Abstract: In this work, we investigated the spatial evolution of optical power in a closed-form optical waveguide configuration consisting of six passive waveguides and each of the waveguides exhibits equal strength of Kerr nonlinearity. We considered only nearest neighbor interaction between the waveguides. We found that in the case of low Kerr nonlinearity, evolution of optical power shows synchronization behavior. But when we increased the strength of Kerr nonlinearity, we discovered that spatial evolution of optical power in all waveguides shows independent characteristics. On the other hand, we have studied the impact of the coupling constant on the synchronization dynamics of our system. Our findings showed us that strong coupling can strengthen the collective dynamics in the presence of strong Kerr nonlinearity. From our results, we can conclude that Kerr nonlinearity in our system plays the role of disorder parameter that destroys as well as alters the synchronization behavior of evolution of optical power in the waveguides and coupling constant plays the role of an antagonist and restores synchronization in the model.

1. Introduction

Synchronization dynamics is one interesting phenomenon in complex systems that gives rise to interesting dynamical behavior in the system such as synchronization. One phenomenon that arises from such complex behavior is the emergence of chimera states or the simultaneous existence of coherent and incoherent states in the system under consideration.

One of the first mathematical models which pertained to the emergence of chimera states was the Kuramoto model of phase oscillators [1-3]. Kuramoto and his colleagues observed such phenomenon in the simulation of arrays of limit-cycle oscillators with non-local coupling. Unihemispherical sleep in the human brain is one such instance where the neuronal network in the human brain exists in both coherent and incoherent states [4]. Furthermore, such phenomenon has been observed in Josephson junction arrays [5], chemical oscillators [1-3], neuronal conditions such as epileptic seizure [6-7] and Parkinson's disease [8], etc.

In this work, we investigated the spatial evolution of optical power in a closed-form optical waveguides configuration. The mathematical model of the system is based on the Discrete Nonlinear Schrodinger Equation [9-12]. This model is famous for the numerical computation of evanescently coupled waveguides, which are also called Optical Oligomers and phenomenon such as gap solitons has been reported in such systems. In addition, transition to chaos has also been reported in such system [13]. In the recent past, we explored the spatial evolution of optical power a class of optical oligomers which follows the condition of parity-time symmetry [14]. Phenomena such as stable dark solitons in dual core waveguides [15], PT-symmetry breaking in a necklace of coupled optical waveguides [16], amplitude death [17], extreme events [18] and so on have been reported in such systems.

In our model, we considered evanescently coupled passive waveguides with nearest neighbour coupling. Using the prescription described in [12], we converted the mathematical model in the polar coordinates. In this system, we employed the Runge-Kutta Fehlberg Method with a step-size of 0.01 for the numerical simulation. This numerical procedure is an adaptive step-size process and hence, the numerical accuracy in the simulation is far more pronounced.

The manuscript is organized as - section 2 is the mathematical modelling of the system, section 3 is the results and discussion, and section 4 is the conclusion.

2. Modelling

Fig. 1. Schematic of the Coupled Passive Waveguides configuration. C is the coupling strength.

We are considering a closed form waveguide coupler exhibiting equal strength of Kerr nonlinearity and equal nearest neighbour coupling as presented in Fig. 1. On top of that, we consider each waveguide is only capable of nearest neighbor evanescent interaction. Hence, using the Discrete Nonlinear Schrodinger Equation (DNLSE) [9], we consider the mathematical model given below.

$$i\frac{dE_{j}}{dz} = C(E_{j-1} + E_{j+1}) + \beta |E_{j}|^{2}E_{j}$$

Here, β is the strength of nonlinearity, and *C* is the coupling constant. All parameters are normalized

units. Using $\dot{r}_j = (x_j \dot{x}_j + y_j \dot{y}_j)/r_j$ and $\dot{\theta}_j = (x_j \dot{y}_j - y_j \dot{x}_j)/r_j^2$ [12], this equation could be transformed into a system of nonlinear ordinary differential equations as follows

$$\frac{dr_j}{dz} = C[r_{j-1}\sin(\theta_{j-1} - \theta_j) + r_{j+1}\sin(\theta_{j+1} - \theta_j)]$$
(1a)

$$\frac{d\theta_j}{dz} = -\beta r_j^2 - C[r_{j-1}\cos(\theta_{j-1} - \theta_j) + r_{j+1}\cos(\theta_{j+1} - \theta_j)]/r_j^2$$
(1b)

The optical power of the waveguides is given by $P_j = |E_j|^2 = r_j^2$. We then prepare the initial state of the system: $r_j = 1$, $\theta_1 = \theta_2 = \theta_6 = 0$ and $\theta_3 = \theta_4 = \theta_5 = \pi$ and the numerical integrator will have stepsize h = 0.01. This means that we have launched equal optical power in all waveguides, but half of them have zero-phase and the rest have π -phase. And this way we could study the influence of phase in the spatial evolution of optical power along the direction of propagation. Moreover, it must be noted that phase lag between two propagation electromagnetic wave is physically equivalent to temporal delay between them. Hence, our model would also enable us to

understand how temporal delay could affect the synchronization dynamics of optical power in a waveguide coupler.

3. Results and Discussion

Fig. 2 depicts the spatial evolution of optical in all six waveguides for C = 1 and $\beta = 0.1$. We can see from Fig. 2(a) that the oscillations of optical power in the 1st and 4th waveguides are of same frequency, phase, and amplitude. But the remaining four waveguides exhibit amplitude. This means that for low strength of Kerr nonlinearity, waveguides display synchronization behavior. In our system, we see that all waveguides display synchronization dynamics in two separate bunches of two and four waveguides. It must be noted that we have initially excited the 1st waveguide with zero-phase and the 4th waveguide with π -phase. So, in a nutshell, we can say that the phase of initial excitation imparted to these waveguides plays a crucial role in the emergence of synchronization behavior in our waveguide coupler configuration.

Fig. 2. Spatial Evolution of optical power in (a) 1^{st} , 4^{th} waveguide, (b) 2^{nd} , 3^{rd} waveguide and (c) 5^{th} , 6^{th} waveguide for C = 1 and $\beta = 0.1$.

In Fig. 3, we have plotted the spatial evolution of optical power by increasing the strength of Kerr nonlinearity to $\beta = 0.75$. We can see that the spatial evolution shows synchronization dynamics up to z > 70 and beyond that, all waveguides start exhibiting aperiodic evolutionary dynamics. It could be seen that now waveguide '3' and '5' and waveguide '2' and '6' are now identically synchronized. This has been elucidated in Fig. 4. From this, we could infer that Kerr nonlinearity plays the role of a disorder parameters which can facilitate desynchronization in our waveguide coupler and also alter the waveguide pair that are identically synchronized.

Fig. 3. Spatial Evolution of optical power in (a) 1^{st} , 4^{th} waveguide, (b) 2^{nd} , 3^{rd} waveguide and (c) 5^{th} , 6^{th} waveguide for C = 1 and $\beta = 0.75$.

Fig. 4. (a) P_6 vs P_2 and (b) P_5 vs P_3

Fig. 5. Power Spectral Density (PSD) of optical power in the 1st waveguide for (a) $\beta = 0.1$ and (b) $\beta = 0.75$.

Fig. 6. (a) Spatial Evolution of optical power in the 1st and 4th waveguide and (b) Power Spectral Density (PSD) and for $\beta = 0.75$ and C = 3.0.

In Fig. 5, we have plotted the power spectral density (PSD) of the time series of optical power in the 1st waveguide for two cases of the strength of Kerr nonlinearity. We can see from Fig. 5(a) that for low strength of nonlinearity, the power spectrum displays one distinct sharp peak at $f \approx 0.1175$. This is why

we observed periodic dynamics in Fig. 2. But when we increase β , we can see that the power spectrum displays an aperiodic time series and in fact, we have observed that in Fig. 3. From this, we can infer that Kerr nonlinearity in our systems is responsible for the transition from periodic to aperiodic dynamics. But when we increased the coupling strength to C = 3.0keeping $\beta = 0.75$, we can see from Fig. 6(a) and 6(b) that the aperiodicity in the spatial evolution of the optical power could be controlled. Now, the power spectrum shows a distinct sharp peak at $f \approx 0.352$ and the spatial evolution is periodic in nature. Thus, we can infer that the coupling strength serves as the antagonist agent in the emergence of aperiodic dynamics in our system and could also alter the waveguide pairs that are identically synchronized.

4. Conclusion

In conclusion, we have analyzed the spatial evolution of optical power in a waveguide coupler using the DNLSE as the mathematical model. We have found that the strength of Kerr nonlinearity could be used as a parameter to initiate synchronization dynamics as well as aperiodic dynamics in the optical power of the waveguides. Moreover, by increasing the strength of Kerr nonlinearity, we can initiate aperiodic spatial dynamics in the evolution of optical power in the waveguides. We also found that the waveguides that are identically synchronized could be altered. On the other hand, the coupling strength between the waveguides could be utilized as a parameter to control aperiodic dynamics and restore synchronization.
