Abstract

Natural language explanations have become a proxy for evaluating explainable and multi-step Natural Language Inference (NLI) models. However, assessing the validity of explanations for NLI is challenging as it typically involves the crowd-sourcing of apposite datasets, a process that is time-consuming and prone to logical errors. To address existing limitations, this paper investigates the verification and refinement of natural language explanations through the integration of Large Language Models (LLMs) and Theorem Provers (TPs). Specifically, we present a neuro-symbolic framework, named Explanation-Refiner, that augments a TP with LLMs to generate and formalise explanatory sentences and suggest potential inference strategies for NLI. In turn, the TP is employed to provide formal guarantees on the logical validity of the explanations and to generate feedback for subsequent improvements. We demonstrate how Explanation-Refiner can be jointly used to evaluate explanatory reasoning, autoformalisation, and error correction mechanisms of state-of-the-art LLMs as well as to automatically enhance the quality of human-annotated explanations of variable complexity in different domains.

1 Introduction

A recent line of research in Natural Language Inference (NLI) focuses on developing models capable of generating natural language explanations in support of their predictions (Thayaparan et al., 2021; Chen et al., 2021; Valentino et al., 2022; Bostrom et al., 2022; Weir et al., 2023). Since natural language explanations can be used as a proxy to evaluate the underlying reasoning process of NLI models (Kumar and Talukdar, 2020; Zhao and Vydiswaran, 2021; Chen et al., 2021), researchers have proposed different methods for assessing their intrinsic quality (Wiegrefe and Marasovic, 2021; Camburu et al., 2020; Valentino et al., 2021; Atanasova et al., 2023; Quan et al., 2024; Dalal et al., 2024), including the

adoption of language generation metrics for a direct comparison between models’ generated explanations and human-annotated explanations.

However, this process is subject to different types of limitations. First, the use of language generation metrics requires the crowd-sourcing of explanation corpora to augment existing NLI datasets (Wiegrefe and Marasovic, 2021), a process that is typically time-consuming and susceptible to errors (Liu et al., 2022; Zhao et al., 2023). Second, language generation metrics have been shown to fail capturing fine-grained properties that are fundamental for NLI such as logical reasoning, faithfulness, and robustness (Atanasova et al., 2023; Camburu et al., 2020; Chan et al., 2022; Quan et al., 2024). Third, human explanations in NLI datasets tend to be incomplete and contain logical errors that could heavily bias the evaluation (Elazar et al., 2021; Valentino et al., 2021).

In this paper, we investigate the integration of state-of-the-art LLM-based explanation generation models for NLI with external logical solvers to jointly evaluate explanatory reasoning (Pan et al., 2023a; Olausson et al., 2023; Jiang et al., 2024b) and enhance the quality of crowd-sourced explanations. In particular, we present a neuro-symbolic framework, named Explanation-Refiner, that augments a Theorem Prover (TP) with Large Language Models (LLMs) to investigate the following research questions: *RQ1*: “Can the integration of LLMs and TPs provide a mechanism for automatic verification and refinement of natural language explanations?”; *RQ2*: “Can the integration of LLMs and TPs improve the logical validity of human-annotated explanations?”; *RQ3*: “To what extent are state-of-the-art LLMs capable of explanatory reasoning, autoformalisation, and error correction for NLI in different domains?”. To answer these questions, Explanation-Refiner employs LLMs to generate and formalise explanatory sentences and to suggest potential inference strategies for build-

ing non-redundant, complete, and logically valid explanations for NLI. In turn, the TP is adopted to verify the validity of the explanations through the construction of deductive proofs and the generation of fine-grained feedback for LLMs.

We instantiate Explanation-Refiner with state-of-the-art LLMs (i.e., GPT-4 (OpenAI, 2023), GPT-3.5 (Brown et al., 2020), LLama (Touvron et al., 2023), and Mistral (Jiang et al., 2024a)) and the Isabelle/HOL proof assistant (Nipkow et al., 2002) utilising Neo-Davidsonian event semantics (Parsons, 1990) coupled with First-Order Logic (FOL) to effectively and systematically translate natural language sentences into logical forms.

Our empirical analysis carried out on three NLI datasets of variable complexity (i.e., e-SNLI (Camburu et al., 2018), QASC (Khot et al., 2019), and WorldTree (Jansen et al., 2018)) reveals that external feedback from TPs is effective in improving the quality of natural language explanations, leading to an increase in logical validity using GPT-4 from 36% to 84%, 12% to 55%, and 2% to 37% (on e-SNLI, QASC, and WorldTree respectively). At the same time, the results demonstrate that integrating external TPs with LLMs can reduce errors in autoformalisation, with an average reduction of syntax errors of 68.67%, 62.31%, and 55.17%. Finally, we found notable differences in performance across LLMs and NLI datasets, with closed-sourced LLMs (i.e., GPT-4 and GPT-3.5) significantly outperforming open-source models (i.e., Mistral and LLama) on both explanatory reasoning and autoformalisation, along with a shared tendency of LLMs to struggle with increasing explanation complexity.

To summarise, the main contributions of this paper are:

1. We introduce *Explanation-Refiner*, a novel neuro-symbolic framework that integrates LLMs with an external theorem prover. This framework automatically verifies and refines explanatory sentences in NLI tasks using an objective external feedback.
2. We utilise Neo-Davidsonian event semantics coupled with FOL to effectively translate natural language sentences into logical forms to minimise semantic information loss. Additionally, we introduce a novel method that leverages a theorem prover and a proof assistant for verifying NLI explanations and a

syntactic refiner to minimise syntax errors in responses generated by LLMs.

3. We conduct a comprehensive series of experiments to assess *Explanation-Refiner* across five LLMs on three datasets, which include between 1 to 16 explanatory sentences. These experiments span a range of tasks from simple textual entailment to complex multiple-choice question answering in different context domains.
4. We perform extensive quantitative and qualitative analyses to explore the explanation refinement process. Our investigations delve into the LLMs’ inference capabilities, revealing the strengths and limitations of different models in producing verifiable and explainable logical reasoning for NLI.

2 Explanation Verification and Refinement

Explanation-based NLI is widely adopted to evaluate the reasoning process of multi-step inference models via the construction of natural language explanations. In this work, we refer to the following formalisation for Explanation-based NLI: given a premise sentence p_i , a hypothesis sentence h_i , and an explanation E_i consisting of a set of facts $\{f_1, f_2, \dots, f_n\}$, the explanation E_i is logically valid if and only if the entailment $p_i \cup E_i \models h_i$ holds. This entailment is considered verifiable if $\{p_i, E_i, h_i\}$ can be translated into a set of logical forms Φ that compose a theory Θ . The validity of this theory, Θ , is subsequently determined by a theorem prover, verifying whether $\Theta \models \psi$, where ψ represents a logical consequence derived from the logical form of h_i .

We aim to automatically verify the logical validity of explanation E_i , and if $\Theta \models \psi$ is rejected by the theorem prover, a further refinement stage should be initiated to refine the facts $\{f_1, f_2, \dots, f_n\}$ based on external feedback, resulting in an updated explanation E'_i . Thus, an explanation is accepted if all the facts are logically consistent, complementary and non-redundant to support the derivation.

3 Explanation-Refiner

To verify the logical validity and refine any logical errors in explanatory sentences for NLI tasks, we

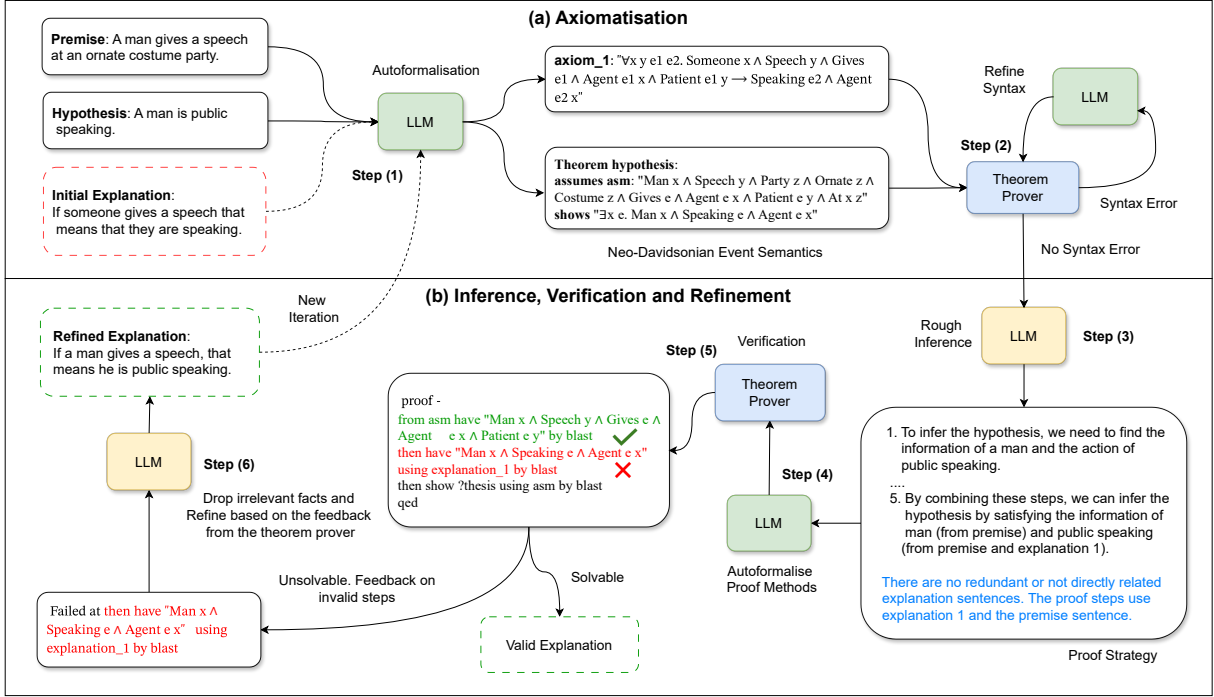

Figure 1: The overall pipeline of Explanation-Refiner: An NLI problem is converted into axioms and theorems as a theorem prover’s theory, along with some proof steps derived from a preliminary inference to send to a theorem prover. In case the proof fails (logically invalid), the erroneous step, along with the proof strategy and proof steps, are extracted as feedback to refine the explanatory sentences in a new iteration.

present a neuro-symbolic framework, Explanation-Refiner, to iteratively check and refine the explanation E_i based on external feedback; Isabelle (Paulson, 1994) and its proof assistant Isabelle/HOL (Nipkow et al., 2002) are applied as external tools to make the logical deduction and provide feedback for explanation refinement.

Figure 1 shows an overview of our proposed framework. Given an NLI task, to evaluate the logical validity of the entailment, the LLM is prompted to perform an autoformalisation process that transforms natural language sentences into formal language represented in the form of Isabelle theory. Each fact $f \in E_i$ is converted into an axiom a_i , where each a_i is an element of the set $A = \{a_1, a_2, \dots, a_n\}$. The premise p_i and corresponding hypothesis h_i , is converted into a theorem for proving $p_i \wedge B \rightarrow h_i$, where $B \subseteq A$. A syntax refinement mechanism is subsequently applied to the previously transferred symbolic forms. The theorem prover is implemented as a checker to identify any syntax errors and provide these error details as feedback to an LLM, enabling the LLM to iteratively correct the syntax errors over a fixed number of iterations, denoted by t .

With the proof assistant, we can perform au-

tomated reasoning in the theorem prover by constructing proof steps. Step 3 initially generate a rough inference to state a preliminary proof strategy in natural language sentences and elicit the facts $f \in E_i$ which are non-redundant and essential for entailing the hypothesis h_i . Based on this preliminary proof strategy, the LLM is prompted to construct and formalise the proof steps for proving the theorem.

In step 5, the theorem prover will verify the constructed theory by attempting to prove the theorem. If it is solvable, we state it as a logically valid explanation. If the prover failed at one of the proof steps, we extract this failed step along with the applied axioms $B \subseteq A$ as the external feedback for an LLM. This feedback is used to refine the logical error within B and consequently refine the facts $f \in E_i$, which were previously converted from natural language.

3.1 Autoformalisation

In order to formally verify the logical validity of the explanations, we adopted Neo-Davidsonian event-based semantics and FOL.

Neo-Davidsonian Event Semantics Preventing the loss of semantic information during the repre-

```

theorem hypothesis:
  (* Premise: A smiling woman is playing the violin in front of a turquoise background. *)
  assumes asm: "Woman x  $\wedge$  Violin y  $\wedge$  Background z  $\wedge$  Turquoise z  $\wedge$  Smiling x  $\wedge$  Playing e  $\wedge$  Agent e
    x  $\wedge$  Patient e y  $\wedge$  InFrontOf x z"
  (* Hypothesis: A woman is playing an instrument. *)
  shows " $\exists$  x y e. Woman x  $\wedge$  Instrument y  $\wedge$  Playing e  $\wedge$  Agent e x  $\wedge$  Patient e y"

```

Figure 2: An example of representing the premise and hypothesis sentences in Isabelle theorem

```

proof -
  from asm have "Woman x  $\wedge$  Violin y  $\wedge$  Playing e  $\wedge$  Agent e x  $\wedge$  Patient e y" by blast
  then have "Woman x  $\wedge$  Instrument y  $\wedge$  Playing e  $\wedge$  Agent e x  $\wedge$  Patient e y" using explanation_1 by
    blast
  then show ?thesis using asm by blast
qed

```

Figure 3: An example of proof constructed by the Isabelle/HOL proof assistant to verify the hypothesis.

sensation of natural language sentences in logical forms, such as FOL, poses significant challenges when using LLMs, particularly with long and complex sentences that are crucial for logical reasoning (Olausson et al., 2023). Neo-Davidsonian event semantics (Parsons, 1990) utilises event variables to represent the verb predicates and their corresponding object arguments as semantic roles. This approach establishes a predicate-argument structure that preserves the information content and faithfulness of complex sentences, closer to the surface form of the sentence. For example, the sentence ‘A wolf eating a sheep is an example of a predator hunting prey’ can be formalised as follows:

$$\begin{aligned}
& \forall xye_1 (\text{wolf}(x) \wedge \text{sheep}(y) \wedge \text{eating}(e_1) \\
& \quad \wedge \text{agent}(e_1, x) \wedge \text{patient}(e_1, y) \rightarrow \\
& \quad (\exists e_2 \text{ predator}(x) \wedge \text{prey}(y) \wedge \\
& \quad \text{hunting}(e_2) \wedge \text{agent}(e_2, x) \wedge \\
& \quad \text{patient}(e_2, y) \wedge \text{example}(e_1, e_2)))
\end{aligned} \tag{1}$$

In 1, the verbs are represented as the events ‘eating’ and ‘hunting,’ where the agent and patient arguments correspond to the entities performing and receiving the actions within these events, respectively. The logical form $\text{example}(e_1, e_2)$ explicitly captures the semantic meaning of this sentence: the event of a wolf eating a sheep as an exemplar of a predator hunting prey. Similarly, whenever there are no action verbs involved in a sentence, we utilise FOL to represent the static or descriptive aspects. For instance:

$$\forall x (\text{gravity}(x) \rightarrow \text{force}(x)) \tag{2}$$

$$\forall xy (\text{greater}(x, y) \rightarrow \text{larger}(x, y)) \tag{3}$$

The above logical forms correspond to the sentences ‘gravity is a kind of force’ and ‘greater means larger’, respectively.

Isabelle Theory Construction For the Isabelle theorem prover, a theory script is essential to facilitate the proof of a theorem. Therefore, we designate explanatory sentences as axioms:

```

(* Explanation 1: A violin is an instrument. *)
axiomatization where
  explanation_1: " $\forall x$ . Violin x  $\rightarrow$  Instrument x"

```

Additionally, as illustrated in Figure 2, both the premises and hypothesis are defined as constituting parts of the theorem. The ‘assumes asm’ clause generally comprises unquantified, specific propositions or conjunctions of propositions, which are recognised as known truths. The ‘show’ clause denotes the conclusion (hypothesis) for which we seek to establish proof through logical deductions based on the assumed propositions and axioms.

Syntax Error Refiner Recent studies (Gou et al., 2024; Olausson et al., 2023) have revealed persistent syntax errors when prompting LLMs for code and symbolic form generation tasks. The method proposed by Pan et al. (2023a) utilises error messages from symbolic solvers to iteratively refine LLM outputs. Following a similar approach, we categorised the syntax errors into two distinct sub-domains based on feedback from Isabelle: type unification errors and other syntax errors. Type unification errors primarily arise from mismatches between declared and actual argument types in logical clauses. Other syntax errors typically involve missing brackets, undefined entity names, or invalid logical symbols. Our process involves using

Isabelle to identify syntax errors in the transferred theory, extracting these error messages, and then prompting the LLM with these messages along with few-shot examples. This guides the model on how to correct each type of syntax error over a series of iterations, allowing for continuous verification and refinement. Details of the autoformalisation prompts are described in Appendix A.4.1.

3.2 Proof Construction

A proof provides a detailed, step-by-step strategy that elucidates the logical connections and unification among axioms to support the reasoning process aimed at achieving the solver’s goal. Initially, we prompt the LLM to create a preliminary proof to assess how it infers the hypothesis and to identify which explanatory sentences are relevant, redundant, or unrelated. Based on this initial proof, we then guide the LLM to develop an Isabelle proof (figure 3) that utilise the Isabelle/HOL proof assistant to clearly demonstrate the explanatory sentences (axioms) required to prove the hypothesis. Details of proof construction process prompts are described in Appendix A.4.2.

3.3 Verify and Refine

Finally, the constructed theory, which includes axioms, theorems, and proof steps, is submitted to the theorem prover for verification. If the theory is validated, it outputs a logically sound explanation. If the proof fails or timeouts, we extract the first error from the solver’s error message, identify the corresponding proof step, and locate the related explanatory sentences (axioms) from the theory. We begin by removing redundant and irrelevant facts that are not present in the preceding Isabelle proof steps or are declared as such in the text inference strategy. Then, we prompt the LLM to refine the explanatory sentences by providing it with the error message, the failed proof step, the associated proof strategy, and the relevant explanatory sentences for further iteration. This process is iterative and progressive; with each iteration, the framework addresses one or more logical errors, continually refining the explanatory sentences to ultimately yield a logically valid and verifiable explanation. Additional details on the prompts used for refinement are described in Appendix A.4.3.

4 Empirical Evaluation

To assess the effectiveness of integrating LLMs with external feedback for refinement purposes, we evaluated the Explanation-Refiner on two NLI tasks: textual entailment and multiple-choice question answering. For textual entailment, given a premise p_i and an explanatory sentence as explanation E_i , the goal is to determine whether p_i and E_i together entail a hypothesis h_i . In the multiple-choice question answering task, there is a question q accompanied by a set of candidate answers $C = \{c_1, c_2, \dots, c_n\}$, with c_i identified as the correct answer. We convert q and the correct answer c_i as the hypothesis h_i . Explanatory facts serve as evidence supporting c_i as the correct answer and are denoted as E_i , with the question’s context sentence as the premise p_i .

4.1 Datasets

We adopted three different NLI datasets for evaluation: e-SNLI (Camburu et al., 2018), QASC (Khot et al., 2019), and WorldTree (Jansen et al., 2018), using a total of 300 samples selected via the sampling strategy defined in (Valentino et al., 2021), which maximises representativeness and mutual exclusivity across syntactic and semantic features expressed in the datasets. e-SNLI is a crowd-sourced dataset typically used as a benchmark for textual entailment. It comprises one premise sentence, one explanatory sentence, and one hypothesis sentence per sample. QASC and WorldTree, on the other hand, are datasets designed for multiple-choice question answering within the scientific domain. QASC includes two explanatory sentences for each correct answer. WorldTree is the most complex of the three, featuring between 1 and 16 explanatory sentences in each sample.

4.2 Theorem Prover

We adopted Isabelle (Paulson, 1994) as our theorem prover and Isabelle/HOL (Nipkow et al., 2002) as the proof assistant. To integrate this theorem prover as a real-time verification tool with LLMs, we employ a Python client (Shminke, 2022) as TCP (Transmission Control Protocol) client to configure Isabelle as a server. This enables the communication of the constructed theory files and the extraction of the response messages from Isabelle.

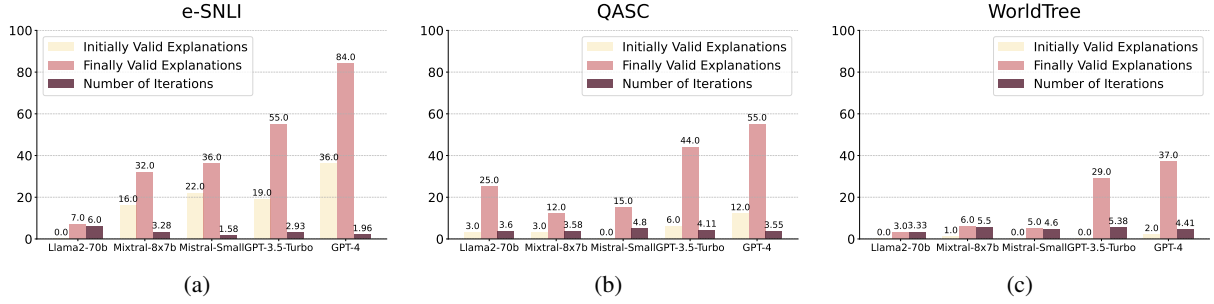

Figure 4: The initial and final number of logically valid explanations, along with the average iteration times required to refine an explanation for each LLM

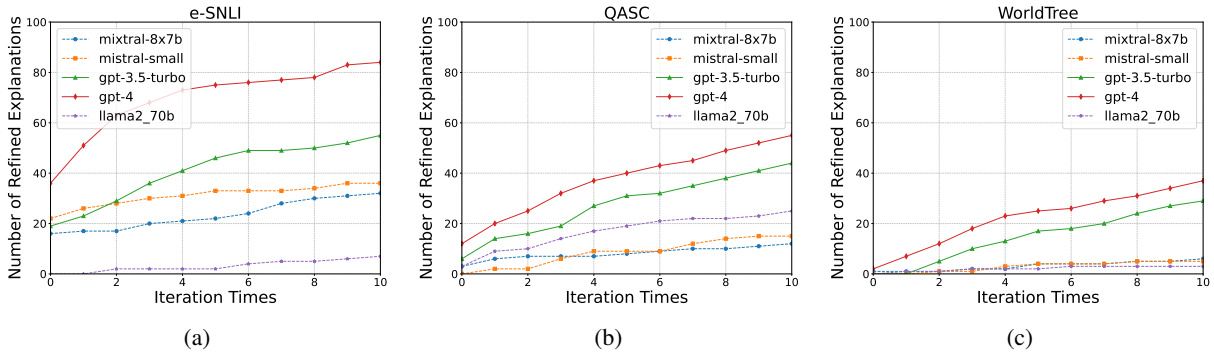

Figure 5: Number of successfully refined explanations at each iteration step.

4.3 Models

We conducted experiments using five LLMs within the proposed framework. The models include two open-sourced models: Llama2-70b (Touvron et al., 2023) and Mixtral-8x7b (Jiang et al., 2024a), as well as Mistral-Small (mistral-small-latest) (Mistral AI, 2024), GPT-Turbo-3.5 (gpt-3.5-turbo) (Brown et al., 2020), and GPT-4 (gpt-4-0613) (OpenAI, 2023). Temperature settings were adjusted to 0 for GPT-Turbo-3.5 and GPT-4, and to 0.01 for Llama2-70b, Mixtral-8x7b, and Mistral-Small, aiming to achieve both determinism in the output and effective code generation for theorem prover.

4.4 Results

Providing feedback on the exact failure step from an external theorem prover effectively guides LLMs in continuously verifying and refining explanations in NLI tasks. To assess the effectiveness of employing an external theorem prover to verify and refine explanations in NLI tasks, we conducted a comparative analysis across various LLMs (Figure 4). The initially valid explanations represent the percentage of explanations that can be verified as logically valid without any further iteration. Although the initial verification results varied among different models, all LLMs

demonstrated a consistent improvement in refining the logical validity of the explanations. This process highlights the positive impact of the external feedback but also shows significant differences between models. We found that lower rates of initial valid explanations often resulted from syntactic errors, which impeded the theorem prover’s ability to generate proofs. Despite this initial variability, all models demonstrate a consistent improvement in the refinement process across the datasets. Notably, GPT-4 outperformed other models, improving the validity of explanations by 48%, 43%, and 35% across the three datasets, respectively, within a maximum number of ten iterations (Figure 4). Figure 5 shows the number of explanations refined at each iteration across the e-SNLI, QASC, and WorldTree datasets. On average, we found that an increasing number of iterations leads to increasing refinement, with models requiring an average of five iterations across the datasets.

Explanation length/complexity impacts formalisation. The e-SNLI dataset, which includes only a single explanatory sentence per example, shows the best overall performance. In contrast, the multiple-choice question answering datasets, QASC and WorldTree, exhibit comparatively lower

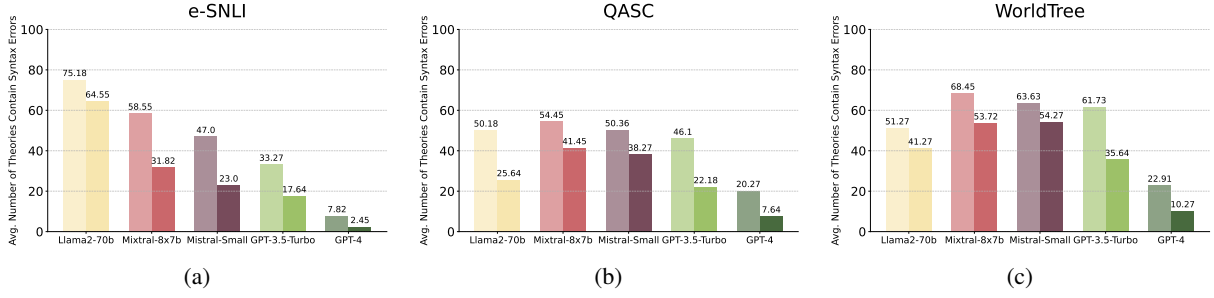

Figure 6: The average number of theories containing syntactic errors before and after the syntax refinement process

Figure 7: AF represents the autoformalisation components, and TI represents the textual inference components. TI+AF (Base Model) indicates the use of the base model for both the autoformalisation and textual inference components. TI+AF (GPT-4) indicates the use of GPT-4 for the autoformalisation components, while the base model is used for textual inference.

performance. QASC typically contains 2 explanatory sentences, while WorldTree ranges from 1 to 16 sentences. As the number of explanatory sentences increases, so does the complexity of the logical reasoning required. The WorldTree dataset, in particular, poses the greatest challenge due to its demand for multi-hop inference strategies. Models show lower refining performance in WorldTree when compared to e-SNLI and QASC, with only 3%, 5%, and 6% of Llama-70b, Mixtral-8x7b, and Mistral-Small explanations being refined in WorldTree. Meanwhile, 29% and 37% of explanations are refined by GPT-3.5-Turbo and GPT-4 in WorldTree, respectively. This process involves synthesising multiple explanatory sentences to fulfill sub-goals, which must then be integrated to meet the overall hypothesis goal.

Iterative and categorical refinement can monotonically reduce syntax errors in responses generated by LLMs. To evaluate the syntax error refinement stage, we quantified the presence of syntax errors in the Isabelle theories both before and after the iterative refinement process. After a maximum of three iterations, all models showed significant reductions, with maximum reductions of 68.67%, 62.31%, and 55.17% from 7.82 to 2.45, 20.27 to 7.64, and 22.91 to 10.27 across the three re-

spective datasets (see Figure 6). While models like Llama2-70b and Mixtral-8x7b still exhibit some syntax errors in the refined theories’ code, this is primarily due to their inability to perform complex autoformalisation, especially for multiple and more complex explanatory sentences such as those in the WorldTree dataset. This result is consistent with the percentage of explanations that were successfully refined across the models, which suggests that the autoformalisation process plays a critical role in the models’ logical reasoning capability.

4.5 Ablation Study

We conducted an ablation study to further evaluate and disentangle the impact of autoformalisation on performance. To this end, we adopted GPT-4 exclusively for the autoformalisation component, while retaining the original models for explanation refinement and proof strategy generation. As shown in Figure 7, integrating GPT-4 for autoformalisation led to a significant increase in the number of explanations successfully refined across all models. For instance, Llama2-70b with GPT-4 as the formalisation component refined explanations from 7% to 65% in the e-SNLI dataset. For the multiple-choice question answering dataset, GPT-3.5-Turbo showed a relatively smaller increase from 44% to

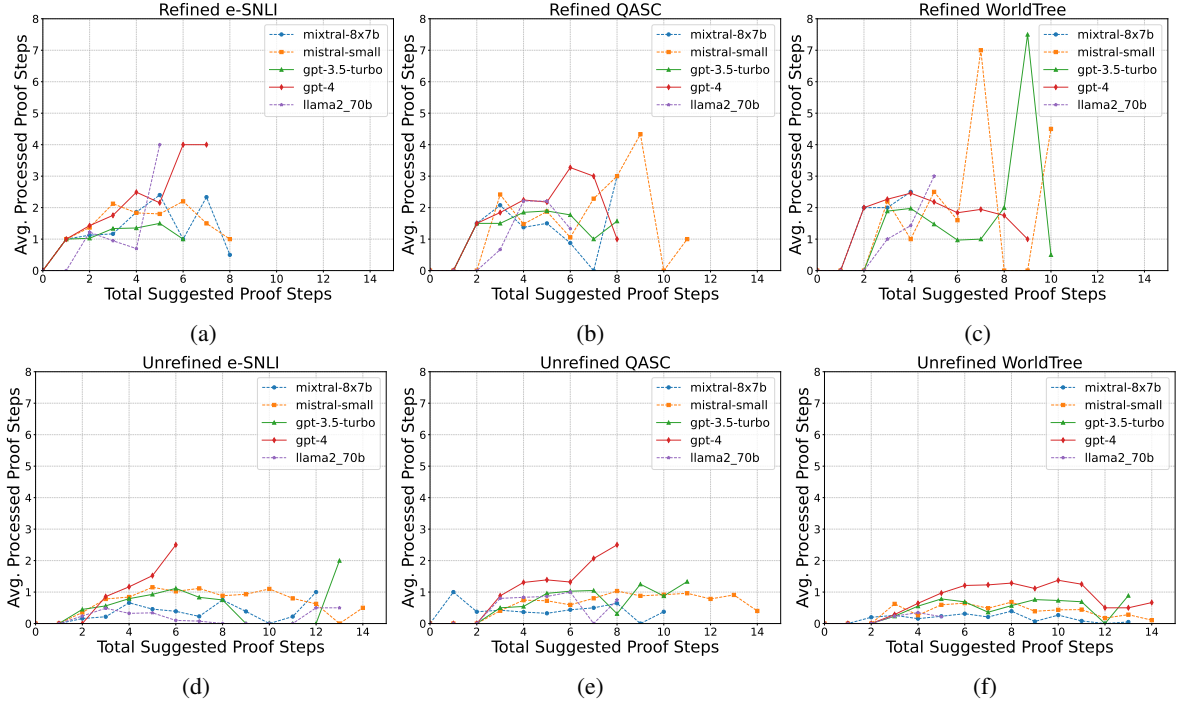

Figure 8: Average of proof steps processed by the proof assistant against the total proof steps suggested by the LLMs in refined and unrefined explanations.

48% and from 29% to 34%. Despite these improvements, a performance gap persists between GPT-4 and the other models, which is attributed to GPT-4’s superior symbolic reasoning capabilities required for explanation refinement from the identified logical errors.

Explanations are progressively made more complete and consistent through iterative symbolic refinement. In order to deliver step-wise logical consistency, explanations need to be made complete and self-contained, leading to the introduction of additional explanatory sentences, leading to an increase in the total number of suggested proof steps. Therefore, we further evaluated how the proof steps vary when the total number of suggested proof steps increases contrasting both refined and unrefined cases. Figure 8 illustrates this trend. In general, all models show a positive trend, as the total suggested proof steps increase, the average number of proof steps processed by the proof assistant also increases. Models like Mistral-Small and GPT-3.5-Turbo tend to suggest more proof steps to accomplish the logical goal, which can result in some redundant steps, such as the significant pulse shown in Figure 8c. For unrefined explanations, as shown in Figure 8d, 8e and 8f, the progression is steadier but retains a positive trend, where

the models generally suggest more proof steps in response to the additional explanatory sentences introduced to correct a logical error identified from the erroneous step. We also conducted experiments on the relationship of average number of successfully processed explanatory sentences in one proof against total planned explanatory sentences in a suggest proof in appendix A.3. Examples of refined and unrefined explanations can be found in Appendix A.5.

4.6 Factual Errors and Trivial Explanations

In addition to evaluating the logical validity of explanations, we also conducted a human evaluation of the refined explanations, considering factual correctness and explanation triviality, for the two best-performing models (GPT-3.5-Turbo and GPT-4). This evaluation focused on two questions: “*Are the refined explanatory sentences factually correct?*” and “*Is the explanation trivial, merely repeating or paraphrasing the content of the premise and hypothesis to achieve logical validity?*”. As illustrated in Figure 9, our findings indicate that all refined explanations in the e-SNLI and WorldTree datasets are consistent with commonsense knowledge. In the QASC dataset, 2.27% and 1.82% of the explanation refined by GPT-3.5-Turbo and GPT-4 contain sentences misaligned with true world

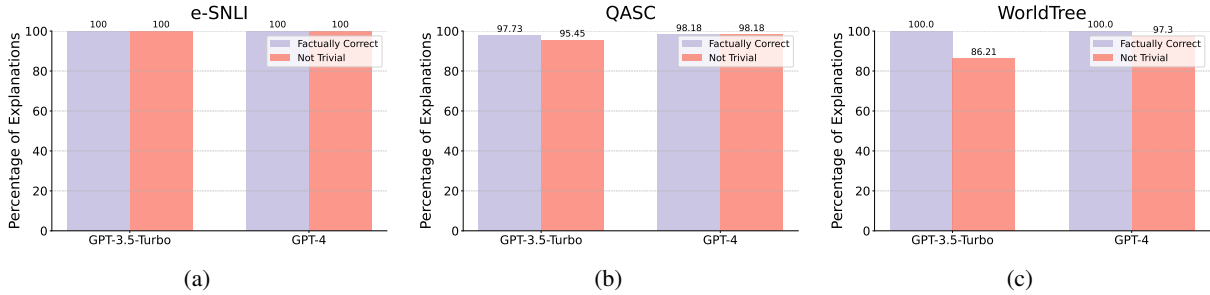

Figure 9: Human evaluation of refined explanations in terms of factuality and triviality. Factually Correct indicates the percentage of explanation sentences that are correct in terms of commonsense knowledge. Not Trivial states the percentage of explanations that contain only explanatory sentences that repeat or paraphrase the premise and/or the hypothesis.

knowledge. We found that the majority of these errors result from over-generalisation, such as the sentence *All tetrapods are defined to have four limbs*, which inaccurately includes snakes.

Finally, we found a relatively low number of explanations that repeat or paraphrase the content of premise and hypothesis. This phenomenon is absent in e-SNLI and becomes more evident when the explanatory sentences increase in complexity (i.e., WorldTree), leading models sometimes to generate explanations that do not include any additional information for the entailment to hold.

5 Related Work

5.1 LLMs Self-Refinement from External Feedback

Self-refinement of LLMs has demonstrated promising effectiveness in generating faithful and trustworthy responses (Pan et al., 2023b). The use of external feedback to guide LLMs has been extensively studied (Olausson et al., 2024a; Yu et al., 2023; Akyurek et al., 2023). Previous work such as Peng et al. (2023) and Li et al. (2024) have employed facts retrieved from external knowledge bases as sources of feedback, while Paul et al. (2024) developed a critic model to provide feedback for reasoning refinement. Additionally, Nathani et al. (2023) have explored the use of feedback models for automated feedback generation. Various works have also investigated tasks related to code generation (Chen et al., 2023; Olausson et al., 2024b) and the creation of either synthetic or expert-written logical natural language expressions (Olausson et al., 2023). Quan et al. (2024) leverage a differentiable logic reasoner to verify and refine explanations through abductive reasoning, enhancing the logical consistency of explanations

in ethical NLI tasks based on the solver’s output. This paper focuses on the automated refinement of natural language sentences created by human annotators. It verifies and refines the logical validity of these human-generated sentences using detailed external feedback, which can identify the exact erroneous steps to effectively refine logical errors in the explanatory sentences.

5.2 Autoformalisation

Autoformalisation refers to the process of translating natural language descriptions into symbolic representations. Research in this area has included the formalisation of mathematical proofs (Cunningham et al., 2022; Wu et al., 2022; First et al., 2023), and efforts to transform natural language sentences into logical forms using LLMs (Pan et al., 2023a; Olausson et al., 2023; Jiang et al., 2024b; Dalal et al., 2024). However, contextual information is frequently lost when sentences are translated in these logical frameworks. To mitigate semantic loss during the transformation process, we leverage Neo-Davidsonian event semantics, which aims to maximise the preservation sentence-level content. This representation paradigm can facilitate a more systematic content-preserving translation to logical forms, which is more independent from particular choices of representation schemas.

5.3 Conclusion

In this work, we present a novel neuro-symbolic framework that automatically verifies and refines natural language explanations using iterative refinement cycles between LLMs and theorem provers (TPs). We have conducted extensive experiments on both textual entailment and multiple-choice question answering tasks, demonstrating that the proposed method, Explanation-Refiner,

effectively enhances the logical validity of such human-annotated explanations. We investigated the model’s performance from simple to complex explanatory/sentence structures and introduced a method to prevent the loss of semantic information in autoformalisation tasks with error correction. Furthermore, we investigated the iterative model at each iteration to evaluate how the explanation is refined at each cycle. In future work, we aspire to enhance the framework’s robustness towards complex and unstructured explanations with fewer iterations required to improve the model’s efficiency.

5.4 Limitations

While this work have demonstrated significant improvements in terms of enhancing the logical consistency of explanations, the connection between improved logical consistency and AI safety still needs further investigation. While the concept of using formal solvers in conjunction with LLMs delivers a promise avenue to improve the consistency of reasoning within LLMs, these methodologies needs to be further developed and critically assessed as a mechanism which can provide guarantees of correctness, consistency and completeness within critical application domains.

A Appendix

A.1 Algorithm

Algorithm 1 shows the overall framework of Explanation-Refiner.

A.2 Scalability

Figure 10 shows the average Isabelle solving time against the number of planned explanatory sentences in a proof and the length of suggested proof

steps, including theories that have syntax errors, respectively. In some cases, the theorem prover may get stuck on a proof step, and we have set a termination time if the solving time exceeds 65 seconds.

A.3 Average Processed vs. Planned Explanatory Sentences per Proof

Figure 11 and Figure 12 shows experiments on average number of successfully processed explanatory sentences in one proof against total planned explanatory sentences in a suggest proof. Figure 13 also shows the comparison of average processed proof steps against total suggested proof steps in all dataset.

A.4 Prompts

A.4.1 Autoformalisation

Figure 14 displays the prompts used to identify action verbs (events) within the premise, explanation, and hypothesis sentences, representing events in Davidsonian-event semantics. Figure 15 displays the prompts used to transfer natural language to logical forms based on the identified events verbs. Figure 16 shows how to convert logical forms into Isabelle code (axioms and type declaration). Figure 17 shows how to convert the premise and hypothesis sentences into the Isabelle theorem code, based on the previously constructed axioms code. Figure 18 shows how to refine the syntax errors based on the types of errors, the provided code, the error messages, and the locations of the errors within the code.

A.4.2 Proof Construction

Figure 19 shows the prompts for making a preliminary inference strategy, which also identifies redundant and related explanatory sentences that will be used for proof generation. Figure 20 shows the prompts for building the proof steps used for Isabelle/HOL Proof assistant based on the provided inference strategy.

A.4.3 Explanation Refinement

Figure 21 shows how to refine the explanatory sentences based on the provided information.

A.5 Examples of Explanation Refinement

A.5.1 e-SNLI Refined Examples

Table 1 shows an example from the e-SNLI dataset of how the explanation changes after each iteration. Figures 22, 23, and 24 illustrate the Isabelle theory

code changes during the refinement process. Green code indicates the proof steps that have successfully progressed, while red code shows where the proof failed at that step.

Table 2 along with Figures 25 and 26, and Table 3 with Figures 27, 28, and 29 are two more examples.

A.5.2 QASC Refined Examples

Table 4 shows an example from the QASC dataset of how the explanation changes after each iteration. Figures 30, 31 illustrate the Isabelle theory code changes during the refinement process. Green code indicates the proof steps that have successfully progressed, while red code shows where the proof failed at that step.

Table 5 along with Figures 32 and 33, and Table 6 with Figures 34, 35 are two more examples.

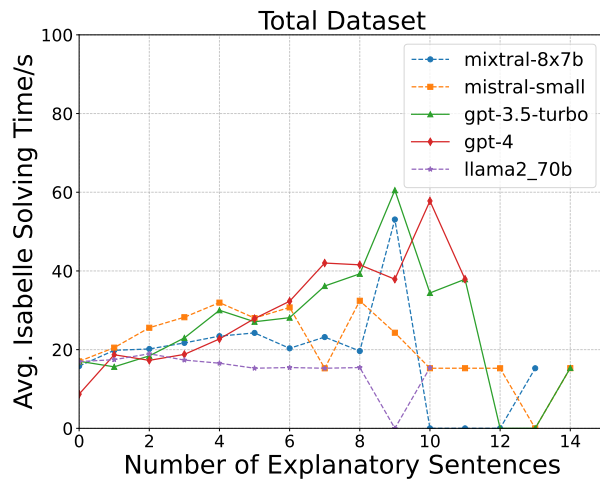

A.5.3 WorldTree Refined Examples

Table 7 shows an example from the WorldTree dataset of how the explanation changes after each iteration. Figures 36, 37, 38, 39, 40, 41, 42 and 43 illustrate the Isabelle theory code changes during the refinement process. Green code indicates the proof steps that have successfully progressed, while red code shows where the proof failed at that step.

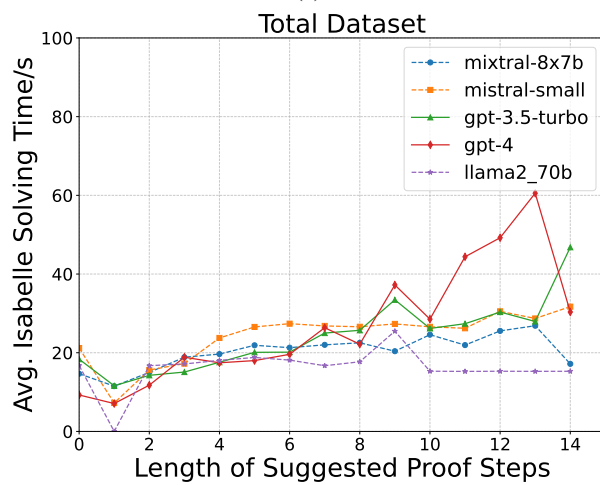

Table 8 and Figures 44, 46, 47 and 48, as well as Table 9 with Figures 49, 50, 51, and 52, provide two more examples.

A.5.4 Unrefined Example

Table 10 and Table 11 shows an example from the WorldTree dataset that does not refine within 10 iterations and is not caused by a syntax error. The figures that follow show the detailed Isabelle theory code of the related iterations.

(a)

(b)

Figure 10: (a) Average Isabelle solving time against number of explanatory sentences planned in a proof. (b) Average Isabelle solving time against number of suggested proof steps in a proof.

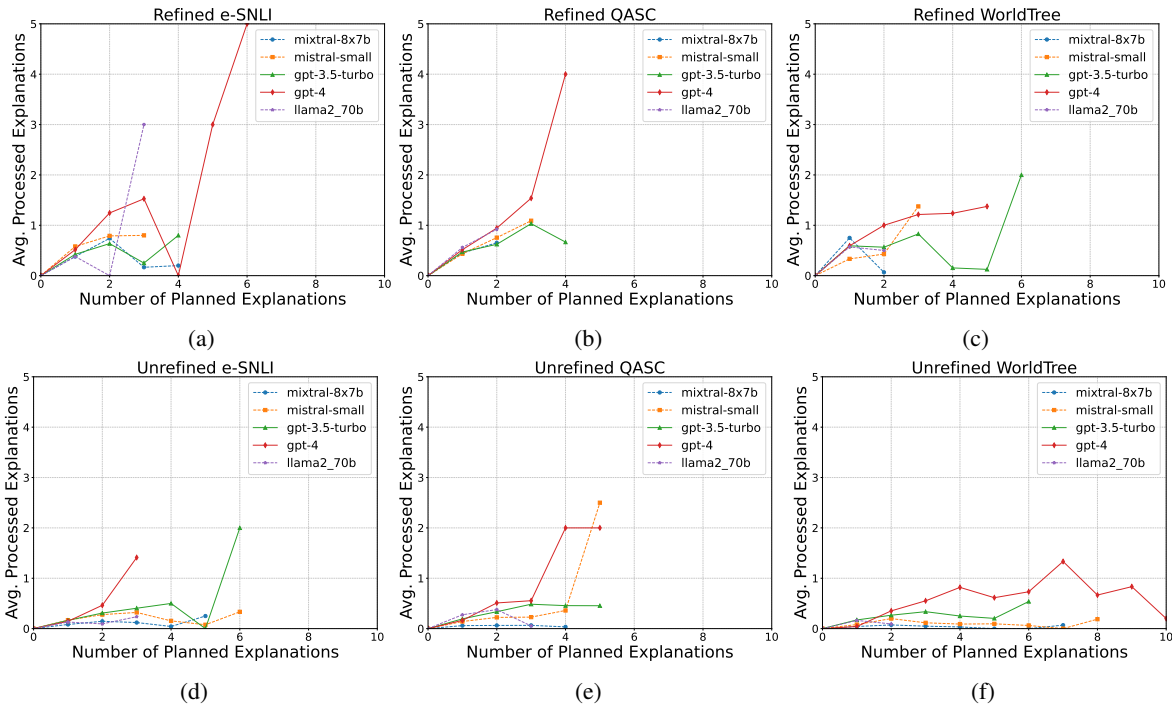

Figure 11: Average Progressed Explanations against Number of Planned Explanations in Refined and Unrefined e-SNLI, QASC and WorldTree Dataset

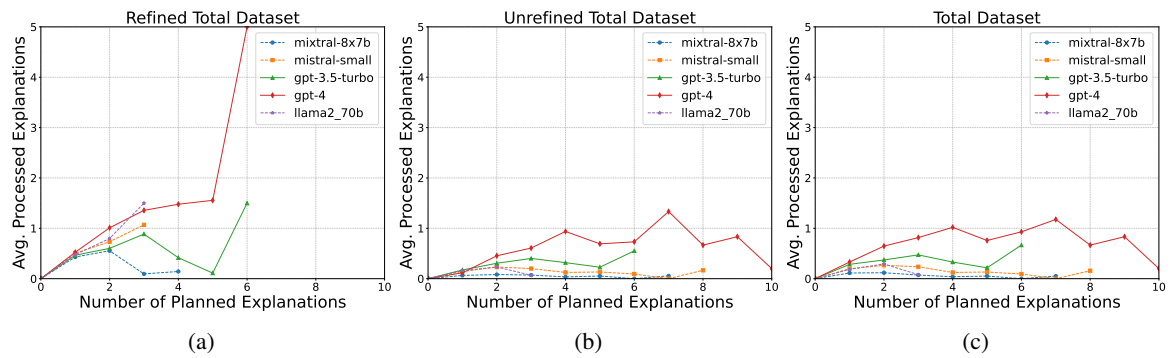

Figure 12: Average Progressed Explanations against Number of Planned Explanations for Refined, Unrefined, and Combined Across All Datasets

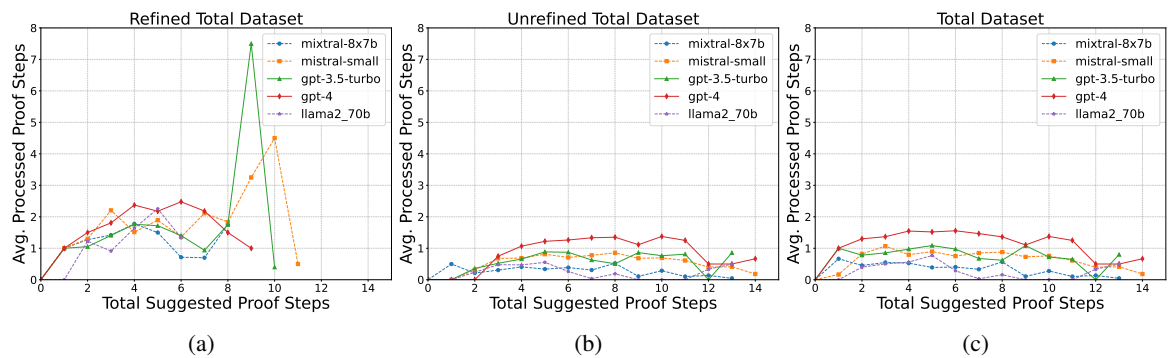

Figure 13: Average Processed Proof Steps against Total Suggested Proof Steps for Refined, Unrefined, and Combined Across All Datasets

Algorithm 1: Explanation-Refiner

Input : Premise p , Explanation E , Hypothesis h , Isabelle server $isabelle$, Autoformalisation model m_a , Isabelle syntax refinement model m_{sr} , Rough inference model m_{ri} , Proof step build model m_{pr} , Facts filter model m_f , Explanation refinement model m_e

Output : Updated Explanation E

```
1  $valid \leftarrow false$

```

SYSTEM: You are an expert in linguistics. You will be provided
with some sentences, find any action verbs of these sentences.
You need to ignore auxiliary verbs and modal verbs.
Some instructions:
1. You must give me the answer for all provided sentences.
2. Do not add any notes.
3. If no premise sentence provided, include it in the answer
as none.
4. Retain the answer words in their original form within the
provided sentence.
USER:
Here are some examples:
###
Hypothesis Sentence:
1. A woman is playing an instrument.
Has action: Yes
Actions: 1. playing

Explanation Sentence:
1. A violin is an instrument.
Has action: No
Actions: none

Premise Sentence:
1. A smiling woman is playing the violin in front of a
turquoise background.
Has action: Yes
Actions: 1. playing
###
...
#####
Strictly follow the instructions that I have claimed.

Provided sentences:
{{input_sentence}}

Answer:

```

Figure 14: Prompts for detecting event-related words in the given sentences

```

SYSTEM: You are an expert in semantics, formal language and
neo-davidsonian event semantics. You will be provided with
some sentences and the action verbs involved in those
sentences. You need to transfer the sentences into symbolic
language. If the sentence has no action, transfer it into
formal language using first-order language. If the sentence
has one action, transfer it using first-order language and
davidsonian event semantics within one event. If the sentence
has two more actions, transfer it using first-order language
and davidsonian event semantics within at most two events.
Some instructions:
1. Capture All Information: Ensure the logical form reflects
every detail from the sentence.
2. Use '→' for Certain Verbs: Represent actions like 'cause',
'lead', 'help' that represent an implication, causal relation
with '→' for clarity.
3. Event Variable 'e': Use 'e' for events, actions, with
action predicates having 'e' as their sole argument.
...
USER: Here are some examples:
###
Sentence: Grass is a kind of plant.
Has action: No
Actions:
Logical form:  $\forall x. \text{Grass}(x) \rightarrow \text{Plant}(x)$ 
###
Sentence: Squirrels typically eat nuts for energy.
Has action: Yes
Actions: 1. eat
Logical form:  $\forall x y z. \text{Squirrels}(x) \wedge \text{Nuts}(y) \rightarrow (\exists e. \text{Eat}(e) \wedge \text{Agent}(e, x) \wedge \text{Patient}(e, y) \wedge \text{ForEnergy}(y, x))$ 
###
...
#####
Strictly followed the instructions that I have claimed.

Provided sentences:
{{input_sentence}}

Answer:

```

Figure 15: Prompts for converting natural language sentences into logical form representations

Dataset	Sentences	Explanation	Iteration	Validity
e-SNLI	Premise: A woman in black framed glasses peruses a photo album while sitting in a red wicker chair. Hypothesis: There is a lady with a book.	The lady is looking through a photo album which is a type of book.	0	Invalid
e-SNLI	Premise: A woman in black framed glasses peruses a photo album while sitting in a red wicker chair. Hypothesis: There is a lady with a book.	A woman can be referred to as a lady. A photo album is a type of book.	1	Invalid
e-SNLI	Premise: A woman in black framed glasses peruses a photo album while sitting in a red wicker chair. Hypothesis: There is a lady with a book.	A woman can be referred to as a lady. A photo album is a type of book. If a woman is perusing a photo album, then the woman is with a book.	2	Valid
