \in [m]$ and $x \in V_i \cap V_j$, $\mu_{sat}(\Phi_{V_i,\phi}) = \pi(i,i)$ for all $i \in [m]$ and $\phi \in \mathbb{Z}_2^{V_i} \backslash C_i$, $\mu_{clause}(\Phi_{V_{ij}, \phi}) = \pi(i,i)/m_i^2$ for all $(i,j) \in [m] \times [m_i]$ and $\phi \in \mathbb{Z}_2^{V_{ij}}$ $\big\{2^{i_j} \backslash D_{ij}, \text{ and}$ $\mu_{comm}([\sigma_i(x), \sigma_i(y)]) = \pi(i, i)$ for all $i \in [m]$ and $x, y \in V_i$,

and $\mu_{inter}(r) = 0$, $\mu_{sat}(r) = 0$, $\mu_{clause}(r) = 0$, and $\mu_{comm}(r) = 0$ for any elements r other than those listed. Let $\mathcal{A}_{free}(B, B', \pi)$ be the weighted algebra $(\mathcal{A}_{free}(B), \mu_{all})$, where $\mu_{all} := \mu_{inter} + \mu_{clause} + \mu_{comm}$.

Note that μ_{inter} is the same as the weight function of the algebra $\mathcal{A}_{inter}(B, \pi)$ defined in Definition [6.4,](#page-16-1) except that it's defined on $\mathcal{A}_{free}(B)$ rather than $\mathcal{A}(B)$. The weight function μ_{sat} comes from the defining relations for $\mathcal{A}(B)$, while μ_{clause}

comes from the defining relations for $\mathcal{A}(B')$, so $\mathcal{A}_{free}(B, B', \pi)$ is a mix of relations from $\mathcal{A}_{inter}(B,\pi)$ and $\mathcal{A}_{inter}(B',\pi)$. As mentioned previously, the context V_i has an order inherited from X , and this is used for the order of the product when talking about $\Phi_{V_i, \phi}$ and $\Phi_{V_i, \phi}$ in $\mathcal{A}_{free}(B)$. In particular, the order on V_{ij} is compatible with the order on V_i .

The weight functions μ_{inter} , μ_{sat} and μ_{clause} can also be defined on $*_{i=1}^{m} \mathbb{CZ}_{2}^{V_{i}}$ using the same formula as in Definition [7.6,](#page-20-0) and we use the same notation for both versions. The following lemma shows that we can relax $\mathcal{A}_{inter}(B,\pi)$ to $(*_{i=1}^{m}\mathbb{C}\mathbb{Z}_{2}^{V_{i}}, \mu_{inter}$ μ_{clause} , as long as π is maximized on the diagonal.

Lemma 7.7. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let π be a probability distribution on $[m] \times [m]$ which is maximized on the diagonal. Suppose μ_{inter} , μ_{sat} and μ_{clause} are the weight functions defined above with respect to π . Then there is an $O(t)$ -homomorphism $\mathcal{A}_{inter}(B,\pi) \to (*_{i=1}^{m} \mathbb{C} \mathbb{Z}_{2}^{V_{i}}, \mu_{inter} + \mu_{sat})$, where t is the connectivity of B. Furthermore, if $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ is a subdivision of B, then there is an M²-homomorphism $(*_{i=1}^{m} \mathbb{C} \mathbb{Z}_2^{V_i}, \mu_{inter} + \mu_{sat}) \rightarrow (*_{i=1}^{m} \mathbb{C} \mathbb{Z}_2^{V_i}, \mu_{inter} + \mu_{clause}),$ where $M = \max_i m_i$ is the maximum number of clauses m_i in constraint i.

Proof. Since C_i is non-empty by convention, we can choose $\psi_i \in C_i$ for every $1 \leq$ $i \leq m$. Define the homomorphism $\alpha : \mathcal{A}_{inter}(B, \pi) \to (*_{i=1}^{m} \mathbb{C} \mathbb{Z}_{2}^{V_{i}}, \mu_{inter} + \mu_{sat})$ by

$$
\alpha(\sigma_i(x)) = \sum_{\varphi \in C_i} \Phi_{V_i, \varphi} \sigma_i(x) + \sum_{\varphi \in \mathbb{Z}_2^{V_i} \setminus C_i} \Phi_{V_i, \varphi} \psi_i(x).
$$

Let $\Phi_i = \sum_{\varphi \in C_i} \Phi_{V_i, \varphi}$, and let $h(a) = a^*a$ denote the hermitian square of a as in Lemma [7.2.](#page-18-2) Then

$$
\alpha [h(\sigma_i(x) - \sigma_j(x))] = h(\Phi_i \sigma_i(x) + (1 - \Phi_i)\psi_i(x) - \Phi_j \sigma_j(x) - (1 - \Phi_j)\psi_j(x))
$$

\n
$$
\leq 4h[\Phi_i \sigma_i(x) + (1 - \Phi_i)\psi_i(x) - \sigma_i(x)]
$$

\n
$$
+ 4h[\Phi_j \sigma_j(x) + (1 - \Phi_j)\psi_j(x) - \sigma_j(x)] + 4h[\sigma_i(x) - \sigma_j(x)].
$$

Observe that $\sigma_i(x) = \sum_{\varphi \in \mathbb{Z}_2^{V_i}} \Phi_{V_i, \varphi} \varphi(x)$, so

$$
h(\Phi_i \sigma_i(x) + (1 - \Phi_i)\psi_i(x) - \sigma_i(x)) = \sum_{\varphi \in \mathbb{Z}_2^{V_i} \backslash C_i} \Phi_{V_i, \varphi}(\psi_i(x) - \varphi(x))^2 \leq 4 \sum_{\varphi \in \mathbb{Z}_2^{V_i} \backslash C_i} \Phi_{V_i, \varphi}.
$$

Thus

$$
\alpha \Big(\sum_{\substack{1 \leq i \neq j \leq m \\ x \in V_i \cap V_j}} \pi(i,j) h(\sigma_i(x) - \sigma_j(x)) \Big) \leq \sum_{\substack{1 \leq i \neq j \leq m \\ x \in V_i \cap V_j}} \pi(i,j) \Big(16 \sum_{\varphi \in \mathbb{Z}_2^{V_i} \backslash C_i} \Phi_{V_i, \varphi} + 16 \sum_{\varphi \in \mathbb{Z}_2^{V_j} \backslash C_j} \Phi_{V_j, \varphi} + 4h(\sigma_i(x) - \sigma_j(x)) \Big)
$$

$$
\leq \sum_{a \in \mathcal{F}_{i-1}^m \subset \mathbb{Z}_2^{V_i}} 4\mu_{inter}(a) a^* a + \sum_{a \in \mathcal{F}_{i-1}^m \subset \mathbb{Z}_2^{V_i}} 32t\mu_{sat}(a) a^* a
$$

$$
\leq O(t) \sum_{a \in \mathcal{F}_{i-1}^m \subset \mathbb{Z}_2^{V_i}} (\mu_{inter}(a) + \mu_{sat}(a)) a^* a,
$$

since π is maximized on the diagonal.

Next, suppose B' is a subdivision of B. If $\phi \in \mathbb{Z}_2^{V_i} \setminus C_i$, then we can choose $j_\phi \in [m_i]$ such that $\phi|_{V_{ij_\phi}} \notin D_{ij_\phi}$. Since \sum ϕ : $\phi|_{V_{ij}} = \phi'$ $\Phi_{V_i, \phi} = \Phi_{V_{ij}, \phi'},$

$$
\sum_{\phi \notin C_i} \Phi_{V_i, \phi} = \sum_{1 \leqslant j \leqslant m_i} \sum_{\phi : j_\phi = j} \Phi_{V_i, \phi} \leqslant \sum_{1 \leqslant j \leqslant m_i} \sum_{\phi : \phi|_{V_{ij}} \notin D_{ij}} \Phi_{V_i, \phi} = \sum_{1 \leqslant j \leqslant m_i} \sum_{\phi' \notin D_{ij}} \Phi_{V_{ij}, \phi'}.
$$

Hence

$$
\sum_r \mu_{sat}(r) r^*r \leqslant M^2 \sum_r \mu_{clause}(r) r^*r,
$$

where the M^2 comes from the fact that we divide by m_i^2 in the definition of μ_{clause} . Thus the identity map $(*_{i=1}^{m} \mathbb{C} \mathbb{Z}_2^{V_i}, \mu_{inter} + \mu_{sat}) \rightarrow (*_{i=1}^{m} \mathbb{C} \mathbb{Z}_2^{V_i}, \mu_{inter} + \mu_{clause})$ is an M^2 -homomorphism. \Box -homomorphism.

The following proposition shows how to construct tracial states on $\mathcal{A}_{inter}(B, \pi)$ from tracial states on $\mathcal{A}_{free}(B, B', \pi)$.

Proposition 7.8. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let π be a probability distribution on $[m] \times [m]$ which is maximized on the diagonal. Let B' $(X, \{V_{ij}, D_{ij}\}_{i,j})$ be a subdivision of B with m_i clauses in constraint C_i . If τ is a trace on $\mathcal{A}_{free}(B, B', \pi)$, then there is a trace $\widetilde{\tau}$ on $\mathcal{A}_{inter}(B, \pi)$ such that def $(\widetilde{\tau}) \leq$ $\operatorname{poly}(m, 2^C, M, K) \operatorname{def}(\tau), \text{ where } C = \max_{ij} |V_{ij}|, K = \max_i |V_i|, \text{ and } M = \max_i m_i.$ Furthermore, if τ is finite-dimensional then so is $\tilde{\tau}$.

Proof. Since π is maximized on the diagonal, if $\pi(i, i) = 0$ then $\pi(i, j) = \pi(j, i) = 0$ for all $j \in [m]$, and the variables in V_i do not appear in supp (μ_{inter}) . Thus we may assume without loss of generality that $\pi(i, i) > 0$ for all $i \in [m]$. Let τ be a trace on $\mathcal{A}_{free}(B, B', \pi)$. By the GNS construction there is a *-representation ρ of $\mathcal{A}_{free}(B, B', \pi)$ acting on a Hilbert space \mathcal{H}_0 with a unit cyclic vector ψ such that $\tau(a) = \langle \psi | \rho(a) | \psi \rangle$ for all $a \in \mathcal{A}_{free}(B)$. Let $\mathcal{M}_0 = \overline{\rho(\mathcal{A}_{free}(B))}$ be the weak operator closure of the image of ρ , and let τ_0 be the faithful normal tracial state on \mathcal{M}_0 corresponding to $|\psi\rangle$ (so $\tau_0 \circ \rho = \tau$).

For all $i \in [m]$ the restriction of ρ to $\mathbb{Z}_2^{*V_i}$ is a def $(\tau; \mu_{comm})/\pi(i, i)$ -homomorphism from $\mathbb{Z}_2^{V_i}$ into (\mathcal{M}_0, τ_0) , so by Lemma [7.1](#page-18-1) there is a representation $\rho_i : \mathbb{Z}_2^{V_i} \to \mathcal{U}(\mathcal{M}_0)$ such that

(7.1)
$$
\|\rho_i(x_j) - \rho(x_j)\|_{\tau_0}^2 \le \frac{\text{poly}(K)}{\pi(i,i)} \det(\tau; \mu_{comm})
$$

for all generators $x_j \in \mathbb{Z}_2^{V_i}$. Suppose $x \in V_i \cap V_j$, and let $\widetilde{\rho}: *_{i=1}^m \mathbb{C} \mathbb{Z}_2^{V_i} \to \mathcal{M}_0$ be the homomorphism defined by $\tilde{\rho}(x) = \rho_i(x)$ for $x \in \mathbb{Z}_2^{V_i}$. Then

$$
\begin{aligned} \|\widetilde{\rho}(\sigma_i(x) - \sigma_j(x))\|_{\tau_0}^2 &\le 4 \|\widetilde{\rho}(\sigma_i(x)) - \rho(\sigma_i(x))\|_{\tau_0}^2 + 4 \|\widetilde{\rho}(\sigma_j(x)) - \rho(\sigma_j(x))\|_{\tau_0}^2 \\ &+ 4 \|\rho(\sigma_i(x) - \sigma_j(x))\|_{\tau_0}^2 \\ &\le \frac{\text{poly}(K)}{\pi(i,i)} \det(\tau; \mu_{comm}) + 4 \|\sigma_i(x) - \sigma_j(x)\|_{\tau}^2. \end{aligned}
$$

Since π is maximalized on the diagonal, and $|\{(i, j, x) : i \neq j \in [n], x \in V_i \cap V_j\}| \leq m t$ where t is the connectivity of B , we conclude that

$$
\begin{split} \operatorname{def}(\tau_{0} \circ \widetilde{\rho}; \mu_{inter}) &\leq \sum_{i \neq j} \sum_{x \in V_{i} \cap V_{j}} \pi(i, j) \left(\frac{\operatorname{poly}(K)}{\pi(i, i)} \operatorname{def}(\tau; \mu_{comm}) + 4 \|\sigma_{i}(x) - \sigma_{j}(x)\|_{\tau}^{2} \right) \\ &\leq O(mt \operatorname{poly}(K) \operatorname{def}(\tau; \mu_{comm}) + \operatorname{def}(\tau; \mu_{inter})). \end{split}
$$

For any $S \subseteq V_i$, let $x_S := \prod_{x \in S} x \in \mathbb{Z}_2^{*V_i}$, where the order of the product is inherited from the order on X . By Equation (7.1) ,

$$
\|\widetilde{\rho}(x_S) - \rho(x_S)\|_{\tau_0}^2 \leq \frac{\text{poly}(K)}{\pi(i,i)} \det(\tau; \mu_{comm}),
$$

where the degree of K has increased by one. Since $\Phi_{V_{ij},\phi} = \frac{1}{2^{|V_i|}}$ $\frac{1}{2^{|V_{ij}|}}\sum_{S\subseteq V_{ij}}\phi(x_S)x_S,$ we get that

$$
\|\widetilde{\rho}(\Phi_{V_{ij},\phi})-\rho(\Phi_{V_{ij},\phi})\|_{\tau_0}^2 \leq \frac{1}{2^{|V_{ij}|}}\sum_{S\subseteq V_{ij}}\|\widetilde{\rho}(x_S)-\rho(x_S)\|_{\tau_0}^2 \leq \frac{\text{poly}(K)}{\pi(i,i)}\det(\tau;\mu_{comm}).
$$

If $1 \leq i \leq m$, $1 \leq j \leq m_i$, and $\phi \notin D_{ij}$, then

$$
\|\widetilde{\rho}(\Phi_{V_{ij},\phi})\|_{\tau_0}^2 \leq 2\|\widetilde{\rho}(\Phi_{V_{ij},\phi})-\rho(\Phi_{V_{ij},\phi})\|_{\tau_0}^2 + 2\|\rho(\Phi_{V_{ij},\phi})\|_{\tau_0}^2,
$$

and hence

$$
\begin{split} \text{def}(\tau_{0} \circ \widetilde{\rho}; \mu_{clause}) &= \sum_{i,j} \frac{\pi(i,i)}{m_{i}^{2}} \sum_{\phi \notin D_{ij}} \|\widetilde{\rho}(\Phi_{V_{ij},\phi})\|_{\tau_{0}}^{2} \\ &\leq \sum_{i,j} \sum_{\phi \notin D_{ij}} \frac{\pi(i,i)}{m_{i}^{2}} \left(\frac{\text{poly}(K)}{\pi(i,i)} \det(\tau; \mu_{comm}) + 2 \|\Phi_{V_{ij},\phi}\|_{\tau}^{2}\right) \\ &\leq \sum_{i,j} 2^{C} \frac{\text{poly}(K)}{m_{i}^{2}} \det(\tau; \mu_{comm}) + 2 \det(\tau; \mu_{clause}) \\ &\leq m^{2} 2^{C} \text{ poly}(K) \det(\tau; \mu_{comm}) + 2 \det(\tau; \mu_{clause}). \end{split}
$$

We conclude that $\tilde{\tau} = \tau_0 \circ \tilde{\rho}$ is a tracial state on $*_{i=1}^m \mathbb{C} \mathbb{Z}_2^{V_i}$ with $\text{def}(\tilde{\tau}; \mu_{inter} + \mu_{clause})$ bounded by

$$
O(\text{def}(\tau; \mu_{inter}) + \text{def}(\tau; \mu_{clause}) + (m^2 2^C + mt) \text{poly}(K) \text{def}(\tau; \mu_{comm})).
$$

Since $t \leq O(mK)$, we conclude that

$$
\text{def}(\widetilde{\tau}; \mu_{inter} + \mu_{clause}) \leq \text{poly}(m, 2^C, K) \text{ def}(\tau; \mu_{inter} + \mu_{clause} + \mu_{comm}).
$$

By Lemma [7.7,](#page-21-0) there is a $O(tM^2)$ -homomorphism $\mathcal{A}_{inter}(B, \pi) \to (*_{i=1}^m \mathbb{C} \mathbb{Z}_2^{V_i}, \mu_{inter} +$ μ_{clause} , and pulling $\tilde{\tau}$ back by this homomorphism gives the proposition.

Finally, we can pull back tracial states from the subdivision algebra $\mathcal{A}_{inter}(B', \pi_{sub})$ to traces on $\mathcal{A}_{free}(B, B', \pi)$.

Proposition 7.9. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, and let $B' = (X, \{V_{ij}, D_{ij}\}_{i,j})$ be a subdivision of B. Let π be a probability distribution on $[m] \times [m]$, and let π_{sub} be the probability distribution defined from π as above. Then there is a poly $(M, 2^C)$ homomorphism $\mathcal{A}_{free}(B, B', \pi) \to \mathcal{A}_{inter}(B', \pi_{sub})$, where $C = \max_{ij} |V_{ij}|$ and $M =$ $\max_i m_i$.

Proof. For each $1 \leq i \leq m$ and $x \in V_i$, choose an index $1 \leq r_{ix} \leq m_i$ such that $x \in V_{ir_{ix}}$. Also, for each $x, y \in V_i$, choose an index i_{xy} such that $x, y \in V_{i_{xy}}$. Define $\alpha : *_{i=1}^m \mathbb{Z}_2^{*V_i} \to \mathcal{A}(B')$ by $\alpha(\sigma_i(x)) = \sigma_{ir_{ix}}(x)$. It follows immediately from the definitions that α is a $O(M^2)$ -homomorphism $(\mathcal{A}_{free}(B), \mu_{inter}) \to \mathcal{A}_{inter}(B', \pi_{sub})$. Moving on to μ_{comm} , observe that if $h(a) = a^*a$ as in Lemma [7.2](#page-18-2) then

$$
\alpha(h([\sigma_i(x), \sigma_i(y)])) = h\left(\sigma_{ir_{ix}}(x)\sigma_{ir_{iy}}(y) - \sigma_{ir_{iy}}(y)\sigma_{ir_{ix}}(x)\right)
$$

\n
$$
\leq 4h((\sigma_{ir_{ix}}(x) - \sigma_{i_{xy}}(x))\sigma_{ir_{iy}}(y)) + 4h(\sigma_{i_{xy}}(x)(\sigma_{i_{xy}}(y) - \sigma_{ir_{iy}}(y))) +
$$

\n
$$
+ 4h((\sigma_{ir_{iy}}(y) - \sigma_{i_{xy}}(y))\sigma_{ir_{ix}}(x)) + 4h(\sigma_{i_{xy}}(y)(\sigma_{ir_{ix}}(x) - \sigma_{i_{xy}}(x)))
$$

\n
$$
\leq 8h(\sigma_{ir_{ix}}(x) - \sigma_{i_{xy}}(x)) + 8h(\sigma_{ir_{iy}}(y) - \sigma_{i_{xy}}(y)),
$$

where we use the fact that $[\sigma_{ixy}(x), \sigma_{ixy}(y)] = 0$, and that $U^* a^* a U$ is cyclically equivalent to a^*a if $UU^* = 1$. For any given $x \in V_i$ and $1 \leq j \leq m_i$, the number of elements $y \in V_i$ with $i_{xy} = j$ is bounded by $|V_{ij}|$. Hence

$$
\sum_{i} \sum_{x,y \in V_i} \pi(i,i) \alpha(h([\sigma_i(x), \sigma_i(y)])) \lesssim O(CM^2) \sum_{i,j,j'} \sum_{x \in V_{ij} \cap V_{ij'}} \frac{\pi(i,i)}{m_i^2} h(\sigma_{ij}(x) - \sigma_{ij'}(x)),
$$

where $\sigma_{ij}: \mathbb{CZ}_2^{V_{ij}} \to \mathcal{A}(B')$ is the inclusion of the *ij*th factor. We conclude that there is an $O(CM^2)$ -homomorphism $(\mathcal{A}_{free}(B), \mu_{comm}) \to \mathcal{A}_{inter}(B', \pi_{sub})$.

Finally, for μ_{clause} , if $i \in [m]$, $j \in [m_i]$, and $\phi \notin D_{ij}$ then $\sigma_{ij}(\Phi_{V_{ij},\phi}) = 0$, so

$$
\alpha(\Phi_{V_{ij},\phi}) = \alpha(\Phi_{V_{ij},\phi}) - \sigma_{ij}(\Phi_{V_{ij},\phi})
$$

=
$$
\frac{1}{2^{|V_{ij}|}} \sum_{S \subseteq V_{ij}} \prod_{x \in S} \phi(x) \sigma_{ir_{ix}}(x) - \frac{1}{2^{|V_{ij}|}} \sum_{S \subseteq V_{ij}} \prod_{x \in S} \phi(x) \sigma_{ij}(x)
$$

=
$$
\frac{1}{2^{|V_{ij}|}} \sum_{S \subseteq V_{ij}} \sum_{x \in S} u_{x,S} \phi(x) (\sigma_{ir_{ix}}(x) - \sigma_{ij}(x)) v_{x,S},
$$

where $u_{x,S}$ is the product of $\phi(y)\sigma_{ij}(y)$ for $y \in S$ appearing before x in the order on V_i , and $v_{x,S}$ is the product of $\phi(y)\sigma_{ir_{iy}}(y)$ for $y \in S$ appearing after x in the order on V_i . Since there are less than $|V_{ij}| \cdot 2^{|V_{ij}|}$ terms in this sum, and $\phi(x)u_{x,S}$ and $v_{x,S}$ are unitary,

$$
h(\alpha(\Phi_{V_{ij},\phi})) \lesssim \frac{2|V_{ij}|}{2^{|V_{ij}|}} \sum_{S \subseteq V_{ij}} \sum_{x \in S} h(\sigma_{ir_{ix}}(x) - \sigma_{ij}(x))
$$

=
$$
\frac{|V_{ij}|}{2^{|V_{ij}|-1}} \sum_{x \in V_{ij}} \sum_{x \in S \subseteq V_{ij}} h(\sigma_{ir_{ix}}(x) - \sigma_{ij}(x))
$$

$$
= |V_{ij}| \sum_{x \in V_{ij}} h(\sigma_{ir_{ix}}(x) - \sigma_{ij}(x)).
$$

Hence

$$
\sum_{i \in [m], j \in [m_i]} \frac{\pi(i, i)}{m_i^2} \sum_{\phi \notin D_{ij}} \alpha(h(\Phi_{V_{ij}, \phi})) \lesssim \sum_{i, j} \frac{\pi(i, i)}{m_i^2} \sum_{\phi \notin D_{ij}} C \sum_{x \in V_{ij}} h(\sigma_{ir_{ix}(x)} - \sigma_{ij}(x))
$$

$$
\leq C \cdot 2^C \sum_{i, j} \frac{\pi(i, i)}{m_i^2} \sum_{x \in V_{ij}} h(\sigma_{ir_{ix}} - \sigma_{ij}(x)).
$$

Since every term in the latter sum occurs in the sum $\sum_r \mu'(r) r^* r$ for the weight function μ' of $\mathcal{A}_{inter}(B', \pi_{sub})$, α is a $C \cdot 2^C$ -homomorphism $(\mathcal{A}_{free}(B), \mu_{clause}) \rightarrow$ $\mathcal{A}_{inter}(B', \pi_{sub})$. We conclude that α is an $O(M^2 + CM^2 + C2^C)$ -homomorphism $\mathcal{A}_{free}(B,\pi) \to \mathcal{A}_{inter}(B',\pi_{sub}),$ and $O(M^2 + CM^2 + C2^C) \leqslant \text{poly}(M, 2^C).$

proof of Theorem [7.5.](#page-20-1) Applying Proposition [7.9](#page-23-0) and Proposition [7.8](#page-22-1) yields the re $sult.$

8. Parallel repetition

Let $\mathcal{G} = (I, \{O_i\}_{i \in I}, \pi, V)$ be a nonlocal game. The *n*-fold parallel repetition of $\mathcal G$ is the game

$$
\mathcal{G}^{\otimes n} = (I^n, \{O_{\underline{i}}\}_{\underline{i} \in I^n}, \pi^{\otimes n}, V^{\otimes n}),
$$

where

- (1) I^n is the *n*-fold product of I ,
- (2) if $\underline{i} \in I^n$, then $O_{\underline{i}} := O_{i_1} \times O_{i_2} \times \cdots \times O_{i_n}$,
- (3) if $\underline{i}, \underline{j} \in I^n$, then $\pi^{\otimes n}(\underline{i}, \underline{j}) = \prod_{k=1}^n \pi(i_k, j_k)$, and
- (4) if $\underline{i}, \underline{j} \in I^n$, $\underline{a} \in O_{\underline{i}}, \underline{b} \in O_{\underline{j}}$, then $V^{\otimes n}(\underline{a}, \underline{b} | \underline{i}, \underline{j}) = \prod_{k=1}^n V(a_k, b_k | i_k, j_k)$.

In other words, the players each receive a vector of questions $i = (i_1, \ldots, i_n)$ and $j = (j_1, \ldots, j_n)$ from G, and must reply with a vector of answers (a_1, \ldots, a_n) and (b_1, \ldots, b_n) to each question. Each pair of questions (i_k, j_k) , $1 \leq k \leq n$ is sampled independently from π , and the players win if and only if (a_k, b_k) is a winning answer to questions (i_k, j_k) for all $1 \leq k \leq n$. If G has questions of length q and answers of length a, then $\mathcal{G}^{\otimes n}$ has questions of length nq and answers of length na.

If p is a correlation for \mathcal{G} , let $p^{\otimes n}$ be the correlation for $\mathcal{G}^{\otimes n}$ defined by

$$
p^{\otimes n}(\underline{a}, \underline{b}|\underline{i}, \underline{j}) = \prod_{k=1}^{n} p(a_k, b_k|i_k, j_k).
$$

It is easy to see that $p^{\otimes n}$ is a quantum (resp. commuting operator) correlation if and only if p is a quantum (resp. commuting operator) correlation, and that $\omega(\mathcal{G}^{\otimes n};p^{\otimes n}) = \omega(\mathcal{G},p)^n$. Hence if $\omega_q(\mathcal{G}) = 1$ (resp. $\omega_{qc}(\mathcal{G}) = 1$) then $\omega_q(\mathcal{G}^{\otimes n}) = 1$ (resp. $\omega_{qc}(\mathcal{G}^{\otimes n}) = 1$) as well. If $\omega_q(\mathcal{G}) < 1$, then $\omega_q(\mathcal{G}^{\otimes n}) \geq \omega_q(\mathcal{G})^n$ (and the same for the commuting operator value), but this inequality is not always tight. However,

Yuen's parallel repetition theorem states that the game value goes down at least polynomially in n:

Theorem 8.1 ([\[Yue16\]](#page-44-0)). For any nonlocal game \mathcal{G} , if $\delta = 1 - \omega_q(\mathcal{G}) > 0$, then $\omega_q(\mathcal{G}^{\otimes n}) \leqslant b/\operatorname{poly}(\delta,n)$, where b is the length of the answers of \mathcal{G} .

Suppose $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS and that π is a probability distribution on $[m] \times [m]$. For any $n \ge 1$, let $X^{(n)} := X \times [n]$, and $V_i^{(k)} = V_i \times \{k\} \subseteq X^{(n)}$. We can think of $X^{(n)}$ as the disjoint union of n copies of X, and $V_i^{(k)}$ $\zeta_i^{(\kappa)}$ as the copy of V_i from the k^{th} copy of X. Since $V_i^{(k)}$ $\mathbb{Z}_i^{(k)}$ is a copy of V_i , we can identify $\mathbb{Z}_2^{V_i^{(k)}}$ with $\mathbb{Z}_2^{V_i}$ in the natural way. If $\underline{i} \in [m]^n$, let $V_{\underline{i}} = \cup_{j=1}^k V_{i_j}^{(k)}$ $C_{i_j}^{(k)}$ and $C_{\underline{i}} = C_{i_1} \times \cdots \times C_{i_k} \subseteq \mathbb{Z}_2^{V_{\underline{i}}}$ $\mathbb{Z}_2^{V_{i_1}^{(1)}} \times \cdots \times \mathbb{Z}_2^{V_{i_k}^{(k)}}$. Let $B^{(n)} := (X^{(n)}, \{(V_{\underline{i}}, C_{\underline{i}})_{\underline{i} \in [m]^n}\})$. Given a distribution π on $[m] \times [m]$, consider the game $\mathcal{G}(B^{(n)}, \pi^{\otimes n})$, where $\pi^{\otimes n}$ is the product distribution as above. In this game, the players are given questions \underline{i} and j from $[m]^n$ respectively, and must reply with elements $\underline{\phi} \in C_i$ and $\underline{\psi} \in C_j$ respectively. They win if and only if $\underline{\phi}$ and $\underline{\psi}$ agree on $V_{\underline{i}} \cap V_{\underline{j}} = \bigcup_{k=1}^n V_{i_k}^{(k)}$ $V^{(k)}_{i_k}\cap V^{(k)}_{j_k}$ $j_k^{(k)}$. But this happens if and only if ϕ_k and ψ_k agree on $V_{i_k} \cap V_{j_k}$. Thus $\mathcal{G}(B^{(n)}, \pi^{\otimes n})$ is the parallel repetition $\mathcal{G}(B, \pi)^{\otimes n}$. We record this in the following lemma:

Lemma 8.2. If G is a BCS game, then so is the parallel repetition $\mathcal{G}^{\otimes n}$.

To illustrate the purpose of parallel repetition, suppose that $(\mathcal{G}_x), S, V$ is a $\text{MIP}^*(2,1,1,s)$ -protocol for a language \mathcal{L} , where $\mathcal{G}_x = (I_x, \{O_{xi}\}, \pi_x, V_x)$ and has answer length a_x . If n_x is a polynomial in $|x|$, then $\pi_x^{\otimes n_x}$ can be sampled in polynomial time by running S independently n times, and $V_x^{\otimes n_x}$ can also be computed in polynomial time by running V repeatedly. If $S^{\otimes n_x}$ and $V^{\otimes n_x}$ are these Turing machines for sampling $\pi_x^{\otimes n_x}$ and computing $V_x^{\otimes n_x}$ respectively, then $(\{\mathcal{G}_x^{\otimes n_x}\}, \mathcal{S}^{\otimes n_x}, V^{\otimes n_x})$ is a MIP^{*} $(2, 1, 1, s')$ -protocol for \mathcal{L} , where $s' = a_x / \text{poly}(1 - s) \cdot \text{poly}(n_x)$. Since a_x is polynomial in |x|, if $1 - s = 1/\text{poly}(|x|)$, then we can choose n_x such that s' is any constant < 1 . By Lemma [8.2](#page-26-0) the same can be done for BCS-MIP^{*}.

9. Perfect zero knowledge

An MIP protocol is perfect zero knowledge if the verifier gains no new information from interacting with the provers. If the players' behaviour in a game $\mathcal{G} = (I, \{O_i\}_{i \in I}, \pi, V)$ is given by the correlation p, then what the verifier (or any outside observer) sees is the distribution $\{\pi(i, j)p(a, b|i, j)\}\$ over tuples $(a, b|i, j)$. Consequently a MIP^{*}-protocol $(\{\mathcal{G}_x\}, S, V)$ is said to be perfect zero-knowledge against an honest verifier if the players can use correlations p_x for \mathcal{G}_x such that the distribution $\{\pi(i, j)p(a, b|i, j)\}\)$ can be sampled in polynomial time in |x|. However, a dishonest verifier seeking to get more information from the players might sample the questions from a different distribution π' from π . To be perfect zero-knowledge against a dishonest verifier, it must be possible to efficiently sample $\{\pi'(i,j)p_x(a,b|i,j)\}\)$ for

any efficiently sampleable distribution π' , and this is equivalent to being able to efficiently sample from $\{p_x(a, b|i, j)\}_{(a, b)\in O_i \times O_j}$ for any i, j. This leads to the definition (following [\[CS19,](#page-42-13) Definition 6.3]):

Definition 9.1. Let $\mathcal{P} = (\{\mathcal{G}_x\}, \mathcal{S}, V)$ be a two-prover one-round MIP^{*} protocol for a language $\mathcal L$ with completeness c and soundness s, where $\mathcal G_x = (I_x, \{O_{xi}\}, \pi_x, V_x)$. The protocol P is **perfect zero knowledge** if for every string x, there is a correlation p_x for \mathcal{G}_x such that

- (1) for all $i, j \in I_x$, the distribution $\{p_x(a, b|i, j)\}\)$ can be sampled in polynomial time in $|x|$, and
- (2) if $x \in \mathcal{L}$ then $p_x \in C_{aa}$ and $\omega(\mathcal{G}_x, p_x) = 1$.

The class PZK-MIP^{*} $(2, 1, c, s)$ is the class of languages with a perfect zero knowledge two-prover one round MIP^{*} protocol with completeness c and soundness s.

By replacing C_{qa} with C_{qc} , we get another class PZK-MIP co . If we replace MIP^* protocols with BCS-MIP^{*} (resp. BCS-MIP^{co}) protocols and C_{qa} with C_{qa}^s (resp. C_{qc}^s) we get the class PZK-BCS-MIP^{*} (resp. PZK-BCS-MIP^{co}).

For the one-round protocols that we are considering, parallel repetition preserves the property of being perfect zero knowledge.

Proposition 9.2. Let $(\{\mathcal{G}_x\}, S, V)$ be a PZK-MIP^{*} $(2, 1, 1, s)$ protocol, and let n_x be a polynomial function of $|x|$. Then the parallel repeated protocol $(\{\mathcal{G}_x^{\otimes n_x}\}, \mathcal{S}^{\otimes n_x}, V^{\otimes n_x})$ is also perfect zero knowledge.

Proof. Let p_x be a correlation for the game G that satisfies the two requirements of Definition [9.1.](#page-27-0) Then $\{p_x^{\otimes n_x}(\underline{a}, \underline{b}|\underline{i}, \underline{j})\}_{\underline{a},\underline{b}}$ can be sampled in polynomial time in |x| for all <u>*i*</u>, *j* by independently sampling from $\{p_x(a, b, i_\ell, j_\ell)\}_{a,b}$ for each pair (i_ℓ, j_ℓ) from $\underline{i} = (\overline{i_1}, \ldots, i_{n_x})$ and $\underline{j} = (j_1, \ldots, j_{n_x})$. If $x \in \mathcal{L}$, then $\omega(\mathcal{G}_x^{\otimes n_x}; p_x^{\otimes n}) = 1$, and it is not hard to see that $p_x^{\otimes n_x}$ \mathbb{R}^n $\overline{x} \in C_{qa}$.

We will now prove our main result that any proof system in BCS-MIP^{*} or BCS- MIP^{co} can be turned into a perfect zero knowledge BCS-MIP^{*} or BCS-MIP^{co} protocol. For this purpose, we use the perfect zero knowledge proof system for 3SAT due to Dwork, Feige, Kilian, Naor, and Safra $[DFK^+92]$, slightly modified for the proof of quantum soundness. For the construction, we assume that we start with a BCS-MIP˚ protocol (and in the proof of Theorem [1.1,](#page-1-0) this will be a 3SAT-MIP˚ protocol). Following $[DFK^+92]$, the new proof system is constructed in three steps. First, we apply a transformation called oblivation, then turn the resulting system into a permutation branching program via Barrington's theorem [\[Bar86\]](#page-41-4), and finally rewrite the permutation branching programs using the randomizing tableaux of Kilian [\[Kil90\]](#page-43-22). We start by describing obliviation.

Definition 9.3. Given a BCS $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ and $n \ge 1$, let $Z = X \times [n]$, and $U_i = V_i \times [n]$ for any $1 \leq i \leq m$. To make the elements of Z look more like variables, we denote (x, i) by $x(i)$. Let $E_i \subseteq \mathbb{Z}_2^{U_i}$ be the set of assignments ϕ to U_i such that the assignment ψ to V_i defined by $\psi(x) = \psi(x(1)) \cdots \psi(x(n))$ is

in C_i . The **obliviation of** B **of degree** n is the constraint system $Obl_n(B)$ = $(Z, \{(U_i, E_i)\}_{i=1}^m)$.

The point of obliviation is the following:

Lemma 9.4. Suppose $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS, and let $B' = \text{Obl}_n(B)$ for some $n \geq 1$, using the notation from Definition [9.3.](#page-27-1) Then:

- (a) There is a classical homomorphism $\alpha : A(B) \to A(B')$ such that $\alpha(\sigma_i(x)) =$ $\sigma_i(x(1)\cdots x(n))$ for all $i \in [m]$ and $x \in V_i$, where σ_i is the inclusion of the ith factor for $A(B)$ and $A(B')$.
- (b) Let Γ be the set of sequences x_1, \ldots, x_k in Z of length $1 \leq k \leq n-1$, such that there is some $i \in [k]$ with $x_i \neq x_j$ for all $j \in [k] \setminus \{i\}$. If π is a probability distribution on $[m] \times [m]$, and τ is a tracial state on $\mathcal{A}(B)$, then there is a tracial state $\tilde{\tau}$ on $\mathcal{A}(B')$ such that $\tau = \tilde{\tau} \circ \alpha$, $\det(\tilde{\tau}; \mu_{\pi}) = \det(\tau; \mu_{\pi})$ and $\tilde{\tau}(\sigma_{i_1}(x_1)\cdots\sigma_{i_k}(x_k)) = 0$ for all sequences x_1, \ldots, x_k in Γ and indices $i_1,\ldots,i_k \in [m]$ such that $x_j \in U_{i_j}$ for all $1 \leqslant j \leqslant k$. If τ is finite-dimensional (resp. Connes-embeddable), then $\tilde{\tau}$ is also finite-dimensional (resp. Connesembeddable).
- (c) For any $1 \leq i \leq m$, the set $\{\prod_{x \in S} x : S \subseteq U_i, |S| < n/2\}$ of monomials in U_i of degree less than $n/2$ is linearly independent in $\mathcal{A}(U_i, E_i)$.

In particular, if τ is perfect then $\tilde{\tau}$ is perfect.

Proof. Define $f_i : \mathbb{Z}_2^{U_i} \to \mathbb{Z}_2^{V_i}$ for each $i \in [m]$ by $f_i(\phi)(x) = \phi(x(1)) \cdots \phi(x(n))$ for $\phi \in \mathbb{Z}_2^{U_i}$ and $x \in V_i$. By definition, $\phi \in E_i$ if and only if $f_i(\phi) \in C_i$, so $f_i(E_i) = C_i$. If $f_i(\phi)(x) \neq f_j(\psi)(x)$ for some $\phi \in \mathbb{Z}_2^{U_i}$, $\psi \in \mathbb{Z}_2^{U_j}$ $2^{\mathcal{O}_j}$, and $x \in V_i \cap V_j$, then we must have $\phi(x(i)) \neq \psi(x(i))$ for some *i*. Since

$$
\sigma_i(x(1)\cdots x(n)) = \sum_{\phi \in \mathbb{Z}_2^{U_i}} f_i(\phi)(x) \Phi_{U_i, \phi}
$$

for all $x \in V_i$, $i \in [m]$, the functions f_i correspond to a classical homomorphism $\alpha : \mathcal{A}(B) \to \mathcal{A}(B')$ with $\alpha(\sigma_i(x)) = \sigma_i(x(1) \cdots x(n))$ for all $i \in [m]$ and $x \in V_i$. This proves part (a).

Conversely, given $y \in \mathbb{Z}_2^{X \times [n-1]}$ $\frac{X \times [n-1]}{2}$ and $\phi \in \mathbb{Z}_2^{V_i}$, define $\phi_y \in \mathbb{Z}_2^{U_i}$ by $\phi_y(x(1)) =$ $\phi(x)y(x, 1), \phi_y(x(j)) = y(x, j-1)y(x, j)$ for $2 \leq j \leq n-1$, and $\phi_y(x(n)) = y(x, n-1)$. Since $f_i(\phi_y) = \phi$, the function $\phi \mapsto \phi_y$ sends C_i to E_i . Also if $\phi \in \mathbb{Z}_2^{V_i}$ and $\psi \in \mathbb{Z}_2^{V_j}$ $\frac{v_j}{2}$, then $\phi_y|_{U_i \cap U_j} \neq \psi_y|_{U_i \cap U_j}$ if and only if $\phi|_{V_i \cap V_j} \neq \psi|_{V_i \cap V_j}$, so the functions $\phi \mapsto$ ϕ_y determine a classical homomorphism $\beta_y : \mathcal{A}(B') \to \mathcal{A}(B)$ with $\beta_y(\sigma_i(x(1))) =$ $\sigma_i(x)y(x, 1), \beta_y(\sigma_i(x(j))) = y(x, j - 1)y(x, j)$ for $2 \leq j \leq n - 1$, and $\beta_y(\sigma_i(x(n))) =$ $y(x, n-1)$ for all $i \in [m]$ and $x \in V_i$.

Given a tracial state τ on $\mathcal{A}(B)$, define a tracial state $\tilde{\tau}$ on $\mathcal{A}(B')$ by $\tilde{\tau} = \frac{|\mathbf{X}|}{\tau}$ $2^{-|X|(n-1)} \sum_{y} \tau \circ \beta_y$, where the sum is over all $y \in \mathbb{Z}_2^{X \times [n-1]}$ $\frac{\lambda}{2}$ ^{$\lambda \times [n-1]$}. Notice that if τ is finite-dimensional (resp. Connes-embeddable), then $\tilde{\tau}$ is also finite-dimensional

(resp. Connes-embeddable). Since $\beta_y \circ \alpha$ is the identity on $\mathcal{A}(B)$, $\tilde{\tau} \circ \alpha = \tau$. Since β_y and α are 1-homomorphisms,

$$
\operatorname{def}(\tau \circ \beta_y; \mu_\pi) \leq \operatorname{def}(\tau; \mu_\pi) = \operatorname{def}(\tau \circ \beta_y \circ \alpha; \mu_\pi) \leq \operatorname{def}(\tau \circ \beta_y; \mu_\pi)
$$

for any y, so $\det(\tau \circ \beta_y; \mu_\pi) = \det(\tau; \mu_\pi)$ and hence $\det(\tilde{\tau}; \mu_\pi) = \det(\tau; \mu_\pi)$.

Finally, if x_1, \ldots, x_k is a sequence in Z, and i_1, \ldots, i_k is a sequence in $[m]$ such that $x_j \in U_{i_j}$, then there is an element $a \in \mathcal{A}(B)$ and set $S \subseteq X \times [n-1]$ such that

$$
\beta_y(\sigma_{i_1}(x_1)\cdots\sigma_{i_k}(x_k))=m_y\tau(a)
$$

for all $y \in \mathbb{Z}_2^{X \times [n-1]}$ $\sum_{i=1}^{X} \sum_{j=1}^{n}$ where $m_y := \prod_{(x,j)\in S} y(x,j)$. If x_1, \ldots, x_k is in Γ , then S is non-empty, and $\sum_{y} m_y = 0$. Hence

$$
\widetilde{\tau}(\sigma_{i_1}(x_1)\cdots\sigma_{i_k}(x_k))=2^{-|X|(n-1)}\sum_y m_y \tau(a)=0.
$$

This proves part (b).

For part (c), pick a tracial state τ on the finite-dimensional C^* -algebra $\mathcal{A}(V_i, C_i)$ (since C_i is non-empty, this algebra is non-trivial). As in the proof of part (b), we can define a tracial state $\tilde{\tau} = 2^{|X|(n-1)} \sum_y \tau \circ \beta_y$ on $\mathcal{A}(U_i, E_i)$ with the property that $\widetilde{\tau}(x_1 \cdots x_k) = 0$ if $1 \leq k \leq n - 1$ and $x_1, \ldots, x_k \in U_i$ are distinct. If $S, T \subseteq U_i$, then

$$
\prod_{x \in S} x \cdot \prod_{x \in T} x = \prod_{x \in S \Delta T} x,
$$

where $S\Delta T := (S \cup T) \setminus (S \cap T)$. If $|S|, |T| < n/2$, then $|S\Delta T| < n$, and $S\Delta T = \emptyset$ if and only if $S = T$. Hence by part (b),

$$
\widetilde{\tau}(\prod_{x \in S} x \cdot \prod_{x \in T} x) = \begin{cases} 1 & S = T \\ 0 & S \neq T \end{cases}
$$

.

It follows that the monomials $\{\prod_{x \in S} x : S \subseteq U_i, |S| < n/2\}$ are linearly independent. \Box

A permutation branching program of width 5 and depth d on a set of variables X is a tuple $P = (X, \{(x_i, \pi_1^{(i)})$ $\mathbf{1}^{(i)},\pi_{-1}^{(i)}$ $\binom{(i)}{-1}\}_{i=1}^d, \sigma)$ where $x_i \in X$ and $\pi_1^{(i)}$ $\mathbf{1}^{(i)},\pi_{-1}^{(i)}$ $\frac{1}{1}$ are elements of the permutation group S_5 for all $1 \leq i \leq d$, and $\sigma \in S_5$ is a 5-cycle. A permutation branching program P defines a map $P: \mathbb{Z}_2^X \to S_5$ via $P(\phi) = \prod_{i=1}^d \pi_{\phi(i)}^{(i)}$ $\frac{\psi(x_i)}{\phi(x_i)}$. A program P recognizes a constraint $C \subseteq \mathbb{Z}_2^X$ if $P(\phi) = \sigma$ for all $\phi \in C$, and $P(\phi) = e$ for all $\phi \notin C$, where e is the identity in S_5 .

Theorem 9.5 (Barrington [\[Bar86\]](#page-41-4)). Suppose a constraint $C \subseteq \mathbb{Z}_2^X$ is recognized by a depth d fan-in 2 boolean circuit. Then C is recognized by a permutation branching program of depth 4^d on the variables X.

For the rest of the section, we assume that we have a canonical way of turning constraints described by fan-in 2 boolean circuits into permutation branching programs using Barrington's theorem.

The final ingredient is randomizing tableaux, which are described using constraints of the form $x_1 \cdots x_n = \gamma$, where the variables x_1, \ldots, x_n take values in S_5 , γ is a constant in S_5 , and the product is the group multiplication. Since $|S_5| = 120 < 2^7$, we can encode permutations as bit strings of length 7 by choosing an enumeration $S_5 = \{e = \gamma_0, \ldots, \gamma_{119}\}$, and identifying γ_j by its index j in binary. This means that any permutation-valued variable can be represented by 7 boolean variables, and similarly a permutation-valued constraint $x_1 \cdots x_n = \gamma$ can be rewritten as the constraint on 7n boolean variables which requires the boolean variables corresponding to x_i to encode a permutation value, and the product of all the permutations to be equal to γ . Since we want our final output to be a boolean constraint system, we use permutation-valued variables and permutationvalued constraints as short-hand for boolean constraint systems constructed in this way. We can now define randomizing tableaux, still following $[DFK^+92]$ $[DFK^+92]$ with small modifications.

Definition 9.6. Let $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ be a BCS, where each C_i is described by a fan-in 2 boolean circuit. Let $P_i = (V_i, \{(x_{ij}, \pi_1^{(ij)})\})$ $\mathcal{L}^{(ij)}_{1}, \pi^{(ij)}_{-1}$ $\begin{bmatrix} (ij) \\ (-1) \end{bmatrix}$ $\begin{bmatrix} d_i \\ j=1 \end{bmatrix}$, σ_i) be the permutation branching program recognizing C_i . For each $i \in [m]$, let

$$
W_i = V_i \sqcup \{T_i(p,q) : (p,q) \in [4] \times [d_i]\} \sqcup \{r_i(j,k) : (j,k) \in [3] \times [d_i - 1]\},
$$

where $T_i(p,q)$ and $r_i(j,k)$ are new permutation-valued variables (and thus represent 7 boolean variables each), and let

$$
Y = X \sqcup \{T_i(p,q), r_i(j,k) : (i, p, q, j, k) \in [m] \times [4] \times [d_i] \times [3] \times [d_i - 1]\}
$$

be the union of all the original and new variables. The variables $T_i(p,q)$ are called tableau elements, and the variables $r_i(j,k)$ are called randomizers.

Let D_i be the constraint on variables W_i which is the conjunction of the following clauses:

- (1) $T_i(1,q) = \pi_{x_q}^{(iq)}$ for all $q \in [d_i]$,
- (2) $T_i(p+1,q) = r_i(p,q-1)^{-1} T_i(p,q) r_i(p,q)$ for $q \in [d_i]$ and $p \in [3]$, where we use the notation $r_i(p, 0) = r_i(p, d_i) = e$,
- (3) $\prod_{1 \leq q \leq d_i} T_i(4, q) = \sigma_i$, and
- (4) a trivial constraint (meaning that all assignment are allowed) on any pair x, y of original or permutation-valued variables which do not appear in one of the above constraints.

The **tableau** of B is $\text{Tab}(B) = (Y, \{(W_i, D_i)\}_{i=1}^m)$, interpreted as a boolean constraint system. We further let $\{W_{ij}, D_{ij}\}_{j=1}^{m_i}$ be a list of the clauses in (1)-(4) making up D_i . The **subdivided tableau** of B is $\text{Tab}_{sub}(B) = (Y, \{(W_{ij}, D_{ij})\}_{i \in [m],j \in [m_i]})$.

Compared to $[DFK^+92]$, we've added the trivial constraints (4), as well as an extra row of the tableau. As mentioned above, the product in the constraints on the permutation-valued variables in parts $(1)-(4)$ of the definition is the group product in S_5 . The constraints in part (1) involve both original variables x_q and permutationvalued variables $T_i(1, q)$, and say that the value of $T_i(1, q)$ is either $\pi_1^{(iq)}$ $i_{1}^{(iq)}$ or $\pi_{-1}^{(iq)}$ -1 depending on the value of x_q . In part (4), x and y can be either an original or a permutation-valued variable. If one of them is a permutation-valued variable, then all the corresponding boolean variables encoding the permutation-valued variable are included in the constraint (so the constraint on x and y may involve up to 14 boolean variables). Since the constraints in part (4) are trivial, they do not contribute to D_i , but they are included in the list of clauses (W_{ij}, D_{ij}) of the subdivided tableau. The point of the constraints in part (4) is that, with them, $\text{Tab}_{sub}(B)$ is a subdivision of Tab (B) . The extra row of the tableau is needed to compensate for the inclusion of these constraints in Tab_{sub} (B) (see Remark [9.11\)](#page-36-0). As in [\[DFK](#page-42-11)⁺92], the constraints D_i encode the constraints C_i as follows:

Lemma 9.7 ([\[DFK](#page-42-11)⁺92]). Suppose $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS, and let $\text{Tab}(B)$ = $(Y, \{(W_i, D_i)\}_{i=1}^m)$. If $\psi \in D_i$, then $\psi|_{V_i} \in C_i$. Conversely, if $r \in S_5^{R_i}$, where $R_i = \{r_i(j,k) : (j,k) \in [3] \times [d_i]\}$ is the set of randomizers in W_i , and $\phi \in C_i$, then there is a unique element $\phi_r \in D_i$ such that $\phi_r|_{V_i} = \phi$ and $\phi_r|_{R_i} = r$.

In this lemma, the statement that $\phi_r|_{R_i} = r$ means that for every randomizer $r_i(j,k) \in R_i$, the restriction of ϕ to the boolean variables corresponding to $r_i(j,k)$ is the encoding of the permutation $r(r_i(j,k))$.

Proof. If $\psi \in D_i$, then by constraint (2), $\prod_q T_i(p+1,q) = \prod_q T_i(p,q)$. Since $\prod_q T_i(4,q) = \sigma_i$ by constraint (3), $\prod_q \pi_{x_q}^{(iq)} = \sigma_i$. Since the permutation branching program P_i recognizes C_i , we conclude that $\psi|_{V_i} \in C_i$.

Conversely, given an assignment $r \in S_5^{R_i}$ to the variables R_i and $\phi \in C_i$, we can set $T_i(1,q) = \pi^{(iq)}_{\phi(x)}$ $\psi^{(qq)}_{\phi(x_q)}$ and $T_i(p+1,q) = r_i(p,q-1)^{-1} T_i(p,q) r_i(p,q)$ to get an assignment where $\prod_q T_i(\vec{4}, q) = \sigma_i$.

Although the permutation-valued variables in $Tab(B)$ are shorthand for boolean variables, it is helpful to be able to work with the permutation-valued variables directly in $\mathcal{A}(\text{Tab}(B))$. Suppose for a moment that x_1, \ldots, x_7 are variables in a set V, and C is a constraint on V which includes the requirement that x_1, \ldots, x_7 encode a permutation-valued variable x. Let $S = \{x_1, \ldots, x_7\}$. If $\phi \in \mathbb{Z}_2^S$, then $\Phi_{S,\phi} = 0$ in $\mathcal{A}(V, C)$ unless ϕ is the binary representation of an index $0 \leqslant j \leqslant j$ 120, in which case we also write $\Phi_{S,\phi}$ as $\Phi_{S,j}$. Hence the subalgebra of $\mathcal{A}(V, C)$ is generated by the single unitary $\sum_{j=0}^{119} e^{2\pi i j/120} \Phi_{S,j}$, which we denote by the same symbol as the permutation-valued variable x. In particular, if $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ and Tab $(B) = (Y, \{(W_i, D_i)\}_{i=1}^m)$ as in Definition [9.6,](#page-30-0) then we can refer to $T_i(p, q)$ and $r_i(j,k)$ as unitary elements of $\mathcal{A}(W_i, D_i)$ of order 120, and they generate the same subalgebra as the boolean variables encoding them. Since these variables do not occur in any other context W_j for $j \neq i$, we also use $T_i(p,q)$ and $r_i(j,k)$ to refer to $\sigma_i(T_i(p,q))$ and $\sigma_i(r_i(j,k))$ in $\mathcal{A}(\text{Tab}(B))$. We use the same convention for $\mathcal{A}(W_{i\ell}, D_{i\ell})$, although since the variables $T_i(p,q)$ and $r_i(j,k)$ occur in more than one constraint of Tab_{sub} (B) , we are stuck with the notation $\sigma_{i\ell}(T_i(p,q))$ and $\sigma_{i\ell}(r_i(j,k))$ when refering to these variables in $\mathcal{A}(\text{Tab}_{sub}(B))$. With these conventions, we can state the following noncommutative version of Lemma [9.7.](#page-31-0)

Lemma 9.8. Suppose that $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS, and let $\text{Tab}(B) =$ $(Y, \{(W_i, D_i)\}_{i=1}^m)$. Let $R_i = \{r_i(j,k) : (j,k) \in [3] \times [d_i-1]\}$ be the set of randomizers in W_i , and let $R = \bigcup_i R_i$.

(a) The natural map

$$
\mathcal{A}(V_i, C_i) \otimes \mathbb{CZ}_{120}^{R_i} \to \mathcal{A}(W_i, D_i) : x_i \mapsto x_i, r_i(j, k) \mapsto r_i(j, k)
$$

is an isomorphism. In particular, $\mathcal{A}(W_i, D_i)$ is generated as an algebra by $V_i \cup R_i$, and $\mathcal{A}(\text{Tab}(B))$ is generated by $\bigcup_i {\{\sigma_i(x) : x \in V_i\}} \cup R$.

- (b) The natural inclusion $\alpha : A(B) \to A(\text{Tab}(B))$ defined by $\alpha(\sigma_i(x)) = \sigma_i(x)$ for $i \in [m]$ and $x \in V_i$ is a classical homomorphism.
- (c) If $r \in S_5^R$, then there is a classical homomorphism $\beta_r : \mathcal{A}(\text{Tab}(B)) \to \mathcal{A}(B)$ such that for all $i \in [m]$, if $x \in V_i$ then $\beta_r(\sigma_i(x)) = \sigma_i(x)$, and if $x \in R_i$ then $\beta_r(x) = e^{2\pi i j/120}$ where $r(x) = \gamma_j$ in the enumeration of S_5 fixed above.
- (d) Let M be the set of monomials in $\mathcal{A}(B)$ of the form $u\sigma_i(z)^a v$, where $z \in \mathcal{R}_i$ for some $i \in [m], 1 \le a < 120$, and u and v are monomials in $\{\sigma_i(x) : j \in$ $[m], x \in V_i \cup R_i$ which do not contain z. If π is a probability distribution on $\lceil m \rceil \times \lceil m \rceil$, and τ is a tracial state on $\mathcal{A}(B)$, then there is a tracial state $\tilde{\tau}$ on $\mathcal{A}(\text{Tab}(B))$ such that $\tau = \tilde{\tau} \circ \alpha$, where α is the classical homomorphism from part (b), $\det(\tilde{\tau}; \mu_{\pi}) = \det(\tau; \mu_{\pi}),$ and $\tilde{\tau}(y) = 0$ for all $y \in \mathcal{M}$. Furthermore, if τ is finite-dimensional (resp. Connes-embeddable), then $\tilde{\tau}$ is also finitedimensional (resp. Connes-embeddable).

Proof. For part (a), the algebra $\mathbb{CZ}_{120}^{R_i}$ has a basis consisting of the joint spectral projections

$$
\Phi_{R_i,r} = \prod_{x \in R_i} \lambda(r(x))^{-1} \prod_{\gamma_k \neq r(x)} (x - e^{2\pi i k/120}), \quad r \in \mathbb{Z}_{120}^{R_i},
$$

where $\lambda(\gamma_j) = \prod_{k \neq j} (e^{2\pi i j/120} - e^{2\pi i k/120})$. Hence $\mathcal{A}(V_i, C_i) \otimes \mathbb{C} \mathbb{Z}_{120}^{R_i}$ has a basis consisting of the elements $\Phi_{V_i,\phi} \otimes \Phi_{R_i,r}$ for $\phi \in C_i$ and $r \in \mathbb{Z}_{120}^{R_i}$. Using the enumeration of S_5 fixed earlier, we can interpret $\mathbb{Z}_{120}^{R_i}$ as the set $S_5^{R_i}$ of permutation-valued assignments to R_i . The natural homomorphism $\mathcal{A}(V_i, C_i) \otimes \mathbb{C} \mathbb{Z}_{120}^{R_i} \to \mathcal{A}(W_i, D_i)$ sends $\Phi_{V_i,\phi}\otimes\Phi_{R_i,r}$ to $\sum_{\psi}\Phi_{W_i,\psi}$, where the sum is across all $\psi\in D_i$ such that $\psi|_{V_i}=\phi$ and $\psi|_{R_i} = r$. By Lemma [9.7,](#page-31-0) the restriction map $\phi \mapsto \phi|_{V_i \cup R_i}$ is a bijection between D_i and $C_i \times S_5^{R_i}$, so this homomorphism is an isomorphism.

Parts (b) and part (c) follow immediately from Lemma [9.7](#page-31-0) and the definition of a classical homomorphism. Alternatively, part (b) also follows from Corollary [6.7.](#page-17-0)

The proof of part (d) is similar to the proof of Lemma [9.4,](#page-28-0) part (b). Given a tracial state τ on $\mathcal{A}(B)$, let $\tilde{\tau}$ be the tracial state on $\mathcal{A}(\text{Tab}(B))$ defined by $\tilde{\tau} =$
 $\frac{1}{\sqrt{2\pi}} \sum_{n=1}^{\infty} \tau_n \circ \beta$, where the sum is over $r \in S^R$. If τ is finite dimensional (resp. $\frac{1}{120^{|R|}}\sum_r \tau \circ \beta_r$, where the sum is over $r \in S_5^R$. If τ is finite-dimensional (resp. \tilde{C} onnes-embeddable), then $\tilde{\tau}$ is finite-dimensional (resp. Connes-embeddable). Since $\beta_r(\sigma_i(x)) = \sigma_i(x)$ for all $i \in [m]$ and $x \in V_i$, $\beta_r \circ \alpha$ is the identity on $\mathcal{A}(B)$, and $\tilde{\tau} \circ \alpha = \tau$. By parts (b) and (c), $\text{def}(\tau \circ \beta_r) \leq \text{def}(\tau) = \text{def}(\tau \circ \beta_r \circ \alpha) \leq \text{def}(\tau \circ \beta_r)$. This means that $\det(\tau \circ \beta_r) = \det(\tau)$, so $\det(\tau) = \det(\tilde{\tau})$. Finally, suppose $y \in \mathcal{M}$, so $y = u\sigma_i(z)^a v$ for some $z \in R_i$, $1 \le a < 120$, and monomials u, v which do not contain z. By part (c), there is some monomial y' in $\{\sigma_j(x) : j \in [m], x \in V_i\}$ such that for all $r \in S_5^R$, we have $\beta_r(y) = e^{2\pi a i j/120} c_{r'} y'$, where $r(z) = \gamma_j$, and $c_{r'} \in \mathbb{C}$ depends only on $r' = r|_{R \setminus \{z\}}$. Hence

$$
\widetilde{\tau}(y) = \frac{1}{120^{|R|}} \sum_{r \in S_5} \tau(\beta_r(y)) = \frac{1}{120^{|R|}} \sum_{j=0}^{120} e^{2\pi a i j/120} \sum_{r' \in S_5^{R\setminus\{z\}}} c_{r'} \tau(y') = 0,
$$

finishing the proof of part (d). \Box

We need one more general fact about permutation-valued variables.

Lemma 9.9. Let $f: S_5^m \to S_5$ be a function, and suppose (V, C) is a boolean constraint encoding the constraint $x = f(y_1, \ldots, y_m)$ on permutation-valued variables x, y_1, \ldots, y_m . If $1 \leq n < 120$, then

$$
x^n = \sum_a c_a y_1^{a_1} \cdots y_m^{a_m}
$$

for some coefficients $c_a \in \mathbb{C}$, where the sum is over all integer vectors $a = (a_1, \ldots, a_m)$ with $0 \leq a_1, \ldots, a_m < 120$. Furthermore, if for every $\pi_1, \ldots, \pi_{m-1} \in S_5$, the set $\{f(\pi_1, \ldots, \pi_{k-1}, \pi, \pi_k, \ldots, \pi_{m-1}): \pi \in S_5\}$ is equal to S_5 , then $c_a = 0$ if $a_k = 0$.

Proof. Let Y_k be the set of boolean variables representing y_k , and let X be the set of boolean variables representing x. The constraint $x = f(y_1, \ldots, y_m)$ states that

$$
\Phi_{X,\ell} = \sum_{(\gamma_{j_1},\ldots,\gamma_{j_m})\in f^{-1}(\gamma_\ell)} \Phi_{Y_1,j_1}\cdots\Phi_{Y_m,j_m},
$$

where $\{\gamma_0, \ldots, \gamma_{119}\}$ is our chosen enumeration of S_5 . Since Φ_{Y_k,j_k} is a polynomial in y_k , and x^m is a linear combination of the projections $\Phi_{X,\ell}$ for $0 \leq \ell < 120$, we get $x^n = g(y_1, \ldots, y_n)$, where $g = \sum_a c_a y_1^{a_1} \cdots y_m^{a_m}$ is a polynomial in y_1, \ldots, y_m . Since $y_k^{120} = 1$, we can further assume that the sum is over vectors $a = (a_1, \ldots, a_k)$ with $0 \leq a_k < 120$ for all k.

Given $0 \leq j_1, \ldots, j_m < 120$, let $\phi_j : \mathcal{A}(V, C) \to \mathbb{C}$ be the homomorphism sending $\Phi_{Y_k,a} \mapsto \delta_{aj_k}$ for all $1 \leq k \leq k$. This homomorphism sends $y_k \mapsto \omega^{j_k}$ and $x \mapsto \omega^{\ell}$, where $\omega = e^{2\pi i/120}$, and $\gamma_{\ell} = f(\gamma_{j_1}, \dots, \gamma_{j_m})$. We use the notation

$$
A_1,\ldots,A_k,\ldots,A_m
$$

to denote the list A_1, \ldots, A_m with the element A_k omitted. If, for some k, we fix $0 \leq j_1, \ldots, j_k, \ldots, j_m < 120$, then

$$
\sum_{0 \leq j_k < 120} \phi_j(g) = \sum_a c_a \prod_{t \neq k} \omega^{j_t a_t} \sum_{0 \leq j_k < 120} \omega^{j_k a_k} = h(\omega^{j_1}, \dots, \check{\omega}^{j_k}, \dots, \omega^{j_m}),
$$

where $h = g(y_1, \ldots, y_{k-1}, 0, y_{k+1}, \ldots, y_m)$. If $\{f(\gamma_{j_1}, \ldots, \gamma_{j_m}) : 0 \leq j_k < 120\}$ is equal to S_5 , then

$$
\sum_{0 \le j_k < 120} \phi_j(x^n) = \sum_{0 \le \ell < 120} \omega^{n\ell} = 0
$$

for $1 \le n < 120$, and we conclude that

$$
h(\omega^{j_1},\ldots,\check{\omega}^{j_k},\ldots,\omega^{j_m})=0.
$$

If this occurs for all choices of $0 \leq j_1, \ldots, j_k, \ldots, j_m < 120$, then h must be the zero polynomial, so $c_a = 0$ if $a_k = 0$.

Although Lemma [9.9](#page-33-0) is stated for general functions f , we are only going to use it for the group multiplication and inverse functions, i.e. $f(y_1, y_2) = y_1y_2$ and $f(y) = y^{-1}$. For these functions, the additional hypothesis on f holds for all indices k. Thus the lemma states that if (V, C) encodes the constraint $x = y_1y_2$, then x is a polynomial in y_1 and y_2 such that all monomials contain both y_1 and y_2 , and similarly for the constraint $x = y^{-1}$.

We can now prove the main algebraic lemma that we use to prove perfect zero knowledge.

Lemma 9.10. Given a $BCSB = (X, \{(V_i, C_i)\}_{i=1}^m)$, let $\text{Tab}(B) = (Y, \{(W_i, D_i)\}_{i=1}^m)$, and let $\text{Tab}_{sub}(B) = (Y, \{(W_{ij}, D_{ij})\}_{i \in [m], j \in [m_i]})$. Let $R_i = \{r_i(j, k) : (j, k) \in$ $[3] \times [d_i - 1]$ be the set of randomizers in W_i . Then:

- (a) Suppose (W_{ij}, D_{ij}) is a constraint from $\text{Tab}_{sub}(B)$ of type (1), (2), or (4) in Definition [9.6.](#page-30-0) If y is a polynomial in W_{ij} , then y is equal in $\mathcal{A}(W_i, D_i)$ to a polynomial in $S \cup R_i$, where $W_{ij} \cap V_i \subseteq S \subseteq V_i$ and $|S| \leq 2$.
- (b) Suppose (W_{ij}, D_{ij}) is a constraint from $\text{Tab}_{sub}(B)$ of type (3). If y is a polynomial in W_{ij} then y is equal in $\mathcal{A}(W_i, D_i)$ to a polynomial in $V_i \cup R_i$ where every non-scalar monomial contains a variable from R_i .
- (c) If y is a polynomial in W_{ij} and z is a polynomial in W_{ik} for some $i \in [m]$, $j, k \in [m_i]$, then yz is equal in $\mathcal{A}(W_i, D_i)$ to a polynomial in $V_i \cup R_i$ in which every monomial either contains a variable from R_i or has degree ≤ 4 .

Proof. Fix $i \in [m]$, and consider the permutation-valued variables $T_i(p, q)$ in $\mathcal{A}(W_i, D_i)$. The constraints of type (1) in Definition [9.6](#page-30-0) imply that $T_i(1, q)$ is a polynomial in x_q for all $q \in [d_i]$. The constraints of type (2) along with Lemma [9.9](#page-33-0) imply that $T_i(p+1, q)$ is a polynomial in $\{r_i(p, q-1), r_i(p, q), T_i(p, q)\}$, and vice versa $T_i(p, q)$ is a polynomial in $\{r_i(p, q - 1), r_i(p, q), T_i(p + 1, q)\}\$. Recall that $r_i(p, 0) = r_i(p, d_i) = 1$; for notational convenience we use the convention that they are present in every monomial, although note they aren't elements of R_i . It follows that $T_i(p,q)$ is a polynomial in $\{x_q\} \cup \{r_i(p', q-1), r_i(p', q): 1 \leqslant p' < p\}$, and also a polynomial in $\{T_i(4,q)\}\cup \{r_i(p',q-1), r_i(p',q): p\leqslant p'\leqslant 3\}.$ Finally, the constraint of type (3) implies that for any $q \in [d_i]$, the variable $T_i(4, q)$ is a polynomial in $\{T_i(4, q'): q' \neq q\}.$

For part (a), suppose that y is a polynomial in W_{ij} . By the previous paragraph, if (W_{ij}, D_{ij}) is a constraint of type (1), then y can be written as a polynomial in x_q , where $\{x_q\} = W_{ij} \cap V_i$. If (W_{ij}, D_{ij}) is a constraint of type (2) then y can be written as a polynomial in $\{x_q\} \cup R_i$ for some $q \in [d_1]$ (and $W_{ij} \cap V_i = \emptyset$). If (W_{ij}, D_{ij}) is a constraint of type (4) then W_{ij} has size two, and y can be written as a polynomial in $\{x_q, x_{q'}\} \cup R_i$ for some $q, q' \in [d_i]$, where $W_{ij} \cap V_i \subseteq \{x_q, x_{q'}\}$. This finishes the proof of part (a).

For part (b), if (W_{ij}, D_{ij}) has type (3), then we can write y as a polynomial in ${T_i(4, q) : q \in [d_i - 1]}$. Suppose $M = T_i(4, q_1)^{a_1} \cdots T_i(4, q_k)^{a_k}$ is a monomial in this latter set of variables, where $k \geq 1, 1 \leq q_1 < \ldots < q_k < d_i$, and $0 \leq a_1, \ldots, a_k < 120$. By Lemma [9.9,](#page-33-0) $T_i(4, q_j)^{a_j}$ is a polynomial in $\{x_{q_j}\}\cup \{r_i(p', q_j-1), r_i(p', q_j) : p' \in [3]\}$ such that every monomial contains all the randomizers. When we multiply these polynomials together to get the monomial M , some of these randomizers may cancel out. However the randomizers $r_i(p', q_k)$ for $p' \in [3]$ appear only in the polynomial for $T_i(4, q_k)$. As a result, M is a polynomial in $V_i \cup R_i$ such that every monomial contains $r_i(p', q_k)$ for all $p' \in [3]$. We conclude that y can be written as a sum of monomials in $V_i \cup R_i$, such that each non-scalar monomial contains the randomizers $\{r_i(p', q) : p' \in [3]\}$ for some $q \in [d_i - 1]$. In particular, every non-scalar monomial contains some randomizer, finishing the proof of (b).

For part (c), suppose y and z are polynomials in W_{ij} and W_{ik} respectively. By part (a), if (W_{ij}, D_{ij}) and (W_{ik}, D_{ik}) are constraints of type (1), (2) or (4) then y and z both have V_i -degree less than or equal to two, and thus yz has V_i -degree less than or equal to four. Suppose without loss of generality that (W_{ij}, D_{ij}) is the constraint of type (3). If (W_{ik}, D_{ik}) is the same constraint, then yz is a polynomial in W_{ij} , and is covered by part (b).

Suppose (W_{ik}, D_{ik}) has type (2), so $W_{ik} = \{r_i(p, q-1), r_i(p, q), T_i(p, q), T_i(p+1, q)\}$ for some $p \in [3], q \in [d_i]$. If $p \in [2]$, then z is a polynomial in $\{x_q\} \cup \{r_i(p', q - \bar{q})\}$ $1, r_i(p', q) : 1 \leq p' \leq p$. Since y can be written as a polynomial in $V_i \cup R_i$ such that every non-scalar monomial contains $r_i(3, q)$ for some $q \in [d_i - 1]$, yz can be written as a polynomial in $V_i \cup R_i$ such that every monomial either has V_i -degree at most one or contains $r_i(3, q)$ some $q \in [d_i - 1]$. If $p = 3$, then z can be written as a polynomial in $\{T_i(4, q), r_i(3, q - 1), r_i(3, q)\}$ for some $q \in [d_i]$. For any $0 \le a < 120$, $T_i(4, q)^a y$ can be written as a polynomial in $V_i \cup R_i$ such that every non-scalar monomial contains the randomizers $r_i(1, q')$, $r_i(2, q')$ for some $q' \in [d_i - 1]$. So yz is a polynomial in $V_i \cup R_i$ such that every monomial either has V_i -degree zero or contains $r_i(1, q')$, $r_i(2, q')$ for some $q' \in [d_i - 1]$.

Next suppose (W_{ik}, D_{ik}) has type (4), and let $F_i = \{T_i(4, q): q \in [d_i]\}.$ For $q \in [d_i], T_i(1,q)$ can be written as a polynomial in $x_q, T_i(2,q)$ can be written as a polynomial in $\{x_q, r_i(1, q-1), r_i(1, q)\}$, and $T_i(3, q)$ can be written as a polynomial in $\{T_i(4, q), r_i(3, q-1), r_i(3, q)\}\.$ Hence every element W_i can be written as a polynomial in $V_i \cup R_i \cup F_i$ of V_i -degree at most one such that no monomial contains $r_i(p,q)$, $r_i(p', q)$ for some $q \in [d_i - 1]$, and $p \neq p'$. Thus z can be written as a polynomial $V_i \cup R_i \cup F_i$ with V_i -degree at most two, and such that for all $q \in [d_i - 1]$, no monomial contains all the randomizers $\{r_i(p,q): p \in \{3\}\}\$. If M is any monomial in F_i then My can be written as a polynomial in $V_i \cup R_i$ such that every non-scalar monomial contains $\{r_i(p,q): p \in [3]\}$ for some $q \in [d_i - 1]$. Hence yz can be written as a polynomial in $V_i \cup R_i$ where every monomial either has V_i -degree at most two or contains a variable from R_i .

Finally if (W_{ik}, D_{ik}) has type (1), then z is a polynomial in x_q for some q, and as in the previous paragraph, yz can be written as a polynomial in $V_i \cup R_i$ where every monomial either has V_i -degree at most two or contains a variable from R_i . We conclude that part (c) holds. \square

Remark 9.11. Note that the proof of Lemma [9.10,](#page-34-0) part (c) fails if we use a threerow tableau in Definition [9.6](#page-30-0) rather than a four-row tableau. Indeed, suppose we used three-row tableaux. If (W_{ij}, D_{ij}) is the constraint of type (3), and (W_{ik}, D_{ik}) is the constraint of type (4) with $W_{ik} = \{r_i(1, q), r_i(2, q)\}\$, then it is possible for yz to have monomials of degree ≥ 5 that do not contain any randomizers. For instance, when $q = 5$, we can take $y = T_i(3, 1) \cdots T_i(3, 5)$. This corresponds to the fact that, with three-row tableaux, we can recover the group product $T_i(1, 1) \cdots T_i(1, q)$ from the variables $T_i(3, q')$, $q' \in [q]$ and the randomizers $r_i(1, q)$, $r_i(2, q)$.

Combining Lemma [9.10](#page-34-0) with Lemma [9.4,](#page-28-0) for any BCS B we can define a perfect correlation p for the BCS game $\mathcal{G}(\text{Tab}_{sub}(Obl_5(B)))$ such that p is a quantum correlation if and only if $\mathcal{G}(B)$ has a perfect quantum strategy.

Proposition 9.12. Suppose $B = (X, \{(V_i, C_i)\}_{i=1}^m)$ is a BCS with m constraints, and π is a probability distribution on $[m] \times [m]$ such that $\pi(i, j) > 0$ for all $i, j \in$ $[m]$. Let $\text{Obl}_5(B) = (Z, \{(U_i, E_i)\}_{i=1}^m)$, $\text{Tab}(\text{Obl}_5(B)) = (Y, \{(W_i, D_i)\}_{i=1}^m)$, and $\text{Tab}_{sub}(\text{Obl}_5(B)) = (Y, \{(W_{ij}, D_{ij})\}_{i \in [m], j \in [m_i]})$. Let $R_i = \{r_i(j,k) : (j,k) \in [3] \times$ $[d_i-1]$ be the set of randomizers in W_i. For any $i \in [m]$ and $n \geq 1$, let $\Lambda_{i,n}$ be the set of non-scalar monomials over $U_i \cup R_i$ which either contain an element of R_i , or have degree at most n. Let Λ be the subspace of $\mathcal{A}(\text{Tab}(\text{Obl}_5(B)))$ defined by

$$
\Lambda = \mathbb{C}1 \ \oplus \ \mathrm{span} \bigcup_{i \in [m]} \sigma_i(\Lambda_{i,4}) \ \oplus \ \mathrm{span} \bigcup_{i \neq j \in [m]} \sigma_i(\Lambda_{i,2}) \sigma_j(\Lambda_{j,2}),
$$

and let $f : \Lambda \to \mathbb{C}$ be the linear functional defined by $f(1) = 1$, $f(\sigma_i(x)) =$ 0 for all $x \in \Lambda_{i,4}$, and $f(\sigma_i(x)\sigma_j(y)) = \delta_{xy}$ for all $x \in \Lambda_{i,2}$, $y \in \Lambda_{j,2}$, where δ_{ab} is the Kronecker delta, i.e. $\delta_{ab} = 1$ if $a = b$, and is 0 otherwise. Let α : $\mathcal{A}(\text{Tab}_{sub}(\text{Obl}_5(B))) \rightarrow \mathcal{A}(\text{Tab}(\text{Obl}_5(B)))$ be the homomorphism sending $\sigma_{ij}(x) \mapsto$ $\sigma_i(x)$ for all $x \in \mathcal{A}(W_{ij}, D_{ij})$, as in Proposition [7.4.](#page-19-0)

For every $i, k \in [m], j \in [m_i], l \in [m_k]$ and assignments ϕ and ψ to W_{ij} and W_{kl} respectively, let

$$
p(\phi, \psi|ij, kl) = f(\alpha(\Phi_{W_{ij}, \phi} \Phi_{W_{kl}, \psi})).
$$

Then p is a perfect correlation for the BCS game $\mathcal{G}(\text{Tab}_{sub}(\text{Obl}_5(B)), \pi_{sub})$, and $p \in C_q$ (resp. C_{qa} , C_{qc}) if and only if $\mathcal{G}(B,\pi)$ has a perfect quantum correlation in C_q (resp. C_{qa} , C_{qc}).

Proof. We first observe that the linear functional f is well-defined, by showing that it can be defined on a larger subspace. Indeed, for any set of variables S, let $\mathcal{M}(S)$ be the set of non-scalar monomials in S, and let $\mathcal{M}_n(S) \subseteq \mathcal{M}(S)$ be the subset of monomials of degree at most *n*. Since we're assuming that (V_i, C_i) has at least one satisfying assignment, $\mathcal{A}(V_i, C_i)$ has a tracial state. Applying part (b) of Lemma [9.4](#page-28-0) to the constraint system containing the single constraint (V_i, C_i) , we see that $\mathcal{A}(U_i, E_i)$ has a tracial state τ_i such that $\tau_i(x) = 0$ for all $x \in \mathcal{M}_4(U_i)$. Hence $\mathbb{C}1 \cap \text{span } \mathcal{M}_4(U_i) = \{0\}$ in $\mathcal{A}(U_i, E_i)$. By Lemma [9.4,](#page-28-0) part (c), the set

 $\mathcal{M}_2(U_i)$ is linearly independent in $\mathcal{A}(U_i, E_i)$. Hence we can choose a basis Ξ_i for $\mathcal{A}(U_i, E_i)$ which contains $\{1\} \cup \mathcal{M}_2(U_i)$, and such that span $\mathcal{M}_4(U_i) \subseteq \text{span } \Xi_i \setminus \{1\}.$ By Lemma [9.8,](#page-31-1) part (a), the set $\{ab : a \in \Xi_i, b \in \mathcal{M}(R_i)\}$ is a basis for $\mathcal{A}(W_i, D_i)$. Let Θ_i be the set of non-identity elements in this basis. Because $\mathcal{A}(\text{Tab}(B))$ is a free product of the algebras $\mathcal{A}(W_i, D_i)$, the set

$$
\Theta:=\{1\}\cup\bigcup_{i\in[m]}\sigma_i(\Theta_i)\cup\bigcup_{i\neq j\in[m]}\sigma_i(\Theta_i)\sigma_j(\Theta_j)
$$

is linearly independent in $\mathcal{A}(\text{Tab}(B))$. Define a linear functional f on the span of Θ by setting $f(1) = 1$, $f(\sigma_i(x)) = 0$ for all $x \in \Theta_i$, and

$$
f(\sigma_i(x)\sigma_j(y)) = \begin{cases} 1 & x \text{ and } y \text{ are both in } \mathcal{M}_2(U_i \cap U_j) \text{ and } x = y \\ 0 & \text{otherwise} \end{cases}
$$

for all $x \in \Theta_i$, $y \in \Theta_j$ with $i \neq j$. The image of the set $\Lambda_{i,4}$ in $\mathcal{A}(W_i, D_i)$ is contained in the span of Θ_i , so the span of Θ contains the subspace Λ . Furthermore, if $x \in \Lambda_{i,4}$, then $f(\sigma_i(x)) = 0$. Suppose $x \in \Lambda_{i,2}$ and $y \in \Lambda_{i,2}$ with $i \neq j$. If x contains an element of R_i , then x is contained in the span of $\{ab : a \in \mathcal{M}(U_i), b \in \mathcal{M}(R_i), b \neq 1\}$, and $f(\sigma_i(x)\sigma_j(y)) = 0 = \delta_{xy}$. The same is true if y contains an element of R_i . If neither x or y contains an element of R_i or R_j respectively, then $x \in M_2(U_i)$ and $y \in \mathcal{M}_2(U_i)$ are elements of Θ_i and Θ_j respectively. The only way for x and y to be equal is if both belong to $\mathcal{M}_2(U_i \cap U_j)$, so $f(\sigma_i(x)\sigma_j(y)) = \delta_{xy}$. Thus the restriction of f to Λ is the linear functional defined in the proposition.

Since f is well defined, Lemma [9.10](#page-34-0) implies that p is well defined. Since $\sum_{\phi} \Phi_{W_{ij}\phi} =$ 1, it follows that $\sum_{\phi,\psi} p(\phi, \psi | i j, k l) = 1$ for every $i, k \in [m], j \in [m_i]$ and $l \in [m_k]$. To show that p is a perfect correlation for $\mathcal{G}(\text{Tab}_{sub}(Obl_5(B)))$, we need to show that $p(\phi, \psi|ij, kl) \geq 0$ for all $\phi \in D_{ij}$, $\psi \in D_{kl}$, $i, k \in [m], j \in [m_i]$ and $l \in [m_k]$, and that $p(\phi, \psi|ij, kl) = 0$ if $\phi|_{W_{ij} \cap W_{kl}} \neq \psi|_{W_{ij} \cap W_{kl}}$. If $i = k$, then $\alpha(\Phi_{W_{ij}, \phi})$ and $\alpha(\Phi_{W_{kl},\psi})$ are both projections in the commutative algebra $\mathcal{A}(W_i, D_i)$, and thus their product is also a projection. Since C_i is non-empty by assumption, $\mathcal{A}(V_i, C_i)$ has a tracial state. If $B_i = (V_i, \{(V_i, C_i)\})$ is the constraint system for the single constraint C_i , then $Obl_5(B_i) = (U_i, \{(U_i, E_i)\})$ and $Tab(Obl_5(B_i))$ = $(W_i, \{(W_i, D_i)\})$. By Lemma [9.4,](#page-28-0) part (b), there is a tracial state τ_i on $\mathcal{A}(U_i, E_i)$ such that $\tau_i(x) = \delta_{x,1}$ for all $x \in \mathcal{M}_4(U_i)$. By Lemma [9.8,](#page-31-1) part (d), there is a tracial state $\tilde{\tau}_i$ on $\mathcal{A}(W_i, D_i)$ such that $\tilde{\tau}_i(x) = \tau_i(x)$ for all $x \in \mathcal{M}(U_i)$, and $\tilde{\tau}_i(x) = 0$ for all monomials $x \in \mathcal{M}(U_i \cup R_i)$ containing an element of R_i . Since $\tilde{\tau}_i(1) = 1$ and $\tilde{\tau}_i(x) = 0$ for all $x \in \Lambda_{i,4}$, the linear functionals f and $\tilde{\tau}_i$ agree on $\mathbb{C}1 \oplus \Lambda_{i,4}$, and $f(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi})) = \tilde{\tau}_i(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi})) \geq 0$. If $\phi|_{W_{ij}\cap W_{kl}} \neq \psi|_{W_{ij}\cap W_{kl}}$ then $\alpha(\Phi_{W_{ij},\phi})\alpha(\check{\Phi}_{W_{kl},\psi})=0$ in $\mathcal{A}(W_i, D_i)$, and $f(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi}))=0$.

If $i \neq k$ and neither (W_{ij}, D_{ij}) or (W_{kl}, D_{kl}) are constraints of type (3) in Def-inition [9.6,](#page-30-0) then by Lemma [9.10](#page-34-0) there exist $S_i \subseteq U_i$ and $S_k \subseteq U_k$ of size at most two, such that $W_{ij} \cap U_i \subseteq S_i$, $W_{kl} \cap U_k \subseteq S_k$, $\Phi_{W_{ij},\phi}$ is a polynomial in $S_i \cup R_i$, and $\Phi_{W_{kl},\psi}$ is a polynomial in $S_k \cup R_k$. Since $\mathcal{M}_2(S_i)$ is a linearly independent in $\mathcal{A}(U_i, E_i)$, part (a) of Lemma [9.8](#page-31-1) implies that the subalgebra of $\mathcal{A}(W_i, D_i)$ generated by $S_i \cup R_i$ is isomorphic to $\mathbb{C}\mathbb{Z}_2^{S_i} \times \mathbb{Z}_{120}^{R_i}$, and similarly with the algebra generated by

 $S_k \cup R_k$ in $\mathcal{A}(W_k, D_k)$. Hence the subalgebra C of $A(\text{Tab}(\text{Obl}_5(B)))$ generated by $S_i \cup S_k \cup R_i \cup R_k$ is isomorphic to the group algebra of $(\mathbb{Z}_2^{S_i} \times \mathbb{Z}_{120}^{R_i}) * (\mathbb{Z}_2^{S_k} \times \mathbb{Z}_{120}^{R_k})$. Let H be the quotient of this free product group by the relations $\sigma_i(x) = \sigma_k(x)$ for all $x \in S_i \cap S_k$, where $\sigma_i(x)$ and $\sigma_k(x)$ are the group generators corresponding to x in the first and second factors of the free product respectively, and let

$$
q: (\mathbb{Z}_2^{S_i} \times \mathbb{Z}_{120}^{R_i}) \ast (\mathbb{Z}_2^{S_k} \times \mathbb{Z}_{120}^{R_k}) \rightarrow H
$$

be the quotient map. Observe that

$$
H = \mathbb{Z}_2^{*S_i \cup S_k} * \mathbb{Z}_{120}^{*R_i \cup R_k}/\langle xy = yx \text{ for } x, y \text{ in } S_i \cup R_i \text{ or } S_k \cup R_k \rangle
$$

is a graph product. By the normal form theorem for graph products [\[Gre90\]](#page-42-17), if $g \in \mathcal{M}(S_i \cup R_i)$ and $h \in \mathcal{M}(S_j \cup R_j)$, then $q(gh) = 1$ if and only if $g, h \in \mathcal{M}(S_i \cap S_j)$ and $g = h$. Hence if τ is the canonical trace on the group algebra $\mathbb{C}H$, then $\tau \circ q(\sigma_i(g)\sigma_k(h)) = f(\sigma_i(g)\sigma_k(h)).$ We conclude that $f(\alpha(\Phi_{W_i,j,\phi}\Phi_{W_k,j,\psi})) = \tau \circ$ $q(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi}))$. Since $\Phi_{W_{ij},\phi}$ and $\Phi_{W_{kl},\psi}$ are projections, $\tau \circ q(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi})) \ge$ 0. Suppose $\phi(x) \neq \psi(x)$ for some $x \in W_{ij} \cap W_{kl}$. Then we must have $x \in U_i \cap U_k$, so $x \in S_i \cap S_k$. Since $\frac{1+\phi(x)x}{2} \Phi_{W_{ij},\phi} = \Phi_{W_{ij},\phi}$ and $\frac{1+\psi(x)x}{2} \Phi_{W_{kl},\psi} = \Phi_{W_{kl},\psi}$, we have

$$
q(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi})) = q\left(\alpha(\Phi_{W_{ij},\phi})\sigma_i\left(\frac{1+\phi(x)x}{2}\right)\sigma_k\left(\frac{1+\psi(x)x}{2}\right)\alpha(\Phi_{W_{kl},\psi})\right)
$$

$$
= q(\alpha(\Phi_{W_{ij},\phi}))\left(\frac{1+\phi(x)x}{2}\right)\left(\frac{1+\psi(x)x}{2}\right)q(\alpha(\Phi_{W_{kl},\psi})) = 0.
$$

Thus $f(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi}))=0$ if $\phi|_{W_{ij}\cap W_{kl}} \neq \psi|_{W_{ij}\cap W_{kl}}$.

Finally, suppose $i \neq k$ and (W_{ij}, D_{ij}) is a constraint of type (3). By Lemma [9.10,](#page-34-0) part (b), we can write $\alpha(\Phi_{W_{ij},\phi}) = \lambda 1 + \sum_x c_x x$ for some coefficients $\lambda, c_x \in \mathbb{C}$, where the sum is over monomials $x \in \mathcal{M}(U_i \cup R_i)$ containing an element of R_i . Let $\tilde{\tau}_i$ and $\tilde{\tau}_k$ be the tracial states on $\mathcal{A}(W_i, D_i)$ and $\mathcal{A}(W_k, D_k)$ defined above. Since $\tilde{\tau}_i$ is equal to f on $\Lambda_{i,4}$ and $\Phi_{W_{ij},\phi}$ is a projection, $\lambda = f(\alpha(\Phi_{W_{ij},\phi})) = \tilde{\tau}_i(\alpha(\Phi_{W_{ij},\phi})) \geq 0.$ Similarly, $f(\alpha(\Phi_{W_{kl},\psi})) = \tilde{\tau}_k(\alpha(\Phi_{W_{kl},\psi})) \geq 0$. If $x \in \mathcal{M}(U_i \cup R_i)$ contains an element of R_i , then $x\alpha(\Phi_{W_{kl},\psi}) \in \sigma_i(\Lambda_{i,4}) \oplus \sigma_i(\Lambda_{i,2})\sigma_k(\Lambda_{k,2}),$ so $f(x\alpha(\Phi_{W_{kl},\psi})) = 0$. We conclude that $f(\alpha(\Phi_{W_{ij},\phi}\Phi_{W_{kl},\psi})) = \lambda f(\alpha(\Phi_{W_{kl},\psi})) \geq 0$. It is not possible to have $\phi|_{W_{ij}\cap W_{kl}} \neq \psi|_{W_{ij}\cap W_{kl}}$ when $i \neq k$ and (W_{ij}, D_{ij}) has type (3), since $W_{ij}\cap W_{kl} = \emptyset$.

This finishes the proof that p is a perfect correlation for $\mathcal{G}(\text{Tab}_{sub}(\text{Obl}_5(B)), \pi_{sub})$. If $p \in C_{qc}$ (resp. C_{qa} , C_q), then $\mathcal{G}(\text{Tab}(\text{Obl}_5(B)), \pi)$ also has a perfect strategy in C_{qc} (resp. C_{qa} , C_q) by Proposition [7.4.](#page-19-0) This means that there is a tracial state (resp. Connes-embeddable tracial state, finite-dimensional tracial state) $\tilde{\tau}$ on $\mathcal{A}(\text{Tab}(\text{Obl}_5(B)))$ with $df(\tau; \mu_\pi) = 0$. By Lemma [9.8,](#page-31-1) part (b), and Lemma [9.4,](#page-28-0) part (a), there is a 1-homomorphism $\mathcal{A}(B) \to \mathcal{A}(\text{Tab}(\text{Obl}_5(B)))$, and pulling back $\tilde{\tau}$ by this 1-homomorphism yields a perfect strategy for $\mathcal{G}(B,\pi)$ in C_{qc} (resp. C_{qa} , C_q). Conversely, if $\mathcal{G}(B, \pi)$ has a perfect strategy in C_{qc} , then there is a tracial state τ on $\mathcal{A}(B)$ with def $(\tau; \mu_{\pi}) = 0$. By Lemma [9.4,](#page-28-0) part (b), there is a tracial state τ' on $\mathcal{A}(\mathrm{Obl}_5(B))$ such that $\mathrm{def}(\tau';\mu_{\pi})=0$, $\tau'(\sigma_i(x))=0$ for all $x \in \mathcal{M}_4(U_i)\setminus\{1\}$, $i \in [m]$, and $\tau'(\sigma_i(x)\sigma_j(y)) = 0$ for all $x \in \mathcal{M}_2(U_i)$, $y \in \mathcal{M}_2(U_j)$, $i \neq j \in [m]$ with $x \neq y$. By Lemma [9.8,](#page-31-1) part (d), there is a tracial state $\tilde{\tau}$ on $\mathcal{A}(\text{Tab}(\text{Obl}_5(B)))$

with def $(\widetilde{\tau}; \mu_{\pi}) = 0$, $\widetilde{\tau}(u) = \tau'(u)$ for all monomials u in $\{\sigma_i(x) : i \in [m], x \in U_i\}$, and $\tilde{\tau}(u\sigma_i(z)^a v) = 0$ for all $i \in [m]$, $z \in R_i$, $1 \le a < 120$, and monomials u, v in $\{\sigma_j(x) : j \in [m], x \in U_j \cup R_j\}$ which do not contain z. Observe that $\tilde{\tau}(1) = 1$, and $\tilde{\tau}(\sigma_i(x)) = 0$ for all $x \in \Lambda_{i,4}$. Similarly, if $x \in \Lambda_{i,2}$ and $y \in \Lambda_{i,2}$ are not equal, then $\tilde{\tau}(\sigma_i(x)\sigma_j(y)) = 0$. By Proposition [6.3,](#page-16-0) def $(\tilde{\tau}; \mu_{inter}) = 0$, and since $\pi(i, j) > 0$ for all $i, j \in [m]$, $\|\sigma_i(x) - \sigma_j(x)\|_{\tilde{\tau}} = 0$ for all $x \in U_i \cap U_j$. Since $\|\cdot\|_{\tilde{\tau}}$ is unitarily bi-invariant, we get that $\|\sigma_i(x) - \sigma_j(x)\|_{\tilde{\tau}} = 0$ for all $x \in \mathcal{M}(U_i \cap U_j)$, and hence $\tilde{\tau}(\sigma_i(x)\sigma_j(x)) = 1$ for all $x \in \mathcal{M}(U_i \cap U_j)$. It follows that $\tilde{\tau}|_{\Lambda} = f$, so $p(\phi, \psi|ij, kl) = \tilde{\tau} \circ \alpha(\Phi_{W_{ij}, \phi} \Phi_{W_{kl}, \psi})$ for all $\phi \in D_{ij}, \psi \in D_{kl}, i, k \in [m], j \in [m_i],$ $l \in [m_k]$. We conclude that $p \in C_{qc}$. If $\mathcal{A}(B)$ has a perfect strategy in C_{qa} (resp. C_q), then we can take τ to be Connes-embeddable (resp. finite-dimensional), so $\tilde{\tau}$ will be Connes-embeddable (resp. finite-dimensional), and $p \in C_{qa}$ (resp. C_q). will be Connes-embeddable (resp. finite-dimensional), and $p \in C_{qa}$ (resp. C_q).

Remark 9.13. The correlation p in Proposition [9.12](#page-36-1) is described algebraically. Alternatively, it's not hard to see that the correlation $p(\phi, \psi|ij, kl)$ can be simulated using the following procedure: If neither (W_{ij}, D_{ij}) or (W_{kl}, D_{kl}) has type (3), then pick an assignment to the variables $Z \cup R$ uniformly at random, and fill in the variables $T_i(p,q)$ so that the constraints (W_{ij}, D_{ij}) of types (1), (2), and (4) are satisfied, to get an assignment γ to Y. Output $\phi = \gamma|_{W_{ij}}$ and $\psi = \gamma|_{W_{kl}}$. If one of (W_{ij}, D_{ij}) or (W_{kl}, D_{kl}) has type (3), then for each $r \in [m]$, pick an assignment to R_r and a satisfying assignments to (U_r, E_r) uniformly at random, and fill in the variables $T_j(p,q)$ to get a satisfying assignment γ_r to (W_r, D_r) . Output $\phi = \gamma_i|_{W_{ij}}$ and $\psi = \gamma_k|_{W_{kl}}$. This procedure will output ϕ, ψ with probability $p(\phi, \psi|ij, kl)$.

The description of the correlation p in Remark [9.13](#page-39-0) is simpler than the algebraic description. On the other hand, without the algebraic description, it's harder to see that the correlation generated in Remark [9.13](#page-39-0) is quantum when $\mathcal{A}(B)$ has a perfect quantum strategy. In fact, if we use three-row tableaux rather than fourrow tableaux in Definition [9.6,](#page-30-0) then the procedure in Remark [9.13](#page-39-0) is still welldefined, and simulates a perfect strategy for the game. However, by Remark [9.11,](#page-36-0) the simulated correlation is not necessarily quantum even if $\mathcal{A}(B)$ has a perfect quantum strategy — something that is not immediately apparent from the description of the procedure.

We are now ready to prove our main result about constructing perfect zero knowledge protocols:

Theorem 9.14. Let $(\{\mathcal{G}(B_x, \pi_x)\}, S, C)$ be a BCS-MIP^{*} protocol for a language $\mathcal L$ with completeness 1 and soundness $1 - f(x)$, such that each context of B_x has constant size, and π_x is maximized on the diagonal. Then there is a PZK-BCS- MIP^* protocol $(\{\mathcal{G}(B_x', \pi_x')\}, \widetilde{S}, \widetilde{C})$ for $\mathcal L$ with completeness 1 and soundness 1 – $f(x)/poly(m_x)$, where m_x is the number of contexts in B_x . If π_x is uniform, then π_x' is also uniform, and if $\mathcal{G}(B_x,\pi_x)$ has a perfect finite-dimensional tracial state, then so does $\mathcal{G}(B'_x, \pi'_x)$.

Proof. Let $B'_x = \text{Tab}_{sub}(\text{Obl}_5(B_x))$, and let π'_x be the subdivision of π_x corresponding to the subdivision of $\text{Tab}(\text{Obl}_5(B_x))$ into $\text{Tab}_{sub}(\text{Obl}_5(B_x))$. If π_x is uniform, then π'_x is also uniform. Let p_x be the correlation for $\mathcal{G}(B'_x, \pi'_x)$ defined in Proposi-tion [9.12.](#page-36-1) Because B_x has contexts of constant size, $\text{Obl}_5(B_x)$ and Tab $(\text{Obl}_5(B_x))$ also have contexts of constant size. As a result, the number of clauses in the constraints of Tab $(Obl_5(B_x))$ is constant, as is the size of each clause (where by clause we mean the constraints of type $(1)-(4)$ in Definition [9.6\)](#page-30-0). Hence the Turing machines S and C can be turned into Turing machines \widetilde{S} and \widetilde{C} such that $(\{\mathcal{G}(B_x', \pi_x')\}, \widetilde{S}, \widetilde{C})$ is a BCS-MIP^{*} protocol. Similarly, since all the constraints of $Tab(Obl₅(B))$ have constant size, there is a Turing machine which, given questions and answers i, j, ϕ, ψ for $\mathcal{G}(B'_x, \pi'_x)$, can produce $p_x(\phi, \psi | i, j)$ in polynomial time in i, j, and x. Since the number of answers for any question is constant, the correlation p_x can be simulated in polynomial time in x .

If $x \in \mathcal{L}$, then B_x has a perfect strategy in C_{qa} , so $p_x \in C_{qa}$, and hence $\mathcal{G}(B'_x, \pi'_x)$ has a perfect strategy in C_{qa} . Similarly, if B_x has a perfect strategy in C_q , then $\mathcal{G}(B'_x, \pi'_x)$ has a perfect strategy in C_q as well. Conversely, suppose that τ is a tracial state on $\mathcal{A}(B_x')$. Since the size of contexts and number of clauses in each constraint of Tab $(\text{Ob}_5(B_x))$ are constant, the parameters C, M, and K in Theo-rem [7.5](#page-20-1) when going from Tab $(\text{Obl}_5(B_x))$ to Tab_{sub} $(\text{Obl}_5(B_x))$ are all constant. Since Tab $(\text{Obl}_5(B_x))$ has m_x contexts, Theorem [7.5](#page-20-1) implies that there is a tracial state τ_0 on $\mathcal{A}(\text{Tab}(\text{Ob}_5(B_x)))$ with $\text{def}(\tau_0) \leq \text{poly}(m_x) \text{def}(\tau)$. Since there is a classical homomorphism $A(B_x) \rightarrow A(\text{Tab}(\text{Obl}_5(B_x)))$ by Lemmas [9.4](#page-28-0) and [9.8,](#page-31-1) we conclude that there is a tracial state τ_1 on $\mathcal{A}(B_x)$ with $\text{def}(\tau) \leq \text{poly}(m_x) \text{def}(\tau)$. Hence if $x \notin \mathcal{L}$, then there is no synchronous strategy p for $\mathcal{G}(B'_x, \pi'_x)$ with $\omega_q(\mathcal{G}(B'_x, \pi'_x), p) \geq$ $1 - f(n) / \text{poly}(m_x)$. Hence $(\{\mathcal{G}(B_x', \pi_x')\}, \widetilde{S}, \widetilde{C})$ is a BCS-MIP^{*} protocol for $\mathcal L$ with soundness $1 - f(x)/\text{poly}(m_x)$.

Theorem 9.15. There is a perfect zero knowledge BCS-MIP^{*} $(2, 1, 1, 1-1/\text{poly}(n))$ protocol for the halting problem in which the verifier selects questions according to the uniform distribution, the questions have length $\text{polylog}(n)$, and the answers have constant length. Furthermore, if a game in the protocol has a perfect strategy, then it has a perfect synchronous quantum strategy.

Proof. By Theorem [3.2,](#page-9-0) there is a BCS-MIP^{*} protocol $(\{\mathcal{G}(B_x, \pi_x)\}, S, V)$ for the halting problem with constant soundness $s < 1$, in which B_x has a constant number of contexts and contexts of size polylog $(|x|)$, and π_x is the uniform distribution on pairs of contexts. Furthermore, if $\mathcal{G}(B_x, \pi_x)$ has a perfect strategy, then it has a perfect synchronous quantum strategy. By Remark [6.8,](#page-18-3) $(\{\mathcal{G}(B_x, \pi_x)\}, S, C)$ can be turned into a BCS-MIP^{*} protocol $(\{\mathcal{G}(B_x', \pi_x)\}, S, C)$ where $B_x' = (X_x', \{(W_i^x, D_i^x)\}),$ D_i is a 3SAT instance with number of clauses polynomial in |x|, and $|W_i^x|$ is polynomial in |x|. Then by subdividing the B'_x into a 3SAT we obtain a 3SAT protocol nomial in [x]. Then by subdividing the D_x into a 3SAT we obtain a 3SAT protocol $(\{\mathcal{G}(B_x^{3SAT}, \pi_x^{3SAT})\}, S, C)$ with number of clauses polynomial in [x], and π_x^{3SAT}
is uniform. There is a 1-homomorphism $\mathcal{A}(B_x^{3SAT}, \mu_{$ $\mathcal{G}(B_x, \pi_x)$ has a perfect synchronous quantum strategy, so does $\mathcal{G}(B_x^{3SAT}, \pi_x^{3SAT})$. The theorem follows from Theorem [9.14.](#page-39-1)

Proof of Theorem [1.1.](#page-1-0) By the discussion after Theorem [3.2,](#page-9-0) it is enough to show that there is a two-prover one-round perfect zero knowledge MIP˚ protocol for the halting problem with completeness 1, soundness $1/2$, and uniform probability distribution. Let $(\{\mathcal{G}(B_x, \pi_x)\}, S, C)$ be the BCS-MIP^{*} protocol from Theorem [9.15,](#page-40-0) so in particular B_x has m_x contexts, where $m_x = \text{poly}(|x|)$, and π_x is the uniform distribution on $[m_x] \times [m_x]$. Since the uniform distribution is $1/2m_x$ -diagonally dominant, Theorem [3.1](#page-8-0) implies that $(\mathcal{G}(B_x, \pi_x), S, C)$ has soundness $1-1/{\rm poly}(n)$ when considered as a MIP˚ protocol. The result follows from Theorem [8.1](#page-26-1) using a polynomial amount of parallel repetition.

As mentioned in the introduction, the proof of Theorem [1.1](#page-1-0) implies that the halting problem is many-one reducible to membership in C_q . In fact, there is a reduction such that if the Turing machine does not halt, then the corresponding correlation is bounded away from the closure C_{qa} of C_q :

Corollary 9.16. There is a polynomial-time computable function p from Turing machines to synchronous correlations such that if M halts then $p(M) \in C_q^s$, and if M does not halt then there is a linear functional f on the space of correlations such that $f(p(M)) = 1$ and $f(p') \leq 1/2$ for all $p' \in C_{qa}$.

Proof. Let $(\{\mathcal{G}(B_M, \pi_M)\}, S, C)$ be the BCS-MIP^{*} protocol for the halting problem with completeness one and soundness $1/2$ constructed in the proof of Theorem [1.1,](#page-1-0) where the index M runs through Turing machines. Let $p(M)$ be the correlation for $\mathcal{G}(B_M, \pi_M)$ as in Definition [9.1.](#page-27-0) That $p(M)$ is in C_q follows from Theorem [9.15,](#page-40-0) and the fact that if $p \in C_q$, then $p^{\otimes n} \in C_q$. The corollary then follows with the linear functional f defined by $f(p') = \omega(\mathcal{G}(B_M, \pi_M), p')$). $\qquad \qquad \Box$

Note that the number of inputs and outputs for the correlation $p(M)$ depends on the size of the Turing machine M.

Finally, we also have:

Theorem 9.17. PZK-BCS-MIP^{co} $(2, 1, 1, 1 - 1/\text{poly}(n)) = BCS-MIP^{co}(2, 1, 1, 1 1/\text{poly}(n)$).

The proof is similar to the proof of Theorem [9.15.](#page-40-0)
