#### Abstract

Given a graph $G=(V, E)$ and an integer $k \in \mathbb{N}$, we investigate the 2-Eigenvalue Vertex Deletion (2-EVD) problem. The objective is to remove at most $k$ vertices such that the adjacency matrix of the resulting graph has at most two eigenvalues. It is established that the adjacency matrix of a graph has at most two eigenvalues if and only if the graph is a collection of equal-sized cliques. Thus, the 2-Eigenvalue Vertex Deletion amounts to removing a set of at most $k$ vertices to transform the graph into a collection of equal-sized cliques. The 2Eigenvalue Edge Editing (2-EEE), 2-Eigenvalue Edge Deletion (2-EED) and 2-Eigenvalue Edge Addition (2-EEA) problems are defined analogously. We present a kernel of size $\mathcal{O}\left(k^{3}\right)$ for 2-EVD, along with an FPT algorithm with a running time of $\mathcal{O}^{*}\left(2^{k}\right)$. For the problem 2-EEE, we provide a kernel of size $\mathcal{O}\left(k^{2}\right)$. Additionally, we present linear kernels of size $5 k$ and $6 k$ for 2-EEA and 2-EED respectively. For the 2-EED, we also construct an algorithm with running time $\mathcal{O}^{*}\left(1.47^{k}\right)$. These results address open questions posed by Misra et al. (ISAAC 2023) regarding the complexity of these problems when parameterized by the solution size.

Keywords: Parameterized Complexity • FPT • Eigenvalue • Uniform Cluster Graphs

## 1 Introduction

Numerous algorithmic challenges involving graphs can be framed as tasks of modifying a graph to meet specific criteria. Notably, over the last three decades, these graph modification tasks have been a significant source of inspiration for innovating new methodologies in parameterized algorithms and complexity theory. This paper delves into a particular graph modification problem known as Uniform Cluster Vertex Deletion, along with several related variations of the same problem. Previously explored in [7], the complexity of reducing the count of distinct eigenvalues of a graph by either removing vertices or editing edges was examined. Notably, it can be observed that an adjacency matrix of graph possesses at most two distinct eigenvalues if and only if it comprises of disjoint unions of equally sized cliques. Our notation aligns with that of the aforementioned paper. Let $G=(V, E)$ be a simple undirected graph, where $V$
denotes the vertex set of $G$ and $E$ denotes the edge set of $G$. We use $n$ to denote $|V|$. For $u \in V$, we define $N(u)=\{v \in V:(u, v) \in E\}$ and $N[u]=N(u) \cup\{u\}$. The degree of $u \in V$ is $|N(u)|$ and denoted by $d_{G}(u)$. A clique $C$ in an undirected graph $G=(V, E)$ is a subset of the vertices $C \subseteq V$ such that every two distinct vertices are adjacent. A cluster graph is a graph where every component is a clique. Observe that a graph is a cluster graph if and only if it does not have an induced $P_{3}$, that is, an induced path on three vertices. Let $U \subseteq V$ be a subset of vertices of $G$ and $F \subseteq\binom{V}{2}$ be a subset of pairs of vertices of $G$. The subgraph induced by $U \subseteq V$ is denoted by $G[U]$. We define $G-U=G[V \backslash U]$, $G-F=(V, E \backslash F), G+F=(V, E \cup F)$ and $G \triangle F=(V, E \triangle F)$. Here, $E \triangle F$ is the symmetric difference between $E$ and $F$. If $U=\{u\}$ or $F=\{e\}$ then we simply write $G-u, G-e$ and $G+e$ for $G-U, G-F$ and $G+F$, respectively. It is known that the spectrum of the adjacency matrix of a graph can be computed in polynomial time. The following lemma is crucial to our discussions:
Lemma 1. [24] The adjacency matrix of a graph $G$ has at most two distinct eigenvalues if and only if $G$ is a disjoint union of equal sized cliques.

We refer to [13] for details on parameterized complexity. Our goal is to present the parameterized complexity landscape of the following problems:

## 2-Eigenvalue Vertex Deletion (2-EVD)

Input: An undirected graph $G=(V, E)$, and a positive integer $k$.
Question: Is there a subset $S \subseteq V$ with $|S| \leq k$ such that $G-S$ is a collection of equal sized cliques?

## 2-Eigenvalue Edge Editing (2-EEE)

Input: An undirected graph $G=(V, E)$, and a positive integer $k$.
Question: Is there a subset $F \subseteq\binom{V(G)}{2}$ with $|F| \leq k$ such that $G \triangle F=$ $(V, E \Delta F)$ is a collection of equal sized cliques?

## 2-Eigenvalue Edge Deletion (2-EED)

Input: An undirected graph $G=(V, E)$, and a positive integer $k$.
Question: Is there a subset $F \subseteq E$ with $|F| \leq k$ such that $G-F=(V, E \backslash F)$
is a collection of equal sized cliques?

## 2-Eigenvalue Edge Addition (2-EEA)

Input: An undirected graph $G=(V, E)$, and a positive integer $k$.
Question: Is there a subset $F \subseteq\binom{V(G)}{2}$ with $|F| \leq k$ such that $G+F=$ $(V, E \cup F)$ is a collection of equal sized cliques?

### 1.1 Our results

In this paper, we study 2 -EVD, 2 -EEE, 2 -EED, and 2 -EEA from the parameterized complexity point of view. Clearly, one can study these problems for any
fixed number of distinct eigenvalues. Using some simple yet powerful structural observations and non-trivial ideas, we have provided combinatorial algorithms for all considered variants of the problem. We give a kernel of size $\mathcal{O}\left(k^{3}\right)$ for 2-EVD. Additionally, we provide an FPT algorithm that runs in time $\mathcal{O}^{*}\left(2^{k}\right)$, which improves upon the FPT algorithm given in [7] based on the standard branching method, which has a running time of $\mathcal{O}^{*}\left(3^{k}\right)$. For the problem 2EEE, we provide a kernel of size $\mathcal{O}\left(k^{2}\right)$. Furthermore, we provide linear kernels of sizes $6 k$ and $5 k$ for 2-EED and 2-EEA, respectively, improving upon the quadratic kernel given in [7] for 2-EEA. We also present an FPT algorithm running in time $\mathcal{O}^{*}\left(1.47^{k}\right)$ for 2-EED, further improving the algorithm from [7]. Through this work, we resolve three open questions listed by Misra et al. [7] concerning the complexity of these problems parameterized by solution size. This study provides a clear picture of the parameterized complexity of the studied problems.

| Uniform cluster | FPT algorithm | Kernel |
| :--- | :---: | ---: |
| Vertex deletion | Theorem (2) $\mathcal{O}^{*}\left(2^{k}\right)$ | Theorem (1) $\mathcal{O}\left(k^{3}\right)$ |
| Edge editing | - | Theorem (3) $\mathcal{O}\left(k^{2}\right)$ |
| Edge deletion | Theorem (5) |  |
|  | $\mathcal{O}^{*}\left(1.47^{k}\right)$ | Theorem (4) $6 k$ |
| Edge Addition | - |  |

### 1.2 Review of previous work

As mentioned in [7], the problem of modifying the graph to reduce the count of distinct eigenvalues to $r$ of the corresponding adjacency matrix was first brought up in [6]. In [7, Misra et al. considered classical and parameterized complexity of this problem. The paper studied mainly four possible operations which are vertex deletion, edge deletion, edge addition and edge editing. For the special case of $r=2$, the vertex deletion variant was shown to be NP-complete even on triangle-free and $3 d$-regular graphs for any $d \geq 2$, and also NP-complete on $d$-regular graphs for any $d \geq 8$. Moreover, the edge deletion, addition, and editing variants were proved to be NP-complete for $r=2$ case. Furthermore, for any fixed $r \geq 3$, they showed that $r$-EVD is NP-complete on bipartite graphs. Also, the 2-EEA was shown to be NP-complete when the input is either a cluster graph, a forest, or a collection of cycles. Apart from studying the classical complexity, the authors also studied and provided numerous results in the realm of parameterized complexity. In particular they gave FPT algorithms for the 2EVD and 2-EED problems with running time $\mathcal{O}^{*}\left(3^{k}\right)$ and $\mathcal{O}^{*}\left(2^{k}\right)$, respectively. We have improved both of these algorithms. The paper also presented a quadratic kernel for 2-EEA.

The clustering problems hold high importance in the complexity theory as they can model multiple scenarios. One more way to view this problem is to modify graph in such a way that the components of the resulting graph have
smaller diameter. This is called as $s$-Club Cluster Vertex Deletion problem where the input is a graph with two integers $s \geq 2$ and $k \geq 1$ and the goal is to decide whether it is possible to remove at most $k$ vertices from $G$ such that each connected component of the resulting graph has diameter at most $s$.

We note that Madathil and Meeks [5] recently explored a generalization of this problem, termed Balanced Cluster Editing, in which, given a graph $G$, and two integers $0 \leq \eta \leq n$ and $k$, we are permitted to "edit" up to $k$ edges. This editing should result in a cluster graph where the size difference between any two connected components of the resulting cluster graph does not exceed $\eta$. One can see that when $\eta=0$, this problem reduces to the Uniform Cluster Editing problem. The authors presented polynomial kernels for Balanced Cluster Completion, Balanced Cluster Deletion, and Balanced Cluster Editing. While they provided polynomial kernels for the general cases, we have achieved better bounds in all considered variants when $\eta=0$. We obtained our results simultaneously with and independent from those by Madathil and Meeks [5].

## 2 Kernelization and FPT algorithm for 2-EVD parameterized by solution size

In this section, we begin by proving the following theorem.

Theorem 1. 2-EVD parameterized by solution size admits a kernel of size $\mathcal{O}\left(k^{3}\right)$.

A cluster graph is a graph in which every connected component is a clique. Note that a graph is a cluster graph if and only if it does not contain an induced $P_{3}$. This observation serves as a cornerstone for our kernelization technique. The first step of the kernelization process is to compute a maximal set $\mathcal{P}_{3}$ of vertexdisjoint induced $P_{3}$ s in $G$. This can be accomplished using the greedy algorithm shown below:

```
Algorithm 1
Require: A graph \(G=(V, E)\).
Ensure: A maximal set \(\mathcal{P}_{3}\) of vertex-disjoint induced \(P_{3}\) in \(G\).
    \(\mathcal{P}_{3}=\emptyset\)
    while \(G\) has an induced \(P_{3}\) do
        Identify an induced \(P_{3}=(u, v, w)\) in \(G\)
        \(\mathcal{P}_{3}=\mathcal{P}_{3} \cup\{(u, v, w)\}\)
        \(G=G-\{u, v, w\}\)
    end while
    return \(\mathcal{P}_{3}\)
```

At the end, if $\left|\mathcal{P}_{3}\right|>k$, we have a no-instance. So we assume that $\left|\mathcal{P}_{3}\right| \leq k$, and let $S$ be the vertices of $\mathcal{P}_{3}$. We have $|S| \leq 3 k$. Let us denote the set of cliques of $G-S$ by $\mathcal{C}$. We have the following simple rules:

Reduction EVD 1 If there exists $s \in S$ with neighbours in at least $k+2$ cliques of $\mathcal{C}=G-S$, then delete $s$ (and its incident edges from $G$ ) and decrement the parameter $k$ by 1. The new instance is $(G-s, k-1)$

Lemma 2. Reduction Rule EVD 1 is safe.
Proof. Let $X$ be a uniform cluster vertex deletion set of $G$ of size at most $k$. For the sake of contradiction, let us assume that $s \in S$, which has neighbours in at least $k+2$ cliques of $\mathcal{C}=G-S$, is not in $X$. Therefore, $s$ must be in a clique of $G-X$. That clique can have vertices from at most one clique, say $C_{i}$ in $\mathcal{C}$. Since $s$ has neighbours in at least $k+2$ cliques, we would need to include neighbours of $s$ in at least $k+1$ cliques other than $C_{i}$ in the solution $X$. This contradicts the condition that the solution size $|X|$ is at most $k$. Hence if $(G, k)$ is a yes-instance (meaning there exists a uniform cluster vertex deletion set of size at most $k$ ), then $s$ must be in $X$.

Next, we partition the set of cliques in $\mathcal{C}$ based on whether they have neighbours in $S$ or not. We define:

$$
\mathcal{C}_{0}=\{C \in \mathcal{C}: \text { no vertex in } C \text { has a neighbour in } S\}
$$

and

$$
\mathcal{C}_{1}=\{C \in \mathcal{C}: \text { some vertex in } C \text { has a neighbour in } S\}
$$

Observe that the exhaustive application of reduction rule EVD 1 completely removes the vertices of $S$ that have neighbours in at least $k+2$ cliques of $\mathcal{C}_{1}$. In other words, after the exhaustive application of reduction rule EVD 1, each vertex of $S$ can have neighbours in at most $k+1$ cliques of $\mathcal{C}_{1}$. Since $|S| \leq 3 k$ and each vertex of $S$ can have neighbours in at most $k+1$ cliques of $\mathcal{C}_{1}$, there are at most $3 k(k+1)$ cliques in $\mathcal{C}_{1}$. Therefore, we have

$$
\left|\mathcal{C}_{1}\right| \leq 3 k(k+1)
$$

An $r$-clique is a clique of size $r$. Now, we have the following simple rule.
Reduction EVD 2 If for some $r \in\{1,2, \ldots, n\}$ there are more than $k+1$ $r$-cliques in $\mathcal{C}_{0}$, then remove all but $k+1 r$-cliques from $G$.

Lemma 3. Reduction rule EVD R is safe.
Proof. Suppose $(G, k)$ is a yes-instance and $X$ is a uniform cluster vertex deletion set of $G$ of size at most $k$. If for some $r \in\{1,2, \ldots, n\}$ there are more than $k+1$ $r$-cliques in $\mathcal{C}_{0}$, then we claim that $r$ is the size of all cliques in $G-X$. For the sake of contradiction, let us assume that $r^{\prime}<r$ is the size of all cliques in $G-X$. In that case, we need to delete at least one vertex from each $r$-clique.

This means we would have to add at least $k+1$ vertices in $X$, which contradicts the assumption that $X$ is of size at most $k$. Thus, we conclude that $r$ is the size of all cliques in $G-X$. Since the solution size is at most $k$, this allows us to remove all but $k+1 r$-cliques from $G$.
To bound the number of cliques in $\mathcal{C}_{0}$, we make the following observation. This observation helps us bound the number of cliques in $\mathcal{C}_{0}$ by limiting the variety of cliques sizes present.

Observation $1 \mathcal{C}_{0}$ contains cliques of at most $k+1$ distinct sizes.
This observation is correct because by deleting at most $k$ vertices we can alter the sizes of at most $k$ cliques. Consequently, $\mathcal{C}_{0}$ can contain cliques of at most $k+1$ distinct sizes. According to Reduction Rule EVD 2, there can be at most $k+1$ cliques of the same size. Therefore, we have:

$$
\left|\mathcal{C}_{0}\right| \leq(k+1)(k+1)
$$

Combining this with our earlier result for $\mathcal{C}_{1}$ :

$$
|\mathcal{C}|=\left|\mathcal{C}_{0}\right|+\left|\mathcal{C}_{1}\right| \leq(k+1)(k+1)+3 k(k+1)=4 k^{2}+5 k+1
$$

Thus, the total number of cliques $|\mathcal{C}|$ is bounded by $4 k^{2}+5 k+1$.
Now, we consider two cases based on the maximum size of a clique in $\mathcal{C}$. Let $\omega(\mathcal{C})=\max _{C \in \mathcal{C}}\{|C|\}$.

### 2.1 Case 1: $\omega(\mathcal{C})<8 k$

In this case, we obtain a kernel of size:
$|S|+\sum_{C \in \mathcal{C}}|C| \leq 3 k+8 k\left(4 k^{2}+5 k+1\right)=\mathcal{O}\left(k^{3}\right)$.

### 2.2 Case 2: $\omega(\mathcal{C}) \geq 8 k$

Let $C_{0}$ be a clique in $\mathcal{C}$ such that $\omega(\mathcal{C})=\left|C_{0}\right|$. Then $C_{0}$ becomes a clique of size at least $\left|C_{0}\right|-k \geq 7 k$ in $G-X$, where $X$ is a solution of size at most $k$. In this case, the resulting graph $G-X$ must be a collection of $r$-cliques, where $r \geq\left|C_{0}\right|-k \geq 7 k$.

Reduction EVD 3 If there exist $C_{1}$ and $C_{2} \in \mathcal{C}$ such that $\left|C_{1}\right|-\left|C_{2}\right|>4 k$, then delete all the vertices in $C_{2}$ and decrement the parameter $k$ by $\left|C_{2}\right|$. The new instance is $\left(G-C_{2}, k-\left|C_{2}\right|\right)$.

Lemma 4. Reduction Rule EVD 3 is safe,

Proof. For the sake of contradiction, let us assume that $v \in C_{2}$ does not belong to some solution $X$ of size at most $k$. First, since $C_{2}$ is a clique, $v$ has at most $\left|C_{2}\right|-1$ neighbours in $C_{2}$ in the resulting graph. Second, $v$ can have at most $3 k$ neighbours in $S$. Thus, $v$ can be part of a clique of size at most $\left(\left|C_{2}\right|-1\right)+3 k+1=\left|C_{2}\right|+3 k$.

On the other hand, there always exist a vertex $u \in C_{1}$ such that $u$ is not contained in $X$. Clearly, $u$ will have at least $\left|C_{1}\right|-k-1$ neighbours in $G-X$. Therefore, $u$ must be contained in a clique of size at least $\left|C_{1}\right|-k>\left|C_{2}\right|+4 k-k=$ $\left|C_{2}\right|+3 k$. Therefore, $u$ and $v$ can never be contained in equal-sized cliques. This contradicts the fact that $G-X$ is a collection of equal sized-cliques. Therefore, we must include all vertices of $C_{2}$ in every uniform cluster vertex deletion set $X$ of $G$ of size at most $k$.

Observation 2 After applying Reduction Rule $E V D$ 3, we get that $\min _{C \in \mathcal{C}}|C| \geq$ $4 k$.

This is true because we have assumed that $\omega(\mathcal{C}) \geq 8 k$.
We now introduce the concept of a heavy neighbour of a vertex $s \in S$ in $\mathcal{C}$, which is a key element for explaining the forthcoming reduction rules.
Definition 1. A clique $C \in \mathcal{C}$ is called a heavy neighbour of $s \in S$ if $s$ is adjacent to at least $\max \{|C|-4 k, k+1\}$ vertices in $C$.
We observe that if $s \in S$ has no heavy neighbour, then this vertex should belong to every solution of size at most $k$. Our next reduction rule is as follows:

Reduction EVD 4 If $s \in S$ has no heavy neighbour, remove $s$ from $G$, and decrement the parameter $k$ by 1. The new instance is $(G-s, k-1)$.
Lemma 5. Reduction rule EVD 4 is safe.
Proof. For the sake of contradiction, let us assume that $s \in S$ has no heavy neighbour and does not belong to some solution $X$ of size at most $k$. It means $s$ must belong to some clique in $G-X$. Since $s$ has no heavy neighbour in $\mathcal{C}, s$ is adjacent to at most $\max \{|C|-4 k, k+1\}-1$ vertices in some $C \in \mathcal{C}$. Additionally, $s$ can have at most $3 k-1$ neighbours in $S$. Now consider two cases:

1. If $\max \{|C|-4 k, k+1\}-1=|C|-4 k-1$, then $s$ can be part of a clique of size at most $(|C|-4 k-1)+(3 k-1)+1=|C|-k-1$. This contradicts the fact that $G-X$ is a collection of $r$-cliques, where $r \geq|C|-k$.
2. If $\max \{|C|-4 k, k+1\}-1=k$, then $s$ can be part of a clique of size at most $k+(3 k-1)+1=4 k$. This contradicts the fact that $G-X$ is a collection of $r$-cliques, where $r \geq 7 k$.
Therefore, $s$ must be part of every solution of size at most $k$.
Next, we observe that if $s \in S$ has at least $k+1$ neighbours in each of two cliques, say $C, C^{\prime} \in \mathcal{C}$, then this vertex should belong to every solution of size at most $k$. Our next reduction rule is the following:

Reduction EVD 5 If $s \in S$ has at least $k+1$ neighbours in more than one clique in $\mathcal{C}$, then remove $s$ from $G$, and decrement the parameter $k$ by 1. The new instance is $(G-s, k-1)$.

Lemma 6. Reduction rule EVD 5 is safe.
Proof. Suppose $s \in S$ has at least $k+1$ neighbours in each of the cliques $C, C^{\prime} \in$ $\mathcal{C}$. For the sake of contradiction, assume that $s \in S$ does not belong to some solution $X$ of size at most $k$. It implies that $s$ must belong to a clique in $G-X$. This clique can contain vertices either from $C$ or $C^{\prime}$, but not both. Therefore, we must include at least $k+1$ neighbours of $s$ from either $C$ or $C^{\prime}$ in $X$. This contradicts the fact that $X$ is of size at most $k$. Hence, $s$ must be part of every solution of size at most $k$. Thus, removing $s$ and decrementing $k$ by 1 is a safe reduction.

Observation 3 After applying reduction rules 4 and 5 exhaustively, each $s \in S$ has exactly one heavy neighbour in $\mathcal{C}$.

Reduction EVD 6 If $s \in S$ has more than $k$ neighbours in cliques other than its heavy neighbour, then remove $s$ from $G$, and decrement the parameter $k$ by 1. The new instance is $(G-s, k-1)$.

Lemma 7. Reduction Rule 6 is safe.
Proof. Note that if $s \in S$ has more than $k$ neighbours in cliques other than its heavy neighbour, then we can construct $k+1$ induced $P_{3}$ 's where the only common vertex is $s$. Therefore, $s$ must be added to the solution.

Let $S_{C}$ denotes the set of vertices in $S$ whose heavy neighbour is $C$. For each $C \in \mathcal{C}$, we define

$$
\mathcal{N}(C)=\bigcup_{s \in S_{C}}(C \backslash N(s)) \cup \bigcup_{s \in S \backslash S_{C}}(N(s) \cap C)
$$

We also define

$$
\mathcal{N}(\mathcal{C})=\bigcup_{C \in \mathcal{C}} \mathcal{N}(C)
$$

Lemma 8. We have $|\mathcal{N}(\mathcal{C})|=\mathcal{O}\left(k^{2}\right)$.
Proof. Let us assume that $C_{s}$ denotes the unique heavy neighbour of $s$. We have

$$
\begin{aligned}
\mathcal{N}(\mathcal{C}) & =\bigcup_{C \in \mathcal{C}}\left[\bigcup_{s \in S_{C}}(C \backslash N(s)) \cup \bigcup_{s \in S \backslash S_{C}}(N(s) \cap C)\right] \\
& =\bigcup_{s \in S}\left[\left(C_{s} \backslash N(s)\right) \cup \bigcup_{C \in \mathcal{C} \backslash C_{s}}(N(s) \cap C)\right]
\end{aligned}
$$

Note that by Reduction Rule 6 for any fixed $s \in S$, we have

$$
\left|\bigcup_{C \in \mathcal{C} \backslash C_{s}}(N(s) \cap C)\right|<(k+1)
$$

Also, for each $s \in S$, we have

$$
\begin{aligned}
\left|C_{s} \backslash N(s)\right| & \leq|C|-(|C|-4 k)=4 k \text { if } \max \{|C|-4 k, k+1\}=|C|-4 k \\
& \leq|C|-(k+1) \leq 4 k \text { if } \max \{|C|-4 k, k+1\}=k+1
\end{aligned}
$$

As there are at most $3 k$ vertices in $S$, we get that $|\mathcal{N}(\mathcal{C})| \leq 3 k[k+4 k]=15 k^{2}=$ $\mathcal{O}\left(k^{2}\right)$.

Lemma 9. For each $C \in \mathcal{C}$, every pair of adjacent vertices $x$ and $y$ in $C \backslash \mathcal{N}(C)$ are true twins, that is, $N[x]=N[y]$.

Proof. By the definition of $\mathcal{N}(C)$, it is evident that for any vertex $v \in C \backslash \mathcal{N}(C)$, we have $N(v) \cap S=S_{C}$. Recall that for the vertices in $S_{C}, C$ is their heavy neighbour. Since $v \in C$ and $C$ is a clique, $v$ is adjacent to all other vertices of $C$. Therefore, for every $v \in C \backslash \mathcal{N}(C)$, we have $N[v]=C \cup S_{C}$.

Reduction EVD 7 If $\min _{C \in \mathcal{C}}\{|C \backslash \mathcal{N}(C)|\}>k+1$, then arbitrarily delete exactly one vertex from each $C \backslash \mathcal{N}(C)$ for every $C \in \mathcal{C}$. The new instance is $(G-W, k)$, where $W$ is the set of vertices deleted from $G$.

Lemma 10. Reduction Rule EVD 7 is safe.
Proof. Let $I^{\prime}=\left(G^{\prime}, k\right)$ be an instance of 2-EVD obtained from $I=(G, k)$ by exhaustively applying Reduction Rule EVD 7. We will show that $I$ is a yesinstance if and only if $I^{\prime}$ is a yes-instance. Let $X \subseteq V(G)$ be a solution of size at most $k$ for the instance $I$. We will construct a solution $X^{\prime}$ of the same size as $X$ for the instance $I^{\prime}$. We know $G-X$ is a collection of equal sized cliques $Q_{1}, Q_{2}, \ldots, Q_{r}$. We observe that there is no clique $Q_{i}$ such that $Q_{i} \subseteq S$. This is true because otherwise $\left|Q_{i}\right| \leq 3 k$ as $|S| \leq 3 k$, and we have already observed that the size of cliques must be at least $7 k$. We construct $X^{\prime}$ from $X$ as follows: if $u \in X \cap(C \backslash \mathcal{N}(C))$ for some $C \in \mathcal{C}$ and $u$ is deleted during the execution of Reduction Rule 7, then remove $u$ from $X$ and include $u$ 's true twin $v \notin X$.

We have to show that $G^{\prime}-X^{\prime}$ is a collection of equal-sized cliques. It is easy to see that $G^{\prime}-X^{\prime}$ is a collection of cliques $Q_{i}^{\prime}=Q_{i} \backslash\{u\}$ where $u \in Q_{i}$ is a vertex deleted by Reduction Rule 7 As $\left|Q_{i}\right|=\left|Q_{j}\right|$, we get $\left|Q_{i}^{\prime}\right|=\left|Q_{j}^{\prime}\right|$ for all $i \neq j$. This shows that $I^{\prime}$ is a yes-instance.
In the other direction, let us assume that $X^{\prime}$ is a solution of size at most $k$ for the instance $I^{\prime}$. Let us denote the equal sized cliques in $G^{\prime}-X^{\prime}$ by $Q_{1}^{\prime}, Q_{2}^{\prime}, \ldots, Q_{r}^{\prime}$. We claim that $X:=X^{\prime}$ is a solution for the instance $I$. Note that $G-X$ is again a collection of cliques $Q_{1}, Q_{2}, \ldots, Q_{r}$ where $Q_{i}=Q_{i}^{\prime} \cup\{u\}$ where $u$ is a vertex deleted by Reduction Rule 7. Clearly, we have $\left|Q_{i}\right|=\left|Q_{j}\right|$ as we know that $\left|Q_{i}^{\prime}\right|=\left|Q_{j}^{\prime}\right|$ for all $i \neq j$.

After exhaustively applying Reduction Rule[7] we know that there exists a clique, say $C_{q} \in \mathcal{C}$, such that $\left|C_{q}\right|-\left|\mathcal{N}\left(C_{q}\right)\right| \leq k+1$. Note that $\max _{C \in \mathcal{C}}|C|-\left|C_{q}\right| \leq 4 k$ due to Reduction Rule EVD 3. Therefore, we get $\max _{C \in \mathcal{C}}|C|-\left|\mathcal{N}\left(C_{q}\right)\right| \leq 5 k+1$. Since $\left|\mathcal{N}\left(C_{q}\right)\right|=\mathcal{O}\left(k^{2}\right)$, we get $\max _{C \in \mathcal{C}}|C| \leq \mathcal{O}\left(k^{2}\right)$. Note that

$$
\begin{aligned}
V(G) & =S \cup \bigcup_{C \in \mathcal{C}} C \\
& =S \cup \bigcup_{C \in \mathcal{C}}(\mathcal{N}(C) \cup(C \backslash \mathcal{N}(C))) \\
& =S \cup \mathcal{N}(\mathcal{C}) \cup \bigcup_{C \in \mathcal{C}}(C \backslash \mathcal{N}(C))
\end{aligned}
$$

To get a cubic kernel, we need to show that the size of the set $\bigcup_{C \in \mathcal{C}}(C \backslash \mathcal{N}(C))$ is bounded by a cubic function of the parameter. To see this, we partition the set of cliques in $\mathcal{C}$ into two parts:

$$
\mathcal{H}=\{C \in \mathcal{C} \mid C \text { is a heavy neighbour of some } s \in S\}
$$

and $\mathcal{L}=\mathcal{C} \backslash \mathcal{H}$. As we have seen, every vertex $s \in S$ has exactly one heavy neighbour, which implies that $|\mathcal{H}| \leq 3 k$. Therefore, we get that $\bigcup_{C \in \mathcal{H}}|(C \backslash \mathcal{N}(C))|=$ $\mathcal{O}\left(k^{3}\right)$ as $\max _{C \in \mathcal{C}}|C| \leq \mathcal{O}\left(k^{2}\right)$. Now, let us focus on the set $\mathcal{L}$. Let us denote $\mathcal{L}^{\prime}=\{C \in \mathcal{L}| | C \backslash \mathcal{N}(C) \mid \geq k+1\}$ and $\mathcal{L}^{\prime \prime}=\mathcal{L} \backslash \mathcal{L}^{\prime}$. It is clear that $\bigcup_{C \in \mathcal{L}^{\prime \prime}}|(C \backslash \mathcal{N}(C))| \leq \mathcal{O}\left(k^{3}\right)$ as $\left|\mathcal{L}^{\prime \prime}\right| \leq|\mathcal{C}| \leq \mathcal{O}\left(k^{2}\right)$. We can assume that $\left|\mathcal{L}^{\prime}\right| \geq 2 k+1 ;$ otherwise, we achieve the required cubic kernel.

Claim. In this case, we can calculate the size $c$ of equal sized cliques obtained after deleting the vertices in a solution in polynomial time, assuming the input is a yes-instance.

Proof. Let us denote $\mathcal{L}^{\prime}=\left\{C_{1}^{\prime}, C_{2}^{\prime}, \ldots, C_{l}^{\prime}\right\}$, where $l \geq 2 k+1$. Let $X$ be a solution of size at most $k$ of the input instance. As $\left|C_{i}^{\prime} \backslash \mathcal{N}\left(C_{i}^{\prime}\right)\right| \geq k+1$, at least one vertex will survive from each set $C_{i}^{\prime} \backslash \mathcal{N}\left(C_{i}^{\prime}\right)$ in $G-X$. Because the vertices in $C_{i}^{\prime} \backslash \mathcal{N}\left(C_{i}^{\prime}\right)$ do not have any neighbours in $S$, the deletion of at most $k$ vertices can change the degree of vertices in at most $k$ sets $C_{i}^{\prime} \backslash \mathcal{N}\left(C_{i}^{\prime}\right)$. This implies that vertices in all but at most $k$ distinct sets $C_{i}^{\prime} \backslash \mathcal{N}\left(C_{i}^{\prime}\right)$ must have same degree. If this is not the case, we can return a no-instance. If it is the case, then let's say the degree is $d$. One can easily see that $c=d+1$. It is important to note that having $\left|\mathcal{L}^{\prime}\right| \geq 2 k+1$ is necessary; otherwise, identifying $d$ is not possible.

Reduction EVD 8 If there is a vertex $v$ such that $d(v)<d$, then add it to the solution. The new instance is $(G-v, k-1)$.

Note that the degree of every vertex in $G-X$ must be equal to $d$. Since $d(v)<d$ and we cannot increase the degree of $v$ through vertex deletion, $v$ must be added to the solution.

Due to Reduction Rule 8, we can assume that all the cliques in $\mathcal{L}^{\prime}$ have size at least $c$.

Reduction EVD 9 If there is a clique $C^{\prime} \in \mathcal{L}^{\prime}$ such that $\left|C^{\prime}\right|=c$, then delete all the vertices in $N\left(C^{\prime}\right)$ from the graph $G$. The new instance is $\left(G-N\left(C^{\prime}\right), k-\right.$ $\left.\left|N\left(C^{\prime}\right)\right|\right)$.

Lemma 11. Reduction Rule 9 is safe.
Proof. Note that at least one vertex $u \in C^{\prime} \backslash \mathcal{N}\left(C^{\prime}\right)$ must survive after deleting the vertices in a solution. This vertex must be part of a clique of size $c$. Therefore, the clique $C^{\prime}$ must appear unchanged in the resulting graph. Hence, we must delete all the neighbours of $C^{\prime}$.

Let us denote by $\mathcal{L}_{\text {iso, }}^{\prime}$ the set of isolated cliques of size $c$ in $\mathcal{L}^{\prime}$ obtained after applying Reduction Rule 9 Similarly, denote by $\mathcal{L}_{>c}^{\prime}$ the set of cliques of size more than $c$ in $\mathcal{L}^{\prime}$.

Reduction EVD 10 If $\left|\mathcal{L}_{\text {iso }, c}^{\prime}\right|>k+1$, then retain only $k+1$ cliques from $\mathcal{L}_{\text {iso,c }}^{\prime}$ and discard the rest.

Lemma 12. Reduction Rule 10 is safe.
Proof. Since the size of cliques after deleting the vertices in a solution of size at most $k$ must be $c$, we can keep $k+1$ cliques of size $c$ to ensure this property holds, and delete the rest. Observe that deleting at most $k$ vertices can alter the size of at most $k$ cliques. By keeping $k+1$ cliques, we ensure that the size of cliques in the resulting graph is equal to $c$.

Reduction EVD 11 If $\left|\mathcal{L}_{>c}^{\prime}\right|>k$, then conclude that we are dealing with a no-instance.

If $\left|\mathcal{L}_{>c}^{\prime}\right|>k$, it implies we need to delete more that $k$ vertices to ensure that each clique in $\mathcal{L}_{>c}^{\prime}$ becomes a clique of size $c$ in the resulting graph. However, since we are constrained to finding a solution of size at most $k$, achieving this is not feasible. Therefore, $\left|\mathcal{L}_{>c}^{\prime}\right| \leq k$.

Observation 4 After applying Reduction Rule 8, 9, 10 and 11, the size of $\mathcal{L}^{\prime}$ is bounded by $2 k+1$.

From Observation 4 it follows that $\bigcup_{C \in \mathcal{L}^{\prime}}|C \backslash \mathcal{N}(C)| \leq \mathcal{O}\left(k^{3}\right)$.
This completes the proof of Theorem 1 Next, we will present an FPT algorithm.

### 2.3 An FPT algorithm for 2-EVD

In this section we give an FPT algorithm for the 2-EVD problem. We prove the following theorem:

Theorem 2. The 2-EVD problem parameterized by solution size $k$ can be solved in $2^{k} . n^{\mathcal{O}(1)}$ time.

We utilize an algorithm from [9] to find a cluster vertex deletion set $X$ of size at most $k$ in $\mathcal{O}^{*}\left(1.811^{k}\right)$ time. If this algorithm determines that no such set exists, conclude that we are dealing with a no-instance. Otherwise, this algorithm returns a cluster vertex deletion set $X$ of size at most $k$. To decide whether $G$ contains a uniform cluster vertex deletion set $S$ of size at most $k$, we proceed as follows:

- We guess the intersection of $S$ with $X$, that is, we guess the set $X_{i n}=X \cap S$, delete $X_{i n}$ from $G$ and reduce parameter $k$ by $\left|X_{i n}\right|$.
- For each guess of $X_{\text {in }}$, we set $X_{\text {out }}=X \backslash X_{\text {in }}$ and solve Disjoint 2-EVD on the instance $\left(G-X_{i n}, X_{\text {out }}, k-\left|X_{i n}\right|\right)$.

For each guess $X_{i n}$, we try to find a uniform cluster vertex deletion set $S^{\prime}$ in $G-X_{i n}$ of size at most $k-\left|X_{i n}\right|$ that is disjoint from $X_{o u t}$. This problem is called Disjoint 2-EVD. If for some guess $X_{i n}$, we find a uniform cluster vertex deletion set $S^{\prime}$ in $G-X_{i n}$ of size at most $k-\left|X_{i n}\right|$ that is disjoint from $X_{o u t}$, then we output $S=X_{i n} \cup S^{\prime}$. Otherwise, we conclude that the given instance of the Disjoint 2-EVD problem is a no-instance. The number of all guesses is bounded by $2^{k}$. Therefore, to obtain an FPT algorithm for 2 -EVD, it is sufficient to solve Disjoint 2-EVD in polynomial time.
2.3.1 An algorithm for Disjoint 2-EVD: Let $\left(G-X_{i n}, X_{\text {out }}, k\right)$ be an instance of Disjoint 2-EVD, and let $H=G-X$, where $X=X_{\text {in }} \cup X_{\text {out }}$. We denote $G^{\prime}=G-X_{i n}$.

Reduction Disjoint-EDV 1 If $G\left[X_{\text {out }}\right]$ is not a disjoint union of cliques or $G-X$ is not a disjoint union of cliques, then return that $\left(G^{\prime}, X_{\text {out }}, k\right)$ is a no-instance.

Reduction Disjoint-EDV 2 If there is a vertex $v$ in $G-X$ which has neighbours in two distinct cliques in $G\left[X_{o u t}\right]$, then delete $v$ from $G$ and decrement the parameter $k$ by 1. The new instance is $\left(G^{\prime}-\{v\}, X_{o u t}, k-1\right)$.

The previous reduction rule is correct because we will get an induced $P_{3}$ where the only vertex that we are allowed to delete is $v$. Therefore, we must add $v$ to the solution.

So from now onwards, we assume that $G\left[X_{o u t}\right]$ is a disjoint union of cliques and $H=G-X$ is a disjoint union of cliques. We also guess the exact size of the solution as $k^{\prime}$. The possible guesses for $k^{\prime}$ range from 1 to $k$. This will be helpful
in the final part of the algorithm. We will solve this problem by guessing the size $c$ of cliques in the resulting graph. At the end, we will compare the solution sizes for each $c$ and return the minimum one. The possible guesses for $c$ ranges from 1 to $n$.

Reduction Disjoint-EDV 3 If there is a clique of size exactly $c$ in $G\left[X_{o u t}\right]$ then delete $N(C)$ and add all the vertices of the set $N(C)$ to the solution. The new instance is $\left(G^{\prime}-N[C], X_{\text {out }}, k-|N(C)|\right)$.

Observation 5 If there is a clique $C$ of size larger than $c$ in $G\left[X_{\text {out }}\right]$, then we can discard such a guess for $c$.

Observation 6 Every clique in $G\left[X_{\text {out }}\right]$ of size less than c must utilize vertices from exactly one clique in $G-X$ to form a clique of size $c$.

Due to Observation 6, for every clique $C$ of size less than $c$ in $G\left[X_{\text {out }}\right]$, there is a unique clique in $G-X$ that helps to form a clique of size $c$ containing vertices from $C$.

We now construct a bipartite graph with bipartition $(A, B)$ in the following way. For a given guess $\left(k^{\prime}, c\right)$, observe that the number of equal-sized cliques in the resulting graph is $p=\frac{\left|V\left(G^{\prime}\right)\right|-k^{\prime}}{c}$. We need a total of $p$ vertices in $A$. Suppose the number of cliques in $G\left[X_{o u t}^{c}\right]$ is $p_{1}$. We add a vertex $a \in A$ corresponding to each clique in $G\left[X_{\text {out }}\right]$. If $p_{1}<p$, we add $p-p_{1}$ dummy vertices in $A$ to ensure the number of vertices in $A$ equals $p$. Similarly, we add a vertex $b \in B$ corresponding to each clique in $G-X$. Due to Reduction Rule Disjoint-EDV 3 and Observation 55 it follows that every clique in $G\left[X_{o u t}\right]$ has size less than $c$. We add an edge between $a \in A$ and $b \in B$ if the clique corresponding to $a$ can be transformed into a clique of size $c$ using some vertices from the clique corresponding to $b$. Additionally, some cliques in $G-X$ can be transformed into cliques of size $c$ by deleting the necessary number of vertices from the respective cliques. We make $b \in B$ adjacent to all dummy vertices in $A$ if the clique corresponding to $b$ can be transformed into a clique of size $c$ by deleting the necessary number of vertices.

We now try to find an $A$-saturated matching in this bipartite graph. If an $A$ saturated matching does not exist, we discard such a guess $\left(k^{\prime}, c\right)$. Otherwise, we find an $A$-saturated matching $M$ of size $p$. We identify $p$ cliques in the resulting graph as follows: If $(a, b) \in M$ and $a$ is not a dummy vertex, then the clique corresponding to $a \in A$ will be transformed into a clique of size $c$ using some vertices from the clique corresponding to $b$. If $(a, b) \in M$ and $a$ is a dummy vertex, then the clique corresponding to $b \in B$ will be transformed to a clique of size $c$ by deleting the necessary number of vertices. Thus we know exactly the cliques in the final graph and can delete the necessary vertices to form the cliques of size $c$. If the solution size $k^{\prime}$ matches the number of vertices that are deleted from $G^{\prime}$, then we return a yes-instance; otherwise, we return a no-instance.

## 3 Kernelization algorithm for 2-EEE parameterized by solution size

In this section, we study the following problem: For a given graph $G$, can we transform $G$ into a uniform cluster graph by editing at most $k$ adjacencies, where editing involves adding or deleting at most $k$ edges? More formally, let $G=(V, E)$ be a graph. Then $F \subseteq V \times V$ is called a uniform cluster editing set for $G$ if $G \triangle F$ is a uniform cluster graph. In this section, we prove the following theorem.

Theorem 3. 2-EEE parameterized by solution size admits a kernel of size $\mathcal{O}\left(k^{2}\right)$.

Note that many preprocessing rules applied in the case of 2 -EEE are also applicable in the cases of 2-EEA and 2-EED. To maintain conciseness, we will refer to the following preprocessing step as the preparation step, which begins here.

A graph is a cluster graph if and only if it does not have an induced $P_{3}$. It is straightforward to compute a maximal set $\mathcal{P}_{3}$ of vertex-disjoint induced $P_{3} \mathrm{~S}$ in $G$ using Algorithm 1 If $\left|\mathcal{P}_{3}\right|>k$, then we have a no-instance. Therefore, we assume that $\left|\mathcal{P}_{3}\right| \leq k$, and let $S$ be the vertices of $\mathcal{P}_{3}$. We have $|S| \leq 3 k$. Let $\mathcal{C}$ denote the set of cliques of $G-S$. Let $F$ be a uniform cluster editing set of size at most $k$ for $G$, and let $V_{F}$ be the vertices of $F$. Then we have $\left|V_{F}\right| \leq 2 k$.

We observe that if there indeed exists a uniform cluster editing set $F$ of size at most $k$, then the vertices in $V \backslash V_{F}$ have equal degree in both $G$ and $G \triangle F$. In other words, for any two distinct vertices $x, y \in V \backslash V_{F}$, we have $d_{G}(x)=d_{G}(y)=d_{G \triangle F}(x)=d_{G \triangle F}(y)$. We assume that $G$ has at least $4 k+1$ vertices; otherwise, we would have a kernel of size $4 k$. It is known that if the input is a yes-instance, then at least $2 k+1$ vertices have the same degree $d$, and at most $2 k$ vertices have degrees not equal to $d$. Therefore, we first check if the input instance $(G, k)$ satisfies this condition. If the input instance does not satisfy this condition, then conclude that we are dealing with a no-instance. If the input instance satisfies this condition, we can calculate the exact value of $d$ in polynomial time. Assuming that the input is a yes-instance, let $c$ be the size of equal sized cliques in $G \triangle F$. It follows that $c$ must be equal to $d+1$ in $G \triangle F$. This implies that the minimum degree of $G$ is at least $d-k$, because executing $k$ edge editing operations can increase the degree of a vertex by at most $k$. Similarly, the maximum degree of $G$ is at most $d+k$, because executing $k$ edge editing operations can decreases the degree of a vertex by at most $k$. The preparation step ends here. The following two rules are safe.

Reduction EEE 1 If $\delta(G)<d-k$ or $\Delta(G)>d+k$ then conclude that we are dealing with a no-instance.

Reduction EEE 2 If the number of vertices in $V(G)$ with degrees not equal to $d$ exceeds $2 k$, then conclude that we are dealing with a no-instance.

We will consider two cases based on the value of $d$.

Case 1: Let us assume that $d \geq 6 k$.
Lemma 13. If $(G, k)$ is a yes-instance, then for each $C \in \mathcal{C}$, we have $|C|>2 k$.
Proof. If there is a clique $C \in \mathcal{C}$ such that $|C| \leq 2 k$, then every vertex $v \in C$ has a degree at most $5 k-1$. This is because $v$ has at most $2 k-1$ neighbours within $C$ and at most $3 k$ neighbours in $S$. Given $d \geq 6 k$, we have $5 k-1<d-k$. This implies $\delta(G)<d-k$. Accordingly to Reduction Rule 1, if $\delta(G)<d-k$, then we conclude that we are dealing with a no-instance. Therefore, we must have $|C|>2 k$.

Reduction EEE 3 If $s \in S$ is adjacent to at least $k+1$ vertices of a clique $C \in \mathcal{C}$, then add all missing edges between $s$ and $C$ and decrement the parameter $k$ by $|W|$, where $W$ is the set of all missing edges between $s$ and $C$. The resulting instance is $(G+W, k-|W|)$. If $|W| \geq k+1$, then conclude that we are dealing with a no-instance.

Lemma 14. Reduction rule 3 is safe.
Proof. The vertices of $C$ must belong to the same connected component in the edited graph. Since $s$ has at least $k+1$ neighbours in $C, s$ must be in the same connected component as the vertices in $C$. Otherwise, to place $s$ in a separate component, we would need to delete at least $k+1$ edges between $s$ and $C$, which contradicts our assumption that $|F| \leq k$. Therefore, we should add all the missing edges between $s$ and $C$.

Reduction EEE 4 If $s \in S$ is not adjacent to at least $k+1$ vertices of a clique $C \in \mathcal{C}$, then delete all edges between $s$ and $C$, and decrement the parameter $k$ by $|W|$, where $W$ is the set of edges between $s$ and $C$. The resulting instance is $(G \triangle W, k-|W|)$. If $|W| \geq k+1$, then conclude that we are dealing with $a$ no-instance.

Lemma 15. Reduction rule 4 is safe.
Proof. All the vertices of $C$ must belong to the same connected component in the edited graph. Note that $s$ cannot be in the same connected component as the vertices in $C$, as it would require adding at least $k+1$ edges. Therefore, we must delete all the edges between $s$ and $C$.

Observe that exhaustive application of reductions EEE 3 and EEE 4 ensures that for each $s \in S$ and each $C \in \mathcal{C}$, either $s$ is adjacent to every vertex of $C$ or $s$ is adjacent to no vertex of $C$.

Reduction EEE 5 If $s \in S$ has neighbours in two distinct cliques $C_{1}, C_{2} \in \mathcal{C}$, then conclude that we are dealing with a no-instance.

Lemma 16. Reduction rule 5 is safe.

Proof. Due to Reduction rules EEE 3 and EEE 4 $s$ must be adjacent to every vertex of $C_{1}$ and $C_{2}$. This implies that the graph contains at least $2 k+1$ edge disjoint induced $P_{3}$ s. Therefore the input instance is a no-instance.

Reduction EEE 6 If $s_{1}$ and $s_{2}$ are two non-adjacent vertices of $S$ and have a neighbour in $C \in \mathcal{C}$, then add the edge $\left(s_{1}, s_{2}\right)$ and decrement the parameter $k$ by 1. The resulting instance is $\left(G+\left(s_{1}, s_{2}\right), k-1\right)$.

Lemma 17. Reduction rule 6 is safe.
Proof. Due to reductions EEE 3 and EEE 4, $s_{1}$ and $s_{2}$ are adjacent to every vertex of $C$. Thus, $s_{1}$ and $s_{2}$ must be in the same connected component as the vertices in $C$ in the edited graph. Therefore, we must add the edge $\left(s_{1}, s_{2}\right)$ to the solution.

Reduction EEE 7 If $s_{1}$ and $s_{2}$ are two adjacent vertices of $S$ and have neighbours in $C_{1} \in \mathcal{C}$ and $C_{2} \in \mathcal{C}$ respectively, then delete the edge $\left(s_{1}, s_{2}\right)$ and decrement the parameter $k$ by 1. The resulting instance is $\left(G-\left(s_{1}, s_{2}\right), k-1\right)$.

Lemma 18. Reduction rule 7 is safe.
Proof. The vertices of $C_{1}$ and the vertices of $C_{2}$ must be in different connected components in the edited graph. Therefore, $s_{1}$ and $s_{2}$ must also be in different connected components in the edited graph. Therefore, we must delete the edge $\left(s_{1}, s_{2}\right)$ and add it to the solution.

Lemma 19. If $(G, k)$ is a yes-instance and none of the reduction rules $E E E[1$ to EEE 7 are applicable to $G$, then $G$ is a disjoint union of cliques, each of size $d+1$.

Proof. When none of the reduction rules EEE 1 to EEE 7 is applicable to $G$, then $G$ is clearly a disjoint union of cliques. Now, we show that these cliques are of size $d+1$. If there exists a clique of size more than $d+1$, then there would be more than $2 k$ vertices whose degree is not equal to $d$. Similarly, if there exists a clique of size less than $d+1$, then there would be more than $2 k$ vertices whose degree is not equal to $d$, because as shown in Lemma 13, all cliques $C \in \mathcal{C}$ have size at least $2 k+1$. This scenario contradicts Reduction Rule 2 ,

In Case 1, we obtain a kernel of size $\mathcal{O}(1)$.
Case 2: Let us assume that $d \leq 6 k-1$.
We partition $\mathcal{C}=G-S$ into four parts as follows:
$-\mathcal{C}_{<}=\{C \in \mathcal{C}:|C|<d+1\}$
$-\mathcal{C}_{0, d+1}=\{C \in \mathcal{C}:|C|=d+1$ and no vertex in $C$ has a neighbour in $S\}$
$-\mathcal{C}_{1, d+1}=\{C \in \mathcal{C}:|C|=d+1$ and some vertex in $C$ has a neighbour in $S\}$
$-\mathcal{C}_{>}=\{C \in \mathcal{C}:|C|>d+1\}$

Lemma 20. If $(G, k)$ is a yes-instance and reduction rule EEE 园 is not applicable to $G$, then $\bigcup_{C \in \mathcal{C}_{>}}|V(C)| \leq 2 k$.

Proof. Note that every vertex in $\bigcup_{C \in \mathcal{C}_{>}} V(C)$ has degree more than $d+1$. Due to Reduction rule 2 the number of vertices with degree more than $d+1$ is bounded by $2 k$.

Reduction EEE 8 If $\left|\mathcal{C}_{0, d+1}\right|>2 k$, then retain only $2 k+1$ cliques from $\mathcal{C}_{0, d+1}$ and discard the rest.

Lemma 21. Reduction Rule 8 is safe.
Proof. An edge editing set of size at most $k$ can change degrees of at most $2 k$ vertices in $\mathcal{C}_{0, d+1}$. In other words, an edge editing set of size at most $k$ can affect at most $2 k$ cliques in $\mathcal{C}_{0, d+1}$. There will still exist at least one clique of size $d+1$ in the final graph. Therefore, we can retain only $2 k+1$ cliques.

Lemma 22. $\left|\mathcal{C}_{1, d+1}\right| \leq 2 k$.
Proof. Each clique $C \in \mathcal{C}_{1, d+1}$, by definition, contains at least one vertex that has a neighbour in $S$. This implies that every clique in $\mathcal{C}_{1, d+1}$ contains at least one vertex whose degree is more than $d$. Due to Reduction Rule 2, there are at most $2 k$ such vertices. Therefore, $\left|\mathcal{C}_{1, d+1}\right| \leq 2 k$.
Therefore, we get $\left|\bigcup_{C \in \mathcal{C}_{d+1}} V(C)\right| \leq(4 k+1)(6 k-1)=24 k^{2}+2 k-1$, where $\mathcal{C}_{d+1}=\mathcal{C}_{0, d+1} \cup \mathcal{C}_{1, d+1}$.

Lemma 23. If $(G, k)$ is a yes-instance and reduction rule EEE 1 is not applicable to $G$, then we have $\left|\bigcup_{C \in \mathcal{C}_{<}} V(C)\right|<21 k^{2}+5 k$.

Proof. Since Reduction Rule 1 is not applicable to $G$, every vertex in $G$ has a degree at most $d+k \leq 7 k-1$. For the sake of contradiction, assume that $\bigcup_{C \in \mathcal{C}_{<}}|V(C)| \geq 21 k^{2}+5 k$. Each clique $C \in \mathcal{C}_{<}$has size less than $d+1$, hence the vertices in $C$ have degree less than $d$. As $(G, k)$ is a yes-instance, $G$ has a uniform cluster vertex editing set of size at most $k$ that can increase the degree of at most $2 k$ vertices. Therefore, at least $21 k^{2}+5 k-2 k$ vertices in $\bigcup_{C \in \mathcal{C}_{<}} V(C)$ have neighbours in $S$. Since $|S| \leq 3 k$ and $S$ has at least $21 k^{2}+53 k$ neighbours in $G-S$, by the Pigeonhole principle, there is a vertex $s \in S$ with at least $7 k+1$ neighbours in $G-S$, which contradicts the fact that $d_{G}(v) \leq 7 k-1$ for all $v \in V$. Therefore, we conclude that $\bigcup_{C \in \mathcal{C}_{<}}|V(C)|<21 k^{2}+5 k$.

Applying the above reduction rules and results, we find that:

$$
\begin{aligned}
|V(G)| & =|S|+|V \backslash S| \\
& =|S|+\left|\bigcup_{C \in \mathcal{C}_{<}} V(C)\right|+\left|\bigcup_{C \in \mathcal{C}_{d+1}} V(C)\right|+\left|\bigcup_{C \in \mathcal{C}>} V(C)\right| \\
& \leq 3 k+\left(21 k^{2}+5 k\right)+\left(24 k^{2}+2 k-1\right)+2 k \\
& =45 k^{2}+12 k-1
\end{aligned}
$$

## 4 Kernelization and FPT algorithm for 2-EED parameterized by solution size

In this section, we shall prove the following theorem.

Theorem 4. 2-EED parameterized by solution size admits a kernel of size at most $6 k$.

We start with the same preparation step as designed for 2-EEE. However, in this preparation step, we apply edge deletion operations instead of edge editing operations.

Reduction EED 1 If $\delta(G)<d$ or $\Delta(G)>d+k$, then conclude that we are dealing with a no-instance.

Reduction EED 2 If the number of vertices in $V(G)$ with degrees not equal to $d$ exceeds $2 k$, then conclude that we are dealing with a no-instance.

Reduction EED 3 If there exists a vertex $u$ of degree d in $G$ such that the subgraph induced by $N[u]$ is not a clique, then conclude that we are dealing with a no-instance.

Lemma 24. Reduction Rule 3 is safe.
Proof. Note that if the input is a yes-instance, then every vertex $u$ of degree $d$ must be part of a clique of size $d+1$ after deleting the edges of the solution. Since the degree of $u$ is $d$, this can only happen if the closed neighborhood of $u$ (denoted $N[u]$ ) forms a clique. Therefore, if the subgraph induced by $N[u]$ is not a clique, the instance is a no-instance.

Reduction EED 4 Let $u \in V(G)$ be a vertex with degree d. If u has a neighbour $v$ with a degree strictly greater than $d+1$, then delete all the edges $(v, w) \in E(G)$ such that $w$ is neither $u$ nor a neighbour of $u$. The set of edges deleted is denoted as $W$. The resulting instance is $G=(V(G), k-|W|)$. Also if $|W| \geq k+1$ then conclude that we are dealing with a no-instance.

Lemma 25. Reduction Rule 4 is safe.

Proof. As we have seen from the proof of Lemma [24, $N[v]$ must form a clique component in the final graph. Therefore, we must delete the edges $(v, w) \in E(G)$ such that $v \in N[u]$ but $w \in V(G) \backslash N[u]$. It is also worth noting that the condition $|V(G)| \geq 4 k+1$ ensures that the resulting graph, obtained by deleting the edges in the solution, must be a cluster graph, where every clique is of size exactly $d+1$.

Reduction EED 5 If there are multiple cliques of size $d+1$, then we retain only $x$ cliques of size $d+1$ where $x(d+1) \geq 2 k+1$ and remove the remaining cliques of size $d+1$.

Lemma 26. Reduction Rule5 is safe.
Proof. The condition $x(d+1) \geq 2 k+1$ in Reduction Rule EED 5 ensures that at least $2 k+1$ vertices have degree exactly $d$, which in turn ensures that the size of cliques, after deleting at most $k$ edges, remains exactly $d+1$. Therefore deleting the extra cliques does not change the size of a solution.

We make two cases based on the size of $d$.
Case 1. Assume $d>2 k$
Reduction EED 6 Let $(G, k)$ be an input instance such that Reduction Rules $E E D 15$ are not applicable to $(G, k)$. If $k \geq 0$ and $G$ is a disjoint union of cliques of size $d+1$, then conclude that we are dealing with an yes-instance.

Lemma 27. Reduction Rule 6 is safe.
Proof. Suppose there exists a vertex $v$ with a degree of at least $d+1$. If $N(v)$ contains a vertex with degree $d$, then Reduction Rule EED 4 could have been applied. Therefore, we assume that all vertices in $N(v)$ have a degree of at least $d+1$. As a result, the number of vertices with degrees not equal to $d$ is at least $d+2>2 k+2$ as $d>2 k$. However, in this scenario, Reduction Rule EED 2 could have been applied because the number of vertices with degrees not equal to $d$ exceeds $2 k$. Consequently, in a reduced graph, every vertex has a degree exactly d. After exhaustively applying Reduction Rules EED 3 and EED 4, $G$ must be a disjoint union of cliques of size $d+1$.

In Case 1, we obtain a kernel of size $\mathcal{O}(1)$.
Case 2. Let us assume $d \leq 2 k$.
After exhaustively applying Reduction Rules EED 3 and EED 4 the components containing a vertex of degree $d$ must form a $d+1$-sized clique. After applying EED 5 the cliques of size $d+1$ collectively contain at most $4 k$ vertices. According to Reduction Rule EED [2, we have at most $2 k$ vertices that do not have degree $d$. Therefore, we have $|V(G)| \leq 6 k$.

This completes the proof of Theorem 4

Theorem 5. The 2-EED problem, parameterized by solution size, can be solved by an algorithm running in $\mathcal{O}^{*}\left(1.47^{k}\right)$ time.

To prove Theorem [5, we will establish a simple yet important lemma. A cluster edge deletion set $E_{s}$ is minimal if it contains no other cluster edge deletion set.

Lemma 28. In a non-cluster graph $G$, any uniform cluster edge deletion set of size at most $k$ will always contain a minimal cluster edge deletion set of size at most $k$.

Proof. Let $E_{s}$ be a uniform cluster edge deletion set. Then, $G \backslash E_{s}$ is a disjoint union of $x$-sized cliques denoted by $\mathcal{C}=\left\{C_{1}, C_{2}, \ldots, C_{l}\right\}$. If $x=1$, then $E_{s}$ equals $E$. In this case, we can find a minimal cluster edge deletion set by identifying a $P_{3}$ (a path of length 3 ) and deleting an arbitrary edge from it. It is evident that such a set of edges is contained in $E$. Now, we assume $x>1$. Algorithm 2 provides a method to construct a minimal cluster edge deletion set contained within a given uniform cluster edge deletion set.

```
Algorithm 2
Require: A graph \(G=(V, E)\) and a uniform cluster edge deletion set \(E_{s}\).
Ensure: A minimal cluster edge deletion set of \(G\) contained in \(E_{s}\).
    Set \(\mathcal{C}=G-E_{s}=\left\{C_{1}, C_{2}, \ldots, C_{l}\right\}\) and \(E^{\prime}=E_{s}\)
    while there exist \(C_{i}\) and \(C_{j}\) in \(\mathcal{C}\) such that \(1 \leq i<j \leq l\) and \(G\left[C_{i} \cup C_{j}\right]\) is a clique
    do
            Remove \(C_{i}\) and \(C_{j}\) from \(\mathcal{C}\), and add \(C_{i} \cup C_{j}\) to \(\mathcal{C}\). Re-enumerate cliques in \(\mathcal{C}\).
            \(E^{\prime}=E^{\prime} \backslash E_{i j}\), where \(E_{i j}\) is the set of edges between \(C_{i}\) to \(C_{j}\).
    end while
    return \(E^{\prime}\)
```

Let us prove the correctness of Algorithm 2. Note that $E^{\prime} \neq \emptyset$, otherwise $G$ would be a cluster graph. Clearly, $E^{\prime}$ is a cluster edge deletion set. We claim that $E^{\prime}$ is a minimal cluster edge deletion set.

For the sake of contradiction, assume there is a proper subset $F$ of $E^{\prime}$ such that $F$ is a cluster edge deletion set. Suppose $(u, v) \in F$ where $u \in C_{i}$ and $v \in C_{j}$. Since $G\left[C_{i} \cup C_{j}\right]$ is not a clique, we find an induced $P_{3}$, which contradicts the fact that $E^{\prime}$ is a cluster edge deletion set.
Let us proceed with the proof of Theorem 5. To begin with, we will enumerate all minimal cluster edge deletion sets of size at most $k$. This enumeration can be done in $\mathcal{O}^{*}\left(1.47^{k}\right)$ time [8]. Next, we will make a guess of a minimal cluster edge deletion set $E^{\prime}$ that is contained in a potential solution. It is evident that $G \backslash E^{\prime}$ forms a cluster graph. Now we guess the size of cliques after deleting edges in a solution. Lets denote it as $c$. It is worth noting that a uniform cluster edge deletion set $E^{\prime} \cup E^{\prime \prime}$ can be readily constructed in polynomial time, where the cliques have size $c$. If such a set does not exist, the guess is discarded. Afterward, we check if the size of set $E^{\prime} \cup E^{\prime \prime}$ is less than or equal to $k$. If it is, we return an
yes-instance, otherwise we discard the guess. If all guesses have been discarded by the end of this process, we return a no-instance.

## 5 Kernelization algorithm for 2-EEA parameterized by solution size

In this section, we shall prove the following theorem.
Theorem 6. 2-EEA admits a kernel with at most $5 k$ vertices.
We start with the same preparation step as designed for 2-EEE. However, in this preparation step, we apply edge addition operations instead of edge editing operations.

Reduction EEA 1 If $\delta(G)<d-k$ or $\Delta(G)>d$, then conclude that we are dealing with a no-instance.

Reduction EEA 2 If the number of vertices in $V(G)$ with degrees not equal to $d$ exceeds $2 k$, then conclude that we are dealing with a no-instance.

Reduction EEA 3 If there is a path between two nonadjacent vertices $u$ and $v$, then make $u$ adjacent to $v$ and decrease $k$ by 1. The new instance becomes $(G+(u, v), k-1)$.

Lemma 29. Reduction Rule 3 is safe.
Proof. Since there is a path between $u$ and $v$, they must belong to the same clique in the edited graph. Therefore, we must connect $u$ and $v$ by an edge.

Observe that exhaustive application of Reduction Rule EEA 3 ensures that the new graph is a collection of disjoint cliques.

Reduction EEA 4 If there are multiple cliques of size $d+1$, then we retain only $x$ cliques of size $d+1$ where $x(d+1) \geq 2 k+1$ and remove the remaining cliques of size $d+1$.

Lemma 30. Reduction Rule 4 is safe.
Proof. Note that Reduction Rule EEA [4 ensures that at least $2 k+1$ vertices have a degree exactly $d$, which in turn ensures that the size of cliques remains exactly $d+1$ after adding at most $k$ edges. Therefore, deleting the extra cliques does not change the size of the solution.
Case 1: Let us assume that $d \geq k+1$.
Reduction EEA 5 If there is a clique of size less than $d+1$ in $G$, then conclude that we are dealing with a no-instance.

Proof. Due to Reduction Rule EEA [1] there cannot be a clique of size more than $d+1$. Let's assume that we have a clique $C$ of size $x<d+1$. To obtain a clique of size $d+1$ from $C$, we would need to add at least $x(d+1-x)$ edges. However, this exceeds the allowable number $k$ of edge addition operations, as $x(d+1-x)>k$.
In Case 1, we obtain a kernel of size $\mathcal{O}(1)$.
Case 2: Let us assume that $d \leq k$.
After applying Reduction Rule EEA [4 the cliques of size $d+1$ collectively contain at most $3 k$ vertices. Accordingly to Reduction Rule 2, there are at most $2 k$ vertices with degrees not equal to $d$. Therefore, we have $|V(G)| \leq 5 k$.
This completes the proof of Theorem 6

## 6 Conclusion and Open Problems

In this paper, we studied the problem of modifying a given graph so that the resulting graph becomes a collection of equal-sized cliques. We provided polynomial kernels for various types of modification problems. It would be interesting to explore whether the kernelization algorithms presented in this paper can be improved to achieve better bounds.
