Abstract

Pathway model for the real scalar variable case is re-explored and its connections to fractional integrals, solutions of fractional differential equations, Tsallis statistics and superstatistics in statistical mechanics, reaction-rate probability integral, Krätzel transform, pathway transform etc are explored. It is shown that the common thread in these connections is the H-function representations. The pathway parameter is shown to be connected to the fractional order in fractional integrals and fractional differential equations.

Keywords: Pathway model, fractional integral, fractional differential equations, reaction-rate probability integral, Krätzel integral, pathway transform.

MSC2020 Numbers: 26A33, 26B15, 33C99, 33E12, 49K05, 62E15, 94A15

1. Introduction

The pathway model was introduced for the real rectangular matrix-variate case in Mathai (2005). Later it was extended to cover the complex rectangular matrixvariate case in Mathai and Provost (2006). The real scalar version of the model is the following:

$$
f_1(x) = c_1 |x|^{\gamma} [1 - a(1 - q)|x|^{\delta}]^{\frac{\eta}{1 - q}}
$$
\n(1.1)

for $a > 0, q < 1, \gamma > -1, \delta > 0, \eta > 0, 1 - a(1 - q)|x|^\delta > 0$, and zero elsewhere, where c_1 can act as the normalizing constant if we wish to create a statistical density out of $f_1(x)$. The model in (1.1) can be looked upon as a generalized and extended type-1 beta model for $q < 1$. The functional part in the basic type-1 beta model is $x^{\alpha-1}(1-x)^{\beta-1}, 0 \le x \le 1, \alpha > 0, \beta > 0$ and zero elsewhere and hence (1.1) is the generalized and extended form of this basic model. Note that (1.1) is a symmetric model for $x < 0$ and $x > 0$. If an asymmetric model is required then different weights can be used for $x < 0$ and $x > 0$ situations. These differing weights can be introduced either by multiplying with constants or through one of the parameters.

For $q > 1$, write $1 - q = -(q - 1), q > 1$, then (1.1) switches into the following model:

$$
f_2(x) = c_2 |x|^{\gamma} [1 + a(q-1)|x|^{\delta}]^{-\frac{\eta}{q-1}} \tag{1.2}
$$

for $-\infty < x < \infty, a > 0, q > 1, \delta > 0, \gamma > -1, \eta > 0$. The model in (1.2) can be looked upon as a generalized and extended type-2 beta family of functions. The functional part of the basic type-2 beta model is $x^{\alpha-1}(1+x)^{-(\alpha+\beta)}, 0 \le x < \infty, \alpha >$ $0, \beta > 0$. Thus, (1.2) is the generalized and extended version of this basic type-2 beta function. When $q \to 1$ in (1.1) and $q \to 1_+$ in (1.2) the models in (1.1) and (1.2) go to the generalized and extended gamma family of functions as follows:

$$
f_3(x) = c_3 |x|^{\gamma} e^{-a\eta |x|^{\delta}}
$$
 (1.3)

for $a > 0, \eta > 0, \delta > 0, \gamma > -1, -\infty < x < \infty$. Thus, the basic pathway model is (1.1) , and (1.2) and (1.3) are available from (1.1) . For $q < 1$ the family of functions is the generalized and extended type-1 beta family of functions. When q goes to 1, then one goes into the generalized and extended gamma family of functions. When q moves to $q > 1$ then we go into the generalized and extended type-2 beta family of functions. The pathway idea in model building situation is to capture the stable as well as the unstable neighborhoods by the same model. If the gamma family, such as a Maxwell-Boltzmann density or a Raleigh density, is the stable situation in a physical problem then the paths leading to this stable situation through the generalized type-1 beta model and generalized type-2 beta model and the transitional stages are captured by the pathway parameter q. If (1.1) to (1.3) are to be treated as statistical densities then the following are the normalizing constants:

$$
c_1 = \delta \left[a(1-q) \right]^{\frac{\gamma+1}{\delta}} \frac{\Gamma(\frac{\eta}{1-q} + 1 + \frac{\gamma+1}{\delta})}{2\Gamma(\frac{\gamma+1}{\delta})\Gamma(\frac{\eta}{1-q} + 1)} \tag{1.4}
$$

for
$$
\gamma > -1
$$
, $a > 0$, $q < 1$, $\eta > 0$, $\delta > 0$

$$
\Gamma(\frac{\eta}{a-1})
$$

$$
c_2 = \delta \left[a(q-1) \right]^{\frac{\gamma+1}{\delta}} \frac{1}{2\Gamma(\frac{\gamma+1}{\delta})\Gamma(\frac{\eta}{q-1} - \frac{\gamma+1}{\delta})}
$$
(1.5)

for
$$
\eta > 0, \delta > 0, a > 0, q > 1, \gamma > -1, \frac{\eta}{q-1} - \frac{\gamma+1}{\delta} > 0
$$

$$
c_3 = \frac{\delta(a\eta)^{\frac{\gamma+1}{\delta}}}{2\Gamma(\frac{\gamma+1}{\delta})}, a > 0, \eta > 0, \delta > 0.
$$
 (1.6)

Note that (1.1) for $\gamma = 0, a = 1, \delta = 1, \eta = 1, q < 1, q > 1, q \to 1$ is Tsallis statistics in non-extensive statistical mechanics (Tsallis, 2009). Equation (1.2) for $q > 1, q \to 1, a = 1, \delta = 1, \eta = 1$ is superstatisites in statistical mechanics (Beck and Cohen, 2003).

If location and scale parameters are to be incorporated into the model then in (1.1) to (1.3), replace x by $\frac{x-\mu}{\sigma}$ for some parameter μ and $\sigma > 0$. Note that (1.3) for $\gamma = 0, \delta = 2$ is the normal or Gaussian density. For $x > 0$, (1.3) produces the generalized gamma density, Weibull density, gamma density, chisquare density, exponential density. Rayleigh density, Maxwell-Boltzmann density etc.

Exponentiation in (1.2), that is put $x = e^{-cy}$, $c > 0$, produces the generalized logistic density of Mathai and Provost (2006a), logistic density and other special cases of the generalized logistic density. (1.2) can produce Cauchy density, Student-t density, F-density etc. As a limiting form one can obtain Fermi-Dirac density from (1.2) and Bose-Einstein density from (1.1), after exponentiation.

2. Optimization of Entropy

In (1.1) to (1.3) we have the distributional pathway or pathway through densities. We can also provide an entropic pathway by deriving (1.1) through optimization of an entropy measure. Consider Mathai's entropy, for an earlier version see Mathai and Haubold (2007),

$$
M_q(f) = \frac{\int_X [f(X)]^{\frac{1-q+\eta}{\eta}} dX - 1}{q-1}, q \neq 1, q < 1+\eta
$$
\n(2.1)

where $f(X)$ is a statistical density where X could be real or complex scalar or matrix variable, and \int_X denotes the integral over the support of f. For $\eta = 1$, one can look upon (2.1) as an expected value of f^{1-q} which then corresponds to Kerridge's measure of inaccuracy, see Mathai and Rathie (1975). In general, (2.1) is the expected value of $f^{\frac{1-q}{n}}$. In the following discussion we consider the real scalar variable case first. Let us optimize (2.1) subject to the following moment-type restrictions for real scalar variables:

$$
\int_{x} x^{\gamma \frac{(1-q)}{\eta}} f(x) dx = \text{ fixed}
$$
 (2.2a)

and

4

$$
\int_{x} x^{\gamma \frac{(1-q)}{\eta} + \delta} f(x) dx = \text{fixed}
$$
 (2.2b)

for $\gamma > -1, q < 1, \delta > 0$, and it is assumed that (2.2a) and (2.2b) exist. Note that for $\gamma = 0$, (2.2a) is equivalent to the statement that the total integral is unity and $(2.2b)$ for $\delta = 1, \gamma = 0$ states that the first moment is given. If we use calculus of variation for the optimization of (2.1) then the Euler equation is the following:

$$
\frac{\partial}{\partial f}[f^{\frac{1-q+\eta}{\eta}} - \lambda_1 x^{\gamma \frac{(1-q)}{\eta}} f + \lambda_2 x^{\gamma \frac{(1-q)}{\eta} + \delta} f] = 0
$$
\n(2.3)

where λ_1 and λ_2 are Lagrangian multipliers \Rightarrow

$$
f^{\frac{(1-q)}{\eta}} = \mu_1 x^{\gamma \frac{(1-q)}{\eta}} [1 - \mu_2 x^{\delta}]
$$

for some constants μ_1 and μ_2 , which then gives

$$
f_1 = \gamma_1 x^{\gamma} [1 - \mu_2 x^{\delta}]^{\frac{\eta}{1-q}}
$$
(2.4)

for some γ_1 and μ_2 . Take $\mu_2 = a(1 - q)$ and γ_1 as the normalizing constant to obtain the model (1.1). The entropy in (2.1) is a modified version of Havrda-Charvat α -generalized entropy, see Mathai and Rathie (1975). Another modified form of Havrda-Charvat entropy is Tsallis entropy (Tsallis, 2009), namely

$$
T(f) = \frac{\int_{x} [f(x)]^q dx - 1}{1 - q}, q \neq 1
$$
\n(2.5)

where $f(x)$ is the density of the real scalar random variable x. Optimization of (2.5) under the restrictions (2.2a) and (2.2b) for $\gamma = 0, \delta = 1$ in an associated escort density will produce Tsallis statistics. Direct optimization of (2.5) will produce qexponential function. But the pathway model is available directly from (2.1) under the restrictions (2.2a) and (2.2b) from where Tsallis statistics and superstatistics are available as special cases. Superstatistics considerations can be explained in

terms of statistical language as the construction of an unconditional density when the conditional density and marginal density belong to generalized gamma families of functions. Such a procedure can produce only the cases $q > 1$ and $q \to 1$, not the case $q < 1$. But optimization of (2.5) through an escort density can produce special cases of the pathway model for all the cases $q < 1, q > 1, q \rightarrow 1$. This is the advantage of Tsallis statistics over superstatistics.

In (2.1) if X is a $p \times 1$ vector random variable and if (2.2a) and (2.2b) are replaced by the following conditions

$$
\int_{X} [(X - \mu)' V^{-1} (X - \mu)]^{\gamma \frac{(q-1)}{\eta}} f(X) dX = \text{ fixed}
$$
 (2.6a)

and

$$
\int_{X} [(X - \mu)' V^{-1} (X - \mu)]^{\gamma \frac{(q-1)}{\eta} + \delta} f(X) dX = \text{ fixed}
$$
 (2.6b)

where V is $p \times p$ real symmetric and positive definite constant matrix, μ is a $p \times 1$ constant vector, a prime denotes transpose, $\gamma > 0, q > 1, \eta > 0$, then from (2.3) and (2.4) we have the following density:

$$
f_4(X) = c_4[(X-\mu)]V^{-1}(X-\mu)]^{\gamma}[1+a(q-1)\{(X-\mu)'V^{-1}(X-\mu)\}^{\delta}]^{-\frac{\eta}{q-1}}, q > 1. \tag{2.7}
$$

Then, when $q \to 1$, $f_4(X)$ goes to $f_5(X)$ given by

$$
f_5(X) = c_5[(X - \mu)'V^{-1}(X - \mu)]^{\gamma} e^{-a\eta[(X - \mu)'V^{-1}(X - \mu)]^{\delta}}.
$$
 (2.8)

Note that (2.7) and (2.8) are also associated with type-2 and gamma distributed random points in Euclidean *n*-space, $p \leq n$, see Mathai (1999) for details. Also, (2.8) for $\gamma = 0, \delta = 1$ is the *p*-variate Gaussian density with mean value vector μ and covariance matrix V .

In (2.1) if X is a $p \times q$, $q \geq p$ rectangular matrix-variate random variable and if the conditions in (2.2a) and (2.2b) are replaced by the following:

$$
\int_{X} [\text{tr}(AXBX')]^{\gamma \frac{(q-1)}{\eta}} f(X) \text{d}X = \text{fixed}
$$
 (2.9a)

and

$$
\int_{X} [\text{tr}(AXBX')]^{\gamma \frac{(q-1)}{\eta} + \delta} f(X) \text{d}X = \text{ fixed}
$$
 (2.9b)

where A is $p \times p$ and B is $q \times q$ constant real positive definite matrices, $q > 1, \eta >$ $0, \delta > 0$ then (2.3) and (2.4) will give the density

$$
f_6(X) = c_6[\text{tr}(AXBX')]^\gamma [1 + a(q-1)\{\text{tr}(AXBX')\}^\delta]^{-\frac{\eta}{q-1}}, q > 1
$$
 (2.10)

which when $q \to 1$ gives

$$
f_7(X) = c_7[\text{tr}(AXBX')]^\gamma e^{-a\eta[\text{tr}(AXBX')]^\delta} \tag{2.11}
$$

for $a > 0, \eta > 0, \delta > 0, \gamma > -1$. Note that (2.11) for $\gamma = 0, \delta = 1$ is the real matrixvariate Gaussian density. By replacing X by $X - M$, where M is a $p \times q$ constant matrix, one can also incorporate a location parameter matrix in the models in (2.10) and (2.11).

3. Connection of Pathway Model to Fractional Integrals

From the geometrical interpretation of the fractional integral given in Mathai (2014) it is evident that a type-1 beta form must be present in the definition of a fractional integral if we wish to encompass all the different definitions of fractional integrals in current use. Hence a definition, covering all fractional integrals in current use, introduced in Mathai (2013, 2014, 2015), is as Mellin convolutions of products and ratios where the functions involved in the Mellin convolutions are of the following form for the real scalar variable case x :

$$
f_1(x_1) = \phi_1(x_1)[1 - a(1 - q)x_1^{\delta}]^{\frac{1}{1 - q}} \& f_2(x_2) = \phi_2(x_2)f(x_2)
$$
 (3.1)

where ϕ_1 and ϕ_2 are prefixed functions and f is an arbitrary function, $a > 0, \delta > 0$ $0, q < 1$. If statistical densities are needed then multiply f_1 and f_2 by appropriate normalizing constants. In this case ϕ_1, ϕ_2, f are to be restricted to be positive functions and $1 - a(1 - q)x^{\delta} > 0$. Mellin convolution of products will correspond to fractional integrals of the second kind or the right-sided integrals and Mellin convolution of ratios will correspond to fractional integrals of the first kind or left-sided integrals.

3.1. Fractional integrals of the second kind

Let $u = x_1 x_2, v = x_2$ or $x_2 = v, x_1 = \frac{u}{v}$ $\frac{u}{v}$ and the Jacobian is $\frac{1}{v}$. Then the Mellin convolution of the product, denoted by $g_2(u)$, is the following, taking the pathway model of (3.1) as $f_1(x_1)$ with $\phi_1(x_1) = x_1^{\gamma}$ $_{1}^{\gamma}, \phi_{2}(x_{2})=1.$

$$
g_2(u) = \int_v \frac{1}{v} \left(\frac{u}{v}\right)^\gamma [1 - a(1 - q)\left(\frac{u}{v}\right)^\delta]^\frac{1}{1 - q} f(v) \, dv, q < 1
$$
\n
$$
= u^\gamma \int_v v^{-\gamma - 1} [1 - a(1 - q)\left(\frac{u^\delta}{v^\delta}\right)]^\frac{1}{1 - q} f(v) \, dv. \tag{3.2}
$$

Let us consider the Mellin transform of $g_2(u)$, with Mellin parameter s. Then

$$
M_{g_2}(s) = \int_{u=0}^{\infty} u^{\gamma+s-1} \int_{v > [a(1-q)]^{\frac{1}{\delta}} u} [1 - a(1-q) \frac{u^{\delta}}{v^{\delta}}]^{\frac{1}{1-q}} f(v) \mathrm{d}v. \tag{3.3}
$$

Let us integrate out u first. Then $0 \leq u \leq \frac{v}{\sqrt{u(1-v)}}$ $\frac{v}{[a(1-q)]^{\frac{1}{\delta}}}$. Integral over u gives the following:

$$
\int_{u=0}^{\frac{v}{[a(1-q)]^{\frac{1}{\delta}}}} u^{\gamma+s-1} [1 - a(1-q) \frac{u^{\delta}}{v^{\delta}}]^{\frac{1}{1-q}} du
$$

$$
= \frac{1}{\delta} \frac{v^{\gamma+s}}{[a(1-q)]^{\frac{\gamma+s}{\delta}}} \int_{0}^{1} t^{\frac{\gamma+s}{\delta}-1} [1-t]^{\frac{1}{1-q}} dt
$$

$$
= \frac{1}{\delta} \frac{\Gamma(\frac{1}{1-q}+1)}{[a(1-q)]^{\frac{\gamma+s}{\delta}}} \frac{\Gamma(\frac{\gamma}{\delta}+\frac{s}{\delta})}{\Gamma(\frac{1}{1-q}+\frac{\gamma}{\delta}+\frac{s}{\delta})}
$$

for $\Re(\gamma + s) > 0, \delta > 0, a > 0, q < 1$ where $\Re(\cdot)$ means the real part of (\cdot). Now taking the integral over v we have the Mellin transform of the arbitrary function $f(v)$, denoted by $f^*(s)$. Therefore

$$
M_{g_2}(s) = \frac{\Gamma(\frac{1}{1-q}+1)}{\delta[a(1-q)]^{\frac{\gamma+s}{\delta}}} \frac{\Gamma(\frac{\gamma+s}{\delta})}{\Gamma(\frac{1}{1-q}+1+\frac{\gamma+s}{\delta})} f^*(s)
$$
(3.4a)

for $\Re(\gamma + s) > 0, a > 0, \delta > 0, q < 1$;

$$
M_{g_2}(s) = \frac{\Gamma(\frac{1}{1-q} + 1)}{\delta(1-q)^{\frac{s}{\delta}}} \frac{\Gamma(\frac{s}{\delta})}{\Gamma(\frac{1}{1-q} + 1 + \frac{s}{\delta})} f^*(s) \text{ for } a = 1, \gamma = 0; \quad (3.4b)
$$

$$
M_{g_2}(s) = \frac{\Gamma(\frac{\gamma+s}{\delta})}{\delta a^{\frac{\gamma+s}{\delta}}} f^*(s) \text{ for } \delta > 0, a > 0, q \to 1.
$$
 (3.4c)

Now, compare (3.4a) with Theorem 3.4.2 of the Mellin transform of Erdélyi-Kober fractional integral of the second kind for $\delta = 1$, see Mathai (2014a). It is the same structure and $\frac{1}{1-q}+1$ corresponds to the order of the fractional integral α . Compare (3.4b) with the Mellin transform of Weyl fractional integral of the second kind for $\delta = 1$ (Mathai, 2014a). Again, the fractional order α corresponds to $\frac{1}{1-q} + 1$.

3.2. Fractional integral of the first kind or left-sided integral

Let $u = \frac{x_2}{x_1}$ $\frac{x_2}{x_1}, v = x_2 \text{ or } x_2 = v, x_1 = \frac{v}{u}$ $\frac{v}{u}$. Jacobian is $-\frac{v}{u^2}$ $\frac{v}{u^2}$. Let $\phi_1(x_1)$ = $x_1^{\gamma-1}$ γ^{-1} , $\phi_2(x_2) = 1$. Let the Mellin convolution of the ratio be denoted by $g_1(u)$. Then

$$
g_1(u) = \int_v \frac{v}{u^2} \left(\frac{v}{u}\right)^{\gamma - 1} [1 - a(1 - q)\left(\frac{v}{u}\right)^{\delta}]^{\frac{1}{1 - q}} f(v) dv
$$

= $u^{-\gamma - 1 - \frac{\delta}{1 - q}} \int_v v^{\gamma} [u^{\delta} - a(1 - q)v^{\delta}]^{\frac{1}{1 - q}} f(v) dv.$ (3.5)

Mellin transform of $g_1(u)$, with Mellin parameter s, is the following:

$$
M_{g_1}(s) = \int_{u=0}^{\infty} u^{-\gamma - 1 + s - 1 - \frac{\delta}{1 - q}} \int_v v^{\gamma} [u^{\delta} - a(1 - q)v^{\delta}]^{\frac{1}{1 - q}} f(v) dv.
$$

Integrating out u first, we have the integral over u as follows:

$$
\int_{u=[a(1-q)]^{\frac{1}{\delta}v}}^{\infty} [u^{\delta}-a(1-q)v^{\delta}]^{\frac{1}{1-q}}u^{-\gamma-1+s-1-\frac{\delta}{1-q}}\mathrm{d}u
$$

=
$$
\frac{1}{\delta}\int_{z=0}^{\infty} z^{\frac{1}{1-q}}[z+a(1-q)v^{\delta}]^{-\frac{1}{\delta}(\gamma+1+\frac{\delta}{1-q}-s)-1}\mathrm{d}z.
$$

This is evaluated with the help of a type-2 beta integral. Then integration over v gives the following final result:

$$
M_{g_1}(s) = \frac{\Gamma(\frac{1}{1-q} + 1)}{[a(1-q)]^{\frac{\gamma+1-s}{\delta}}} \frac{\Gamma(\frac{\gamma+1-s}{\delta})}{\Gamma(\frac{1}{1-q} + 1 + \frac{\gamma+1-s}{\delta})} f^*(s), \Re(\gamma+1-s) > 0.
$$
 (3.6)

The fractional order α corresponds to $\frac{1}{1-q}+1$, as seen before. The pathway parameter for $q < 1$ is such that

$$
\frac{1}{1-q} + 1 = \alpha, q < 1
$$

where α is the fractional order in the fractional integrals of the first and second kinds.

4. Mellin Convolutions of Products and Ratios for Other Functions

When f_1 is connected to pathway model for $q < 1$ and f_2 an arbitrary function then the Mellin convolutions of products and ratios are seen to be connected to fractional integrals of the second and first kind, respectively. Let f_1 and f_2 be generalized gamma functions which are actually the pathway model for $q \to 1$. Take (1.1) for $q \to 1$ and (1.2) for $q \to 1_+$. Let us see what happens to the Mellin convolutions of products and ratios. Let $u = x_1x_2, v = x_1, x_1 = \frac{u}{v}$ $\frac{u}{v}$. Jacobian is $\frac{1}{v}$. Let

$$
f_1(x_1) = C_1 x^{\gamma_1 - 1} e^{-a_1 x_1^{\delta_1}} \& f_2(x_2) = C_2 x_2^{\gamma_2 - 1} e^{-a_2 x_2^{\delta_2}}
$$
(4.1)

for $\gamma_i > 0, a_i > 0, \delta_i > 0, j = 1, 2$, where C_1 and C_2 can be normalizing constants if $f_i(x_i)$, $j = 1, 2$ are to be treated as statistical densities. Let the Mellin convolution of a product be again denoted by $g_2(u)$. Then

$$
g_2(u) = C_1 C_2 \int_v \frac{1}{v} \left(\frac{u}{v}\right)^{\gamma_1 - 1} v^{\gamma_2 - 1} e^{-a_1 \left(\frac{u}{v}\right)^{\delta_1} - a_2 v^{\delta_2}}
$$

= $C_1 C_2 u^{\gamma_1 - 1} \int_{v=0}^{\infty} v^{\gamma_2 - \gamma_1 - 1} e^{-\frac{a_1 u^{\delta_1}}{v^{\delta_1}} - a_2 v^{\delta_2}} dv$ (4.2)

For $\delta_1 = 1, \delta_2 = 1$, (4.2) gives the basic Krätzel integral, and associated with it we have the Krätzel transform (Krätzel, 1979). See Mathai (2012) for some properties of generalized Krätzel integral and its connection to statistical distribution theory and connection to reaction rate probability integral in nuclear reaction rate theory (Mathai and Haubold, 1988)]. For $\delta_2 = 1, \delta_1 = \frac{1}{2}$ $\frac{1}{2}$, (4.2) gives the reaction rate probability integral. For $\delta_1 = 1, \delta_2 = 1$ and $\gamma_2 - \gamma_1 = -\frac{1}{2}$ $\frac{1}{2}$ the integrand in (4.2) gives the inverse Gaussian density in stochastic processes. The structure in (4.2) is also that of the unconditional density in a Bayesian set up with the conditional density belonging to the generalized gamma family of the type $b_1x_1^{\gamma_1}$ $i_1^{\gamma_1} e^{-ax_1^{\delta_1}/x_2^{\delta_1}}$ and the marginal density also belonging to generalized gamma family of the form $x_2^{\gamma_2}e^{-bx_2^{\delta_2}}$. Then the unconditional density is of the form of the integral in (4.2). Observe that the generalized gamma functions that we considered in (4.2) are nothing but the limiting forms of the pathway models in (1.1) and (1.2) for $q \to 1$ or the model in (1.3).

5. Connection of Pathway Parameter to Fractional Indices in Fractional Differential Equations

For illustrative purposes let us consider the fractional space-time diffusion equation, see Haubold et al. (2011a).

$$
{}_{0}D_{t}^{\beta}N(x,t) = \eta \, {}_{x}D_{\theta}^{\alpha}N(x,t) \tag{5.1}
$$

with the initial condition $_0D_x^{\beta-1}N(x,0) = \sigma(x), 0 \le \beta \le 1$, $\lim_{x\to\pm\infty}N(x,t) = 0$, η is the diffusion constant. $\eta, t > 0, x \in R, \alpha, \theta, \beta$ are real parameters, $0 < \alpha \leq 2, |\theta| \leq$ $\min{\{\alpha, 2-\alpha\}}$. The solution of (5.1) for the case $\alpha = \beta$ is available from Haubold et al. (2011a) in the following form for $\rho = \frac{\alpha - \theta}{2\alpha}$ $\frac{\alpha-\theta}{2\alpha}$:

$$
N(x,t) = \frac{t^{\beta-1}}{\alpha|x|} H_{3,3}^{2,1} \left[\frac{|x|}{t\eta^{\frac{1}{\alpha}}} \Big|_{(1,\frac{1}{\alpha}),(1,1),(1,\rho)}^{(1,\frac{1}{\alpha}),(1,1),(1,\rho)} \right]
$$

$$
= \frac{t^{\alpha-1}}{\alpha|x|} \frac{1}{2\pi i} \int_{L} \frac{\Gamma(1+\frac{s}{\alpha})\Gamma(1+s)\Gamma(-\frac{s}{\alpha})}{\Gamma(1-\rho s)\Gamma(\alpha+s)\Gamma(1+\rho s)} \left[\frac{|x|}{t\eta^{\frac{1}{\alpha}}} \right]^{-s} ds
$$
 (5.2)

, where L is an appropriate contour and $i = \sqrt{-1}$. Let

$$
g(x,t) = \frac{\alpha |x|}{t^{\beta - 1}} N(x,t)
$$

=
$$
\frac{1}{2\pi i} \int_L \frac{\Gamma(1 + \frac{s}{\alpha}) \Gamma(-\frac{s}{\alpha})}{\Gamma(-\rho s) \Gamma(1 - \rho + \rho s)} \frac{\Gamma(1 + s)}{\Gamma(\alpha + s)} \left[\frac{|x|}{t\eta^{\frac{1}{\alpha}}}\right]^{-s} ds.
$$
 (5.3)

Therefore, the Mellin transform of $g(x, t)$, with Mellin parameter s, and argument $|x|$ $\frac{|x|}{t\eta^{\frac{1}{\alpha}}}$ is given by the following:

$$
M_g(s) = \frac{\Gamma(1+s)}{\Gamma(\alpha+s)} f^*(s), \quad f^*(s) = \frac{\Gamma(1+\frac{s}{\alpha})\Gamma(-\frac{s}{\alpha})}{\Gamma(-\rho s)\Gamma(1+\rho s)}.
$$
\n(5.4)

Now compare (5.4) with (3.4b) for $\delta = 1$. The pathway integrals of the second kind for $q < 1$ is of the form $c \frac{\Gamma(1+s)}{\Gamma(\alpha+s)}$ $\frac{\Gamma(1+s)}{\Gamma(\alpha+s)}f^*(s)$ where c is a constant and $\alpha=\frac{1}{1-q}+1$ is the order of the fractional integral of the second kind and α is also order of the fractional differential equation. But (5.4) is the Mellin transform of the solution of fractional space-time diffusion equation for the case $\alpha = \beta$ where α is the fractional index in the fractional differential equation. This is the same α appearing in (5.4) which is also equal to $\frac{1}{1-q} + 1 = \alpha$. This is the same α entering as the coefficient of s in the H-function representation, the coefficients being $\frac{1}{\alpha}$, and ρ which is a function of α . Note also that in (5.4) , $f^*(s)$ has an interesting structure. Both the numerator and denominator are of the form $\Gamma(z)\Gamma(1-z)$ for different z. Hence the gamma product can be written in terms of $\sin \pi z$.

6. The H-function Thread

What we have seen is that the pathway model, fractional integrals of the first and second kinds, and fractional differential equation are all connected through the pathway model and the basic representation is in terms of the H-function. Solutions of simple fractional differential equations are available in terms of Mittag-Leffler functions. Mittag-Leffler functions are special cases of the H-function. For an overview of Mittag-Leffler function and its properties, see Haubold et al. (2011). Mittag-Leffler functions, as solutions of fractional differential equations, may be seen from Gorenflo et al. (2000), Carpinteri and Mainardi (1997), Kiryakova (1994). For example, a three-parameter Mittag-Leffler function has the H-function representation:

$$
E_{\alpha,\beta}^{\gamma}(z) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{\Gamma(s)\Gamma(\gamma - s)}{\Gamma(\gamma)\Gamma(\beta - \alpha s)} z^{-s} ds
$$

=
$$
\frac{1}{\Gamma(\gamma)} H_{1,2}^{1,1} \left[z \Big|_{(0,1),(1-\beta,\alpha)}^{(1,1)}, \right]
$$
(6.1)

for $i = \sqrt{-1}$, $0 < c < \gamma, \alpha > 0, \beta > 0$. Note that the basic Mittag-Leffler parameter α enters into the H-function as the coefficient of the complex variable s. In all the Hfunction representations of fractional integrals and solutions of fractional differential equations, the fractional index or fractional order α , or a function of α , enters as the coefficient of the complex variable s in the H-function representation.

7. Diffusion Equation

We consider the following diffusion model with fractional-order spatial and temporal derivatives

$$
{}_{0}D_{t}^{\beta}N(x,t) = \eta \, {}_{x}D_{\theta}^{\alpha}N(x,t), \tag{7.1}
$$

with the initial conditions $_0D_t^{\beta-1}N(x,0) = \sigma(x), 0 \leq \beta \leq 1$, $\lim_{x\to\pm\infty}N(x,t) = 0$, where η is a diffusion constant; $\eta, t > 0, x \in R$; α, θ, β are real parameters with the constraints

$$
0 < \alpha \le 2, |\theta| \min(\alpha, 2 - \alpha),
$$

and $\delta(x)$ is the Dirac-delta function. Then for the fundamental solution of (7.1) with initial conditions, there holds the formula

$$
N(x,t) = \frac{t^{\beta - 1}}{\alpha |x|} H_{3,3}^{2,1} \left[\frac{|x|}{(\eta t^{\beta})^{1/\alpha}} \left| \begin{array}{l} (1,1/\alpha), (\beta, \beta/\alpha), (1,\rho) \\ (1,1/\alpha), (1,1), (1,\rho) \end{array} \right|, \alpha > 0 \tag{7.2}
$$

where $\rho = \frac{\alpha - \theta}{2\alpha}$ $\frac{\alpha-\theta}{2\alpha}$. The following special cases of (1) are of special interest for fractional diffusion models:

(i) For $\alpha = \beta$, the corresponding solution of (7.1), denoted by N_{α}^{θ} , can be expressed in terms of the H-function as given below and can be defined for $x > 0$:

Non-diffusion: $0 < \alpha = \beta < 2; \theta \le \min{\{\alpha, 2 - \alpha\}}$,

$$
N_{\alpha}^{\theta}(x) = \frac{t^{\alpha - 1}}{\alpha |x|} H_{3,3}^{2,1} \left[\frac{|x|}{t \eta^{1/\alpha}} \left| \begin{array}{l} (1,1/\alpha), (\alpha,1), (1,\rho) \\ (1,1/\alpha), (1,1), (1,\rho) \end{array} \right] , \ \rho = \frac{\alpha - \theta}{2\alpha}.
$$
 (7.3)

(ii) When $\beta = 1, 0 < \alpha \leq 2; \theta \leq \min\{\alpha, 2 - \alpha\}$, then (7.1) reduces to the spacefractional diffusion equation, which is the fundamental solution of the following spacetime fractional diffusion model:

$$
\frac{\partial N(x,t)}{\partial t} = \eta \, \, _x D_\theta^\alpha N(x,t), \eta > 0, x \in R,\tag{7.4}
$$

with the initial conditions $N(x, t = 0) = \sigma(x)$, $\lim_{x \to \pm \infty} N(x, t) = 0$, where η is a diffusion constant and $\sigma(x)$ is the Dirac-delta function. Hence for the solution of (1) there holds the formula

$$
N_{\alpha}^{\theta}(x) = \frac{1}{\alpha(\eta t)^{1/\alpha}} H_{2,2}^{1,1} \left[\frac{(\eta t)^{1/\alpha}}{|x|} \left| \frac{(\mu, \mu, \rho, \rho)}{(\frac{1}{\alpha}, \frac{1}{\alpha}), (\rho, \rho)} \right] , \ 0 < \alpha < 1, |\theta| \le \alpha, \tag{7.5}
$$

where $\rho = \frac{\alpha - \theta}{2\alpha}$ $\frac{\alpha-\theta}{2\alpha}$. The density represented by the above expression is known as α -stable Lévy density. Another form of this density is given by

$$
N_{\alpha}^{\theta}(x) = \frac{1}{\alpha(\eta t)^{1/\alpha}} H_{2,2}^{1,1} \left[\frac{|x|}{(\eta t)^{1/\alpha}} \left| \begin{array}{c} (1 - \frac{1}{\alpha}, \frac{1}{\alpha}), (1 - \rho, \rho) \\ (0, 1), (1 - \rho, \rho) \end{array} \right] , 1 < \alpha < 2, |\theta| \le 2 - \alpha.
$$
 (7.6)

(iii) Next, if we take $\alpha = 2, 0 < \beta < 2; \theta = 0$, then we obtain the time-fractional diffusion, which is governed by the following time-fractional diffusion model:

$$
\frac{\partial^{\beta} N(x,t)}{\partial t^{\beta}} = \eta \frac{\partial^2}{\partial x^2} N(x,t), \eta > 0, x \in R, \ 0 < \beta \le 2,
$$
\n(7.7)

with the initial conditions $_0D_t^{\beta-1}N(x,0) = \sigma(x)$, $D_t^{\beta-2}N(x,0) = 0$, for $x \in r$, $\lim_{x\to\pm\infty}N(x,t) = 0$, where η is a diffusion constant and $\sigma(x)$ is the Dirac-delta function, whose fundamental solution is given by the equation

$$
N(x,t) = \frac{t^{\beta - 1}}{2|x|} H_{1,1}^{1,0} \left[\frac{|x|}{(\eta t^{\beta})^{1/2}} \Big|_{(1,1)}^{(\beta,\beta/2)} \right]. \tag{7.8}
$$

(iv) If we set $\alpha = 2, \beta = 1$ and $\theta \to 0$, then for the fundamental solution of the standard diffusion equation

$$
\frac{\partial}{\partial t}N(x,t) = \eta \frac{\partial^2}{\partial x^2}N(x,t),\tag{7.9}
$$

with initial condition

$$
N(x, t = 0) = \sigma(x), \lim_{x \to \pm \infty} N(x, t) = 0,
$$
\n(7.10)

there holds the formula

$$
N(x,t) = \frac{1}{2|x|} H_{1,1}^{1,0} \left[\frac{|x|}{\eta^{1/2} t^{1/2}} \Big|_{(1,1)}^{(1,1/2)} \right] = (4\pi \eta t)^{-1/2} \exp[-\frac{|x|^2}{4\eta t}], \tag{7.11}
$$

which is the classical Gaussian density.
