ABSTRACT

Personalized learning (PL) aspires to provide an alternative to the one-size-fits-all approach in education. Technology-based PL solutions have shown notable effectiveness in enhancing learning performance. However, their alignment with the broader goals of modern education is inconsistent across technologies and research areas. In this paper, we examine the characteristics of AI-driven PL solutions in light of the OECD Learning Compass 2030 goals. Our analysis indicates a gap between the objectives of modern education and the current direction of PL. We identify areas where most present-day PL technologies could better embrace essential elements of contemporary education, such as collaboration, cognitive engagement, and the development of general competencies. While the present PL solutions are instrumental in aiding learning processes, the PL envisioned by educational experts extends beyond simple technological tools and requires a holistic change in the educational system. Finally, we explore the potential of large language models, such as ChatGPT, and propose a hybrid model that blends artificial intelligence with a collaborative, teacher-facilitated approach to personalized learning.

Keywords personalized learning · artificial intelligence · adaptive learning systems · educational technology · intelligent tutoring systems · large language models · self-regulated learning

1 Introduction

Prominent educational researchers and organizations agree that education must be learning-centered for every pupil to reach their potential (Bransford et al., 2000; Groff, 2017; O’Brien et al., 2009; OECD, 2006; Vygotsky & Cole, 1978). The learning-centered paradigm stems from changes in industry and society: The predominantly knowledge-based form of work requires an education system that values individual differences and promotes lifelong learning skills (Lee, 2014). Since early experiments demonstrated the benefits of one-on-one tutoring over group-level instruction (Bloom, 1984; Salvin & Karweit, 1985), researchers have sought technological solutions to achieve cost-effective personalized tutoring (Lee et al., 2018). Personalized learning (PL) aims to achieve this goal by tailoring instruction, pace, methods, and content to the interests, needs, and goals of individual learners (Beese, 2019; US Department of Education, 2010; Walkington & Bernacki, 2020). Breakthroughs in technology and artificial intelligence (AI) have led to a rapid increase in the applications of PL (Chen et al., 2020). AI-driven adaptive learning systems (Corbett et al., 1997; Maghsudi et al., 2021; VanLehn, 2011) have emerged to provide learners with individualized lesson sequences, content recommendations, tasks, and automated assessments (Zawacki-Richter et al., 2019). A prevailing view in the application of AI to Education (AIEd) literature is that personalized adaptive learning systems increase access to high-quality education and are contrasted with a “traditional,” one-size-fits-all approach (Tetzlaff et al., 2020; Maghsudi et al., 2021; St-Hilaire et al., 2022). However, previous reviews have pointed to limited analysis of the educational underpinnings of AIEd (Chen et al., 2020; Hinojo-Lucena et al., 2019; Zawacki-Richter et al., 2019).

Here, we analyze the PL approach from the perspective of the educational goals set by the OECD Learning Compass 2030 as a framework to support our arguments (OECD, 2019b). In addition to core knowledge and skills, the framework highlights three main goals of education: focus on general competencies, developing learners’ agency, and building on the Anticipation-Action-Reflection (AAR) cycle. First, the AAR cycle reflects the need for deeper cognitive engagement before and during learning (Bransford et al., 2000; Chi & Wylie, 2014; Dehaene, 2020), also known as active learning. Second, agency is a broad and interdisciplinary term that denotes the skills necessary for lifelong learning (Brod et al., 2023; Council of the EU, 2002; OECD, 2006). An essential part of agency is related to self-directed and self-regulated learning (SRL) skills that enable the learner to take the initiative in leading their learning, monitor their level of understanding, setting goals, planning tasks, and taking action toward them, and evaluate their performance (Knowles, 1975; Zimmerman, 1986, 2000; Saks & Leijen, 2014; Panadero, 2017). It has been consistently shown that without proper SRL skills, learners overwhelmingly choose the least effective strategies for learning (McCabe, 2011). Third, we define general competencies as personal attributes or behaviors developed through action, experience, and reflection (UNESCO, 2017). Examples of these competencies include critical thinking, collaboration skills, creating new value, and complex problem-solving skills (OECD, 2019b; UNESCO, 2022). We will expand and use these overarching goals in our analysis of the challenges of personalized learning systems.

We recognize the value of PL technologies as supportive tools for teachers and effective knowledge acquisition, particularly when they promote self-regulated learning, enhance learner’s agency, and engage students cognitively (e.g., Azevedo et al., 2022; Biswas et al., 2016; du Boulay, 2019; Long & Alevin, 2017). The benefits of AI-enabled PL systems are manifold, including flexibility in time and location, timely feedback, and faster student progression (Moreno-Guerrero et al., 2020; Pliakos et al., 2019), offering a more dynamic approach to knowledge acquisition compared to traditional methods. However, PL is described as an AI-based individualized learning approach and is often used synonymously with “adaptive learning” (Bernacki et al., 2021; Maghsudi et al., 2021; Shemshack et al., 2021; Shemshack & Spector, 2020; Tetzlaff et al., 2021). Rather than being the antithesis of the traditional one-size-fits-all approach, PL, as currently implemented, is simply a more effective method of knowledge acquisition. In contrast to the PL as currently implemented, the “ideal” personalized learning adheres to all principles of modern learning and aspires to a broader change in the school, educational strategy, curricula, effective pedagogies, etc., in which technology plays only a supporting role (Hopkins, 2010; Lee, 2014; Lee et al., 2018; Miliband, 2006; Watters, 2023).

We explore this perspective by examining how the PL literature emphasizes certain aspects of modern education while neglecting others. AIED is still in its infancy, and there is an opportunity to guide its development in line with the principles of contemporary education (Shemshack et al., 2021; Cukurova et al., 2023). In the concluding sections, we explore the potential of large language models (such as ChatGPT) and propose a hybrid framework that envisions a collaborative relationship between AI and teachers.

2 Benefits of personalized learning systems

The framework for personalized learning was outlined in the early 1960s in Richard D. Smallwood’s dissertation on “teachable machines” (Smallwood, 1962). As envisioned by Smallwood, these machines would provide an individualized pace of learning, apply repetition until mastery, provide immediate feedback, and record student performance (Smallwood, 1962, pp. 2–3 as cited by Essa 2016). The need for individualized learning was fueled by experiments that demonstrated higher learning gains in 1:1 tutoring than in traditional group instruction, named the 2-sigma problem (Bloom, 1984; Salvin & Karweit, 1985). Today, Smallwood’s vision is reflected in the widely used definition of the U.S. Department of Education (2010, 2017), which refers to PL as “instruction in which the pace of learning and the instructional approach are optimized for the needs of each learner.” While this definition does not emphasize individualization per se, a superficial understanding of PL as a technology-facilitated, individualized, and automated approach is prevalent in the AIED literature (Lee et al., 2018; Shemshack & Spector, 2020; Tetzlaff et al., 2021).

The individualized approach has several advantages over group-level instruction (Luckin et al., 2016). Typical PL systems include three core components: a content model, a student model, and a pedagogical model (Martin et al., 2020). The pedagogical model identifies and sequences learning objectives, guides learners through individual learning paths, and provides timely feedback and assessment (Ezzaim et al., 2022; Martin et al., 2020; Pelánek, 2017). The pedagogical model usually provides distributed practice until the learning objective is mastered, an effective learning strategy for long-lasting comprehension and memory formation (Dempster & Farris, 1990; Gerbier & Toppino, 2015; Hintzman, 1974; Soderstrom & Bjork, 2015; Srinivasan, 2022; Tetzlaff et al., 2021). The pedagogical model provides continuous corrective feedback, a highly effective teaching strategy for empowering learners to improve their understanding (Dehaene, 2020; Hattie, 2011; Hattie & Timperley, 2007; Osakwe et al., 2022). The student model stores learner characteristics and tracks the learner’s evolving level of understanding (Greer & McCalla, 1991). Together with the pedagogical model, dynamic student models allow task difficulty to be adapted to the individual’s zone of proximal development, where tasks are neither too boring nor too difficult to cause discouragement, making learning

naturally engaging and challenging (Bransford et al., 2000; Vygotsky & Cole, 1978). The individual learning steps are recommendations on the content model, a digitized, connected domain knowledge graph (Bartl & Belohlavek, 2011). The presentation of appropriate levels of tasks is continued until the student has mastered the topic at hand (Shute & Towle, 2010). In short, PL systems that monitor each student’s progress and adapt learning content, methods, and assessment to individuals on an ongoing basis (Shemshack & Spector, 2020; Xie et al., 2019; Vandewaetere & Clarebout, 2013) are efficient for mastering domain knowledge and improving learning performance (Walkington & Bernacki, 2020; Cui et al., 2018; Feng et al., 2018; Steenbergen-Hu & Cooper, 2014; Urh et al., 2015).

In addition, there are necessary theoretical guidances and empirical basis for designing learning environments that foster self-regulation and metacognition (for a comprehensive overview, see Azevedo & Aleven, 2013). Scaffolding SRL behaviors has been an important research focus on intelligent learning environments and ITS. For instance, much work has been done with an ITS called MetaTutor that scaffolds SRL processes, such as goal setting, evaluation of learning strategies, self-monitoring of progress, and supports cognitive processes of learning required for long-term memory retention, e.g., note-taking, connecting prior and new knowledge, hypothesis generation (Azevedo et al., 2022). Extending domain-level ITS systems with metacognitive tutoring has positively affected student help-seeking strategies and learning outcomes (Aleven et al., 2006; Hacker et al., 2009; Roll et al., 2007). Extensive studies have been done with a cognitive science tutoring system called Betty’s Brain, where middle-school students learn by teaching a virtual agent and creating causal models (Biswas et al., 2005). For example, Leelawong & Biswas (2008) showed that Betty’s Brain led to higher performance and skill transfer to novel domains with self-regulation features such as self-monitoring, goal setting, and self-assessment. In Betty’s Brain, students must also develop and apply metacognitive strategies for goal setting, planning, and evaluation to make effective decisions from information-seeking to solution assessment (Biswas et al., 2016). Recent experiments showed how scaffolding SRL behavior needs to be strategically tailored to specific learning contexts and proficiency levels (Munshi et al., 2023). Overall, some research and PL solutions elegantly apply learning science and support some of the goals of modern education.

Nevertheless, we explicitly differentiate research-based ITS solutions from the personalized learning platforms that i) do not employ dialogue-based tutoring and ii) are not specifically designed to develop SRL, metacognition, collaboration, or other general competence. Similarly to other researchers, we call the PL systems that primarily focus on effective domain-knowledge delivery “adaptive learning systems” (e.g., Brod et al., 2023; Järvelä et al., 2021; Molenaar, 2022a).

3 Challenges of personalized learning systems

3.1 Individualization

In the current approach to PL, learners interact individually with an adaptive learning system that sequences learning objectives and paces instruction according to individual needs (Figure 1A). Compared to traditional one-size-fits-all approaches, tailoring learning content to individual learners has been shown to increase scores and learning efficiency (Cui et al., 2018; St-Hilaire et al., 2022; Tetzlaff et al., 2021). However, while adaptive learning systems enhance the acquisition of subject-based knowledge and skills, we question the power of these systems to facilitate collaborative, human-human social learning settings. The learning-centered paradigm stems from social constructivist theory, which posits that learning occurs through social interactions (Hendrick, 2020; Palincsar, 1998; Vygotsky & Cole, 1978). Therefore, learning requires shared knowledge construction and collaboration (Hadwin et al., 2018). Although AI has been used to support collaborative learning processes (Tan et al., 2022; Ouyang et al., 2023) and strong theoretical and practical foundations have been laid by the field of Computer-Supported Collaborative Learning (Rosé & Ferschke, 2016; Hernández-Sellés et al., 2019; Jeong et al., 2019), PL systems are specifically designed to empower independent problem-solving and free learning from space and time constraints (Biswas et al., 2016). Face-to-face collaborative learning is seldom supported by PL systems (Han et al., 2021). Critically, PL is not about separating students to learn alone at their preferred pace (Miliband, 2006). Instead, the desired learning is collaborative and exercised in social contexts with peers, teachers, families, and communities (Figure 1B) (OECD, 2019c; Walkington & Bernacki, 2020).

3.2 Focus on performance

PL systems are predominantly subject-based platforms that dynamically adapt instruction to individual learners’ characteristics, such as learning style and ability, to maximize learning achievement (Capuano & Caballé, 2020; Kerr, 2016). While recognizing the extensive research done by learning psychologists behind some ITS mentioned above (Azevedo & Aleven, 2013; Azevedo et al., 2022; Aleven et al., 2006; Hacker et al., 2009; Roll et al., 2007; Biswas et al., 2005; Leelawong & Biswas, 2008; Biswas et al., 2016; du Boulay, 2019; Munshi et al., 2023), the adaptive learning/personalized learning literature has overwhelmingly focused on learning achievements, and only a fraction measure other cognitive aspects such as higher-order thinking and collaboration/communication (Xie et al., 2019).

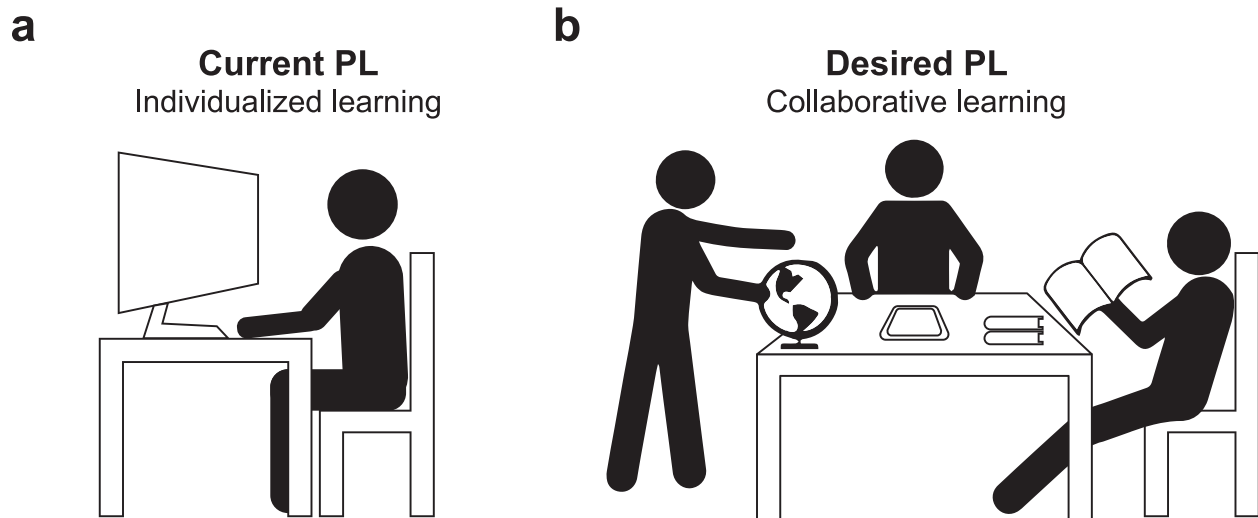

Figure 1: **a** The prevailing view of personalized learning (PL) as “individualization,” where an adaptive learning system tailors learning content to individual learners to improve their performance. This approach is mainly effective in improving the learning of subject-based knowledge. **b** The goals of modern education require a collaborative learning environment where learners can share ideas, receive and give feedback, and co-regulate. Figure adapted from (Winter, 2018) with permission from John Wiley and Sons.

In other words, the main goal of most PL technologies is to increase learning efficiency (Li & Wong, 2021). The efficiency of adaptive learning systems is measured by the increase in learning gains in a given time, i.e., the difference between pre- and post-test scores. Studies of adaptive learning platforms show their efficiency over non-adaptive approaches when measured by student scores and learning speed (Ma et al., 2014; Steenbergen-Hu & Cooper, 2014; Roschelle et al., 2016). First, the gain in efficiency is remarkable. For example, students instructed by Yixue (Squirrel AI) scored up to 456% higher in less time than students in traditional classrooms (Cui et al., 2018; Feng et al., 2018; H. Li et al., 2018). The AI-powered PL platform Korbit showed 2.5 times higher scores compared to a non-adaptive Moodle course (St-Hilaire et al., 2022). The Rimac physics tutoring system has been shown to produce better learning outcomes for high and low prior knowledge students when the system has a dynamic student model compared to a non-adaptive one (Katz et al., 2021, p. 202). A meta-analysis of post-test scores found that intelligent tutoring systems for medical practice and physics had the same effect size as 1:1 human tutors (VanLehn, 2011). While the efficient acquisition of foundational knowledge is certainly commendable, it is essential to recognize that modern education aims to achieve more than just higher scores in less time. Conversely, a focus on performance is often associated with traditional, teaching-centered classrooms, where factors such as learner self-regulation, agency, well-being, and conceptual understanding may not be given the same level of priority. Notably, there is a major concern with the exclusive focus on learning performance.

A century of experimentation has shown that it is critical to distinguish learning - the long-term ability to exhibit new behaviors and knowledge - from performance - temporary fluctuations in knowledge and behavior measured during acquisition (Metcalf et al., 1994). An integrative review illustrates why performance is a highly imperfect index of long-term learning (Soderstrom & Bjork, 2015). First, the authors provide extensive evidence that learning can occur without changes in performance. For example, according to a well-documented psychological phenomenon called “latent learning,” learning often becomes visible only after a reward or incentive is provided (Tolman & Honzik, 1930). These early results have been confirmed in human studies and suggest that latent learning, i.e., learning that does not improve performance, may be more effective than learning in which rewards (e.g., scores) are given at the beginning of the learning experience. Second, Soderstrom and Bjork show how changes in performance may not correspond to changes in understanding. For example, repeating the same content over and over (massing) improves short-term performance but does not improve long-term learning. Lastly, the authors show that errors and mistakes are often interpreted as a decrease in performance but actually improve long-term retention and transfer (Soderstrom & Bjork, 2015). In summary, measures of performance during acquisition may not be indicative of lasting learning, and measures that show degraded performance during learning may improve long-term retention and transfer (Metcalf et al., 1994).

3.3 Domain-specific knowledge

The predominant focus of adaptive learning platforms is on specific subjects, such as computer science and engineering (35%), mathematics (20%), and foreign languages (10%) (Ezzaim et al., 2022; Zawacki-Richter et al., 2019; Zhang & Aslan, 2021). Some ITS have enabled learning by doing in STEM subjects and provided students with elaborate problem-solving opportunities (Koedinger et al., 2015). However, even these innovative solutions remain subject-specific because of their architecture and reliance on the domain content model (Doignon & Falmagne, 2012; Zhang & Aslan, 2021). The domain model serves as a knowledge space, forming a connected graph of domain-specific knowledge components (Bartl & Belohlavek, 2011). However, given the quantitative nature of these knowledge graphs, these learning systems are significantly constrained in the breadth and depth of what could be effectively learned (Essa, 2016). Consequently, PL can only support the effective acquisition of foundational knowledge and skills (Pedaste & Leijen, 2018). Although core knowledge forms the essential building blocks of understanding, the evolving demands of the modern world also necessitate the cultivation of non-epistemic competencies (UNESCO, 2022).

It is not apparent how these non-epistemic competencies, often labeled as 21st-century skills, fit into the model of mastery-based adaptive learning (Tuomi, 2023). From the perspective of knowledge graphs, the concept of optimizing “soft skills” and the feasibility of their assessment through error-correcting and automated assessment remains an open challenge (Shemshack & Spector, 2020). For example, what questions would effectively gauge a student’s mastery of critical thinking and creating new value? Incorporating competencies, such as critical thinking, into knowledge spaces can be a formidable undertaking. Adaptive learning systems are inherently limited to machine-assessable knowledge and skills. To unlock their potential, learners must creatively extend their learning outside the subject domain (UNESCO, 2017). Developing creative and novel ideas requires opportunities for experimentation, exploration, and problem-solving beyond the boundaries of the majority of the existing adaptive learning systems (Stanley & Lehman, 2015; Turner, 2014).

Technically, the purportedly “personalized” learning paths fall short of delivering the freedom and choice behind PL (see Hopkins, 2010). Precisely because being limited to the same underlying knowledge spaces, AI-recommended learning paths are merely different routes for mastering the same knowledge at an individualized order and pace. In that regard, PL systems seem to optimize the traditional educational system without providing learners much agency and customization for setting their goals outside the provided task and existing subject domain.

3.4 Limited agency and learning skills

Rather than blindly following the predefined sequence of learning objectives, OECD Learning Compass 2030 emphasizes the need for learners to navigate unfamiliar contexts and find direction through their own agency (OECD, 2019c). Learners with agency and proficient SRL skills can set learning goals, choose actions toward them, and adjust their strategies when needed (Jarvis, 2004; UNESCO, 2017; Winne, 2017; World Economic Forum, 2021). Numerous studies have shown the importance of self-regulation for effective learning in distant, e-learning, digital, or other self-directed learning situations (Barnard-Brak et al., 2010; Bail et al., 2008; Hofer & Yu, 2003; Azevedo et al., 2009; Puziferro, 2008). Hence, there is a strong consensus that supporting learners’ agency and ability to self-regulate should be the priority of adaptive learning systems (Brod et al., 2023; Järvelä et al., 2021).

As described above, great ITS exist that specifically develop student self-regulation, agency, and other more generic competencies besides subject-domain expertise. However, even the most sophisticated adaptive learning solutions (not the ITS mentioned above) do not support learners’ agency and self-regulation (Molenaar, 2022a). Moreover, PL requires students to possess self-regulated learning skills to effectively learn individually. Recognizing this issue, one K-12 adaptive platform allows students lacking self-regulated learning training to override the platform’s suggestions (Cukurova et al., 2023). Notably, a recent study of a well-studied learning platform showed a significant decline in students’ self-regulated learning skills while working with the system (Harati et al., 2021).

Dignath and Veenman (2021) bring out four essential preconditions that enhance SRL: self-direction (decision-making freedom), cooperative learning (students work together), constructive learning principles (e.g., problems have several solutions), and fostering transfer (learning is integrated into a real-life context). Similarly, information-theoretically, a system is autonomous when (i) it is not determined by its environment and (ii) it determines its own goals (Bertschinger et al., 2008). Because recommendation engines effectively control learning goals, content, sequence of tasks, etc., they potentially reduce the learner’s agency and take away the freedom required for developing healthy SRL skills. The need for agency over one’s learning can be illustrated by the classic experiment (Figure 2A) in which only the kitten that could exhibit self-directed movements developed normal vision (Held & Hein, 1963). Similarly, if the learner is passively moved along the prescribed learning path, he or she may not acquire normal learning and self-regulation (Figure 2B). The lack of support for learner’s learning skills in some adaptive learning systems has been mentioned previously (Pedaste & Leijen, 2018). Although a framework for the adaptive assignment of agency (Brod et al., 2023)

Figure 2: **a** Adapted illustration of the experimental setup of Held and Hein (1963) in which two kittens were reared in darkness from birth and learned to see the world only in a carousel. While kitten P was passively moved around in a casket, kitten A could rotate around on its own. Significantly, only kitten A, exhibiting self-directed movement, developed normal vision. **b** Illustration of two learners in an open educational field. Learner P is moved by an adaptive learning system (the cross with attached strings) along a prescribed learning path (light gray line) consisting of knowledge bits (darker gray dots) in the fixed knowledge space (circle). Learner A, not bound to the fixed knowledge space, is self-directed and freely explores the educational field, leaving a record of past activities (black dotted line). Like the kittens, only learner A would develop agency and self-regulated learning skills.

and a prototype for the transition from AI regulation to self-regulation in adaptive learning systems (Molenaar, 2022a) has been proposed, real-world implementation of these approaches is needed to improve learning outcomes and keep learners motivated and engaged (Ryan & Deci, 2020).

3.5 Engagement and motivation from gamification

Decades of research have shown that learning occurs when the learner’s mind is actively engaged in the learning process (Dehaene, 2020). Broadly, to activate their minds, learners need to be behaviorally and cognitively engaged in their actions: taking notes while reading, writing summaries, participating in discussions, and solving problems (Bonwell & Eison, 1991). According to the ICAP framework, the more cognitively and behaviorally engaged learners are during learning, the more they learn (Chi & Wylie, 2014). Some adaptive learning systems, such as Korbit, promote active learning by alternating instruction with interactive problem-solving exercises, coding exercises, project-based learning, Socratic tutoring, and video lectures (St-Hilaire et al., 2022). However, a common misconception in the adaptive learning literature is that these systems must incorporate gamification, the application of game design elements such as leaderboards, badges, levels, and points, in non-game settings to increase engagement (Dicheva et al., 2015; Maghsudi et al., 2021).

In this context, an important distinction has been made between extrinsic and intrinsic motivation (Buckley & Doyle, 2016; Mekler et al., 2017; Ryan & Deci, 2000). Extrinsic motivation stems from extrinsic rewards (e.g., badges, points, or even grades), whereas intrinsic motivation is an inherent interest and enjoyment in anticipating and obtaining new information (Ryan & Deci, 2000). Decades of research have shown that students must be intrinsically motivated to be engaged for extended periods (Deci et al., 2001; Oudeyer et al., 2016). Furthermore, direct attempts to control learning outcomes through extrinsic rewards and evaluations typically result in lower-quality motivation and performance (Ryan & Deci, 2020).

In principle, when designed according to the principles of cognitive psychology, educational games can effectively support intrinsic motivation by directing children’s attention to the content and stimuli (Dehaene, 2020). Games can give students the freedom to fail, choose their next actions, provide rapid feedback, and often offer social engagement, all of which support learning (Dicheva et al., 2015). For example, adding quests to a foreign language course elicited long-term intrinsic motivation and made the course more enjoyable, challenging, and meaningful (Philpott & Son, 2022). However, the effect of game elements on learner motivation in educational settings varies greatly depending on the specific gamification element (Sailer & Homner, 2020).

Firstly, much evidence suggests that rewards, incentives, and competition can decrease intrinsic motivation (Deci et al., 2001; Hanus & Fox, 2015; Ryan & Deci, 2020). For example, a comparison of a social networking site

and a gamified learning management system found that gamification increased competition and decreased student collaboration, sharing, and participation (de-Marcos et al., 2014). Courses gamified with leaderboards and badges have been shown to lower final exam scores and decrease intrinsic motivation compared to non-gamified classes (Hanus & Fox, 2015). An experiment examining the specific effects of individual gamification elements showed that points, leaderboards, and levels did not affect intrinsic motivation and only increased the performance quantity (Mekler et al., 2017). A meta-analysis found psychological effects of gamification, such as increasing enjoyment, fostering enthusiasm, and satisfying learners' need for recognition while providing no additional benefit and sometimes causing anxiety and jealousy (Bai et al., 2020). In summary, some gamification elements, such as leaderboards and badges, may decrease intrinsic motivation while providing no additional benefit.

Secondly, while there is sufficient evidence that gamification impacts learning outcomes, there is a paucity of data on the long-term benefits of gamification applied in educational settings (Dichev & Dicheva, 2017). At the short-term performance level, two recent meta-analyses found a positive medium correlation between gamification and learning outcomes (Huang et al., 2020; Sailer & Homner, 2020). However, the impact of individual gamification elements on learning has been less studied (Dicheva et al., 2015). One of the more recent meta-analyses showed how including game fiction/storytelling and collaborative social interactions has a small positive effect on behavioral, but not cognitive and motivational, learning outcomes (Sailer & Homner, 2020). The second meta-analysis showed large effect sizes when collaboration and quests/missions/modules were included in the intervention and more significant effects when some elements, such as leaderboards and timed activities, were excluded (Huang et al., 2020).

Taken together, a scarcity of theoretical foundations marks the application of gamification in education, inconsistent empirical findings, and poor experimental design (Seaborn & Fels, 2015). In addition, a recent longitudinal study showed that even well-designed educational games may not have sustained benefits for educational goals (Potier Watkins & Dehaene, 2023). Hence, designers of PL technologies need to exercise caution when considering integrating both gamification elements and games into computer-based learning environments. As an alternative to gamification, solid evidence supports active learning methods' effectiveness in eliciting intrinsic motivation and enhancing deep understanding, motivation, and creativity (Chi & Wylie, 2014).

4 Beyond adaptive learning systems

Our analysis of adaptive learning systems reveals a mismatch with the educational goals set out in the OECD Learning Compass 2030 (OECD, 2019b). While adaptive learning approaches effectively foster foundational knowledge and skills, they are limited in enhancing learners' agency, general competencies and activating learners' minds. However, recent advances in Large Language Models (LLMs, such as ChatGPT) may address some of these issues and enable a reset of personalized learning approaches (Kasneji et al., 2023).

4.1 Potential of LLMs

The potential of LLMs to play a pivotal role in supporting the goals of contemporary education is demonstrated by research on intelligent tutoring systems (ITS), a sub-category of adaptive learning systems that provide personalized instruction through natural language (speech or text) dialogues inspired by human tutoring strategies (VanLehn, 2006; Nye et al., 2014). While ITS are fundamentally limited to domain-specific knowledge and suffer from some of the same problems as other adaptive learning systems (VanLehn, 2011; Mousavinasab et al., 2021), some ITS solutions are specifically developed to foster more general competencies (Benvenuti et al., 2023). Specifically, much research has been done on ITS that promote student self-regulation and metacognition (Duffy & Azevedo, 2015; Jones & Castellano, 2017; Azevedo et al., 2022; Roll et al., 2007; Daradoumis & Arguedas, 2020), especially when accompanied by open learner models that tacitly invite learners to regulate learning (Long & Aleven, 2017; Winne, 2021). Other ITS solutions have been shown to improve argumentation skills (Wambsganss et al., 2021) and facilitate collaborative learning (Haq et al., 2020; Diziol et al., 2010; Han et al., 2021).

Extending the promising potential of LLMs in education, their domain-agnostic architecture and natural language comprehension offer opportunities to address the limitations of adaptive learning systems and facilitate modern learning experiences. By prompt engineering LLMs (Peng et al., 2023), the models could be used in educational settings to provide more general personal tutoring (Jeon & Lee, 2023; Kasneji et al., 2023). Specifically, ITS has been using curated content and predefined dialogues (e.g., Azevedo et al., 2022), which could be improved by having more dynamic content and feedback to students (e.g., Abdelghani, Wang, et al., 2022). With proper instructions, LLM-based chat and voice bots could promote learners' self-regulation and enhance conceptual understanding (Abdelghani, Oudeyer et al., 2022). Similarly to specific ITS solutions, LLMs could act as pedagogical agents and prompt learners to engage in specific cognitive and metacognitive self-regulation strategies that increase learning effectiveness beyond simple knowledge acquisition (Dever et al., 2022; Azevedo et al., 2022; Wu et al., 2023). LLMs-based pedagogical agents

could be tailored to guide learners through the Anticipation-Action-Reflection cycle by asking them to anticipate the consequences critically and reflect on their actions (Brod et al., 2018; OECD, 2019a).

While research on LLMs is ongoing, several examples offer promising confirmation of their potential. For example, prompt responses to students' questions using a ChatGPT-based solution have been shown to support self-regulated progress and knowledge construction and increase intrinsic motivation and behavioral engagement compared to traditional Google searches (Wu et al., 2023). Another recent GPT-3-driven conversational agent helped learners generate more divergent questions and increased their intrinsic motivation compared to manually predefined curiosity-prompting systems (Abdelghani, Wang et al., 2022). Perhaps we are no longer "a long way from systems being able to have natural language dialogues with learners about their interests in a topic and their potential willingness to put effort in that day" (du Boulay, 2019). LLMs-based AI assistants could play a learning-enhancing role if they focus on activating learners' minds, developing learners' self-regulation skills, and supporting collaborative learning rather than being a homework-solving tool. In other words, LLMs could be a "force multiplier" for student learning if implemented carefully and thoughtfully in the service of evidence-based learning practices (Mollick & Mollick, 2023).

Another promising avenue for LLMs could be assisting teachers and promoting personalized learning activities in more collaborative settings. LLMs could help teachers orchestrate collaborative learning activities (Hadwin & Oshige, 2011; Kasepalu et al., 2022) by supporting learner-learner and tutor-group interactions (Walker & Ogan, 2016; Haq et al., 2020; Mena-Guacas et al., 2023). A recent study showed how teachers use OpenAI's ChatGPT as a partner for students in interactive role-playing, recommending and differentiating learning materials, acting as a teaching assistant (e.g., correcting grammar), and preparing and evaluating tests (Jeon & Lee, 2023). A recent study showed how to integrate ChatGPT into realistic K-12 classroom learning settings where students are positioned as active agents in their learning, building upon each other's ideas to advance collective understanding and solve authentic problems (Chen & Zhu, 2023). In addition, ChatCPT could support evidence-based teaching strategies, including revealing student misconceptions, distributed practice, continuous testing, and assessment of student learning (Mollick & Mollick, 2023). In summary, LLMs have promising potential to support both learners and teachers in personalizing learning content in scientifically proven ways.

4.2 Towards a hybrid model

The future of formal education is likely to be a hybrid model of reciprocal interactions between humans and AI rather than a fully automated system (Molenaar, 2022b). In order to effectively self-direct their learning and keep learning throughout life (e.g., using ChatGPT), learners must have the relevant self-regulation skills that enable them to learn independently (Sutarni et al., 2021; Theobald, 2021; van Alten et al., 2020). The paramount importance of self-regulation skills was exposed during distance learning prompted by the COVID-19 pandemic. Findings indicate a positive correlation between an individual's self-regulation skills and satisfaction, well-being, performance, and self-efficacy during distance learning (Jia, 2022; Peteros et al., 2022; Sutarni et al., 2021). We recognize that a system-wide effort to support self-regulated learning is needed for the hybrid model (Hopkins, 2010; Molenaar, 2022b). Resources should be directed towards training children in SRL skills as early as possible, preferably in the preschool years, which is the most influential period for such training (Dignath et al., 2008; Kochanska et al., 2001; Moffitt et al., 2011; Muir et al., 2023).

Because SRL skills develop with age (Panadero, 2017), the younger the learner, the more collaborative and socially rooted the learning environment should be. Conversely, the older the learner, the more effectively they could use AI assistants for their learning (Figure 3). In the early years, learning should be more social, involving interactions with peers, parents, teachers, and the community to develop SRL skills (Zimmerman, 2000). Collaborative learning is at the heart of learning-centered education and is part of developing general competencies such as critical thinking and complex problem-solving skills (Hadwin et al., 2018; Hendrick, 2020). One could also imagine that because LLMs are neither transparent nor robust, the less self-regulatory a learner is (i.e., less critical thinking, self-monitoring, etc.), the more important a teacher's role is in detecting errors that LLMs unknowingly create (Hlosta et al., 2022). Because the need for relatedness, i.e., a sense of connection and belonging, is fundamental to human motivation, wellness, and academic performance, there will always be a portion of learning that needs to be grounded in social interactions (white portion of Figure 3; Ryan & Deci, 2020).

5 Conclusion

This paper explored the AI-driven approach to personalized learning, particularly the adaptive learning systems that focus primarily on effective domain knowledge acquisition. Our analysis focused on the goals of modern learning-centered education set out in the OECD Learning Compass 2030: fostering students' agency and self-regulation skills for lifelong learning, developing general competencies (such as creating new value), and cognitive activation of the

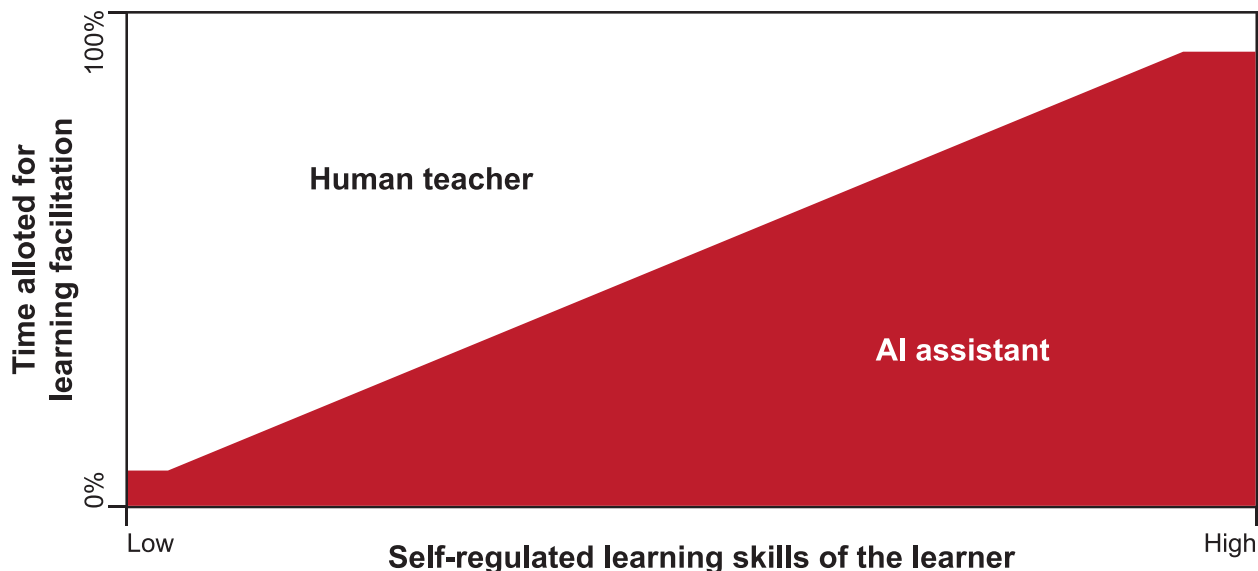

Figure 3: Human instructors are needed to support learners with limited self-regulated learning skills. Younger students require more guidance and a social learning environment, while older students require less assistance. AI assistants can be most effective for learners who exhibit specific self-regulation skills.

learners' minds (OECD, 2019b). Although much research has been done to develop educationally sound ITS, these research areas are largely neglected in the literature on AIEd for personalized learning. Moreover, even the best ITS have limited value in the modern classroom. In examining the existing PL literature, we identified five discrepancies between the educational goals and the current technological approach to PL. First, PL is predominantly used as a synonym for individualization, whereas modern education aspires to be highly collaborative and social. Second, although laudable, the goal of education is not to improve student performance but to foster long-term conceptual understanding through methods that cognitively engage with the learner's mind. While many specific ITS solutions are based on educational psychology and are designed to foster self-regulation, metacognition, collaboration, etc., most adaptive learning systems are limited to predefined subject-based knowledge, limiting learner creativity and the development of more general competencies. Fourth, by recommending learning paths without a deliberate focus on learner autonomy, PL systems could inhibit the development of healthy learning skills required for lifelong learning. Finally, we pointed out the need to cognitively engage with the learners' minds rather than using gamification as a motivational basis.

Taken together, we recognize a misalignment between the educational goals outlined in the OECD Learning Compass 2030 and the current AIEd solutions for personalized learning. While adaptive learning systems have proven effective for effectively acquiring domain knowledge and skills, their limitations become apparent when fostering learner agency, developing general competencies, and promoting collaboration. The main impetus behind the technology-based approach to PL is to provide each student with a virtual tutor similar to human tutoring to solve Bloom's 2-sigma problem (1984). However, the aspirations of modern education have moved beyond effective knowledge delivery, emphasizing the need for developing broader competencies and skills necessary for lifelong learning, transfer, and well-being. From that perspective, PL is not a juxtaposition to the traditional one-size-fits-all approach but a more efficient knowledge delivery method.

Why the current approach to PL is highly limited to adaptive learning requires further analysis. However, it may be that it is simply more profitable for the multi-billion dollar market of AIEd (Guan et al., 2020; Holmes et al., 2019; Miao et al., 2021) to apply existing recommendation systems (e.g., those in YouTube, Amazon, TikTok, etc.) rather than investing in solving serious educational needs and problems (Holmes et al., 2022; Reeves & Lin, 2020; Zawacki-Richter et al., 2019). We are concerned that applying AI without a deeper consideration of its educational value could slow educational progress by diverting focus and resources from scientifically proven changes that need to be made in education systems. For example, as we have argued above, moving learners along a prescribed learning path can rob them of opportunities for playful discovery, limit their agency, and ultimately become a barrier to innovation, creativity, and even happiness (Stanley & Lehman, 2015). As noted nearly a decade ago, AIEd should start with education goals and then choose the appropriate technology to support PL, not the other way around (Vandewaetere & Clarebout, 2014).
