Decentralized Kernel Ridge Regression Based on Data-Dependent Random Feature

Ruikai Yang, Fan He, Mingzhen He, Jie Yang, *Senior Member, IEEE*, and Xiaolin Huang ∗ , *Senior Member, IEEE*

Abstract—Random feature (RF) has been widely used for node consistency in decentralized kernel ridge regression (KRR). Currently, the consistency is guaranteed by imposing constraints on coefficients of features, necessitating that the random features on different nodes are identical. However, in many applications, data on different nodes varies significantly on the number or distribution, which calls for adaptive and data-dependent methods that generate different RFs. To tackle the essentia l difficulty, we propose a new decentralized KRR algorithm tha t pursues consensus on decision functions, which allows grea t flexibility and well adapts data on nodes. The convergence is rigorously given and the effectiveness is numerically verified: by capturing the characteristics of the data on each node, whil e maintaining the same communication costs as other methods, we achieved an average regression accuracy improvement of 25.5% across six real-world data sets.

Index Terms—Kernel methods, decentralized learning, random feature, data-dependent algorithm.

I. INTRODUCTION

K ERNEL methods are widely applied and insightfully investigated for their ability to handle complex nonlinear investigated for their ability to handle complex nonlinear problems into simple linear problems [\[1\]](#page-8-0)–[\[4\]](#page-8-1). For a compact data set $\mathcal{X} \subset \mathbb{R}^d$ in kernel methods, there is usually a nonlinear mapping $\phi: \mathcal{X} \to \mathbb{R}^P$ (*P* can be infinite) to transform data from the sample space to a high-dimensional space. Suppose that ϕ belongs to a reproducing kernel Hilbert space (RKHS) \mathcal{H}_k that is endowed with a positive definite kernel function $k(\cdot, \cdot) : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$, where d is the dimension of data. Thanks to the kernel trick, one can compute the inner product in the RKHS with a given kernel function without knowing the explicit expression of ϕ . Kernel ridge regression (KRR, [\[5\]](#page-8-2)) is an important non-parametric kernel-based learning method. Given a data set $\mathcal{D} = \{ (x_i, y_i) \}_{i=1}^N$ and $x_i \in \mathcal{X} \subseteq \mathbb{R}^d$, $y_i \in \mathcal{Y} \subseteq \mathbb{R}$, KRR considers the following optimization problem,

$$
\min_{f \in \mathcal{H}_k} \quad \frac{1}{N} \sum_{i=1}^N \ell(f(\boldsymbol{x}_i), y_i) + \lambda \|f\|_{\mathcal{H}_k}^2 \,, \tag{1}
$$

where $\lambda > 0$ is the regularization parameter and $\ell : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is a given loss function.

In today's large-scale settings, distributed computing frame-works [\[6\]](#page-8-3)–[\[10\]](#page-8-4) have attracted much attention in many areas. Massive distributed sensors and devices, for example, collect data in wireless communication networks [\[11\]](#page-8-5) and the Internet of Things [\[12\]](#page-8-6). To protect patients' privacy, some biological big data must be dispersed across institutions and intentionally isolated [\[13\]](#page-8-7). The advantages and necessity of distributed computing frameworks have prompted research into distributed KRR (DKRR). Let J be the number of machines or nodes and $\mathcal{D} = \bigcup_{j=1}^{J} \mathcal{D}_j$ be divided into J mutually disjoint subsets, where each subset $\mathcal{D}_j = \{(\boldsymbol{x}_{j,i}, y_{j,i})\}_{i=1}^{N_j}$ $(1 \leq j \leq J)$. DKRR considers the following optimization problem,

$$
\min_{\{f_j \in \mathcal{H}_k\}_{j=1}^J} \sum_{j=1}^J \left\{ \frac{1}{N} \sum_{i=1}^{N_j} \ell(f_j(\boldsymbol{x}_{j,i}), y_{j,i}) + \lambda_j \|f_j\|_{\mathcal{H}_k}^2 \right\}
$$
\n
$$
\text{s.t.} \quad f_1 = f_2 = \dots = f_J. \tag{2}
$$

Distributed algorithms can be categorized as *centralized* and *decentralized* ones. Compared to centralized KRR algorithms [\[14\]](#page-8-8)–[\[17\]](#page-8-9), decentralized algorithms do not require a fusio n center and thus are more suitable for applications that care about privacy. But since the local function learned from KRR is supported by local data, namely $\{k(\cdot, \boldsymbol{x}_{j,i})\}_{i=1}^{N_j}$, imposing constraints on combination coefficients is almost impossible and in fact unreasonable. To address the aforementioned difficulty, researchers introduced random features (RFs, [\[18\]](#page-8-10)) into decentralized frameworks recently [\[19\]](#page-8-11)–[\[23\]](#page-8-12). For a kernel function $k(x_i, x_j)$, RF constructs an explicit mapping $z : \mathbb{R}^d \to \mathbb{R}^D$ to approximate $k(x_i, x_j) \approx z(x_i)^\top z(x_j)$, where the explicit mapping is obtained by sampling from a certain data-independent distribution. Furthermore, since the RF mapping is not bijective, it can ensure the security of x_i even when nodes communicate $z(x_i)$. Compared to some decentralized methods that require transmitting raw data [\[24\]](#page-9-0)– [\[27\]](#page-9-1), this approach will provide crucial assistance in domains where data privacy protection is necessary and prohibits crossnode transmission of raw data [\[28\]](#page-9-2)–[\[31\]](#page-9-3). A typical decentralized KRR with RF, namely decentralized kernel learning via ADMM (DKLA) [\[22\]](#page-8-13), can be written as below,

$$
\min_{\{\boldsymbol{\theta}_j \in \mathbb{R}^D\}_{j=1}^J} \sum_{j=1}^J \left\{ \frac{1}{N} \sum_{i=1}^{N_j} \ell\left(\boldsymbol{\theta}_j^\top z(\boldsymbol{x}_{j,i}), y_{j,i}\right) + \lambda_j \|\boldsymbol{\theta}_j\|_2^2 \right\}
$$
\ns.t. $\boldsymbol{\theta}_j = \boldsymbol{\theta}_p, p \in \mathcal{N}_j, \forall j,$ \n(3)

where \mathcal{N}_j denotes one-hop neighbors of the *j*-th node.

There has been significant progress on RF in the past ten years; see, e.g., a recent survey [\[32\]](#page-9-4). Nowadays, one can generate RF adaptive to data, i.e., for specific data, one can use fewer features to achieve better kernel approximation or performance on subsequent tasks. Typically, these datadependent RF (DDRF) methods sample D_0 features from a given probability density, score these features by a predefined metric, and then directly select $D (D < D₀)$ features with the highest scores [\[33\]](#page-9-5), [\[34\]](#page-9-6) or resample those features with higher probability [\[35\]](#page-9-7), [\[36\]](#page-9-8). The advantages of these methods come from the fact that the features are data-dependent, from which it follows that the corresponding RFs could be different on different nodes. But this does not apply to the current RF-based decentralized algorithms [\[37\]](#page-9-9)–[\[40\]](#page-9-10), which share the same premise as the model proposed in [\[22\]](#page-8-13), relying on consensus on feature coefficients. For these algorithms to work, features on different nodes must be identical. Moreover, when algorithms deal with imbalanced data, it is preferable to use variable D_j because it can improve communication efficiency without damaging the approximation ability. Due to the requirement mentioned before, such a setting also cannot be adopted to current decentralized algorithms.

The purpose of this paper is to develop a decentralized KRR algorithm that allows different nodes to use different RFs. We propose to align decision functions on different nodes and iteratively solve the problem with a primal-only method, the convergence of which is proven to be controlled by the local penalty parameter. Most of the computations and communications can be done before the iteration, and only the $\{\theta_i\}$ needs to be communicated in iterations. Because decision functions rather than coefficients are used to reach consensus, RFs could adapt to the data on nodes. This can greatly improve the performance, especially when the data size, data distribution, noise intensity, etc., are different among different nodes. For example, a heterogeneous setting of responses $\{y_{j,i}\}_{i=1}^{N_j}$ on each node is tested. For the *houses* data set, we run tests on a network of 10 nodes and each node has 4 neighbors. When DKLA [\[22\]](#page-8-13) and our algorithm follow the same convergence rate, DKLA uses $D_i = 100$ and our algorithm uses only $D_j = 20$ to attain a similar error, which significantly reduces the communication costs. All of the scenarios above are possible, and the suggested algorithm is promising in actual practice.

The main contributions of this paper are:

- We propose a decentralized algorithm named DeKRR-DDRF, which allows the features on each node to be inconsistent. It thus provides the possibility for each node to apply data-dependent RF techniques to benefit in both accuracy and efficiency.
- In DeKRR-DDRF, we give a fast and communicationefficient solving method, where the analytical solution can be directly obtained at every step in iterations. We also prove the convergence of our solving method.
- Several numerical experiments with non-IID and imbalanced data are conducted to test DeKRR-DDRF. The results show that our algorithm outperforms others because it can select features based on the node data

Organization and Notations. This paper is organized as follows. In Section [II,](#page-1-0) after reformulating the decentralized KRR problem and introducing RF methods, we propose our decentralized algorithm with DDRF. In Section [III,](#page-3-0) we present the convergence conditions of our solving method. In Section [IV,](#page-5-0) we conduct several experiments to demonstrate that our algorithm is more flexible and efficient than other algorithms with the same communication costs. In Section [V,](#page-7-0) we give a brief conclusion of our work.

In this paper, $\mathbb R$ denotes the set of real numbers. $\mathbb E[\cdot]$ denotes the expectation operator. $\lVert \cdot \rVert_2$ denotes the Euclidean norm of a vector. $Tr(\cdot)$, $\lambda_{max}(\cdot)$ and $\lambda_{min}(\cdot)$ denote the trace, the largest eigenvalue and the smallest eigenvalue of a square matrix, respectively. Given a matrix A , $(A)_{i,j}$ denotes (i, j) -th entry of A. $A \succeq B$ denotes that $A - B$ is a positive semi-definite (PSD) matrix.

II. DECENTRALIZED KRR WITH DATA-DEPENDENT RANDOM FEATURES

A. Problem Formulation

Consider a connected network with J nodes which can be described as a symmetric undirected graph $\mathcal{G} = \{V, \mathcal{E}\}\$, where V is the set of nodes and its cardinality $|\mathcal{V}| = J$, and $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ is the set of edges. For the j-th node in the network, $\mathcal{N}_i \subset \mathcal{V}$ is the set of its one-hop neighbors and $\hat{\mathcal{N}}_j = \mathcal{N}_j \cup \{j\},\$ where $(j, p), (p, j) \in \mathcal{E}, \forall p \in \mathcal{N}_j$. In decentralized settings, a node can only communicate with its one-hop neighbors. In addition, we assume that each node j has a data set $\mathcal{D}_j = \{X_j, Y_j\}$ which is drawn from a data distribution ρ_j on $\mathcal{X}_j \times \mathcal{Y}_j$. Here $\mathbf{X}_j = [\mathbf{x}_{j,1} \ \mathbf{x}_{j,2} \ \dots \ \mathbf{x}_{j,N_j}] \in \mathbb{R}^{d \times N_j}$, $Y_j = [y_{j,1} \ y_{j,2} \ \dots \ y_{j,N_j}] \in \mathbb{R}^{1 \times N_j}$. And we assume a potential total data set $\mathcal{D} = \cup_j \mathcal{D}_j = \{X, Y\}$. Here $X =$ $[X_1 X_2 \dots X_J] \in \mathbb{R}^{d \times N}$, $\boldsymbol{Y} = [\boldsymbol{Y_1} Y_2 \dots Y_J] \in \mathbb{R}^{1 \times N}$ and we let $N = \sum_{j=1}^{J} N_j$. Throughout, we suppose the decision function f belongs to a RKHS \mathcal{H}_k that is equipped with a positive definite kernel function $k(\cdot, \cdot) : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$, and we use $\langle \cdot, \cdot \rangle_{\mathcal{H}_k}$ and $\|\cdot\|_{\mathcal{H}_k}$ to denote the inner product and the norm in \mathcal{H}_k , respectively.

In general, decentralized learning solves the following expected risk minimization problem,

$$
\min_{\{f_j \in \mathcal{H}_k\}_{j=1}^J} \sum_{j=1}^J \mathbb{E}_{(\mathbf{x}_j, y_j) \sim \rho_j} [\ell(f_j(\mathbf{x}_j), y_j)]
$$
\n
$$
\text{s.t.} \quad f_1 = f_2 = \dots = f_J.
$$
\n(4)

It is impractical to know every distribution ρ_i . Thus, we usually consider the empirical risk with a given data set, i.e.,

$$
\min_{\{f_j \in \mathcal{H}_k\}_{j=1}^J} \sum_{j=1}^J \frac{N_j}{N} \left\{ \frac{1}{N_j} \sum_{i=1}^{N_j} \ell(f_j(\boldsymbol{x}_{j,i}), y_{j,i}) + \lambda_j \|f_j\|_{\mathcal{H}_k}^2 \right\}
$$
\n
$$
\text{s.t.} \quad f_1 = f_2 = \dots = f_J,
$$
\n(5)

where the task-dependent loss function $\ell(f(\boldsymbol{x}), y)$ measures the difference between the prediction $f(x)$ and the response y, and the local regularization parameter λ_i is used to control the model's complexity and prevent over-fitting. Typically, we choose the squared loss $\ell(f(\boldsymbol{x}), y) := (f(\boldsymbol{x}) - y)^2$ in KRR.

According to the representer theorem [\[41\]](#page-9-11), the optimal decision function of [\(5\)](#page-1-1) can be represented as follows,

$$
f_j^*(\cdot) = \boldsymbol{\alpha}^\top K(\cdot, \boldsymbol{X}),\tag{6}
$$

where $\boldsymbol{\alpha} \in \mathbb{R}^N$ and $K(\cdot, \boldsymbol{X}) = [k(\cdot, \boldsymbol{x}_{1,1}); \dots; k(\cdot, \boldsymbol{x}_{J,N_J})].$ Using the reproducing property $\langle k(\cdot, x), k(\cdot, x') \rangle_{\mathcal{H}_k}$ = $k(\mathbf{x}, \mathbf{x}')$, we have $||f||_{\mathcal{H}_k}^2 = \boldsymbol{\alpha}^\top \mathbf{K} \boldsymbol{\alpha}$ with $(\mathbf{K})_{i,j} = k(\mathbf{x}_i, \mathbf{x}_j)$ $(1 \le i, j \le N)$. Then with the squared loss, the problem [\(5\)](#page-1-1) can be rewritten as below,

$$
\min_{\{\boldsymbol{\alpha}_j \in \mathbb{R}^N\}_{j=1}^J} \sum_{j=1}^J \frac{1}{N} \left\| \boldsymbol{\alpha}_j^{\top} \tilde{\mathbf{K}}_j - \boldsymbol{Y} \right\|_2^2 + \frac{N_j}{N} \lambda_j \boldsymbol{\alpha}_j^{\top} \mathbf{K} \boldsymbol{\alpha}_j
$$
\n
$$
\text{s.t.} \quad \boldsymbol{\alpha}_1 = \boldsymbol{\alpha}_2 = \dots = \boldsymbol{\alpha}_J,
$$
\n(7)

where $\tilde{\mathbf{K}}_j \coloneqq [K(\boldsymbol{x}_{j,1}, \boldsymbol{X}) \; K(\boldsymbol{x}_{j,2}, \boldsymbol{X}) \; \dots \; K(\boldsymbol{x}_{j,N_j}, \boldsymbol{X})] \in$ $\mathbb{R}^{N \times N_j}$. In decentralized settings, however, it will face two main problems. Firstly, solving [\(7\)](#page-2-0) requires constructing the matrix \bf{K} on each node j, which calls for the node to receive raw data sets $\{\mathcal{D}_i\}_{i\in\mathcal{V}\backslash\{j\}}$ from all other nodes. This is impractical in today's privacy-conscious world. Moreover, because the dimension of α_j is related to the total amount of data, the high computation, storage, and communication costs are unacceptable for large-scale problems.

B. Random Features in Decentralized Settings

 $\psi(\boldsymbol{\omega}_i, \boldsymbol{x}) = \frac{1}{\sqrt{D}}$

The main idea of RF methods is sampling $\Omega = {\{\omega_i\}}_{i=1}^D$ in a pre-given probability density $p(\boldsymbol{\omega})$ to construct an explicit mapping $z : \mathbb{R}^d \to \mathbb{R}^D$ to approximate a kernel function:

$$
k(\boldsymbol{x}, \boldsymbol{x}') = \langle \phi(\boldsymbol{x}), \phi(\boldsymbol{x}') \rangle_{\mathcal{H}_k} \approx \langle z(\boldsymbol{\Omega}, \boldsymbol{x}), z(\boldsymbol{\Omega}, \boldsymbol{x}') \rangle, \quad (8)
$$

where $z(\mathbf{\Omega}, \mathbf{x}) \coloneqq [\psi(\boldsymbol{\omega}_1, \mathbf{x}); \psi(\boldsymbol{\omega}_2, \mathbf{x}); \dots; \psi(\boldsymbol{\omega}_D, \mathbf{x})]$. The feature mappings $\psi(\omega, x)$ and the probability densities $p(\omega)$ for some common kernel functions are summarized in [\[42\]](#page-9-12). For example, given the Gaussian kernel function $k(x, x') =$ $\exp\left(\frac{\|\mathbf{x}-\mathbf{x}'\|_2^2}{2\sigma^2}\right)$, we sample ω from $\mathcal{N}(0, \frac{1}{\sigma^2}\mathbf{I}_d)$, and there are two ways to construct the real-valued mapping $\psi(\omega_i, x)$:

or

$$
\psi(\boldsymbol{\omega}_i, \boldsymbol{x}) = \sqrt{\frac{2}{D}} \cos(\boldsymbol{\omega}_i^{\top} \boldsymbol{x} + b_i), \qquad (10)
$$

 $\left[\cos(\omega_i^\top x);\sin(\omega_i^\top x)\right]$ (9)

where b_i is sampled uniformly from $[0, 2\pi]$. These ways of building the mapping are also called random Fourier features (RFFs, [\[18\]](#page-8-10)).

The original process of RFF is data-independent and quite straightforward. Data-dependent RF methods could further improve the performance, i.e., lower approximation error with fewer features. Successful attempts include re-weighted RFF [\[33\]](#page-9-5), [\[43\]](#page-9-13), [\[44\]](#page-9-14) and leverage score based RFF [\[35\]](#page-9-7), [\[36\]](#page-9-8). A typical way, e.g., energy-based RFF [\[33\]](#page-9-5), is first to generate D_0 random features and then introduce a score function $S(\omega)$ to select good features. Since $S(\omega)$ is calculated on data, the features selected on each node will differ, resulting in a different explicit mapping. This renders requiring consensus on the combination coefficients meaningless.

C. Algorithm Development

With the features selected by DDRF methods, the local decision function $f_j(\cdot)$ can be written as follows,

$$
f_j(\cdot) = \alpha_j^\top Z_j^\top(\boldsymbol{X}) z_j(\cdot) \coloneqq \boldsymbol{\theta}_j^\top z_j(\cdot), \tag{11}
$$

where $Z_j(\boldsymbol{X}) \coloneqq [z(\boldsymbol{\Omega}_j, \boldsymbol{x}_1) \; z(\boldsymbol{\Omega}_j, \boldsymbol{x}_2) \; \dots \; z(\boldsymbol{\Omega}_j, \boldsymbol{x}_N)] \in$ $\mathbb{R}^{D_j \times N}$. Then we propose the following decentralized KRR model to get consensus among decision functions on different nodes,

$$
\min_{\{\boldsymbol{\theta}_j \in \mathbb{R}^{D_j}\}_{j=1}^J} \quad \sum_{j=1}^J \frac{N_j}{N} \left\{ \frac{1}{N_j} \left\| \boldsymbol{\theta}_j^\top Z_j(\boldsymbol{X}_j) - \boldsymbol{Y}_j \right\|_2^2 + \lambda_j \|\boldsymbol{\theta}_j\|_2^2 \right\} \n\text{s.t.} \quad \boldsymbol{\theta}_j^\top z_j(\cdot) = \boldsymbol{\theta}_p^\top z_p(\cdot), \ p \in \hat{\mathcal{N}}_j, \ \forall j.
$$
\n(12)

When all nodes utilize the same features, that is, $D_j =$ D_p and $z_j(\cdot) = z_p(\cdot)$, the constraint is equal to pursuing the consistency of $\{\theta_j\}$. In that case, [\(12\)](#page-2-1) reduces to the model in [\[22\]](#page-8-13). When the feature mappings are data-dependent, they differ between nodes, causing the equality constraint $\theta_j^{\top} z_j(\cdot) = \theta_p^{\top} z_p(\cdot)$ to be excessively strict to satisfy all $x \in \mathcal{X}$. Thus, we consider the following relaxed problem with an objective function $\mathcal{L}(\theta_1, \theta_2, \ldots, \theta_J)$, where we use the data on each node and its neighbors to pursue the consistency of decision functions,

$$
\min_{\{\boldsymbol{\theta}_j \in \mathbb{R}^{D_j}\}_{j=1}^J} \sum_{j=1}^J \left\{ \frac{1}{N} \left\| \boldsymbol{\theta}_j^\top Z_j(\boldsymbol{X}_j) - \boldsymbol{Y}_j \right\|_2^2 + \frac{N_j}{N} \lambda_j \|\boldsymbol{\theta}_j\|_2^2 + \sum_{p \in \hat{\mathcal{N}}_j} \frac{c_{j,p}}{N |\hat{\mathcal{N}}_j|} \left\| \boldsymbol{\theta}_j^\top Z_j(\boldsymbol{X}_j) - \boldsymbol{\theta}_p^\top Z_p(\boldsymbol{X}_j) \right\|_2^2 \right\}.
$$
\n(13)

Here the penalty parameters $c_{j,p}$ control the alignment of decision functions on different nodes, and different quadratic terms can be multiplied by different $c_{j,p}$. In the detailed solution and theoretical analysis later, we use two values:

$$
c_{j,p} \Rightarrow \begin{cases} c_{j,\text{self}}, & j=p, \\ c_{j,\text{nei}}, & j \neq p. \end{cases}
$$
 (14)

Roughly, the objective function $\mathcal L$ is convex w.r.t. $\Theta :=$ $[\theta_1; \theta_2; \ldots; \theta_J]$ and easy to solve with a fusion center, e.g., using the analytical formulation. In decentralized frameworks, however, this would be unfeasible. Furthermore, $\mathcal L$ cannot be decoupled to each node, which complicates algorithm design in decentralized frameworks. By "decouple", we mean that the objective function can be represented as $\mathcal{L} = \sum_{j=1}^{J} \mathcal{L}_j$, where \mathcal{L}_j only depends on the information of the j-th node. In the following, we establish a decentralized iterative method to solve (13) .

Considering that each node can only get information about itself and its one-hop neighbors, we extract the following terms from $\mathcal L$ and merge them as

$$
S_j (\theta_j, \{\theta_p\}_{p \in \mathcal{N}_j})
$$

\n
$$
:= \frac{1}{N} ||\theta_j^{\top} Z_j(\boldsymbol{X}_j) - \boldsymbol{Y}_j||_2^2 + \frac{N_j \lambda_j}{N} ||\theta_j||_2^2
$$

\n
$$
+ \sum_{p \in \hat{\mathcal{N}}_j} \tilde{c}_{j,p} ||\theta_j^{\top} Z_j(\boldsymbol{X}_j) - \theta_p^{\top} Z_p(\boldsymbol{X}_j)||_2^2
$$
(15)
\n
$$
+ \sum_{p \in \hat{\mathcal{N}}_j} \tilde{c}_{p,j} ||\theta_j^{\top} Z_j(\boldsymbol{X}_p) - \theta_p^{\top} Z_p(\boldsymbol{X}_p)||_2^2,
$$

where $\tilde{c}_{j,p} := c_{j,p}/(N|\hat{\mathcal{N}}_j|)$. The first two terms in [\(15\)](#page-3-1) are only related to the local information, and the last two are coupled with neighbors. In iterations, each node locally optimizes the following sub-problem, where $\{\theta_p\}_{p \in \mathcal{N}_j}$ are known and are viewed to be constants,

$$
\min_{\boldsymbol{\theta}_j} \quad S_j\left(\boldsymbol{\theta}_j; \{\boldsymbol{\theta}_p\}_{p \in \mathcal{N}_j}\right). \tag{16}
$$

To well describe the details, we define $\mathbf{Z}_{i,j} := Z_i(\mathbf{X}_j) \in \mathbb{R}^{D_j \times N_j}$, $\lambda_j := \frac{\lambda N}{J N_j}$ and the following local auxiliary matrices,

$$
G_j \coloneqq \left[(1/N + 2\tilde{c}_{j,\text{self}} + |\mathcal{N}_j|\tilde{c}_{j,\text{nei}}) \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top + \frac{\lambda}{J} \mathbf{I}_{D_j} + \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{j,p}^\top \right]^{-1} \in \mathbb{R}^{D_j \times D_j},
$$

\n
$$
d_j \coloneqq \frac{1}{N} \mathbf{Z}_{j,j} \mathbf{Y}_j^\top \in \mathbb{R}^{D_j},
$$

\n
$$
S_j \coloneqq 2\tilde{c}_{j,\text{self}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top \in \mathbb{R}^{D_j \times D_j},
$$

\n
$$
P_{j,p} \coloneqq \tilde{c}_{j,\text{nei}} \mathbf{Z}_{j,j} \mathbf{Z}_{p,j}^\top + \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{p,p}^\top \in \mathbb{R}^{D_j \times D_p}.
$$
\n(17)

Note that these auxiliary matrices can be constructed by a finite number of communications with one-hop neighbors before the iteration and remain unchanged throughout our algorithm, which is helpful to simplify the calculation process. Due to the use of RF methods, the communication only involves $Z_i(\boldsymbol{X}_i)$ $((i, j) \in \mathcal{E})$, which ensures data privacy. Assuming that at time k, the j-th node has received $\{\theta_p^k\}_{p \in \mathcal{N}_j}$. And then we locally update θ_j by solving $\nabla_{\theta_j} S_j = 0$ in [\(16\)](#page-3-2), which yields

$$
\theta_j^{k+1} = \left[\left(\frac{1}{N} + 2 \tilde{c}_{j,\text{self}} + |\mathcal{N}_j| \tilde{c}_{j,\text{nei}} \right) \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top + \frac{\lambda}{J} \mathbf{I}_{D_j} + \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{j,p}^\top \right]^{-1} \bullet \left[\frac{1}{N} \mathbf{Z}_{j,j} \mathbf{Y}_j^\top + 2 \tilde{c}_{j,\text{self}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top \boldsymbol{\theta}_j^k + \sum_{p \in \mathcal{N}_j} \left(\tilde{c}_{j,\text{nei}} \mathbf{Z}_{j,j} \mathbf{Z}_{p,j}^\top + \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{p,p}^\top \right) \boldsymbol{\theta}_p^k \right].
$$
\n(18)

By the local auxiliary matrices in [\(17\)](#page-3-3), equation above can be further reduced to

$$
\boldsymbol{\theta}_j^{k+1} = \boldsymbol{G}_j \Big(\boldsymbol{d}_j + \boldsymbol{S}_j \boldsymbol{\theta}_j^k + \sum_{p \in \mathcal{N}_j} \boldsymbol{P}_{j,p} \boldsymbol{\theta}_p^k \Big). \tag{19}
$$

The above algorithm is summarized in Algorithm [1.](#page-3-4)

For a distributed method, we care about the computation and communication costs. Due to the simplicity of our solving method, the costs can be easily given below,

Algorithm 1 Decentralized KRR with Data-dependent RF

- **Input:** the data set $\{\mathcal{D}_j\}_{j=1}^J$, the shift-invariant kernel k, the number of random features $\{D_j\}_{j=1}^J$, the regularization parameter λ , and the penalty parameters $c_{j,p}$.
- **Output:** the decision function $\{f_j(\cdot) = \boldsymbol{\theta}_j^{\top} Z_j(\cdot)\}_{j=1}^J$.
- 1: **Initialize:** $\theta_j^{(0)} = 0$.
- 2: For all local nodes $j = 1, \dots, J$, do in parallel:
- 3: Utilize a data-dependent random feature method to select D_j features.
- 4: Send $\{\omega_{j,i}\}_{i=1}^{D_j}$ (using [\(9\)](#page-2-3)) or $\{\omega_{j,i}, b_{j,i}\}_{i=1}^{D_j}$ (using [\(10\)](#page-2-4)) and $Z_j(\mathbf{X}_j)$ to one-hop neighbors.
- 5: Receive $\{\omega_{p,i}\}_{i=1}^{D_p}$ or $\{\omega_{p,i}, b_{p,i}\}_{i=1}^{D_p}$ and $\{Z_p(\boldsymbol{X}_p)\}_{p \in \mathcal{N}_j}$ from one-hop neighbors.
- 6: Compute $\{Z_p(\boldsymbol{X}_j)\}_{p \in \mathcal{N}_j}$ and send them to one-hop neighbors.
- 7: Construct G_j , d_j , S_j , $\{P_{j,p}\}_{p \in \mathcal{N}_j}$ by [\(17\)](#page-3-3).
- 8: Set $k = 0$.
- 9: repeat
- 10: Send θ_j^k to one-hop neighbors.
- 11: Receive $\{\theta_p^k\}_{p \in \mathcal{N}_j}$ from one-hop neighbors.
- 12: Update θ_j^{k+1} by [\(19\)](#page-3-5).
- 13: $k = k + 1$.
- 14: until the stop criteria is satisfied.
	- 1) The main computational costs arise from calculating [\(17\)](#page-3-3) and [\(19\)](#page-3-5). For the former, the computational complexities of constructing the four types of auxiliary matrices G_j , d_j , S_j , and $\{P_{j,p}\}_{p \in \mathcal{N}_j}$ on each node, are $\mathcal{O}(D_j^3)$, $\mathcal{O}(D_j N_j)$, $\mathcal{O}(D_j^2 N_j)$, and $\mathcal{O}(D_j D_p \max\{N_j, N_p\})$, respectively. As for the latter, the required computational complexity is $\mathcal{O}(\max\{D_j^2, D_j \max_{p \in \mathcal{N}_j} \{D_p\})$. For the sake of simplification, we assume that the mean of all $\{D_j\}_{j=1}^J$ is D . Therefore, the overall computational complexity is dominated by

$$
\mathcal{O}\left(\max\left\{\bar{D}^3,\bar{D}^2N_j\right\}\right).
$$

2) In iterations, our method only needs to communicate $\{\boldsymbol{\theta}_j\}$. For the whole network, the communication costs are proportional to

$$
\sum_{j=1}^J |\mathcal{N}_j| D_j.
$$

When the network topology is fixed, reducing D_i on each node can lower total communication costs, which reflects the benefit of adopting DDRF.

III. CONVERGENCE ANALYSIS

In this section, we give the convergence analysis for Algorithm [1.](#page-3-4) The challenge stems from the fact that the update to each θ_i is performed in parallel instead of sequentially as in [\[45\]](#page-9-15). For a coupled objective function, updating θ_i by [\(16\)](#page-3-2) intuitively only ensures $\mathcal{L}(\theta_j^{k+1}, {\theta_i^{k}})_{i \in \mathcal{V} \setminus \{j\}}$ \leq $\mathcal{L}(\theta_j^k, {\theta_i^k}_{i\in\mathcal{V}\setminus\{j\}})$. However, when the ${\theta_i^k}_{i\in\mathcal{V}\setminus\{j\}}$ on the left side are replaced by their updates $\{\theta_i^{k+1}\}_{i\in\mathcal{V}\backslash\{j\}}$, it is not clear whether the objective function value is still decreasing. Therefore, we present the following proposition.

Proposition 1. *Supposing that*

$$
\tilde{c}_{j,\text{self}} \geqslant \frac{|\mathcal{N}_j|\tilde{c}_{j,\text{nei}}}{2} + \frac{\boldsymbol{\lambda}_{\text{max}}\left(\sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \boldsymbol{Z}_{j,p} \boldsymbol{Z}_{j,p}^\top\right)}{2\boldsymbol{\lambda}_{\text{min}}\left(\boldsymbol{Z}_{j,j} \boldsymbol{Z}_{j,j}^\top\right)} \tag{20}
$$

on each node, the objective value of [\(13\)](#page-2-2) is decreasing, i.e.,

$$
\mathcal{L}(\boldsymbol{\theta}_1^{k+1},\boldsymbol{\theta}_2^{k+1},\ \ldots\ ,\boldsymbol{\theta}_J^{k+1})-\mathcal{L}(\boldsymbol{\theta}_1^k,\boldsymbol{\theta}_2^k,\ \ldots\ ,\boldsymbol{\theta}_J^k)\leqslant 0. \tag{21}
$$

Proposition [1](#page-4-0) points out that when penalty parameters $\tilde{c}_{j,\text{self}}$ are chosen large enough, the value of the objective function decreases monotonically. Since $\mathcal{L}(\Theta)$ is a convex function, it follows that $\{\mathcal{L}(\Theta^k)\}\)$ possesses a lower bound and converges. On the other hand, the right-hand side of [\(20\)](#page-4-1) is a theoretical lower bound. In practice, one can start $\tilde{c}_{j,\text{self}}$ with a small value and gradually increase it as the number of iterations increases.

Proof of Proposition [1.](#page-4-0) First, recalling the definition of S_j $(\theta_j; {\theta_p}_{p \in \mathcal{N}_j})$ in [\(15\)](#page-3-1) and $\mathcal{L}(\theta_1, \theta_2, \dots, \theta_J)$ in [\(13\)](#page-2-2), we can get the following two expressions:

$$
\sum_{j=1}^{J} S_{j} (\theta_{j}^{k+1}; {\theta_{p}^{k}}_{p \in \mathcal{N}_{j}})
$$
\n
$$
= \sum_{j=1}^{J} \left(\frac{1}{N} \left\| (\theta_{j}^{k+1})^{\top} \mathbf{Z}_{j,j} - \mathbf{Y}_{j} \right\|_{2}^{2} + \frac{\lambda}{J} \left\| \theta_{j}^{k+1} \right\|_{2}^{2} \right)
$$
\n
$$
+ \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{j,p} \left\| (\theta_{j}^{k+1})^{\top} \mathbf{Z}_{j,j} - (\theta_{p}^{k})^{\top} \mathbf{Z}_{p,j} \right\|_{2}^{2} (22)
$$
\n
$$
+ \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{p,j} \left\| (\theta_{j}^{k+1})^{\top} \mathbf{Z}_{j,p} - (\theta_{p}^{k})^{\top} \mathbf{Z}_{p,p} \right\|_{2}^{2}
$$

and

$$
\mathcal{L} (\theta_1^{k+1}, \theta_2^{k+1}, \dots, \theta_J^{k+1})
$$
\n
$$
= \sum_{j=1}^J \left(\frac{1}{N} \left\| (\theta_j^{k+1})^\top \mathbf{Z}_{j,j} - \mathbf{Y}_j \right\|_2^2 + \frac{\lambda}{J} \left\| \theta_j^{k+1} \right\|_2^2 \right)
$$
\n
$$
+ \sum_{j=1}^J \sum_{p \in \hat{\mathcal{N}}_j} \tilde{c}_{j,p} \left\| (\theta_j^{k+1})^\top \mathbf{Z}_{j,j} - (\theta_p^{k+1})^\top \mathbf{Z}_{p,j} \right\|_2^2.
$$
\n(23)

We suppose S_j $(\theta_j; {\theta_p}_{p \in \mathcal{N}_j})$ is a μ_j -strong convex function w.r.t θ_j , and then the following inequality holds:

$$
S_j \left(\theta_j^{k+1}; \{ \theta_p^k \}_{p \in \mathcal{N}_j} \right) - S_j \left(\theta_j^k; \{ \theta_p^k \}_{p \in \mathcal{N}_j} \right)
$$

\$\leq -\frac{\mu_j}{2} ||\theta_j^k - \theta_j^{k+1}||_2^2\$ (24)
\$\leq 0\$.

Summing the expressions for all nodes on both sides of [\(24\)](#page-4-2) and substituting in [\(22\)](#page-4-3) and [\(23\)](#page-4-4), we obtain the following inequality:

$$
\begin{split} &\sum_{j=1}^{J} S_{j} \left(\boldsymbol{\theta}_{j}^{k+1}; \{ \boldsymbol{\theta}_{p}^{k} \}_{p \in \mathcal{N}_{j}} \right) - \sum_{j=1}^{J} S_{j} \left(\boldsymbol{\theta}_{j}^{k}; \{ \boldsymbol{\theta}_{p}^{k} \}_{p \in \mathcal{N}_{j}} \right) \\ & = \mathcal{L} \left(\boldsymbol{\theta}_{1}^{k+1}, \boldsymbol{\theta}_{2}^{k+1}, \ldots, \boldsymbol{\theta}_{J}^{k+1} \right) - \mathcal{L} \left(\boldsymbol{\theta}_{1}^{k}, \boldsymbol{\theta}_{2}^{k}, \ldots, \boldsymbol{\theta}_{J}^{k} \right) \\ & \Bigg\{ - \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{j,p} \left\| \left(\boldsymbol{\theta}_{j}^{k+1} \right)^{\top} \boldsymbol{Z}_{j,j} - \left(\boldsymbol{\theta}_{p}^{k+1} \right)^{\top} \boldsymbol{Z}_{p,j} \right\|_{2}^{2} \\ & + \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{j,p} \left\| \left(\boldsymbol{\theta}_{j}^{k+1} \right)^{\top} \boldsymbol{Z}_{j,j} - \left(\boldsymbol{\theta}_{p}^{k} \right)^{\top} \boldsymbol{Z}_{p,j} \right\|_{2}^{2} \\ & + \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{p,j} \left\| \left(\boldsymbol{\theta}_{j}^{k+1} \right)^{\top} \boldsymbol{Z}_{j,p} - \left(\boldsymbol{\theta}_{p}^{k} \right)^{\top} \boldsymbol{Z}_{p,p} \right\|_{2}^{2} \\ & - \sum_{j=1}^{J} \sum_{p \in \hat{\mathcal{N}}_{j}} \tilde{c}_{p,j} \left\| \left(\boldsymbol{\theta}_{j}^{k} \right)^{\top} \boldsymbol{Z}_{j,p} - \left(\boldsymbol{\theta}_{p}^{k} \right)^{\top} \boldsymbol{Z}_{p,p} \right\|_{2}^{2} \Bigg\} \\ & \leqslant \sum_{j=1}^{J} - \frac{\mu_{j}}{2} \left\| \boldsymbol{\theta}_{j}^{k} - \boldsymbol{\theta}_{j}^{k+1} \right\|_{2
$$

Referring to the operation in [\(14\)](#page-2-5), we split $\tilde{c}_{j,p}$ into terms w.r.t. $p = j$ and terms w.r.t. $p \in \mathcal{N}_j$ and define them as $\tilde{c}_{j,\text{self}}$ and $\tilde{c}_{j,nei}$, respectively. Hence the terms between the two braces in [\(25\)](#page-4-5) can be rewritten as

$$
- \sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} \sum_{p \in \mathcal{N}_j} \left\| \left(\boldsymbol{\theta}_j^{k+1} \right)^{\top} \boldsymbol{Z}_{j,j} - \left(\boldsymbol{\theta}_p^{k+1} \right)^{\top} \boldsymbol{Z}_{p,j} \right\|_2^2 + \sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} \sum_{p \in \mathcal{N}_j} \left\| \left(\boldsymbol{\theta}_j^{k+1} \right)^{\top} \boldsymbol{Z}_{j,j} - \left(\boldsymbol{\theta}_p^{k} \right)^{\top} \boldsymbol{Z}_{p,j} \right\|_2^2 + \sum_{j=1}^{J} \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \left\| \left(\boldsymbol{\theta}_j^{k+1} \right)^{\top} \boldsymbol{Z}_{j,p} - \left(\boldsymbol{\theta}_p^{k} \right)^{\top} \boldsymbol{Z}_{p,p} \right\|_2^2 \qquad (26) - \sum_{j=1}^{J} \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \left\| \left(\boldsymbol{\theta}_j^{k} \right)^{\top} \boldsymbol{Z}_{j,p} - \left(\boldsymbol{\theta}_p^{k} \right)^{\top} \boldsymbol{Z}_{p,p} \right\|_2^2 + \sum_{j=1}^{J} 2 \tilde{c}_{j,\text{self}} \left\| \left(\boldsymbol{\theta}_j^{k+1} \right)^{\top} \boldsymbol{Z}_{j,j} - \left(\boldsymbol{\theta}_j^{k} \right)^{\top} \boldsymbol{Z}_{j,j} \right\|_2^2.
$$

We know from the symmetry of undirected graphs that if there is a term w.r.t. (j, p) , then there must also be a term w.r.t. (p, j) $(j, p \in [J])$. By expanding and merging terms w.r.t. (j, p) and (p, j) , [\(26\)](#page-4-6) is transformed into

$$
\sum_{(j,p)\in\tilde{\mathcal{E}}} (\Delta \theta_p^k)^{\top} \left(2\tilde{c}_{j,\text{nei}} \mathbf{Z}_{p,j} \mathbf{Z}_{j,j}^{\top} + 2\tilde{c}_{p,\text{nei}} \mathbf{Z}_{p,p} \mathbf{Z}_{j,p}^{\top}\right) (\Delta \theta_j^k) \n+ \sum_{j=1}^J (\Delta \theta_j^k)^{\top} \left(2\tilde{c}_{j,\text{self}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^{\top}\right) (\Delta \theta_j^k) \n= \sum_{(j,p)\in\mathcal{E}} (\Delta \theta_p^k)^{\top} (\tilde{c}_{j,\text{nei}} \mathbf{Z}_{p,j} \mathbf{Z}_{j,j}^{\top} + \tilde{c}_{p,\text{nei}} \mathbf{Z}_{p,p} \mathbf{Z}_{j,p}^{\top}) (\Delta \theta_j^k) \n+ \sum_{j=1}^J (\Delta \theta_j^k)^{\top} \left(2\tilde{c}_{j,\text{self}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^{\top}\right) (\Delta \theta_j^k),
$$
\n(27)

where $\tilde{\mathcal{E}}$ is the set of edges when graph \mathcal{G} is assumed to be a directed graph and $\Delta \theta_j^k := \theta_j^{k+1} - \theta_j^k$ is defined for brevity. To further simplify the expression, we introduce a block matrix A and a diagonal block matrix U. The (m, n) -th block $((m, n) \in$ $V \times V$) of A is defined as

$$
[\mathcal{A}]_{m,n} \coloneqq \begin{cases} & \tilde{c}_{n,\text{nei}} \mathbf{Z}_{m,n} \mathbf{Z}_{n,n}^{\top} \\ & + \tilde{c}_{m,\text{nei}} \mathbf{Z}_{m,m} \mathbf{Z}_{n,m}^{\top} \end{cases}, \quad (m,n) \in \mathcal{E}, \qquad (28)
$$

otherwise,

and each diagonal block of U is defined as

$$
[\mathcal{U}]_{j,j} := 2\tilde{c}_{j,\text{self}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^{\top}, \quad j \in \mathcal{V}.
$$
 (29)

With [\(28\)](#page-5-1) and [\(29\)](#page-5-2), we can reduce [\(27\)](#page-4-7) to the following,

$$
\left(\mathbf{\Theta}^{k+1}-\mathbf{\Theta}^{k}\right)^{\top}\left(\mathcal{A}+\mathcal{U}\right)\left(\mathbf{\Theta}^{k+1}-\mathbf{\Theta}^{k}\right),\qquad(30)
$$

where $\mathbf{\Theta}^k \coloneqq [\theta_1^k; \theta_2^k; \dots; \theta_J^k] \in \mathbb{R}^{D_s}$ and $D_s \coloneqq \sum_{j=1}^J D_j$. Substituting [\(30\)](#page-5-3) into [\(25\)](#page-4-5) yields

$$
\mathcal{L} \left(\boldsymbol{\theta}_1^{k+1}, \boldsymbol{\theta}_2^{k+1}, \ldots, \boldsymbol{\theta}_J^{k+1} \right) - \mathcal{L} \left(\boldsymbol{\theta}_1^k, \boldsymbol{\theta}_2^k, \ldots, \boldsymbol{\theta}_J^k \right) \n\leqslant - \left(\boldsymbol{\Theta}^{k+1} - \boldsymbol{\Theta}^k \right)^{\top} \left(\mathcal{A} + \mathcal{U} \right) \left(\boldsymbol{\Theta}^{k+1} - \boldsymbol{\Theta}^k \right).
$$
\n(31)

To prove [\(21\)](#page-4-0), we only need to show that $A + U$ is a PSD matrix, i.e., $A+U \succeq 0$. We rearrange the terms in $A+U$ and split them into two parts:

$$
\mathcal{A} + \mathcal{U} = \left(\sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} \mathcal{W}_j \mathcal{W}_j^{\top} \right) + \mathcal{S}.
$$
 (32)

For the first part, each block of W_j is defined as

$$
[\mathcal{W}_j]_{m,n} := \begin{cases} \mathbf{Z}_{j,j}, & m = j \text{ and } n \in \mathcal{N}_j, \\ \mathbf{Z}_{m,j}, & m = n \text{ and } m \in \mathcal{N}_j, \\ \mathbf{0}, & \text{otherwise.} \end{cases}
$$
(33)

Apparently, the first part is PSD because

$$
\boldsymbol{x}^{\top} \left(\sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} \mathcal{W}_{j} \mathcal{W}_{j}^{\top} \right) \boldsymbol{x} = \sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} \boldsymbol{x}^{\top} \mathcal{W}_{j} \mathcal{W}_{j}^{\top} \boldsymbol{x}
$$
\n
$$
= \sum_{j=1}^{J} \tilde{c}_{j,\text{nei}} ||\mathcal{W}_{j}^{\top} \boldsymbol{x}||_{2}^{2} \geqslant 0, \quad \forall \boldsymbol{x} \in \mathbb{R}^{D_{s}}.
$$
\n(34)

The second part S is a block diagonal matrix, and each of its blocks is

$$
[\mathcal{S}]_{j,j} := [\mathcal{U}]_{j,j} - |\mathcal{N}_j| \tilde{c}_{j,\text{nei}} \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top - \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{j,p}^\top = (2\tilde{c}_{j,\text{self}} - |\mathcal{N}_j| \tilde{c}_{j,\text{nei}}) \mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^\top - \sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{j,p}^\top, \quad j \in \mathcal{V}.
$$
\n(35)

All that remains is to determine when S is also PSD. We consider its sufficient condition that every diagonal block $[\mathcal{S}]_{i,j}$ is PSD. When the following condition is satisfied,

$$
(2\tilde{c}_{j,\text{self}} - |\mathcal{N}_j|\tilde{c}_{j,\text{nei}})\boldsymbol{\lambda}_{\text{min}} (\boldsymbol{Z}_{j,j}\boldsymbol{Z}_{j,j}^\top) \n\geq \boldsymbol{\lambda}_{\text{max}} \left(\sum_{p \in \mathcal{N}_j} \tilde{c}_{p,\text{nei}} \boldsymbol{Z}_{j,p} \boldsymbol{Z}_{j,p}^\top \right),
$$
\n(36)

which is equivalent to

$$
\tilde{c}_{j,\text{self}} \geqslant \frac{|\mathcal{N}_j|\tilde{c}_{j,\text{nei}}}{2} + \frac{\boldsymbol{\lambda}_{\text{max}}\left(\sum_{p\in\mathcal{N}_j} \tilde{c}_{p,\text{nei}} \mathbf{Z}_{j,p} \mathbf{Z}_{j,p}^{\top}\right)}{2\boldsymbol{\lambda}_{\text{min}}\left(\mathbf{Z}_{j,j} \mathbf{Z}_{j,j}^{\top}\right)},\tag{37}
$$

 $[\mathcal{S}]_{j,j} \succeq 0$ is established and consequently $\mathcal{A} + \mathcal{U} \succeq 0$ holds. From [\(31\)](#page-5-4) we have

$$
\mathcal{L} \left(\boldsymbol{\theta}_1^{k+1}, \boldsymbol{\theta}_2^{k+1}, \dots, \boldsymbol{\theta}_J^{k+1} \right) - \mathcal{L} \left(\boldsymbol{\theta}_1^k, \boldsymbol{\theta}_2^k, \dots, \boldsymbol{\theta}_J^k \right) \n\leq - \left(\boldsymbol{\Theta}^{k+1} - \boldsymbol{\Theta}^k \right)^{\top} \left(\mathcal{A} + \mathcal{U} \right) \left(\boldsymbol{\Theta}^{k+1} - \boldsymbol{\Theta}^k \right) \n\leq 0.
$$
\n(38)

This completes the proof that the objective value is decreasing with each iteration. □

IV. NUMERICAL EXPERIMENTS

In this section, we will evaluate our algorithm in non-IID and imbalanced data settings, which are the two main scenarios where the features on different nodes should differ. All experiments are implemented in MATLAB and run on a machine with Intel[®] CoreTM i7-11700KF CPU (3.60 GHz) and 32GB RAM. The source code is available in [https://github.com/Yruikk/DeKRR-DDRF.](https://github.com/Yruikk/DeKRR-DDRF)

A. Experimental Settings

Metric. In our experiments, algorithms are evaluated by the relative square error (RSE) defined below,

$$
RSE = \frac{\sum_{i=1}^{N} (f(\mathbf{x}_i) - y_i)^2}{\sum_{i=1}^{N} (y_i - \bar{y})^2},
$$

where y_i is the observation, \bar{y} is the mean of $\{y_i\}_{i=1}^N$, and $f(x_i)$ is the prediction. All experiments are repeated 10 times and the mean RSE is reported.

Data sets and preprocessing. We choose six real-world data sets from libsvm [\[46\]](#page-9-16) and UCI [\[47\]](#page-9-17), including *houses*, *air quality*, *energy*, *twitter*, *Tom's hardware*, and *wave*. The details of the data sets are shown in Tab. [1.](#page-5-5) For preprocessing, we normalize the data such that x_i are scaled to [0, 1] and y_i are scaled to $[-1, 1]$. Each node is trained with half of the local data and tested with the remaining half ($N_{j,\text{train}} = N_{j,\text{test}} =$ $N_i/2$).

TABLE 1 DATA SETS STATISTICS: d and N denote the number of data DIMENS IONS AND TOTAL DATA, RESPECTIVELY.

Data sets	d.	
Houses		20640
Air Quality	13	9357
Energy	27	19735
Twitter	77	98704
Tom's Hardware	96	29179
Wave	148	63600

Parameter settings. The parameters for centralized KRR, DKLA, and our DeKRR-DDRF are set according to the following approach.

Fig. 1. The RSE (mean \pm std) on six test sets versus the average number of features used by each node (\bar{D}) in the first non-IID data setting (different $|y_{i,i}|$). $J = 10$, $|\mathcal{N}_j| = 4$, and ten nodes contain the same amount of data N_j and the same number of features D_j .

Fig. 2. The RSE (mean \pm std) on six test sets versus the average number of features used by each node (\bar{D}) in the second non-IID data setting (different $\|\boldsymbol{x}_{j,i}\|_2$). $J = 10$, $|\mathcal{N}_j| = 4$, and ten nodes contain the same amount of data N_j and the same number of features D_j .

- 1) Centralized KRR: We choose the shift-invariant Gaussian kernel $k(x, x') = \exp\left(\frac{\|x - x'\|_2^2}{2\sigma^2}\right)$ for all experiments. For the regularization parameter λ and the bandwidth σ , we select them by 5-fold cross-validation from candidate sets $\lambda \in \{10^i, i = -8, -7, \dots, -2\},\$ $\sigma \in \{2^i, i = -2, -1, \ldots, 2\}.$
- 2) DKLA [\[22\]](#page-8-13): For the augmented coefficient ρ , we set it as 10^{-4} and double it after every 200 iterations.
- 3) DeKRR-DDRF (Ours): For the penalty parameters $\{c_{j,\text{nei}}\}_{j=1}^J$, we select them by 5-fold cross-validation: $c_{j,\text{nei}} \in \{2^iN, i = -1, 0, \dots, 3\}, \forall j \in \mathcal{V}$, and we set $c_{i,\text{self}} = 5c_{i,\text{nei}} = 5c_{p,\text{nei}}, \ \forall (j,p) \in \mathcal{E}$. For the ratio

of D_0 to D_j , we follow the settings in [\[33\]](#page-9-5) and set $D_0/D_i = 20.$

B. Experimental Results

1) Non-IID data: We consider an undirected connected graph with 10 nodes, where each node has 4 neighbors. Since each node has the same number of neighbors, that is $|\mathcal{N}_1| = \ldots = |\mathcal{N}_J|$, the total communication costs will be proportional to $D_{\text{all}} := J\bar{D} = \sum_{j=1}^{J} D_j$. By following the approach outlined in [\[39\]](#page-9-18), we simulate the non-IID scenario by making the mean value of $\{|y_{j,i}|\}_{i=1}^{N_j}$ or $\{\|x_{j,i}\|_2\}_{i=1}^{N_j}$ of the data on each node different. We centrally compute $\{|y_i|\}_{i=1}^N$

TABLE 2 RSE COMPARISON RESULTS OF DIFFERENT ALGORITHMS IN THE FIRST NON-IID DATA SETTING (DIFFERENT $\lvert y_{j,i} \rvert).$ The bold values indicate THAT OUR METHOD IS SIGNIFICANTLY BETTER THAN OTHER METHODS VIA PAIRED T-TEST AT THE 1% SIGNIFICANCE LEVEL.

Data sets		DKLA (RFF)	DKLA-DDRF	Ours
Houses	70	0.334	0.290	0.244
Air Quality	80	0.167	0.103	0.088
Energy	100	0.827	0.822	0.816
Twitter	130	0.067	0.063	0.054
Tom's Hardware	150	0.076	0.069	0.059
Wave	200	0.033	0.028	0.022

or $\{\Vert \boldsymbol{x}_i\Vert_2\}_{i=1}^N$, sort them in descending order, and assign N_j data to the j -th node in that order. In these settings, all nodes have the same amount of data and use the same number of random features.

In order to verify that our algorithm can fully exploit the characteristics of each node's data in the non-IID setting, we compare DeKRR-DDRF to a data-independent algorithm that uses the plain RFF (DKLA) and an algorithm that only utilizes data from one node (named DKLA-DDRF). The mean RSEs are reported in Tab. [2,](#page-7-1) where our method is highlighted in bold, indicating its significant superiority over other methods at the 1% significance level based on paired t-tests conducted across repeated experiments. Across six real-world datasets, DeKRR-DDRF exhibited average improvements of 25.5% and 13.6% in terms of RSE compared to DKLA and DKLA-DDRF, respectively. The results clearly illustrate that the datadependent algorithms can achieve lower regression errors than the data-independent one. Additionally, previous algorithms that require consistent features on all nodes can only use a portion of data for feature selection, making them less effective than our algorithm which can utilize data on all nodes.

Next, we evaluate DeKRR-DDRF with DKLA and DKLA-DDRF at different communication costs. Fig. [1](#page-6-0) and Fig. [2](#page-6-1) show that as the communication costs increase, our DeKRR-DDRF outperforms the other two algorithms in terms of both mean regression error and deviation. Although DKLA-DDRF leverages information from a subset of the data and shows some improvement in the mean regression error compared to DKLA, our algorithm considers the characteristics of all the data comprehensively. Particularly, the DeKRR-DDRF demonstrates superior performance on the *houses*, *twitter*, *Tom's hardware*, and *wave* data sets. Furthermore, because a set of data always has some good features that correspond to it, our data-dependent algorithm can select these features before communication, resulting in more stable results.

2) Imbalanced Data: We consider an undirected connected graph with 10 nodes, each with 4 neighbors. And we set the number of data on each node to $N_j = \frac{2j-1}{100} N_j$, making the N_j of each node significantly different and $\sum_{j=1}^{J} N_j = N$. Because DKLA requires the same number of features on each node, it is evident that $D_{j,DLLA} = \overline{D}$. In DeKRR-DDRF, the setting of $D_{j, \text{Ours}}$ is more flexible. An intuitive idea is to assign more features to nodes that have more data, from which we set $D_{j, \text{Ours}} = \sqrt{N}_j J \bar{D} / \sum_{j=1}^J \sqrt{N}_j$. However, in reality, it can also be flexibly adjusted according to specific needs to

Fig. 3. The RSE (mean±std) on *twitter* data set versus the average number of features used by each node (\bar{D}) in the imbalanced data setting, where the jth node has $N_j = \frac{2j-1}{100}N$ data $(\sum_{j=1}^J N_j = N)$. $J = 10$, $|N_j| = 4$, $\lambda = 10^{-6}$, and $\sigma = 4$. Set $D_{j,\text{Ours}} = \overline{D}$ for the equal D_j setting and $D_{j,\text{Ours}} = \sqrt{N}_j J \bar{D} / \sum_{j=1}^J \sqrt{N}_j$ for the different D_j setting.

prevent the regression ability from being excessively reduced due to a lack of features in small data nodes or the occurrence of redundancy caused by an excessive number of features in big data nodes. In this way, the total communication costs are consistent with DKLA, but the feature numbers are more appropriate.

To investigate the benefits, we conduct experiments on the *twitter* with imbalanced data. For our algorithm, we test two settings: equal D_i and different D_i , and compare them with DKLA and DKLA-DDRF. In the case of DKLA-DDRF, we utilized the node with the largest amount of data (node 10) for feature selection and broadcast the selected features to all other nodes. As shown in Fig. [3,](#page-7-2) when the total number of features used by the four methods is the same, i.e., under the condition of equal communication costs during iterative optimization, our algorithm outperforms DKLA and its DDRF version in terms of regression performance in both settings of D_i . And by using different D_j , our DeKRR-DDRF achieves adaptive adjustment of the number of features for each node, resulting in further improvement in regression performance. Additionally, user's data is more likely to appear on nodes with more data in reality. Fig. [4](#page-8-14) illustrates that when the communication costs are unchanged, our algorithm can use the selected features to improve overall regression performance and, in particular, the performance of big data nodes $(j = 6, 7, \ldots, 10)$ by assigning these nodes additional features.

V. CONCLUSION

In this paper, a novel decentralized KRR algorithm is proposed. Unlike the constraint of aligning parameter vectors in previous works, we instead pursue the consistency of the decision function on each node. This makes our algorithm more flexible because nodes are no longer required to adhere to the RF consistency premise. When dealing with more general data types, such as non-IID or imbalanced data, our algorithm can adjust the number of features that each node uses based on the node's computational ability, communication capacity,

Fig. 4. Each node's RSE performance on *twitter* data set in the imbalanced data setting when $\overline{D} = 100$. $J = 10$, $|\mathcal{N}_j| = 4$, $\lambda = 10^{-6}$, $\sigma = 4$, and Fig. 4. Each node's RSE performance on *twitter* data set in the imbalanced data setting when $D = 100$. $J = 10$, $|\mathcal{N}_j| = 4$, $\lambda = 10^{-6}$, $\sigma = 4$, and $\sum_{j=1}^{j} N_j = N$. Set $D_{j,\text{Ours}} = \bar{D}$ for the equal D_j setting and $D_{j,\text{Ours}} = \sqrt{N_j} J \bar{D}/\sum_{j=1}^J \sqrt{N_j}$ for the different D_j setting. By selecting the features and adjusting D_j for each node, the accuracy of big data nodes $(j = 6, 7, \ldots, 10)$ is further improved, while the total number of features used by the network remains unchanged.

or data size. In addition, our algorithm can leverage wellbehaved DDRF methods on all nodes to improve the kernel function approximation ability or generalization performance. The numerical experimental results demonstrate that, under the condition of using the same number of RFs at each node in the network, our DeKRR-DDRF exhibits lower regression errors compared to other algorithms. Furthermore, because of the feature selection, our algorithm outperforms other algorithms in terms of stability across multiple experiments.
