How much symmetry do symmetric measurements need for efficient operational applications?

Katarzyna Siudzińska

Institute of Physics, Faculty of Physics, Astronomy and Informatics, Nicolaus Copernicus University in Toruń, ul. Grudziądzka 5, 87–100 Toruń, Poland

We introduce a generalization of symmetric measurements to collections of unequinumerous positive, operator-valued measures (POVMs). For informationally complete sets, we propose construction methods from orthonormal Hermitian operator bases. The correspondence between operator bases and measurements can be as high as four-to-four, with a one-to-one correspondence following only under additional assumptions. Importantly, it turns out that some of the symmetry properties, lost in the process of generalization, can be recovered without fixing the same number of elements for all POVMs. In particular, for a wide class of unequinumerous symmetric measurements that are conical 2-designs, we derive the index of coincidence, entropic uncertainty relations, and separability criteria for bipartite quantum states.

1. INTRODUCTION

Quantum measurements are important tools widely used in many quantum information processing tasks. Their applications include quantum communication protocols [\[1,](#page-13-0) [2\]](#page-13-1), quantum filtering [\[3\]](#page-13-2), entanglement detection [\[4\]](#page-13-3), quantum teleportation [\[5\]](#page-13-4), and quantum tomography [\[6](#page-13-5)]. In quantum information theory, measurements are represented via positive operator-valued measures (POVMs), which are sets of positive operators that sum up to the identity operator. Examples of popular POVMs are symmetric, informationally complete (SIC) POVMs [\[7\]](#page-13-6) and mutually unbiased bases (MUBs) [\[8,](#page-13-7) [9](#page-13-8)]. Both SIC POVMs and MUBs are projective measurements because their elements are rank-1 projectors. Their non-projective counterparts – general SIC POVMs and mutually unbiased measurements (MUMs) [\[10,](#page-13-9) [11\]](#page-13-10) – find uses in quantum state discrimination and other postprocessing tasks [\[12,](#page-13-11) [13\]](#page-13-12).

Recently, there has been an increased interest in generalizations of SIC POVMs. Semi-SIC POVMs relax the condition for measurement operators to be of equal trace [\[14\]](#page-13-13). This simple change leads to discrete values of the Hilbert-Schmidt product between different measurement operators in any $d \geq 3$. An analogical property is observed in equioverlapping measurements, which additionally drop the condition of informational completeness [\[15](#page-13-14)[–17](#page-13-15)]. Importantly, both semi-SIC POVMs and equioverlapping measurements are composed of rank-1 projectors.

On a different note, there is a generalization of both SIC POVMs and MUBs that allows for non-projective measurements. Symmetric measurements, or (N, M) -POVMs, are collections of N mutually unbiased POVMs, each with M elements [\[18\]](#page-13-16). Despite being a relatively recent construction, symmetric measurements have already found applications in characterizations of entropic uncertainty relations [\[19,](#page-13-17) [20](#page-13-18)], average coherences [\[21](#page-13-19)], quantum steerability [\[22\]](#page-13-20), and the Brukner-Zeilinger invariants [\[23\]](#page-13-21). Other implementations of (N, M) -POVMs include optimal state estimation [\[24\]](#page-13-22) and entanglement detection via improved separability criteria [\[25](#page-13-23)[–29](#page-13-24)] or entanglement witnesses [\[30](#page-13-25)].

In this paper, we provide a further generalization of (N, M) -POVMs by relaxing the requirement for equal number of POVM elements. In other words, we introduce collections of N POVMs \mathcal{E}_{α} , where each consists in M_{α} measurement operators. This simple change greatly increases the number of characteristic parameters and complexity, especially for high values of N. Now, we pose two important questions: (i) How much symmetry can be recovered without assuming that $M_{\alpha} = M_{\beta}$? (ii) Which properties and applications carry over to his generalization?

We start from a definition of generalized symmetric measurements in any finite dimension. We show that they form an informationally complete set if and only if the total number of measurement operators is $d^2 + N - 1$. Next, we propose four methods of construction from Hermitian orthonormal bases and analyze when these methods give rise to distinct collections of measurement operators. A separate section is dedicated to symmetrizations of generalized symmetric measurements that do not restrict the numbers of POVM elements. Of particular interest if a wide class of unequinumerous symmetric measurements that is a conical 2-design. As it turns out, it possesses enough symmetry properties to allow for analytical calculations of the index of coincidence, entropic uncertainty relations, and separability criteria for bipartite quantum states.

2. GENERALIZED SYMMETRIC MEASUREMENTS

Recently, we have introduced the notion of a symmetric measurement $\{E_{\alpha,k}; k = 1, \ldots, M; \alpha = 1, \ldots, N\}$ called an (N, M) -POVM. From definition, it is a collection of N POVMs with M elements each [\[18\]](#page-13-16). Its distinguishing property is that the measurement operators $E_{\alpha,k}$ satisfy strong symmetry conditions

$$
\text{Tr}(E_{\alpha,k}) = w,
$$

\n
$$
\text{Tr}(E_{\alpha,k}^2) = x,
$$

\n
$$
\text{Tr}(E_{\alpha,k}E_{\alpha,\ell}) = y, \qquad \ell \neq k,
$$

\n
$$
\text{Tr}(E_{\alpha,k}E_{\beta,\ell}) = z, \qquad \beta \neq \alpha,
$$

\n(1)

where

$$
w = \frac{d}{M}, \qquad y = \frac{d - Mx}{M(M-1)}, \qquad z = \frac{d}{M^2}, \tag{2}
$$

and x is a free parameter from the range

$$
\frac{d}{M^2} < x \le \min\left\{\frac{d^2}{M^2}, \frac{d}{M}\right\}.\tag{3}
$$

Projective measurements follow for $x = d^2/M^2$, which lies in the admissible range only for $M \ge d$. It has been shown that there exist at least four informationally complete families of (N, M) -POVMs in $d \geq 3$. In $d = 2$, this number drops to two: general SIC POVMs and mutually unbiased measurements. Therefore, (N, M) -POVMs can be viewed as collections of mutually unbiased symmetric POVMs. Partial conditions for the existence of symmetric measurements for the maximal value of x have recently been proposed [\[31](#page-13-26)].

In what follows, we consider a natural generalization of (N, M) -POVMs by taking a collection $\mathcal{E} = \{E_{\alpha,k}; k =$ $1, \ldots, M_{\alpha}; \alpha = 1, \ldots, N$ of N POVMs that no longer have to be equinumerous (in general, $M_{\alpha} \neq M_{\beta}$ for $\alpha \neq \beta$). Now, the symmetry conditions depend on the chosen POVM α but not on its element k.

Definition 1. A generalized symmetric measurement is a set of N POVMs $\mathcal{E}_{\alpha} = \{E_{\alpha,k}; k = 1,\ldots,M_{\alpha}\}\$ such that

$$
\operatorname{Tr}(E_{\alpha,k}) = w_{\alpha},
$$

\n
$$
\operatorname{Tr}(E_{\alpha,k}^{2}) = x_{\alpha},
$$

\n
$$
\operatorname{Tr}(E_{\alpha,k}E_{\alpha,\ell}) = y_{\alpha}, \qquad \ell \neq k,
$$

\n
$$
\operatorname{Tr}(E_{\alpha,k}E_{\beta,\ell}) = z_{\alpha\beta}, \qquad \beta \neq \alpha.
$$
\n(4)

In Appendix [Asection*.12,](#page-8-0) we show that the defining parameters are constrained by

$$
w_{\alpha} = \frac{d}{M_{\alpha}}, \qquad y_{\alpha} = \frac{d - M_{\alpha} x_{\alpha}}{M_{\alpha}(M_{\alpha} - 1)}, \qquad z_{\alpha\beta} = \frac{d}{M_{\alpha} M_{\beta}},
$$
\n
$$
(5)
$$

where the free parameters x_{α} belong to the range

$$
\frac{d}{M_{\alpha}^2} < x_{\alpha} \le \min\left\{\frac{d^2}{M_{\alpha}^2}, \frac{d}{M_{\alpha}}\right\}.\tag{6}
$$

Additionally, the total number of measurement operators

$$
\sum_{\alpha=1}^{N} M_{\alpha} \le d^2 + N - 1 \tag{7}
$$

is constrained by the dimension d and the number of POVMs N . The equality is reached if and only if the generalized symmetric measurement is informationally complete, which is proven in Appendix [Bsection*.13.](#page-8-1)

Note that the generalized symmetric measurement can be understood as a collection of $N(1, M_{\alpha})$ -POVMs, each characterized by its own parameter x_{α} . The (N, M) -POVMs are recovered if all $M_{\alpha} = M$ and $x_{\alpha} = x$. Therefore, there exists a subclass of equinumerous generalized symmetric measurements that are not (N, M) -POVMs due to x_{α} being dependent on the choice of a POVM \mathcal{E}_{α} .

Example 1. Contrary to (N, M) -POVMs, the generalized symmetric measurements introduce one new informationally complete class for $d = 2$. It corresponds to the choice $M_1 = 2$ and $M_2 = 3$. An example of projective measurements consists in $E_{1,1} = \text{diag}(1,0), E_{1,2} = \text{diag}(0,1),$ as well as

$$
E_{2,1} = \frac{1}{3} \begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}, \qquad E_{2,2} = \frac{1}{6} \begin{pmatrix} 2 & i + \sqrt{3} \\ -i + \sqrt{3} & 2 \end{pmatrix}, \qquad E_{2,3} = \frac{1}{6} \begin{pmatrix} 2 & i - \sqrt{3} \\ -i - \sqrt{3} & 2 \end{pmatrix}.
$$
 (8)

3. CONSTRUCTION METHODS

To construct informationally complete generalized symmetric measurements, let us take a Hermitian orthonormal operator basis $\{G_0 = \mathbb{I}_d/\sqrt{d}, G_{\alpha,k}; \alpha = 1, ..., N, k = 1, ..., M_{\alpha} - 1\}$ with traceless $G_{\alpha,k}$. We use it to define another set of traceless operators,

$$
H_{\alpha,k} = \begin{cases} G_{\alpha} - \sqrt{M_{\alpha}} (1 + \sqrt{M_{\alpha}}) G_{\alpha,k}, & k = 1, \dots, M_{\alpha} - 1, \\ (1 + \sqrt{M_{\alpha}}) G_{\alpha}, & k = M_{\alpha}, \end{cases}
$$
(9)

where $G_{\alpha} = \sum_{k=1}^{M_{\alpha}-1} G_{\alpha,k}$, so that $\sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} H_{\alpha,k} = 0$. The measurement operators follow from

$$
E_{\alpha,k} = \frac{1}{M_{\alpha}} \mathbb{I}_d + t_{\alpha} H_{\alpha,k},\tag{10}
$$

where t_{α} is related to x_{α} via

$$
t_{\alpha}^2 = \frac{M_{\alpha}^2 x_{\alpha} - d}{M_{\alpha}^2 (M_{\alpha} - 1)(1 + \sqrt{M_{\alpha}})^2}.
$$
\n
$$
(11)
$$

Moreover, the positivity condition $E_{\alpha,k} \geq 0$ imposes the following constraint on t_{α} ,

$$
-\frac{1}{M_{\alpha}} \frac{1}{\lambda_{\alpha, \max}} \le t_{\alpha} \le \frac{1}{M_{\alpha}} \frac{1}{|\lambda_{\alpha, \min}|},\tag{12}
$$

where $\lambda_{\alpha,\text{max}}$ and $\lambda_{\alpha,\text{min}}$ are the minimal and maximal eigenvalues from among all eigenvalues of $H_{\alpha,k}$, for a fixed α . It is straightforward to recover the inverse relation. That is, if the measurement operators are known, then the associated orthonormal Hermitian basis operators read

$$
G_{\alpha,k} = \frac{1}{t_{\alpha}M_{\alpha}(1+\sqrt{M_{\alpha}})^2} \Big[\mathbb{I}_d + \sqrt{M_{\alpha}} E_{\alpha,M_{\alpha}} - \sqrt{M}(1+\sqrt{M}) E_{\alpha,k} \Big]. \tag{13}
$$

Remark 1. Actually, there is a non-empty range of t_{α} , where $\pm t_{\alpha}$ correspond to the same value of x_{α} . Following eq. [\(12equation.3.12\)](#page-2-0), let us denote the boundary t_{α} by

$$
t_{\alpha_*} = \frac{1}{M_\alpha} \frac{1}{\max\left\{\lambda_{\max}, |\lambda_{\min}|\right\}}.\tag{14}
$$

In this case,

$$
E_{\alpha,k}^{(\pm)} = \frac{1}{M_{\alpha}} \mathbb{I}_d \pm t_{\alpha} H_{\alpha,k} \tag{15}
$$

are both valid generalized symmetric measurements for a positive $t_{\alpha} \leq t_{\alpha,*}$. Observe that

$$
\begin{aligned} \operatorname{Tr} E_{\alpha,k}^{(+)} E_{\alpha,k}^{(-)} &= 2z_{\alpha\alpha} - x_{\alpha}, \\ \operatorname{Tr} E_{\alpha,k}^{(+)} E_{\alpha,\ell}^{(-)} &= y_{\alpha} - \frac{2}{M_{\alpha} - 1} z_{\alpha\alpha}, \qquad k \neq \ell. \end{aligned} \tag{16}
$$

In particular, $E_{\alpha,k}^{(+)}$ and $E_{\alpha,k}^{(-)}$ are orthogonal in the Hilbert-Schmidt inner product for $x_{\alpha} = 2d/M_{\alpha}^2$.

Example 2. As a simple example of mutually orthogonal $E_{\alpha,k}^{(+)}$ and $E_{\alpha,k}^{(-)}$, consider the POVM with $M_{\alpha} = 2$ measurement operators, characterized by $x_{\alpha} = d/M_{\alpha}$. Then, $y_{\alpha} = 0$ and

$$
\operatorname{Tr} E_{\alpha,k}^{(+)} E_{\alpha,k}^{(-)} = 0,
$$

\n
$$
\operatorname{Tr} E_{\alpha,k}^{(+)} E_{\alpha,\ell}^{(-)} = \frac{d}{2}.
$$
\n(17)

In the special case of $d = 2$ (MUBs), ${E_{\alpha,k}^{(+)}}={E_{\alpha,k}^{(-)}}$.

Example 3. In $d = 3$, let us take two diagonal elements of a Hermitian orthonormal basis [\[31](#page-13-26)],

$$
G_1 = \frac{1}{\sqrt{3}(\sqrt{3}+1)} \begin{pmatrix} -2-\sqrt{3} & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1+\sqrt{3} \end{pmatrix}, \qquad G_2 = \frac{1}{\sqrt{3}(\sqrt{3}+1)} \begin{pmatrix} 1 & 0 & 0\\ 0 & -2-\sqrt{3} & 0\\ 0 & 0 & 1+\sqrt{3} \end{pmatrix}, \tag{18}
$$

and construct two (1,3)-POVMs $\mathcal{E}_{\pm} = \{E_{k,\pm}; k = 1, 2, 3\}$ using eq. [\(10equation.3.10\)](#page-2-1) (the index α is dropped). For $t > 0$, take $t = t_{\text{max}} = \frac{\sqrt{3}-1}{2\sqrt{3}}$, so that the corresponding measurement operators

$$
E_{1,+} = \text{diag}(1,0,0), \qquad E_{2,+} = \text{diag}(0,1,0), \qquad E_{3,+} = \text{diag}(0,0,1) \tag{19}
$$

are projectors onto the operational basis $(x_{+} = 1)$. For $t < 0$, take instead $t = t_{\min} = \frac{1-\sqrt{3}}{4\sqrt{3}}$ $\frac{1-\sqrt{3}}{4\sqrt{3}}$, for which

$$
E_{1,-} = \frac{1}{2} \text{diag}(0,1,1), \qquad E_{2,-} = \frac{1}{2} \text{diag}(1,0,1), \qquad E_{3,-} = \frac{1}{2} \text{diag}(1,1,0) \tag{20}
$$

are rank-2 projectors $(x_0 = 1/2)$ and also orthonormal completions of respective $E_{k,+}$ to the identity operator. Note that $t_{\text{max}} \ge |t_{\text{min}}|$, and hence, even though we use the same formulas for $H_{\alpha,k}$, t_{max} allows for $x_+ > x_-$. However, we can construct

$$
\widetilde{E}_{k,\pm} = \frac{1}{3} \mathbb{I}_3 \pm t_* H_{\alpha,k}, \qquad t_* = \min\{t_{\max}, |t_{\min}|\} = |t_{\min}|.
$$
\n(21)

Obviously, $E_{k,-} = E_{k,-}$ remain unchanged. However, we have found another set of rank-2 projectors

$$
\widetilde{E}_{1,+} = \frac{1}{6} \text{diag}(4,1,1), \qquad \widetilde{E}_{2,+} = \frac{1}{6} \text{diag}(1,4,1), \qquad \widetilde{E}_{1,+} = \frac{1}{6} \text{diag}(1,1,4)
$$
\n(22)

characterized by $x_* = x_- = 1/2$.

The above method is in full analogy with the construction of (N, M) -POVMs [\[18\]](#page-13-16), which is based on the construction methods for general SIC POVMs [\[11\]](#page-13-10) and mutually unbiased measurements [\[10\]](#page-13-9). In these works, the correspondence between the measurement operators $E_{\alpha,k}$ and the basis operators $G_{\alpha,k}$ is stated to be one-to-one. However, as already seen in Example 2Example.2, this statement is incorrect. Moreover, there exists yet another correspondence based on an alternative way to introduce the operators $H_{\alpha,k}$ for the same set of $G_{\alpha,k}$. Namely, one defines

$$
H'_{\alpha,k} = \begin{cases} G_{\alpha} + \sqrt{M_{\alpha}} (1 - \sqrt{M_{\alpha}}) G_{\alpha,k}, & k = 1, \dots, M_{\alpha} - 1, \\ (1 - \sqrt{M_{\alpha}}) G_{\alpha}, & k = M_{\alpha}. \end{cases}
$$
(23)

We denote the associated measurement operators by

$$
E'_{\alpha,k} = \frac{1}{M_{\alpha}} \mathbb{I}_d + t'_{\alpha} H'_{\alpha,k},\tag{24}
$$

where the relation between the parameter t'_{α} and x_{α} reads

$$
t'^{2}_{\alpha} = \frac{M_{\alpha}^{2} x_{\alpha} - d}{M_{\alpha}^{2} (M_{\alpha} - 1)(1 - \sqrt{M_{\alpha}})^{2}}.
$$
\n(25)

Observe that $t'_\alpha \neq t_\alpha$ but instead $t'^2_\alpha(1-\sqrt{M_\alpha})^2 = t^2_\alpha(1+\sqrt{M_\alpha})^2$. For the sake of completion, we present the formulas for $G_{\alpha,k}$ in terms of $E'_{\alpha,k}$;

$$
G_{\alpha,k} = \frac{1}{t'_{\alpha}M_{\alpha}(1-\sqrt{M_{\alpha}})^2} \Big[\mathbb{I}_d - \sqrt{M_{\alpha}} E'_{\alpha,M_{\alpha}} + \sqrt{M}(1-\sqrt{M}) E'_{\alpha,k} \Big]. \tag{26}
$$

Now, let us compare the measurement \mathcal{E}_{α} and $\mathcal{E}'_{\alpha} = \{E'_{\alpha,k}; k = 1,\ldots,M_{\alpha}\}\$ that have been constructed using eqs. [\(10equation.3.10\)](#page-2-1) and [\(24equation.3.24\)](#page-3-0), respectively.

Proposition 1. Traceless orthonormal Hermitian operators $\{G_{\alpha,k}; k = 1, \ldots, M_{\alpha}\}\$ produce two POVMs \mathcal{E}_{α} , \mathcal{E}'_{α} with the same elements if and only if $M_{\alpha} \leq 3$ and $sgn(t_{\alpha}) = -sgn(t'_{\alpha}).$

The proof is given in Appendix [Csection*.14.](#page-9-0) Example 3Example.3 provides a simple subset of orthonormal Hermitian operator basis that construct $\mathcal{E}_{\alpha} = \mathcal{E}'_{\alpha}$ but with $E_{\alpha,k} \neq E'_{\alpha,k}$.

An analogical reasoning to that of Remark 1 also follows for $E'_{\alpha,k}$. This means that, for $M_\alpha \ge 4$ and sufficiently small x_{α} , there exist a total of four ways of constructing $(1, M_{\alpha})$ -POVMs from the same $\{G_{\alpha,k}; k = 1, \ldots, M_{\alpha}\}$. Moreover, each $(1, M_\alpha)$ -POVM inside the same generalized symmetric measurement can be constructed using a different method due to $H_{\alpha,k}$ and $H'_{\beta,\ell}$ being mutually orthogonal for $\beta \neq \alpha$.

Remark 2. The presented construction methods provide up to 4N distinct (generalized) symmetric measurements that arise from the same partition $\{G_{\alpha,k}; k = 1, \ldots, M_{\alpha}; \alpha = 1, \ldots, N\}$ of traceless orthonormal Hermitian operators.

An example for $N = 1$ is presented in Appendix [Dsection*.15.](#page-10-0) Whether there exist unequivalent constructions that use a parametrization of $H_{\alpha,k}$ different from

$$
H_{\alpha,k} = \begin{cases} G_{\alpha} + AG_{\alpha,k}, & k = 1, \dots, M_{\alpha} - 1, \\ BG_{\alpha}, & k = M_{\alpha}, \end{cases}
$$
 (27)

where A and B are constants, is an open question.

4. RECOVERING SYMMETRIES OF MEASUREMENTS

Due to their high symmetry, the (N, M) -POVMs are characterized via only four parameters: (w, x, y, z) . In the process of generalization to the generalized symmetric measurements, which are collections of POVMs that are in general unequinumerous, some of this symmetry is lost. In particular, one now needs N sets of parameters $(w_\alpha, x_\alpha, y_\alpha, z_{\alpha\beta})$ to characterize them. Luckily, there are certain cases in which it is possible to recover some of the symmetry conditions of the (N, M) -POVMs. In Section 2, we have already discussed equinumerous measurements $(M_\alpha = M)$, which correspond to $w_\alpha = w$ and $z_{\alpha,\beta} = z$. On the contrary, if $z_{\alpha\beta} = z$, then equinumerous measurements follow only for $N \geq 3$, which will allow for further symmetrization of other special classes that are listed below.

- If $\max\{d/M_{\alpha}^2\} < x \leq \min\{d/M_{\alpha}, d^2/M_{\alpha}^2\}$ is a non-empty set, then there exist generalized symmetric measurements for which $x_{\alpha} = x$. However, $y_{\alpha} = y_{\beta}$ only for $M_{\alpha} = M_{\beta}$.
- If $\max\{0, \frac{d(M_\alpha-d)}{M_\alpha^2(M_\alpha-1)}\} < y \le \min\{d/M_\alpha^2\}$ is a non-empty set, then there exist generalized symmetric measurements such that $y_{\alpha} = y$. In this case, $x_{\alpha} = w_{\alpha} - y(M_{\alpha} - 1) \neq x_{\beta}$ for $M_{\alpha} \neq M_{\beta}$.

Example 4. In $d = 2$, the only unequinumerous generalized symmetric measurements that are also informationally complete follow from $M_1 = 2$ and $M_2 = 3$. Note that $z_{12} = z_{21} = 1/3$ is constant, even though $w_1 \neq w_2$. As unequinumerous measurements allow for at most two α -independent parameters, we now consider two distinct classes.

- (i) There is no measurement with $x_1 = x_2 = x$ due to $1/2 < x \le 4/9$ being an empty set. However, already for $d = 3$, the range $3/4 < x \leq 1$ of x is non-empty.
- (ii) There exist measurements with $y_1 = y_2 = y$, where $1/9 < y \le 2/9$. In this case, $x_1 = 1 y$ and $x_2 = 2/3 2y$.

In the upcoming section, it will become evident that other forms of symmetry are even more important for the applicational purposes.

Proposition 2. If the generalized symmetric measurement is characterized by

$$
x_{\alpha} = \frac{d + rM_{\alpha}(M_{\alpha} - 1)}{M_{\alpha}^2}, \qquad y_{\alpha} = \frac{d - rM_{\alpha}}{M_{\alpha}^2}
$$
(28)

with the constant parameter r from the range

$$
0 < r \le \min\left\{\frac{d}{M_{\alpha}}, \frac{d(d-1)}{M_{\alpha}(M_{\alpha}-1)}\right\},\tag{29}
$$

then $x_{\alpha} - y_{\alpha} = r$.

Proposition 3. If the generalized symmetric measurement is characterized by

$$
x_{\alpha} = \frac{d}{M_{\alpha}^2} [1 + s(M_{\alpha} - 1)], \qquad y_{\alpha} = \frac{d}{M_{\alpha}^2} (1 - s), \tag{30}
$$

where the parameter s satisfies

$$
0 < s \le \min\left\{1, \frac{d-1}{M_\alpha - 1}\right\},\tag{31}
$$

then $x_{\alpha} - y_{\alpha} = sw_{\alpha}$.

In particular, for the class of generalized symmetric measurements from Example 4Example.4, the maximal value of $x_{\alpha} - y_{\alpha} = r$ is $r_{\text{max}} = 1/3$. On the other hand, if $x_{\alpha} - y_{\alpha} = sw_{\alpha}$, then $s_{\text{max}} = 1/2$.

5. APPLICATIONS

5.1. Conical 2-designs

Complex projective 2-designs are families or rank-1 projectors P_k , where $\sum_k P_k \otimes P_k$ commutes with $U \otimes U$ for any unitary operator U. Important examples include SIC POVMs and mutually unbiased bases. Their applications include quantum state tomography [\[32,](#page-13-27) [33\]](#page-13-28), quantum key distribution [\[34,](#page-13-29) [35\]](#page-13-30), and quantum entanglement detection [\[36,](#page-13-31) [37\]](#page-13-32). Appleby and Graydon introduced a generalization to conical 2-designs by replacing rank-1 projectors P_k with positive operators E_k [\[38](#page-13-33), [39\]](#page-13-34). From definition, it follows that E_k are conical 2-designs if and only if

$$
\sum_{k} E_k \otimes E_k = \kappa_+ \mathbb{I}_d \otimes \mathbb{I}_d + \kappa_- \mathbb{F}_d,\tag{32}
$$

where $\kappa_+ \geq \kappa_- > 0$ and $\mathbb{F}_d = \sum_{m,n=1}^d |m\rangle\langle n| \otimes |n\rangle\langle m|$ is the flip operator [\[38\]](#page-13-33). Known conical 2-designs include general SIC POVMs and mutually unbiased measurements [\[40\]](#page-13-35). Recently, it has been shown that informationally complete (N, M) -POVMs are also conical 2-designs [\[24](#page-13-22), [41](#page-13-36)].

Let us show that eq. [\(32equation.5.32\)](#page-5-0) is satisfied for even more general measurements. We start by introducing N linear maps

$$
\Phi_{\alpha}[X] = \sum_{k=1}^{M_{\alpha}} E_{\alpha,k} \text{Tr}(X E_{\alpha,k}),\tag{33}
$$

the maximally depolarizing channel $\Phi_0[X] = \mathbb{I}_d \text{Tr}(X)/d$, and the identity operator 1l. In Appendix [Esection*.16,](#page-10-1) we prove that if

$$
\sum_{\alpha=1}^{N} \Phi_{\alpha} = \kappa_{-}1 + \kappa_{+} d\Phi_{0},\tag{34}
$$

then the corresponding $E_{\alpha,k}$ are a conical 2-design

$$
\sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} E_{\alpha,k} \otimes E_{\alpha,k} = \kappa_{+} \mathbb{I}_{d} \otimes \mathbb{I}_{d} + \kappa_{-} \mathbb{F}_{d}
$$
\n(35)

characterized by the same values of κ_{\pm} . However, for arbitrary generalized symmetric measurements, the condition in eq. [\(34equation.5.34\)](#page-5-1) turns out to be too strong. It becomes necessary to impose the additional constraints on the measurement operators.

Proposition 4. If $E_{\alpha,k}$ belong to the class of measurements from Proposition 2Proposition.2, for which $x_{\alpha} - y_{\alpha} = r$, then they are a conical 2-design with

$$
\kappa_+ = \mu - \frac{r}{d}, \qquad \kappa_- = r. \tag{36}
$$

For the proof, see Appendix [Fsection*.17.](#page-11-0) Analogical calculations can be repeated for the measurements from Proposition 3Proposition.3, for which instead $x_{\alpha} - y_{\alpha} = sw_{\alpha}$. In this case, one first constructs entanglement breaking channels Φ_α such that

$$
\widetilde{\Phi}_{\alpha}[X] = \sum_{k=1}^{M_{\alpha}} \frac{1}{w_{\alpha}} E_{\alpha,k} \text{Tr}(E_{\alpha,k} X), \qquad \sum_{\alpha=1}^{N} \widetilde{\Phi}_{\alpha} = s \mathbb{1} + (N - s) \Phi_{0}.
$$
\n(37)

However, as it turns out, these measurements are not conical 2-designs. Rather than eq. [\(32equation.5.32\)](#page-5-0), they satisfy

$$
\sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} \frac{1}{w_{\alpha}} E_{\alpha,k} \otimes E_{\alpha,k} = \kappa_{+} \mathbb{I}_{d} \otimes \mathbb{I}_{d} + \kappa_{-} \mathbb{F}_{d},
$$
\n(38)

which reduces to conical 2-designs only in a very special case of mutually unbiased bases $(w_\alpha = 1)$. For more details, see Appendix [Gsection*.18.](#page-11-1)

5.2. Index of coincidence

From definition, the index of coincidence is a sum of squared probabilities [\[42\]](#page-13-37). For the generalized symmetric measurements, one has

$$
C = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} p_{\alpha,k}^{2},
$$
\n(39)

where the probability distributions $\{p_{\alpha,k}; k = 1, \ldots, M_{\alpha}\}\$ follow from the expansion of a mixed state

$$
\rho = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} p_{\alpha,k} F_{\alpha,k},\qquad(40)
$$

in the dual frame (see Appendix [Hsection*.19\)](#page-12-0)

$$
F_{\alpha,k} = \frac{1}{x_{\alpha} - y_{\alpha}} \left[E_{\alpha,k} - \frac{1}{d} \mathbb{I}_d \left(w_{\alpha} - \frac{x_{\alpha} - y_{\alpha}}{N} \right) \right]. \tag{41}
$$

Calculating the index of coincidence is crucial in order to derive entropic uncertainty relations and separability criteria, as will be seen in the upcoming subsections. Once again, it turns out that obtaining an analytical formula for C is possible only for a special class of measurements.

Proposition 5. If $E_{\alpha,k}$ belong to the class of measurements from Proposition 2Proposition.2, for which $x_{\alpha} - y_{\alpha} = r$, then the index of coincidence C is bounded by

$$
C \le C_{\text{max}} = \frac{d-1}{d}r + \mu,\tag{42}
$$

where $\mu = \sum_{\alpha=1}^{N} M_{\alpha}^{-1}$.

The proof is provided in Appendix [Isection*.20.](#page-12-1) The upper bound C_{max} is reached on pure states.

5.3. Entropic uncertainty relations

Uncertainty relations are one of the fundamental concepts in quantum theory. In quantum information, they are ofter expressed in terms of entropies for probability distributions associated with measurement operators. Entropic uncertainty relations have important applications e.g. in quantum cryptography [\[43](#page-13-38), [44](#page-13-39)] and quantum entanglement [\[45,](#page-13-40) [46\]](#page-13-41). An important problem is finding bounds for sums of entropies [\[47,](#page-13-42) [48\]](#page-13-43).

We derive entropic uncertainty relations for the generalized symmetric measurements in terms of the index of coincidence. For the Shannon entropy $H(\mathcal{E}_{\alpha}, \rho) = -\sum_{k=1}^{M_{\alpha}} p_{\alpha,k} \log p_{\alpha,k}$ associated with the measurement $\mathcal{E}_{\alpha} = \{E_{\alpha,k}; k = 1, 2, \ldots, n\}$ $1, \ldots, M_{\alpha}$, one finds

$$
\frac{1}{N} \sum_{\alpha=1}^{N} H(\mathcal{E}_{\alpha}, \rho) \ge \log \frac{N}{C}.
$$
\n(43)

The proof is analogical to this in ref. [\[18\]](#page-13-16). It uses the concavity of logarithms and Jensen's inequality $H(\mathcal{E}_{\alpha}, \rho) \geq$ $R(\mathcal{E}_{\alpha}, \rho)$ [\[49,](#page-13-44) [50](#page-13-45)], where the Rényi 2-entropy $R(\mathcal{E}_{\alpha}, \rho) = -\log \sum_{k=1}^{M_{\alpha}} p_{\alpha,k}^2$ [\[51\]](#page-13-46).

In particular, if $d = 2$, there is the following relation for the lower bounds from eq. [\(43equation.5.43\)](#page-6-0),

$$
\left. \frac{N}{C_{\text{max}}} \right|_{\text{SIC}} = \log 3 \ge \left. \frac{N}{C_{\text{max}}} \right|_{\text{GSM}} = \log 2 \ge \left. \frac{N}{C_{\text{max}}} \right|_{\text{MUB}} = \log \frac{3}{2},\tag{44}
$$

where GSM are the generalized symmetric measurements from Example 4Example.4 with the maximal value of $r = 1/3$. Interestingly, a pair of unequinumerous measurements corresponds to a higher entropic bound than a triple of mutually unbiased bases.

5.4. Separability criteria

Quantum entanglement is a type of non-classical correlations and a crucial feature in quantum theory. It becomes a useful resource for many quantum tasks, e.g. quantum computation [\[52\]](#page-13-47), quantum communication [\[53\]](#page-14-0), quantum cryptography [\[54](#page-14-1)], or quantum teleportation [\[55](#page-14-2)]. For this reason, it is important to develop methods to detect entangled states and quantify the amount of entanglement.

Consider a bipartite state ρ on the composite Hilbert space $\mathcal{H} = \mathcal{H}_A \otimes \mathcal{H}_B$, where dim $\mathcal{H}_{A/B} = d_{A/B}$. For each subsystem, let us introduce generalized symmetric measurements and denote them by $\{E_{\alpha,k}^{A/B}\}\$. Now, linear correlations between $\{E^{A}_{\alpha,k}\}$ and $\{E^{B}_{\alpha,k}\}$ are encoded in the correlation matrix

$$
\mathcal{P}_{\alpha,k;\beta,\ell} = \text{Tr}\Big[\rho(E_{\alpha,k}^A \otimes E_{\beta,\ell}^B)\Big].\tag{45}
$$

This matrix can be used to formulate two necessary conditions for separability of ρ .

Proposition 6. If a bipartite state ρ is separable, then

$$
\text{Tr}\mathcal{P} \le \frac{C_{\text{max}}^A + C_{\text{max}}^B}{2} \qquad \text{for} \quad d_A = d_B,\tag{46}
$$

$$
\|\mathcal{P}\|_{\text{Tr}} \le \sqrt{C_{\text{max}}^A C_{\text{max}}^B} \qquad \text{for any} \quad d_A, d_B,
$$
\n⁽⁴⁷⁾

where $C_{\text{max}}^{A/B}$ is the upper bound for the index of coincidence corresponding to $\{E_{\alpha,k}^{A/B}\}.$

This is proven exactly as in ref. [\[18](#page-13-16)]: by computing TrP and $||P||_{\text{Tr}}$ on product states and then extending the results to all separable states (from the convexity of the trace norm and linearity of trace). For $d_A = d_B$, it remains inconclusive which of the two conditions is stronger. In the special case where $C_{\text{max}}^A = C_{\text{max}}^A$, both upper bounds coincide. Also, the smaller the values of $r = x_\alpha - y_\alpha$ and $\mu = \sum_{\alpha=1}^N M_\alpha^{-1}$, the tighter these bounds are. This means that taking nonprojective, unequinumerous measurements proves to be more beneficial for entanglement detection.

6. CONCLUSIONS

In this paper, we introduce generalized symmetric measurements, which are collections of M_{α} -elemental POVMs \mathcal{E}_{α} that satisfy additional symmetry constraints. In general these POVMs are unequinumerous, and hence mutual unbiasedness is preserved only between pairs. For informationally complete measurements, we present construction methods from Hermitian orthonormal operator bases. In particular, we find that a single M_{α} -elemental subset of Hermitian orthonormal bases can produce up to four distinct POVMs \mathcal{E}_{α} , which was believed to be a one-to-one correspondence [\[10,](#page-13-9) [11,](#page-13-10) [18\]](#page-13-16). In the main part, we prove that some of the symmetry conditions of (N, M) -POVMs can be recovered for their generalizations. Interestingly, the class with the greatest potential for applications is characterized not by a single measurement-independent parameter but by a difference;

$$
x_{\alpha} - y_{\alpha} = \text{Tr}\Big[E_{\alpha,k}(E_{\alpha,k} - E_{\alpha,\ell})\Big] \equiv r \qquad \forall_{k \neq \ell}.
$$
\n(48)

If the generalized symmetric measurements satisfy this condition, then they are conical 2-designs, and the corresponding index of coincidence is analytically computable. Finally, we present possible applications of such measurements in entropic uncertainty relations and separability criteria for bipartite quantum states.

In further research, it would be essential to further characterize the properties of generalized symmetric measurements. In particular, there might exist non-trivial relations between the POVMs constructed from the same Hermitian operator bases. It would be interesting to characterize the families of projective measurements and compare their applicational prowess with MUBs and SIC POVMs. Also, there is an open question about possible applications for the measurements that are not conical 2-designs.

Appendix A: Characterizing parameters

To obtain the values of parameters w_{α} , y_{α} , and $z_{\alpha\beta}$ that characterize the generalized symmetric measurements, we compute the trace conditions using decompositions of the identity $\mathbb{I}_d = \sum_{k=1}^{M_\alpha} E_{\alpha,k}$. For w_α , one has

$$
d = \text{Tr}\mathbb{I}_d = \sum_{k=1}^{M_\alpha} \text{Tr} E_{\alpha,k} = M_\alpha w_\alpha.
$$
 (A1)

Then, $z_{\alpha\beta}$ follows from

$$
w_{\alpha} = \text{Tr} E_{\alpha,k} = \sum_{\ell=1}^{M_{\beta}} \text{Tr} E_{\alpha,k} E_{\beta,\ell} = M_{\beta} z_{\alpha\beta}.
$$
 (A2)

Finally, we obtain the relation between x_{α} and y_{α} from

$$
w_{\alpha} = \text{Tr} E_{\alpha,k} = \sum_{\ell=1}^{M_{\alpha}} \text{Tr} E_{\alpha,k} E_{\alpha,\ell} = x_{\alpha} + (M_{\alpha} - 1)y_{\alpha}.
$$
 (A3)

The range of x_α depends on the dimension d and the number of elements M_α of the given POVM. The lower bound $x_{\alpha} = d/M_{\alpha}^2$ corresponds to the trivial choice of $E_{\alpha,k} = \mathbb{I}_d/M$. The upper bound $x_{\alpha} = d^2/M_{\alpha}^2$ is reached by projective measurements, whereas $x_{\alpha} = d/M_{\alpha}$ for rank- w_{α} projectors.

Appendix B: Informationally complete measurements

Any set of measurements is informationally complete if and only if it consists in d^2 linearly independent operators. Because of the constraint $\sum_{k=1}^{M_{\alpha}} E_{\alpha,k} = \mathbb{I}_d$, every POVM $\{E_{\alpha,k}; k = 1,\ldots,M_{\alpha}\}$ contains at most $M_{\alpha} - 1$ linearly independent operators. Therefore, the generalized symmetric measurements are spanned by the identity operator \mathbb{I}_d and $d^2 - 1$ operators $E_{\alpha,k}$. This imposes the following condition on M_{α} ,

$$
\sum_{\alpha=1}^{N} (M_{\alpha} - 1) = d^2 - 1,
$$
\n(B1)

which is exactly the equality in eq. [\(7equation.2.7\)](#page-1-0). Now, to show that $\{\mathbb{I}_d, E_{\alpha,k}; k = 1, \ldots, M_\alpha - 1; \alpha = 1, \ldots, N\}$ is indeed a set of linearly independent operators, it is enough to prove that

$$
\mathbb{E} = r_0 \mathbb{I}_d + \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}-1} r_{\alpha,k} E_{\alpha,k} = 0
$$
\n(B2)

implies $r_0 = r_{\alpha,k} = 0$. First, observe that

$$
\text{Tr}(\mathbb{E}) = dr_0 + \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}-1} r_{\alpha,k} w_{\alpha} = 0.
$$
 (B3)

Using this result, one obtains

$$
\operatorname{Tr}(\mathbb{E}E_{\beta,M}) = \sum_{k=1}^{M_{\beta}-1} r_{\beta,k}(y_{\beta}-z_{\beta\beta}) = 0.
$$
 (B4)

As $y_{\beta} \neq z_{\beta\beta}$ due to $x_{\beta} > d/M_{\beta}^2$, the only solution is

$$
\sum_{k=1}^{M_{\beta}-1} r_{\beta,k} = 0.
$$
 (B5)

Now, eq. [\(B5equation.B.5\)](#page-9-1) together with eq. [\(B3equation.B.3\)](#page-8-2) return $r_0 = 0$. Finally, for any $\ell = 1, \ldots, M_\beta - 1$,

$$
\text{Tr}(\mathbb{E}E_{\beta,\ell}) = r_{\beta,\ell}(x_{\beta} - y_{\beta}) = 0,\tag{B6}
$$

where $x_{\beta} \neq y_{\beta}$. Therefore, one indeed has $r_{\beta,\ell} = r_0 = 0$.

Appendix C: Conditions for $\mathcal{E}'_{\alpha} = \mathcal{E}_{\alpha}$

To prove that $E_{\alpha,k}$ and $E'_{\alpha,k}$ constructed according to eqs. [\(10equation.3.10\)](#page-2-1) and [\(24equation.3.24\)](#page-3-0), respectively, can indeed produce distinct measurement operators, it is enough to calculate the trace cross-relations

$$
\text{Tr}E_{\alpha,k}E'_{\alpha,\ell} = \frac{d}{M_{\alpha}^2} + t_{\alpha}t'_{\alpha}\text{Tr}H_{\alpha,k}H'_{\alpha,\ell} = z_{\alpha\alpha} + \text{sgn}(t_{\alpha})\text{sgn}(t'_{\alpha})\frac{x_{\alpha} - y_{\alpha}}{M_{\alpha}(M_{\alpha} - 1)}\text{Tr}H_{\alpha,k}H'_{\alpha,\ell}, \qquad k, \ell = 1, \ldots, M_{\alpha}, \tag{C1}
$$

where

$$
\operatorname{Tr} H_{\alpha,k} H'_{\alpha,k} = M_{\alpha}^2 - 2M_{\alpha} - 1,
$$

\n
$$
\operatorname{Tr} H_{\alpha,M_{\alpha}} H'_{\alpha,M_{\alpha}} = -(M_{\alpha} - 1)^2,
$$

\n
$$
\operatorname{Tr} H_{\alpha,k} H'_{\alpha,\ell} = -(M_{\alpha} + 1),
$$

\n
$$
\operatorname{Tr} H_{\alpha,k} H'_{\alpha,M_{\alpha}} = \operatorname{Tr} H_{\alpha,M_{\alpha}} H'_{\alpha,k} = M_{\alpha} - 1
$$
\n(C2)

for $k, \ell = 1, \ldots, M_\alpha - 1$ and $k \neq \ell$. Because of the symmetry properties for the generalized symmetric measurements, some of the above traces have to be equal to one another. This is possible only for $M_{\alpha} \leq 3$.

First, let us see what happens if $M_\alpha = 2$. Observe that the trace relations on eq. [\(C2equation.C.2\)](#page-9-2) reduce to

$$
\text{Tr}H_{\alpha,1}H'_{\alpha,1} = \text{Tr}H_{\alpha,2}H'_{\alpha,2} = -1,
$$

\n
$$
\text{Tr}H_{\alpha,1}H'_{\alpha,2} = \text{Tr}H_{\alpha,2}H'_{\alpha,1} = 1.
$$
\n(C3)

Therefore, the relations between measurement operators

$$
\text{Tr}E_{\alpha,1}E'_{\alpha,1} = \text{Tr}E_{\alpha,2}E'_{\alpha,2} = \frac{d}{4} - \text{sgn}(t_{\alpha})\text{sgn}(t'_{\alpha})\frac{4x_{\alpha} - d}{4} = x_{\alpha},
$$
\n
$$
\text{Tr}E_{\alpha,1}E'_{\alpha,2} = \text{Tr}E_{\alpha,2}E'_{\alpha,1} = \frac{d}{4} + \text{sgn}(t_{\alpha})\text{sgn}(t'_{\alpha})\frac{4x_{\alpha} - d}{4} = \frac{d - 2x_{\alpha}}{2} = y_{\alpha}
$$
\n(C4)

recover the symmetry conditions of the generalized symmetric measurements from eq. [\(4equation.2.4\)](#page-1-1) when $sgn(t_{\alpha})$ = $-\text{sgn}(t'_{\alpha})$. Actually, one has $E_{\alpha,1} = E'_{\alpha,1}$ and $E_{\alpha,2} = E'_{\alpha,2}$.

Next, we fix the number of elements to $M_{\alpha} = 3$. In this case, eq. [\(C2equation.C.2\)](#page-9-2) returns

$$
\begin{aligned}\n\text{Tr}H_{\alpha,1}H'_{\alpha,1} &= \text{Tr}H_{\alpha,2}H'_{\alpha,2} = 2, \\
\text{Tr}H_{\alpha,3}H'_{\alpha,3} &= -4, \\
\text{Tr}H_{\alpha,1}H'_{\alpha,2} &= \text{Tr}H_{\alpha,2}H'_{\alpha,1} = -4, \\
\text{Tr}H_{\alpha,1}H'_{\alpha,3} &= \text{Tr}H_{\alpha,2}H'_{\alpha,3} = \text{Tr}H_{\alpha,3}H'_{\alpha,1} = \text{Tr}H_{\alpha,3}H'_{\alpha,2} = 2.\n\end{aligned}\n\tag{C5}
$$

For the measurement operators, it follows that

$$
\begin{split} \text{Tr}E_{\alpha,1}E'_{\alpha,2} &= \text{Tr}E_{\alpha,2}E'_{\alpha,1} = \text{Tr}E_{\alpha,3}E'_{\alpha,3} = \frac{d}{9} - \text{sgn}(t_{\alpha})\text{sgn}(t'_{\alpha})\frac{9x_{\alpha} - d}{9} = x_{\alpha},\\ \text{Tr}E_{\alpha,1}E'_{\alpha,1} &= \text{Tr}E_{\alpha,2}E'_{\alpha,2} = \text{Tr}E_{\alpha,1}E'_{\alpha,3} = \text{Tr}E_{\alpha,2}E'_{\alpha,3} = \text{Tr}E_{\alpha,3}E'_{\alpha,1} = \text{Tr}E_{\alpha,3}E'_{\alpha,2}\\ &= \frac{d}{9} + \text{sgn}(t_{\alpha})\text{sgn}(t'_{\alpha})\frac{9x_{\alpha} - d}{18} = \frac{d - 3x}{6} = y_{\alpha}, \end{split} \tag{C6}
$$

and hence the symmetry conditions from eq. [\(4equation.2.4\)](#page-1-1) once again hold for $sgn(t_{\alpha}) = -sgn(t'_{\alpha})$. However, contrary to the case for $M_{\alpha} = 2$, we have $E_{\alpha,1} = E'_{\alpha,2}$, $E_{\alpha,2} = E'_{\alpha,1}$, and $E_{\alpha,3} = E'_{\alpha,3}$.

Appendix D: Construction of four SIC POVMs in $d = 2$

For qubit systems, SIC POVMs are recovered if $N = 1$ and $M = d^2 = 4$. From the Pauli matrices $G_k = \sigma_k/\sqrt{2}$, eqs. [\(10equation.3.10\)](#page-2-1) and [\(24equation.3.24\)](#page-3-0) lead to four families of projective measurements:

$$
\begin{cases}\nE_{1,+} = \frac{\sqrt{3}}{36} \begin{pmatrix} 1+3\sqrt{3} & -5-i \\ -5+i & -1+3\sqrt{3} \end{pmatrix}, & E_{2,+} = \frac{\sqrt{3}}{36} \begin{pmatrix} 1+3\sqrt{3} & 1+5i \\ 1-5i & -1+3\sqrt{3} \end{pmatrix}, \\
E_{3,+} = \frac{\sqrt{3}}{36} \begin{pmatrix} -5+3\sqrt{3} & 1-i \\ 1+i & 5+3\sqrt{3} \end{pmatrix}, & E_{4,+} = \frac{\sqrt{3}}{12} \begin{pmatrix} 1+\sqrt{3} & 1-i \\ 1+i & -1+\sqrt{3} \end{pmatrix},\n\end{cases}
$$
\n(D1)

$$
\begin{cases}\nE_{1,-} = \frac{\sqrt{3}}{36} \begin{pmatrix} -1+3\sqrt{3} & 5+i \\ 5-i & 1+3\sqrt{3} \end{pmatrix}, & E_{2,-} = \frac{\sqrt{3}}{36} \begin{pmatrix} -1+3\sqrt{3} & 5+i \\ 5-i & 1+3\sqrt{3} \end{pmatrix}, \\
E_{3,-} = \frac{\sqrt{3}}{36} \begin{pmatrix} 5+3\sqrt{3} & -1+i \\ -1-i & -5+3\sqrt{3} \end{pmatrix}, & E_{4,-} = \frac{\sqrt{3}}{12} \begin{pmatrix} -1+\sqrt{3} & -1+i \\ -1-i & 1+\sqrt{3} \end{pmatrix},\n\end{cases}
$$
\n(D2)

$$
\begin{cases}\nE'_{1,+} = \frac{\sqrt{3}}{12} \begin{pmatrix} 1+\sqrt{3} & -1-i \\ -1+i & -1+\sqrt{3} \end{pmatrix}, & E'_{2,+} = \frac{\sqrt{3}}{12} \begin{pmatrix} 1+\sqrt{3} & 1+i \\ 1-i & -1+\sqrt{3} \end{pmatrix}, \\
E'_{3,+} = \frac{\sqrt{3}}{12} \begin{pmatrix} -1+\sqrt{3} & 1-i \\ 1+i & 1+\sqrt{3} \end{pmatrix}, & E'_{4,+} = \frac{\sqrt{3}}{12} \begin{pmatrix} -1+\sqrt{3} & -1+i \\ -1-i & 1+\sqrt{3} \end{pmatrix},\n\end{cases} (D3)
$$

$$
\begin{cases}\nE'_{1,-} = \frac{\sqrt{3}}{12} \begin{pmatrix} -1+\sqrt{3} & 1+i \\ 1-i & 1+\sqrt{3} \end{pmatrix}, & E'_{2,-} = \frac{\sqrt{3}}{12} \begin{pmatrix} -1+\sqrt{3} & -1-i \\ -1+i & 1+\sqrt{3} \end{pmatrix}, \\
E'_{3,-} = \frac{\sqrt{3}}{12} \begin{pmatrix} 1+\sqrt{3} & -1+i \\ -1-i & -1+\sqrt{3} \end{pmatrix}, & E'_{4,-} = \frac{\sqrt{3}}{12} \begin{pmatrix} 1+\sqrt{3} & 1-i \\ 1+i & -1+\sqrt{3} \end{pmatrix},\n\end{cases} (D4)
$$

where $E_{k,\pm} = E_k(\pm t_*)$ with $1/t_* = 6\sqrt{6}$ and $1/t_* = 2\sqrt{6}$. By reverse engineering the operator bases from these measurement operators, we find that any of these SIC POVMs can be constructed from $G_k = \pm \sigma_k/\sqrt{2}$ or $G_k = \pm g_k$ with

$$
g_1 = \frac{1}{3\sqrt{2}} \begin{pmatrix} 2 & -1 - 2i \\ -1 + 2i & -2 \end{pmatrix}, \qquad g_2 = \frac{1}{3\sqrt{2}} \begin{pmatrix} 2 & 2 + i \\ 2 - i & -2 \end{pmatrix}, \qquad g_3 = \frac{1}{3\sqrt{2}} \begin{pmatrix} -1 & 2 - 2i \\ 2 + 2i & 1 \end{pmatrix}.
$$
 (D5)

Appendix E: Conical 2-designs

From the Choi-Jamiołkowski isomorphism, we construct the Choi map

$$
C(\Phi T) = \sum_{\alpha=1}^{N} (\mathbb{1}_d \otimes \Phi_{\alpha} T)[dP_+]
$$
 (E1)

for $\Phi = \sum_{\alpha=1}^{N} \Phi_{\alpha}$, where $P_+ = (1/d) \sum_{m,n=1}^{d} |m\rangle\langle n| \otimes |m\rangle\langle n|$ is the maximally entangled state. Direct calculations show that

$$
C(\Phi T) = \sum_{\alpha=1}^{N} \sum_{m,n=1}^{d} |m\rangle\langle n| \otimes \Phi_{\alpha}[|n\rangle\langle m|] = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} \sum_{m,n=1}^{d} |m\rangle\langle m| E_{\alpha,k} |n\rangle\langle n| \otimes E_{\alpha,k} = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} E_{\alpha,k} \otimes E_{\alpha,k}.
$$
 (E2)

On the other hand, using the relation from eq. [\(34equation.5.34\)](#page-5-1), one finds

$$
C(\Phi T) = \left(\mathbb{1}_d \otimes \left[\kappa_+ d\Phi_0 + \kappa_- T\right]\right) [dP_+] = \sum_{m,n=1}^d |m\rangle\langle n| \otimes \left(\kappa_+ \mathbb{I}_d \delta_{mn} + \kappa_- |n\rangle\langle m|\right) = \kappa_+ \mathbb{I}_d \otimes \mathbb{I}_d + \kappa_- \mathbb{F}_d. \tag{E3}
$$

By comparing the above results, we finally obtain

$$
\sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} E_{\alpha,k} \otimes E_{\alpha,k} = \kappa_{+} \mathbb{I}_{d} \otimes \mathbb{I}_{d} + \kappa_{-} \mathbb{F}_{d},
$$
\n(E4)

and therefore $E_{\alpha,k}$ is a conical 2-design.

Appendix F: Derivation of κ_{\pm}

Multiplying $\Phi[X] = \sum_{\alpha=1}^{N} \Phi_{\alpha}[X]$ by $E_{\beta,\ell}$ and taking the trace results in

$$
\operatorname{Tr}(\Phi[X]E_{\beta,\ell}) = \sum_{\alpha=1}^{N} \operatorname{Tr}(\Phi_{\alpha}[X]E_{\beta,\ell}) = (x_{\beta} - y_{\beta})\operatorname{Tr}(E_{\beta,\ell}X) + (y_{\beta} - z_{\beta\beta} + \mu w_{\beta})\operatorname{Tr}X.
$$
 (F1)

Equivalently, this can be rewritten into the following relation,

$$
\operatorname{Tr}\left\{ \left(\Phi - \left[(x_{\beta} - y_{\beta}) \mathbb{1} + (d\mu - x_{\beta} + y_{\beta}) \Phi_0 \right] \right) [X] E_{\beta, \ell} \right\} = 0, \tag{F2}
$$

which must hold for any Hermitian X and $E_{\beta,\ell}$. It is easy to notice that the terms multiplying TrX and Tr $E_{\beta,\ell}X$ have to be independent on β or ℓ . This is true only for $x_{\alpha} - y_{\alpha} = r$. After substituting this into eq. [\(F2equation.F.2\)](#page-11-2), it follows that

$$
\sum_{\alpha=1}^{N} \Phi_{\alpha} = r \mathbb{1} + (d\mu - r) \Phi_{0} = \kappa_{-} \mathbb{1} + \kappa_{+} d\Phi_{0},
$$
\n(F3)

where κ_{\pm} are given by eq. (36 equation.5.36).

From Proposition 2Proposition.2, we recall the range of the parameter r ,

$$
0 < r \le \min\left\{\frac{d}{M_{\alpha}}, \frac{d(d-1)}{M_{\alpha}(M_{\alpha}-1)}\right\}.\tag{F4}
$$

Obviously, κ > 0 because $r > 0$. Moreover, the upper bound implies that

$$
\forall_{\alpha} \quad r \le \frac{d}{M_{\alpha}} \quad \text{and} \quad \forall_{\alpha} (M_{\alpha} - 1)r \le \frac{d}{d - 1} M_{\alpha}.
$$
 (F5)

Taking the sum over $\alpha = 1, \ldots, N$ results in the following conditions,

$$
r \le \min\left\{\frac{d\mu}{N}, \frac{d\mu}{d+1}\right\},\tag{F6}
$$

which is equivalent to $\kappa_+ \geq \kappa_-$.

Appendix G: Entanglement breaking channels

Let us prove the following proposition.

Proposition 7. If $E_{\alpha,k}$ belong to the class of measurements from Proposition 3Proposition.3, for which $x_{\alpha}-y_{\alpha}=sw_{\alpha}$, then it holds that

$$
\sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} \frac{1}{w_{\alpha}} E_{\alpha,k} \otimes E_{\alpha,k} = \kappa_{+} \mathbb{I}_{d} \otimes \mathbb{I}_{d} + \kappa_{-} \mathbb{F}_{d}
$$
\n(G1)

with

$$
\kappa_{+} = \frac{N - s}{d}, \qquad \kappa_{-} = s. \tag{G2}
$$

Calculations are analogical to those in Appendix [Fsection*.17.](#page-11-0) We denote the sum of entanglement breaking channels by $\widetilde{\Phi} = \sum_{\alpha=1}^{N} \widetilde{\Phi}_{\alpha}$ and compute

$$
\operatorname{Tr}(\widetilde{\Phi}[X]E_{\beta,\ell}) = \frac{x_{\beta} - y_{\beta}}{w_{\beta}} \operatorname{Tr}(E_{\beta,\ell}X) + \frac{1}{d}(Nw_{\beta} - x_{\beta} + y_{\beta}) \operatorname{Tr}X. \tag{G3}
$$

This equation is then rewritten into

$$
\operatorname{Tr}\left\{ \left(\widetilde{\Phi}[X] - \left[\frac{x_{\beta} - y_{\beta}}{w_{\beta}} X + \frac{N w_{\beta} - x_{\beta} + y_{\beta}}{d w_{\beta}} \mathbb{I}_{d} \operatorname{Tr}(X) \right] \right) E_{\beta,\ell} \right\} = 0, \tag{G4}
$$

which holds for any $E_{\beta,\ell}$ and Hermitian operator X. The terms that multiply TrX and Tr $E_{\beta,\ell}X$ are constant in β and ℓ if $x_{\alpha} - y_{\alpha} = sw_{\alpha}$. Then,

$$
\Phi = s1 + (N - s)\Phi_0 = \kappa_1 1 + d\kappa_+ \Phi_0,\tag{G5}
$$

where κ_{\pm} are given by eq. [\(G2equation.G.2\)](#page-11-3). By the Choi-Jamiołkowski isomorphism, we arrive at the formula in eq. [\(G1equation.G.1\)](#page-11-4).

Appendix H: Dual frame operators

Let us begin the proof by assuming that every frame operator

$$
F_{\alpha,k} = a_{\alpha} E_{\alpha,k} - b_{\alpha} \mathbb{I}_d
$$
\n(H1)

dual to a given $E_{\alpha,k}$ is linearly proportional only to $E_{\alpha,k}$ and the identity operator. In this case,

$$
p_{\beta,\ell} = \text{Tr}(\rho E_{\beta,\ell}) = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} p_{\alpha,k} \Big[a_{\alpha} \text{Tr}(E_{\alpha,k} E_{\beta,\ell}) - b_{\alpha} w_{\beta} \Big]. \tag{H2}
$$

Using the properties of the measurement operators and the fact that $\{p_{\alpha,k}; k = 1, \ldots, M_\alpha\}$ is a probability distribution, we arrive at

$$
p_{\beta,\ell} = p_{\beta,\ell} a_{\beta} (x_{\beta} - y_{\beta}) + a_{\beta} (y_{\beta} - z_{\beta \beta}) + \sum_{\alpha=1}^{N} a_{\alpha} z_{\alpha \beta} - \sum_{\alpha=1}^{N} b_{\alpha} w_{\beta},
$$
\n(H3)

where $z_{\beta\beta} = d/M_{\beta}^2$. This equality must hold for all $p_{\beta,\ell}$, which means that

$$
a_{\beta} = \frac{1}{x_{\beta} - y_{\beta}}, \qquad a_{\beta}(y_{\beta} - z_{\beta \beta}) = \sum_{\alpha=1}^{N} (b_{\alpha} w_{\beta} - a_{\alpha} z_{\alpha \beta}). \tag{H4}
$$

Now, observe that

$$
a_{\beta}(y_{\beta} - z_{\beta\beta}) = \frac{y_{\beta} - z_{\beta\beta}}{x_{\beta} - y_{\beta}} = -\frac{w_{\beta}}{d}, \qquad a_{\alpha}z_{\alpha\beta} = \frac{w_{\beta}}{d(x_{\alpha} - y_{\alpha})}.
$$
(H5)

Therefore, the terms proportional to w_{β} in the second formula from eq. [\(H4equation.H.4\)](#page-12-2) cancel out. The solution for a_{α} and b_{α} reads

$$
a_{\alpha} = \frac{1}{x_{\alpha} - y_{\alpha}}, \qquad b_{\alpha} = \frac{w_{\alpha}}{d(x_{\alpha} - y_{\alpha})} - \frac{1}{dN}.
$$
 (H6)

Appendix I: Index of Coincidence

Recall that ρ can be written in terms of the dual frame $F_{\alpha,k}$ as

$$
\rho = \sum_{\alpha=1}^{N} \sum_{k=1}^{M_{\alpha}} p_{\alpha,k} F_{\alpha,k},\tag{I1}
$$

where $\{p_{\alpha,k}; k=1,\ldots,M_{\alpha}\}\$ are N probability distributions. To calculate $\text{Tr}\rho^2$, we first show that

$$
\operatorname{Tr}(F_{\alpha,k}F_{\beta,\ell}) = \frac{1}{(x_{\alpha} - y_{\alpha})(x_{\beta} - y_{\beta})} [\operatorname{Tr}(E_{\alpha,k}E_{\beta,\ell}) - z_{\alpha\beta}] + \frac{1}{dN^2},\tag{I2}
$$

where

$$
\text{Tr}(E_{\alpha,k}E_{\beta,\ell}) = \delta_{\alpha\beta}\delta_{k\ell}(x_{\alpha} - y_{\alpha}) + \delta_{\alpha\beta}(y_{\alpha} - z_{\alpha\beta}) + z_{\alpha\beta}.
$$
\n(13)

Using the above equations, it is straightforward to calculate

$$
\text{Tr}\rho^2 = \frac{1}{d} + \sum_{\alpha=1}^N \frac{1}{x_\alpha - y_\alpha} \left(\sum_{k=1}^{M_\alpha} p_{\alpha,k}^2 - \frac{1}{M_\alpha} \right). \tag{I4}
$$

Observe that the index of coincidence C does not appear in the formula for $\text{Tr}\rho^2$ unless $x_\alpha - y_\alpha \equiv r$. Therefore, in order to find the relation between $\text{Tr}\rho^2$ and C, one needs a constant $x_\alpha - y_\alpha \equiv r$. Only under this assumption, eq. [\(I4equation.I.4\)](#page-12-3) simplifies to

$$
\text{Tr}\rho^2 = \frac{C - \mu}{r} + \frac{1}{d}, \qquad \mu = \sum_{\alpha=1}^N \frac{1}{M_\alpha}.
$$
 (15)

Finally, due to $\text{Tr}\rho^2 \leq 1$, the index of coincidence is bounded by

$$
C_{\text{max}} = \frac{d-1}{d}r + \mu
$$
