— Abstract

This paper focuses on the runtime verification of hyperproperties expressed in Hyper-recHML, an expressive yet simple logic for describing properties of sets of traces. To this end, we first consider a simple language of monitors that can observe sets of system executions and report verdicts w.r.t. a given Hyper-recHML formula. In this setting, a unique omniscient monitor observes all system traces, and, in this sense, it is 'centralized'. However, in a possibly distributed system, having a centralized entity is undesirable; hence, we also provide a language for 'decentralized' monitors, where each trace has its own monitor, and monitors for different traces can yield a unique verdict by communicating their observations. For both the centralized and the decentralized settings, we provide a synthesis procedure that, given a formula, yields a monitor that is correct (i.e., sound and violation complete). A key step in proving the correctness of the synthesis for decentralized monitors is a result showing that, for each formula, the synthesized centralized monitor and its corresponding decentralized one are weakly bisimilar for a suitable notion of weak bisimulation.

1 Introduction

Runtime verification (RV) [5] is a verification technique that observes system executions to determine whether some given specification is satisfied or violated. This runtime analysis is usually conducted by a computational entity called a *monitor* [27]. RV is a lightweight verification technique that is carried out as the system under observation executes. Whereas model checking suffers from scalability issues related to the state-explosion problem, RV avoids this. Recently, this verification technique has been extended to parallel set-ups [9,17,34], and a large body of work in that setting aims to verify *hyperproperties* at runtime [1,10,11,20,24].

XX:2 Centralized vs Decentralized Monitors for Hyperproperties

Hyperproperties [20] are sets of hypertraces, *i.e.* sets of traces that may be seen as describing different system executions or the contributions of different sequential processes to a system execution (In fact, as argued in [14], many properties of concurrent and distributed systems can be viewed as hyperproperties). This means that, when verifying hyperproperties at runtime, several traces (i.e. several execution sequences) are observed instead of just one, possibly at the same time. Several extensions of temporal logics have been defined to express hyperproperties, such as HyperLTL, HyperCTL* [19], Hyper²LTL [7] and variations of the μ -calculus, e.g., [1], defining the basis of the logic we will use in this paper, and [29], which studies asynchronous semantics.

Since they were proposed by Clarkson and Schneider in [20], hyperproperties have become a fundamental, trace-based formalism for expressing security and privacy properties, and for reasoning about such properties using techniques from model checking and RV [4, 7, 8, 10, 10]14, 16, 18, 24 that have been embodied in software tools such as those presented in [6, 8, 23]. There is a large body of work detailing a variety of algorithms for monitoring (fragments of) hyperlogics under different assumptions and providing several correctness guarantees—see, for instance, [?, 4, 30]. However, such proposals either construct a centralized monitoring algorithm that has access to all traces in the observed hypertrace, or verify single trace properties, over a distributed set-up¹. Having an omniscient monitor simplifies the runtime analysis since the monitoring algorithm can compare all traces as needed by simply accessing different parts of its local memory. But this power comes with some drawbacks. For instance, having a centralized monitor is not always realistic (e.g. in distributed systems, trace analysis is typically confined to locations in the network so as to minimize communication across nodes) and may create single points of failure during verification. Furthermore, it can be inefficient to have to store all the traces locally, especially in light of the wide availability of multi-core systems. Synthesizing monitors with local views of the system with the purpose of verifying global properties (such as hyperproperties) is the goal of the decentralized synthesis of monitors from logical specifications that we present in this paper. To the best of our knowledge, such a message-passing monitoring set-up has not been studied for the purpose of verifying hyperproperties.

In this paper, we study procedures for the *automated synthesis of centralized and decentralized monitors* from hyperproperties described in the logic Hyper-recHML [1]. That logic extends the μ -calculus [31] (also known as Hennessy-Milner logic with recursion [33]) in its linear-time interpretation [40] with facilities to describe properties of hypertraces that stem from the work on HyperLTL, namely variables ranging over traces, modal operators that are parametrized by trace variables, matching and mismatching between trace variables, and existential and universal quantification over them. *Hyper*-rec*HML is an expressive logic* that one can use to write hyperproperties not expressible in HyperLTL or HyperCTL* (see Section 2.2). Moreover, the choice of Hyper-recHML allows us to give a general monitor synthesis that covers properties such as periodicity and consensus (in the centralized case), which could not be handled by previous work (see the discussion in Section 5).

In both the centralized and decentralized set-ups, we work in the parallel model [24], where a fixed number of system executions is processed in parallel by monitors in an online fashion. We specify monitors using a process-algebraic formalism that builds on the one presented in [2,28] to define a class of monitors called regular. Such monitors are easy to describe, resemble (alternating) automata, and have sufficient expressive power to provide standard

¹ See, for instance, [12, 13, 21, 26] for distributed monitoring algorithms for classic specification logics interpreted over traces.

monitoring guarantees. Moreover, their algebraic structure supports the compositional definition of their operational semantics and monitor synthesis procedures from formulas, building on classic work on algebraic process calculi and previous work on RV.

In the centralized case, for each formula in the fragment of Hyper-recHML that only uses greatest-fixed-point operators, our synthesis procedure yields a monitor that has access to all the traces in an observed hypertrace. In the decentralized setting, as shown in [1], in order to synthesize monitors for a sufficiently expressive fragment of the logic, it is necessary to extend the monitor capabilities with communication. For instance, to monitor for the property: "If there is a trace where event a occurs, then there exists another trace where event b does not occur thereafter", monitors observing different traces need to communicate to record that event a occurred in some trace at some point and that there is some trace where b does not occur from that point onwards. Allowing monitors to send and receive messages significantly complicates their operational semantics (see Section 4), the monitor synthesis procedure (see Section 4.2), and all consequent proofs. The operational semantics for communicating monitors is one of the main contributions of the paper since its design is crucial to obtain the correctness guarantees provided by the decentralized synthesis procedure. In particular, the semantics of decentralized monitors and their synthesis from formulas have to be designed carefully to ensure that monitors are reactive (they are always ready to process any system event) and input-enabled (they can always receive any input from other monitors in their environment), properties that are desirable in any decentralized RV set-up.

We show that both the centralized and the decentralized monitor synthesis procedures are correct. More precisely, the monitors synthesized from formulas are sound and violationcomplete, meaning that (1) if the monitor synthesized from a formula φ reports a positive (resp., negative) verdict when observing a hypertrace T, then T does (resp., does not) satisfy φ , and (2) if T does not satisfy φ , then its associated monitor will report a negative verdict when observing T (see Theorems 3.2 and 3.3, and Corollaries 4.2 and 4.3). The proof of correctness in the decentralized case is considerably more technical than the corresponding proof in the centralized setting, due to the intricate communication semantics. To address the resulting technical challenges, we develop a proof strategy where we prove the correctness of the decentralized monitor synthesis procedure using the centralized one as a yardstick.

This methodology is one of the key contributions we offer in this study. More precisely, in Section 4.1 we identify six properties of a decentralized monitor synthesis that make it 'principled' (see Definition 4.5) and we show that, when a decentralized monitor synthesis is principled, the centralized and decentralized monitors synthesized from a formula are related by a suitable notion of weak bisimulation (Theorem 4.6). Apart from supporting the definition of decentralized monitor synthesis procedures, that result allows us to reduce the correctness of our decentralized monitor synthesis to that of the centralized one and can drive the definition of further synthesis procedures in future work. Furthermore, our methodology may provide a path to proving similar results for other models of communicating monitors independent of the monitoring strategy.

In summary, our contributions are the following:

- a framework for monitoring hyperproperties by a central monitor that has access to all locations (Section 3) and a decentalized monitoring set-up for hyperproperties, with monitors that communicate (Section 4);
- a synthesis function that returns a correct centralized monitor for every formula without least fixed points (Section 3);
- a synthesis function that returns a correct decentralized, communicating monitor set-up for every formula without least fixed points that has no location quantifier within a fixed

XX:4 Centralized vs Decentralized Monitors for Hyperproperties

point operator (Section 4); and

a methodology to prove the correctness of a synthesis of communicating monitors, by establishing a list of desirable properties and relating the behavior of the decentralized monitors to that of the corresponding centralized monitor (Definition 4.5 and Theorem 4.6).

2 The Model and the Logic

Let Act be a finite set of actions with at least two elements², ranged over by a, b; the set of (infinite) traces over Act is $\mathsf{Trc} = \mathsf{Act}^{\omega}$, ranged over by t. Given a finite and non-empty set of locations \mathcal{L} ranged over by ℓ , a hypertrace T on \mathcal{L} is a function from \mathcal{L} to Trc ; the set of hypertraces on \mathcal{L} is denoted by $\mathsf{HTrc}_{\mathcal{L}}$. \mathcal{L} and Act are fixed throughout this paper.

A hypertrace describes a (distributed) system with $|\mathcal{L}|$ users, and every user is located at a unique location chosen from \mathcal{L} . A system behavior is captured by a hypertrace T on \mathcal{L} , mapping every user to the trace they perform, where users are sequential processes.

For $t, t' \in \operatorname{Trc}$, we write $t \xrightarrow{a} t'$ whenever t = at'. Let $A : \mathcal{L} \to \operatorname{Act}$; for $T, T' \in \operatorname{HTrc}_{\mathcal{L}}$, we write $T \xrightarrow{A} T'$ whenever $T(\ell) \xrightarrow{A(\ell)} T'(\ell)$, for every $\ell \in \mathcal{L}$. Notice that, for each T, there is a *unique* pair A and T' such that $T \xrightarrow{A} T'$: more precisely, for every $\ell \in \mathcal{L}$, we have that $A(\ell) = a$ and $T'(\ell) = t'$, whenever $T(\ell) = at'$. We denote the A and T' just defined by hd(T) and tl(T) respectively. For a partial function $f : D \to E$ (where D and E are sets ranged over by d and e, respectively), we denote by $\operatorname{dom}(f)$ the set $\{d \in D \mid f(d) \text{ is defined}\}$ and by $\operatorname{rng}(f)$ the set $\{e \mid \exists d \in \operatorname{dom}(f).f(d) = e\}$. Notation $f[d \mapsto e]$ denotes the (partial) function mapping d to e and behaving like f otherwise.

2.1 The Logic Hyper-recHML

We consider Hyper-recHML as the logic to specify hyperproperties. We assume two disjoint and countably infinite sets Π and V of location variables and recursion variables, ranged over by π and x, respectively. Formulas of Hyper-recHML are constructed as follows:

 $\varphi ::= \mathsf{tt} \mid \mathsf{ff} \mid \varphi \land \varphi \mid \varphi \lor \varphi \mid \max x.\varphi \mid \min x.\varphi \mid x \mid \exists \pi.\varphi \mid \forall \pi.\varphi \mid \pi = \pi \mid \pi \neq \pi \mid [a_{\pi}]\varphi \mid \langle a_{\pi} \rangle \varphi$

A formula is said to be *guarded* if every recursion variable appears within the scope of a modality within its fixed-point binding. All formulas are assumed to be guarded (without loss of expressiveness [32]). We write $\mathsf{FVloc}(\varphi)$ to denote the free location variables of φ , and $\mathsf{FVrec}(\varphi)$ for the free recursion variables.

▶ Remark 2.1. We consider formulas where bound location variables are all pairwise distinct (and different from the free variables); hence, the formula $\forall \pi.[a_{\pi}] \exists \pi.\varphi$ denotes the formula $\forall \pi.[a_{\pi}] \exists \pi'.(\varphi\{\pi'/_{\pi}\})$, where $\varphi\{\pi'/_{\pi}\}$ denotes the capture-avoiding substitution of π' for π in φ . A similar notation for other kinds of substitutions is used throughout the paper.

The semantics of a Hyper-recHML formula φ is defined over $\operatorname{HTrc}_{\mathcal{L}}$ by exploiting two partial functions: $\rho: V \rightharpoonup 2^{\operatorname{HTrc}_{\mathcal{L}}}$, which assigns a set of hypertraces on \mathcal{L} to all free recursion variables of φ , and $\sigma: \Pi \rightharpoonup \mathcal{L}$, which assigns a location to all free location variables of φ . In what follows, we tacitly assume that the free recursion and location variables in a formula φ are always included in dom (ρ) and dom (σ) , respectively.

 $^{^{2}}$ When Act is a singleton, the logic we study in this paper is trivial since each property is equivalent to true or false.

$$\begin{split} \llbracket \mathsf{t} \mathsf{t} \rrbracket_{\sigma}^{\rho} &= \mathsf{H} \mathsf{Trc}_{\mathcal{L}} \qquad \llbracket \mathsf{ff} \rrbracket_{\sigma}^{\rho} = \emptyset \qquad \llbracket x \rrbracket_{\sigma}^{\rho} = \rho(x) \\ \llbracket \varphi \land \varphi' \rrbracket_{\sigma}^{\rho} &= \llbracket \varphi \rrbracket_{\sigma}^{\rho} \cap \llbracket \varphi' \rrbracket_{\sigma}^{\rho} \qquad \llbracket \varphi \lor \varphi' \rrbracket_{\sigma}^{\rho} = \llbracket \varphi \rrbracket_{\sigma}^{\rho} \cup \llbracket \varphi' \rrbracket_{\sigma}^{\rho} \\ \llbracket \max x . \psi \rrbracket_{\sigma}^{\rho} &= \bigcup \{ S \mid S \subseteq \llbracket \psi \rrbracket_{\sigma}^{\rho[x \mapsto S]} \} \qquad \llbracket \min x . \psi \rrbracket_{\sigma}^{\rho} = \bigcap \{ S \mid S \supseteq \llbracket \psi \rrbracket_{\sigma}^{\rho[x \mapsto S]} \} \\ \llbracket \exists \pi . \varphi \rrbracket_{\sigma}^{\rho} &= \bigcup \llbracket \varphi \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho} \qquad \llbracket \forall \pi . \varphi \rrbracket_{\sigma}^{\rho} = \bigcap \{ S \mid S \supseteq \llbracket \psi \rrbracket_{\sigma}^{\rho[x \mapsto S]} \} \\ \llbracket \pi = \pi' \rrbracket_{\sigma}^{\rho} &= \begin{cases} \mathsf{HTrc}_{\mathcal{L}} \quad \text{if } \sigma(\pi) = \sigma(\pi') \\ \emptyset \quad \text{otherwise} \end{cases} \qquad \llbracket \pi \neq \pi' \rrbracket_{\sigma}^{\rho} = \begin{cases} \mathsf{HTrc}_{\mathcal{L}} \quad \text{if } \sigma(\pi) \neq \sigma(\pi') \\ \emptyset \quad \text{otherwise} \end{cases} \\ \llbracket [a_{\pi}] \varphi \rrbracket_{\sigma}^{\rho} = \{ T \mid hd(T)(\sigma(\pi)) = a \text{ implies} \qquad tl(T) \in \llbracket \varphi \rrbracket_{\sigma}^{\rho} \} \\ \llbracket \langle a_{\pi} \rangle \varphi \rrbracket_{\sigma}^{\rho} = \{ T \mid hd(T)(\sigma(\pi)) = a \land tl(T) \end{cases} \end{cases}$$

Table 1 The semantics of Hyper-recHML.

The semantics for formulas in Hyper-recHML is given through the function $\llbracket - \rrbracket_{\sigma}^{\rho}$ as shown in Table 1. A formula $\langle a_{\pi} \rangle \varphi$ holds true at hypertrace T if the trace in T at the location bound to π starts with an a and tl(T) satisfies φ ; by contrast, a formula $[a_{\pi}]\varphi$ can also hold true if the trace in T at the location associated to π does not start with an a. Whenever φ is *closed* (i.e., without any free variable), the semantics is given by $\llbracket \varphi \rrbracket_{\emptyset}^{\emptyset}$, where \emptyset denotes the partial function with empty domain. Notationally, we shall simply write $\llbracket \varphi \rrbracket$ instead of $\llbracket \varphi \rrbracket_{\emptyset}^{\emptyset}$. We say that T satisfies the closed formula φ if $T \in \llbracket \varphi \rrbracket$.

For example, consider the set of actions $\{a, b\}$; then, the hyperproperty $\varphi_a = \forall \pi . \max x. (\langle b_{\pi} \rangle x \lor \exists \pi'. (\pi' \neq \pi \land \langle a_{\pi'} \rangle x)$ means that, for every trace, at every position, whenever there is an *a* there is another trace that also has *a*.

2.2 On the Expressiveness of Hyper-recHML

The logic Hyper-recHML adapts linear-time μ HML [33] to express properties of hypertraces, just as HyperLTL and HyperCTL* [19] are variations on LTL [36] and CTL* [22], respectively, interpreted over hypertraces. It is well known that μ HML is more expressive than LTL and CTL* [41]. It is, therefore, natural to wonder whether Hyper-recHML can express properties that cannot be described using HyperLTL and HyperCTL*.

We claim that the strictness of the inclusion of LTL in μ HML is preserved for their hyper-extensions. To justify our claim, we present two arguments to demonstrate that Hyper-recHML is more expressive than HyperLTL, which rely on classic results on the inexpressiveness of LTL, the embedding of LTL in μ HML, and the ability of Hyper-recHML to quantify over traces more liberally than HyperLTL.

First, we recall that Wolper showed in [41] that the property "event *a* occurs at all even positions in a trace" cannot be expressed in LTL (see [41, Corollary 4.2] that is based on Theorem 4.1 in that reference). We will refer to this property as φ_e , where "*e*" stands for even. Let φ_{h_e} be the hyperproperty that results if one adds an existential trace quantifier $\exists \pi$ at the beginning of φ_e , and replaces all modalities with π -indexed ones:

$$\varphi_{h_e} = \exists \pi. \max x. ([a_\pi] \langle a_\pi \rangle x \land [b_\pi] \langle a_\pi \rangle x) \tag{1}$$

on the set of actions $\{a, b\}$. Its evaluation over singleton hypertraces coincides with the evaluation of φ_e and this can be used to prove the following result.

XX:6 Centralized vs Decentralized Monitors for Hyperproperties

$$\begin{array}{ccc} v \xrightarrow{A} v & \frac{A(\ell) = a}{a_{\ell}.m \xrightarrow{A} m} & \frac{A(\ell) \neq a}{a_{\ell}.m \xrightarrow{A} \operatorname{end}} & \frac{m\{ \operatorname{rec} x.m/_x\} \xrightarrow{A} m'}{\operatorname{rec} x.m \xrightarrow{A} m'} & \frac{m \xrightarrow{A} m'}{m + n \xrightarrow{A} m'} \\ \\ \frac{n \xrightarrow{A} n'}{m + n \xrightarrow{A} n'} & \frac{m \xrightarrow{A} m' & n \xrightarrow{A} n'}{m \odot n \xrightarrow{A} m' \odot n'} \end{array}$$

Table 2 The operational semantics for centralized monitors, where $\odot \in \{\otimes, \oplus\}$.

$v \Rightarrow v$	$ \begin{aligned} & m \Rrightarrow \text{ end} \\ & n \Rrightarrow \text{ end} \\ & \hline & m \odot n \Rrightarrow \text{ end} \end{aligned} $	$\frac{m \Rrightarrow {\rm yes}}{m \oplus n \Rrightarrow {\rm yes}}$	$\frac{m \Rightarrow no}{m \otimes n \Rightarrow no}$	$\frac{m \xrightarrow{A} m' \qquad T \xrightarrow{A} T'}{m \triangleright T \rightarrowtail m' \triangleright T'}$

$m+n \Rrightarrow v$	$m\oplus n \Rrightarrow v$	$m\otimes n \Rrightarrow v$	$rec \; x.m \Rrightarrow v$	Table 4 The instrumenta-
Table 3 Ve mutativity of	erdict evaluation $+, \otimes, \text{ and } \oplus$).	tion rules for centralized mon- itors.		

▶ **Proposition 2.2.** *Hyper-recHML is more expressive than HyperLTL.*

As a second witness to the fact that Hyper-recHML is more expressive than HyperLTL, we also consider the possibility to use quantifiers in any part of a formula. For example, we see that the hyperproperty φ_a from before will potentially spawn an unbounded number of quantifiers, by unfolding the recursion when encountering *a* events.

▶ **Proposition 2.3.** *Hyper-recHML is more expressive than HyperCTL*.*

We shall see later on that part of this additional expressiveness of Hyper-recHML is present in the fragments for which we synthesize monitors.

3 Centralized Monitoring

The set of centralized monitors CMon is given by the following grammar:

```
\mathsf{CMon} \ni m ::= \mathsf{yes} \mid \mathsf{no} \mid \mathsf{end} \mid a_{\ell} \cdot m \mid m + m \mid m \oplus m \mid m \otimes m \mid \mathsf{rec} x \cdot m \mid x
```

Notationally, we denote with \odot any of \otimes and \oplus , and use v to range over the verdicts {yes, no, end}. The operational semantics of centralized monitors is given in Table 2. Notice that monitors that wait for an action at some location (as prescribed by writing a_{ℓ}) and do not see that action therein (as stated by A) stop their monitoring activity, by reporting end.

Monitors can yield *verdicts* at any point of their computation. This is represented by the judgement \Rightarrow , whose intended use is to evaluate monitors and reach a verdict, whenever possible. The rules are given in Table 3; as one may expect, verdict evaluation is non-deterministic, due to the presence of +. Also notice that there can be multiple ways to infer the same verdict for the same monitor: e.g., for $yes \oplus no$ we can either use the third or the (symmetric version of the) fourth rule from the first line of Table 3. However, the inferred value is of course the same (i.e., yes, in the previous situation).

$$\begin{split} & \operatorname{Cm}_{\sigma}(\operatorname{tt}) = \operatorname{yes} \quad \operatorname{Cm}_{\sigma}(\operatorname{ff}) = \operatorname{no} & \operatorname{Cm}_{\sigma}(x) = x & \operatorname{Cm}_{\sigma}(x) \\ & \operatorname{Cm}_{\sigma}(\varphi \land \varphi') = \operatorname{Cm}_{\sigma}(\varphi) \otimes \operatorname{Cm}_{\sigma}(\varphi') & \operatorname{Cm}_{\sigma}(\varphi) \\ & \operatorname{Cm}_{\sigma}(\forall \pi.\varphi) = \bigotimes_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi) & \operatorname{Cm}_{\sigma}(\varphi) \\ & \operatorname{Cm}_{\sigma}(\pi = \pi') = \begin{cases} \operatorname{yes} \text{ if } \sigma(\pi) = \sigma(\pi') \\ \operatorname{no \ otherwise} & \operatorname{Cm}_{\sigma}(\pi \neq \varphi) \\ & \operatorname{cm}_{\sigma}(\pi = \pi') \end{cases} \\ & \operatorname{Cm}_{\sigma}(\pi = \pi') = \operatorname{Cm}_{\sigma}(\varphi) + \sum_{b \neq a} b_{\sigma(\pi)} \operatorname{yes} & \operatorname{Cm}_{\sigma}(\langle a_{\pi} \rangle \varphi) = a \end{cases} \end{split}$$

$$\begin{split} \operatorname{Cm}_{\sigma}(x) &= x & \operatorname{Cm}_{\sigma}(\max x.\varphi) = \operatorname{rec} x.\operatorname{Cm}_{\sigma}(\varphi) \\ \operatorname{Cm}_{\sigma}(\varphi \lor \varphi') &= \operatorname{Cm}_{\sigma}(\varphi) \oplus \operatorname{Cm}_{\sigma}(\varphi') \\ \operatorname{Cm}_{\sigma}(\exists \pi.\varphi) &= \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi) \\ \operatorname{Cm}_{\sigma}(\pi \neq \pi') &= \begin{cases} \text{yes if } \sigma(\pi) \neq \sigma(\pi') \\ \text{no otherwise} \\ \operatorname{Cm}_{\sigma}(\langle a_{\pi} \rangle \varphi) &= a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\varphi) + \sum_{b \neq a} b_{\sigma(\pi)}.\text{no} \end{cases} \end{split}$$

Table 5 Centralized monitor synthesis.

We instrument a monitor m on a hypertrace T based on the rules of Table 4. As usual, we write \rightarrow^* for the reflexive-transitive closure of \rightarrow .

3.1 From Formulas to Centralized Monitors

We derive monitors for the subset of formulas without least fixed-points, denoted with Hyper-maxHML. More precisely, given a formula φ , we want to derive a monitor that, when monitoring a hypertrace T, returns **no** if and only if T does not belong to the semantics of φ ; furthermore, if it returns **yes**, then T belongs to the semantics of φ . All regular properties of infinite traces that can be monitored for violations with the aforementioned guarantees can be expressed without using least fixed-point operators (see the maximality results presented in [2, Proposition 4.18] and [3, Theorem 5.2] in the setting of logics interpreted over infinite traces). Intuitively, we use least fixed-points to describe liveness properties, whose violation does not have a finite witness in general.

The definition of the synthetized monitor is given by induction on φ . This definition is parametrized by a partial function σ , assigning a location to all the free location variables of φ ; when φ is closed, we consider $\operatorname{Cm}_{\emptyset}(\varphi)$. The formal definition is given in Table 5. The interesting cases are for the quantifiers (that are treated as conjunctions and disjunctions, respectively) and for the modal operators.

▶ **Example 3.1.** Let $\mathcal{L} = \{1, 2\}$ and Act = $\{a, b\}$, and consider the formula (1). The monitor synthesis in Table 5 produces the following monitor *m* when applied to that formula:

$$m = \bigoplus_{\ell \in \{1,2\}} \operatorname{rec} x.((a_{\ell}.(a_{\ell}.x + b_{\ell}.\mathsf{no}) + b_{\ell}.\mathsf{yes}) \otimes (b_{\ell}.(a_{\ell}.x + b_{\ell}.\mathsf{no}) + a_{\ell}.\mathsf{yes}))$$

When that monitor is instrumented with the hypertrace T mapping location 1 to a^{ω} and location 2 to $(ab)^{\omega}$, the verdict **no** cannot be reached: indeed, T satisfies the formula φ since the trace at location 1 has a at all positions. On the other hand, when m is instrumented with the hypertrace T' mapping location 1 to b^{ω} and location 2 to $(ab)^{\omega}$, the **no** verdict is reached after the monitor has observed the first two actions at locations 1 and 2; this is in line with the fact that T' does not satisfy φ_{h_e} .

The main results of this section are that the centralized monitors synthesized from formulas report sound verdicts and their verdicts are complete for formula violations. We refer the reader to [3] for a discussion on notions of correctness for monitors and the significance of soundness and violation-completeness. See Appendix B for the proofs. ▶ **Theorem 3.2** (Soundness). Let $\varphi \in Hyper-maxHML$ be a closed formula and $T \in HTrc_{\mathcal{L}}$. If $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow^* no$, then $T \notin \llbracket \varphi \rrbracket$; if $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow^* yes$, then $T \in \llbracket \varphi \rrbracket$.

▶ **Theorem 3.3** (Violation Completeness). Let $\varphi \in Hyper-maxHML$ be a closed formula and $T \in HTrc_{\mathcal{L}}$. If $T \notin \llbracket \varphi \rrbracket$, then $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow^*$ no.

4 Decentralized Monitoring

When verifying a distributed system, having a central authority that performs any type of runtime verification is a strong assumption, as it reduces the appeal of distribution. Thus, we study to what extent hyperproperties can be monitored by decentralized monitors.

We associate monitors to locations, denoted ℓ , and monitors associated to ℓ monitor only actions required to happen at ℓ , thus allowing the processing of events to happen locally. This imposes some form of coordination between monitors at different locations. For this reason, we introduce the possibility for monitors to communicate.

We define a communication alphabet Com, ranged over by c, over some finite alphabet of communication constants Con (that contains Act), ranged over by γ , as

 $\mathsf{Com} \ni c ::= (!G, \gamma) \mid (?G, \gamma),$

where $G \subseteq \mathcal{L}$ and $\gamma \in \mathsf{Con}$. We have a communication action $(!G, \gamma)$ for sending γ to group G (multicast communication), and one $(?G, \gamma)$ for receiving γ from any monitor from the set G. Point-to-point communication can be represented by taking singleton sets for G.

The syntax of decentralized monitors is given by the following grammar:

 $\begin{array}{l|l} \mathsf{DMon} \ni M ::= [m]_{\ell} & \mid M \lor M & \mid M \land M \\ \mathsf{LMon} \ni m ::= \mathsf{yes} & \mid \mathsf{no} \mid \mathsf{end} \mid a.m \mid c.m \mid m + m \mid m \oplus m \mid m \otimes m \mid \mathsf{rec} \ x.m \mid x \end{array}$

Monitor $[m]_{\ell}$ denotes that m monitors the trace located at location ℓ , so, it is 'localized' at ℓ (this justifies the name LMon). Monitors assigned to the same trace run in parallel and observe identical events; contrary to [1], monitors assigned to different traces are no longer completely isolated from each other, but can now communicate, which is the main new feature of the decentralized set-up.

The operational rules for $m \in \mathsf{LMon}$ are given in Table 6. Notice that, when we have parallel monitors, only one of them at a time can send; by contrast, all those that can receive from some location ℓ are forced to do so.

For $M \in \mathsf{DMon}$, the operational semantics can be found in Table 7 (the rules concerning communication) and Table 8 (the rules concerning action steps). The operational semantics in Table 7 defines multicast, where a monitor located at ℓ sends a message to group G and every monitor at a location in G that can receive from ℓ does so; every monitor that cannot, or that is not in G, does not change its state. The first four rules capture the judgment for inferring when all components of a monitor which are able to receive a certain γ sent from a location do so. Intuitively, ℓ is the location from which message γ was sent to group G, and $M \xrightarrow{G:(?\ell,\gamma)} N$ indicates that every monitor in M located at a location in G that can receive γ from ℓ indeed has received γ and transitioned appropriately in N. The last two rules then actually define communication. In particular, the last rule in Table 7 implements multicast by stipulating that the outcome of the synchronization between a send action $\ell : (!G, \gamma)$ and a receive one of the form $G : (?\ell, \gamma)$ is the send action itself, which can be received by other monitors at locations in G in a larger monitor of which $M \diamond N$ is a sub-term. We note,

$$\begin{split} a.m \xrightarrow{a} m & \frac{\ell \in G}{(?G,\gamma).m \xrightarrow{(?\ell,\gamma)} m} \qquad (!G,\gamma).m \xrightarrow{(!G,\gamma)} m \qquad v \xrightarrow{a} v \\ \\ \frac{m\{\begin{smallmatrix} \mathsf{rec} \ x.m/x \} \xrightarrow{\lambda} m'}{\mathsf{rec} \ x.m \xrightarrow{\lambda} m'} & \frac{m \xrightarrow{a} m' \quad n \xrightarrow{a} n'}{m \odot n \xrightarrow{a} m' \odot n'} & \frac{m \xrightarrow{(?\ell,\gamma)} m' \quad n \xrightarrow{(?\ell,\gamma)} m' \quad n'}{m \odot n \xrightarrow{(?\ell,\gamma)} m' \odot n'} \\ \\ \\ \frac{m \xrightarrow{\lambda} m'}{m + n \xrightarrow{\lambda} m'} & \frac{m \xrightarrow{(!G,\gamma)} m'}{m \odot n \xrightarrow{(!G,\gamma)} m' \odot n} & \frac{m \xrightarrow{(?\ell,\gamma)} m' \quad n \xrightarrow{(?\ell,\gamma)} m' \odot n'}{m \odot n \xrightarrow{(?\ell,\gamma)} m' \odot n} \end{split}$$

Table 6 The operational semantics for decentralized local monitors (up to commutativity of +, \otimes and \oplus), where we let λ denote either a, $(!G, \gamma)$ or $(?\ell, \gamma)$ for $\ell \in \mathcal{L}$, $G \subseteq \mathcal{L}$.

$\underbrace{ m \xrightarrow{(!G,\gamma)} m'} m \underbrace{ m \xrightarrow{(?\ell',\gamma)} m'} \ell \in G$

$m \xrightarrow{(?\ell',\gamma)} \ell \notin G$					
$[m]_{\ell} \xrightarrow{G:(?\ell',\gamma)} [m]_{\ell} [m]_{\ell} \xrightarrow{G:(?\ell',\gamma)} [m]_{\ell}$					
$M \xrightarrow{G: (?\ell, \gamma)} M' \qquad N \xrightarrow{G: (?\ell, \gamma)} N' \\ \longleftrightarrow \\ \land \lor \land$					
$M \diamond N \xrightarrow{G : (?\ell, \gamma)} M' \diamond N'$					
$\underbrace{M \xrightarrow{\ell:(!G,\gamma)} M' \qquad N \xrightarrow{G:(?\ell,\gamma)} N'}_{\longleftrightarrow} \leqslant \{\land,\lor\}$					
$M \diamond N \xrightarrow{\ell: (!G, \gamma)} M' \diamond N'$					

$$\begin{split} \frac{A(\ell) &= a \qquad m \xrightarrow{a} m'}{[m]_{\ell} \xrightarrow{A} [m']_{\ell}} \\ \frac{A(\ell) &= a \qquad m \xrightarrow{a} m \xrightarrow{c}}{[m]_{\ell} \xrightarrow{A} [\mathsf{end}]_{\ell}} \\ \frac{M \xrightarrow{A} M' \qquad N \xrightarrow{A} N'}{M \diamond N \xrightarrow{A} M' \diamond N'} \diamond \in \{\land, \lor\} \end{split}$$

Table 8 Operational semantics for actions of $M \in \mathsf{DMon}$ (up to commutativity of \land , \lor).

Table 7 Operational semantics for communication of $M \in \mathsf{DMon}$ (up to commutativity of \land , \lor).

in passing, that monitors $M \in \mathsf{DMon}$ are 'input-enabled': for each M, G, ℓ and γ , there is always some M' such that $M \xrightarrow{G : (?\ell, \gamma)} M'$. So the last rule in Table 7 (and its symmetric version) can always be applied when the send transition in its premise is available.

Monitors can also locally observe an action, as prescribed by a location-to-action function A; the rules are given in Table 8. Monitors at the same location observe the same action. If a monitor cannot take the action prescribed by A at its location, the monitor becomes end, as stipulated by the second rule given in Table 8. Note that it is not sufficient to trigger that rule when m cannot exhibit action $A(\ell)$: we also require that m cannot communicate. Intuitively, this is because monitors exhibit an 'alternating' behavior in which they observe the next action produced by a system hypertrace and then embark in a sequence of communications with other monitors to inform them of what they observed. As will be made clear in our definition of a weak bisimulation relation presented in Definition 4.1, such communications are interpreted as internal actions in monitor behavior. Therefore, the inability of some monitor $[m]_{\ell}$ to perform action $A(\ell)$ can only be gauged in 'stable states'—that is, monitor states in which no communication is possible. This design choice is akin to that underlying the definition of refusal testing presented in [35] and of the stable-failures model for (Timed)

Table 10 The evolution of a decentralized monitor instrumented on a hypertrace.

CSP defined in [38, 39], where the inability of a process to perform some action can only be determined in states that afford no internal computation steps.

Verdict evaluation for $M \in \mathsf{DMon}$ is defined in Table 9 and relies on that for $m \in \mathsf{CMon}$ provided in Table 3. Finally, given a decentalized monitor M and a hypertrace T, the instrumentation of the monitor on the trace is described by the rules of Table 10. As before, we denote with \rightarrow^* the reflexive transitive closure of \rightarrow .

4.1 Synthesizing Decentralized Monitors Correctly

In this section we describe how to synthesize decentralized monitors 'correctly' from formulas, i.e. such that their behavior corresponds to that of the corresponding centralized monitors. The advantage of this approach is that it simplifies the proof that monitors synthesized via a 'correct' decentralized synthesis function are sound and violation-complete, by utilizing the correspondence to centralized monitors. Moreover, it identifies desirable properties of a 'correct' decentralized synthesis function that can guide the development of further automated decentralized-monitor synthesis algorithms.

We first define the correspondence between centralized and decentralized monitors and by showing that this correspondence is sufficient to obtain soundness and violation-completeness in the decentralized setting from the corresponding results in the centralized setting (Theorems 3.2 and 3.3). In the remainder of the section, given a synthesis function which takes as inputs a formula φ and a mapping σ from location variables to locations, and outputs a monitor $\mathcal{M}_{\sigma}(\varphi) \in \mathsf{DMon}$, we specify criteria that allow us to derive this correspondence.

We write $M \to M'$ to denote the existence of an integer h > 0 and of h monitors M_1, \ldots, M_h , locations $\ell_1, \ldots, \ell_{h-1}$ and communication actions c_1, \ldots, c_{h-1} such that $M_1 = M$, $M_h = M'$, and $M_i \xrightarrow{\ell_i:c_i} M_{i+1}$ (for every $i = 1, \ldots, h-1$). By definition of \to on communicating monitors, each c_i is $(!G_i, \gamma_i)$, for some $G_i \subseteq \mathcal{L}$ and $\gamma_i \in \text{Con}$. Similarly, at the level of local monitors we write $m \to m'$ to denote the existence of an integer h > 0, of local monitors m_1, \ldots, m_h and of $c_1, \cdots, c_h \in \{(!G, \gamma), (?\ell, \gamma) \mid G \subseteq \mathcal{L}, \ell \in \mathcal{L}, \gamma \in \text{Con}\}$ such that $m_1 = m, m_h = m'$ and $m_i \xrightarrow{c_i} m_{i+1}$.

The correspondence between the centralized and the decentralized monitors is characterized as a weak bisimulation:

▶ **Definition 4.1.** A binary relation \mathcal{R} over DMon × CMon is a weak bisimulation if and only if, whenever $M\mathcal{R}m$, it holds that:

1. $\exists M' \in \mathsf{DMon} \text{ such that } M \to M' \text{ and } M' \Rrightarrow v \text{ if and only if } m \Rrightarrow v.$

2. If $M \xrightarrow{A} M'$ then $\exists m' \in \mathsf{CMon}$ such that $m \xrightarrow{A} m'$ and $M'\mathcal{R}m'$.

- **3.** If $M \xrightarrow{c} M'$ then $M'\mathcal{R}m$, where $c = \ell : (!G, \gamma)$ for some $\ell \in \mathcal{L}, G \subseteq \mathcal{L}, \gamma \in \mathsf{Con}$.
- 4. If $m \xrightarrow{A} m'$ then there exist M_1, M_2, M' such that $M \to M_1 \xrightarrow{A} M_2 \to M'$ and $M'\mathcal{R}m'$.

One of the main features of weak bisimilarity is that, if $\mathcal{M}_{\sigma}(\varphi)$ and $\operatorname{Cm}_{\sigma}(\varphi)$ are weakly bisimilar, then they report the same verdict when observing any hypetrace T; thus, we obtain violation-completeness and soundness for decentralized monitors from the corresponding results for centralized monitors:

▶ Corollary 4.2 (Soundness). Let $T \in \mathsf{HTrc}_{\mathcal{L}}$, $\varphi \in Hyper-maxHML$ be a closed formula such that $\mathcal{M}_{\emptyset}(\varphi)$ is defined, and \mathcal{R} a weak bisimulation such that $(\mathcal{M}_{\emptyset}(\varphi), \mathsf{Cm}_{\emptyset}(\varphi)) \in \mathcal{R}$. If $\mathcal{M}_{\emptyset}(\varphi) \triangleright T \rightarrow^*$ no, then $T \notin \llbracket \varphi \rrbracket$; if $\mathcal{M}_{\emptyset}(\varphi) \triangleright T \rightarrow^*$ yes, then $T \in \llbracket \varphi \rrbracket$.

▶ Corollary 4.3 (Violation Completeness). Let $T \in \mathsf{HTrc}_{\mathcal{L}}$, $\varphi \in Hyper-maxHML$ be a closed formula such that $\mathcal{M}_{\emptyset}(\varphi)$ is defined, and \mathcal{R} a weak bisimulation such that $(\mathcal{M}_{\emptyset}(\varphi), Cm_{\emptyset}(\varphi)) \in \mathcal{R}$. If $T \notin \llbracket \varphi \rrbracket$, then $\mathcal{M}_{\emptyset}(\varphi) \triangleright T \rightarrow^*$ no.

We now describe sufficient conditions for any decentralized synthesis function such that there is a weak bisimulation between the centralized and the decentralized monitors synthesized from a formula φ and a location environment σ . Whenever we write $M \xrightarrow{c} N$ for $M, N \in \mathsf{DMon}$, we assume that $c \in \{\ell : (!G, \gamma) \mid \ell \in \mathcal{L}, G \subseteq \mathcal{L}, \gamma \in \mathsf{Con}\}$, as per the labeling of the communication transitions of decentralized monitors. We write $[m]_{\ell} \in M$, for $M \in \mathsf{DMon}$, if $[m]_{\ell}$ is one of its constituents: formally, $[m]_{\ell} \in [m]_{\ell}$ and, if $[m]_{\ell} \in M$, then $[m]_{\ell} \in M \diamond N$ and $[m]_{\ell} \in N \diamond M$ (recall that \diamond denotes either \land or \lor).

We start with a definition of when $M \in \mathsf{DMon}$ can(not) communicate:

▶ **Definition 4.4.** Let $M \in \mathsf{DMon}$. We say $M \in \mathsf{DMon}$ can communicate, if there exists $[m]_{\ell} \in M$ such that $m \xrightarrow{c} n$ for some $c \in \mathsf{Com}$. Otherwise, we say M cannot communicate.

▶ **Definition 4.5.** We say that a monitor synthesis $\mathcal{M}_{-}(-)$ is principled when it satisfies the following conditions, for every formula φ and environment σ such that $\mathcal{M}_{\sigma}(\varphi)$ is defined: **Verdict Agreement:** for every verdict v, $\operatorname{Cm}_{\sigma}(\varphi) \Rightarrow v$ if and only if $\mathcal{M}_{\sigma}(\varphi) \Rightarrow v$;

Verdict Irrevocability: for every verdict v and $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M_1 \rightarrow M_2 \rightarrow M$, if $M_2 \Rightarrow v$, then $M \Rightarrow v$;

Reactivity: for every A, there exists M such that $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M$;

Bounded Communication: for every $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \to M'$, there exists M'' such that $M' \to M''$ and M'' cannot communicate;

Processing-Communication Alternation: for every $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \rightarrow M_1$,

1. $\mathcal{M}_{\sigma}(\varphi)$ cannot communicate, and

2. $M_1 \xrightarrow{c} M_2$ implies $M_1 \xrightarrow{A}$ for every c and A;

Formula Convergence: if $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \to M'$, M' cannot communicate, and $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$ for some formula φ' and environment σ' , then $M' = \mathcal{M}_{\sigma'}(\varphi')$.

Let $\mathcal{M}_{-}(-)$ be a decentralized synthesis function. We define relation $\mathcal{R}_{\mathcal{M}}$ as follows:

$$\begin{aligned} \mathcal{R}_{\mathcal{M}} &\triangleq \mathcal{R}_{1} \cup \mathcal{R}_{2} \\ \mathcal{R}_{1} &\triangleq \{ (\mathcal{M}_{\sigma}(\varphi), \operatorname{Cm}_{\sigma}(\varphi)) \mid \mathsf{FVloc}(\varphi) \subseteq \mathsf{dom}(\sigma) \} \\ \mathcal{R}_{2} &\triangleq \Big\{ (M', \operatorname{Cm}_{\sigma'}(\varphi')) \mid \mathsf{FVloc}(\varphi) \subseteq \mathsf{dom}(\sigma) \text{ and } \mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \to M' \to \mathcal{M}_{\sigma'}(\varphi') \Big\} \end{aligned}$$

The crucial property of any principled synthesis function is the following:

▶ Theorem 4.6. For every principled synthesis $\mathcal{M}_{-}(-)$, $\mathcal{R}_{\mathcal{M}}$ is a weak bisimulation.

XX:12 Centralized vs Decentralized Monitors for Hyperproperties

$$\begin{split} \mathrm{Dm}_{\sigma}^{\ell}(\mathrm{tt}) &= \mathrm{yes} \quad \mathrm{Dm}_{\sigma}^{\ell}(\mathrm{ff}) = \mathrm{no} \quad \mathrm{Dm}_{\sigma}^{\ell}(x) = x \quad \mathrm{Dm}_{\sigma}^{\ell}(\max x.\psi) = \mathrm{rec} \; x.\mathrm{Dm}_{\sigma}^{\ell}(\psi) \\ \mathrm{Dm}_{\sigma}^{\ell}(\psi \wedge \psi') &= \mathrm{Dm}_{\sigma}^{\ell}(\psi) \otimes \mathrm{Dm}_{\sigma}^{\ell}(\psi') \quad \mathrm{Dm}_{\sigma}^{\ell}(\psi \vee \psi') = \mathrm{Dm}_{\sigma}^{\ell}(\psi) \oplus \mathrm{Dm}_{\sigma}^{\ell}(\psi') \\ \mathrm{Dm}_{\sigma}^{\ell}([a_{\pi}]\psi) &= \begin{cases} a.(!(\mathrm{rng}(\sigma) \setminus \{\ell\}), a).\mathrm{Dm}_{\sigma}^{\ell}(\psi) + \sum_{b \neq a} b.(!(\mathrm{rng}(\sigma) \setminus \{\ell\}), b).\mathrm{yes} & \mathrm{if} \; \sigma(\pi) = \ell \\ \\ \sum_{b \in \mathrm{Act}} b.\left((?\{\sigma(\pi)\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi) + \sum_{b \neq a}(?\{\sigma(\pi)\}, b).\mathrm{yes}\right) & \mathrm{otherwise} \end{cases} \\ \mathrm{Dm}_{\sigma}^{\ell}(\pi = \pi') &= \begin{cases} \mathrm{yes} \; \; \mathrm{if} \; \sigma(\pi) = \sigma(\pi') \\ \mathrm{no} \; \; \mathrm{otherwise} & \mathrm{Dm}_{\sigma}^{\ell}(\pi \neq \pi') = \begin{cases} \mathrm{yes} \; \; \mathrm{if} \; \sigma(\pi) \neq \sigma(\pi') \\ \mathrm{no} \; \; \mathrm{otherwise} & \end{cases} \\ \mathrm{DM}_{\sigma}(\psi) &= \begin{cases} \bigvee_{\ell \in \mathrm{rng}(\sigma)} [\mathrm{Dm}_{\sigma}^{\ell}(\psi)]_{\ell} & \mathrm{if} \; \sigma \neq \emptyset \\ [v]_{\ell_{0}} & \mathrm{if} \; \sigma = \emptyset \wedge \mathrm{Cm}_{\sigma}(\psi) \Rightarrow v \\ \mathrm{DM}_{\sigma}(\forall\pi.\varphi) &= \bigwedge_{\ell \in \mathcal{L}} \mathrm{DM}_{\sigma[\pi \mapsto \ell]}(\varphi) & \mathrm{DM}_{\sigma}(\exists\pi.\varphi) = \bigvee_{\ell \in \mathcal{L}} \mathrm{DM}_{\sigma[\pi \mapsto \ell]}(\varphi) \\ \mathrm{DM}_{\sigma}(\varphi \wedge \varphi') &= \mathrm{DM}_{\sigma}(\varphi) \wedge \mathrm{DM}_{\sigma}(\varphi') & \mathrm{DM}_{\sigma}(\varphi \vee \varphi') = \mathrm{DM}_{\sigma}(\varphi) \vee \mathrm{DM}_{\sigma}(\varphi') \end{cases} \end{split}$$

Table 11 Decentralized monitor synthesis, where ℓ_0 is any fixed element of \mathcal{L} .

4.2 From Formulas to Decentralized Monitors

We now describe how to synthesize decentralized monitors for a fragment of Hyper-maxHML, and show that this synthesis function satisfies Definition 4.5. This allows us to apply Theorem 4.6 and obtain soundness and violation-completeness of these synthesized monitors.

In what follows, we consider formulas from PHyper-recHML– the subset of Hyper-recHML given by the following grammar (see Section 5 for a discussion on the choice of fragment):

$$\begin{split} \varphi &::= \exists \pi.\varphi \ | \ \forall \pi.\varphi \ | \ \varphi \land \varphi \ | \ \varphi \lor \varphi \ | \ \psi \\ \psi &::= \mathsf{tt} \ | \ \mathsf{ff} \ | \ \pi = \pi \ | \ \pi \neq \pi \ | \ \psi \land \psi \ | \ \psi \lor \psi \ | \ \max x.\psi \ | \ \min x.\psi \ | \ x \ | \ [a_{\pi}]\psi \ | \ \langle a_{\pi} \rangle \psi \end{split}$$

We denote the class of formulas of type ψ with Qf (quantifier free). PHyper-recHML is a subset of Hyper-recHML and thus its semantics over $\mathsf{HTrc}_{\mathcal{L}}$ is the one given in Table 1.

We synthesize decentralized monitors for the fragment of PHyper-recHML only containing formulas of type ψ without diamonds and least fixed-points, which we call PHyper-maxHML. The synthesis for decentralized monitors is given in Table 11. First, we derive a monitor belonging to LMon for formulas of type $\psi \in Qf$; this synthesis function is parametrized by a location $\ell \in \mathcal{L}$ and a partial function σ from Π to \mathcal{L} that is defined for every free location variable in ψ . Then we derive monitors belonging to DMon for formulas of type φ .

Note that, in the definition of $DM_{\sigma}(\psi)$, $Cm_{\sigma}(\psi)$ is the monitor resulting from the centralized synthesis function defined in Table 5. Intuitively $DM_{\sigma}(\psi)$ synthesizes a local monitor at each location relevant to ψ , which are the locations associated by σ to the free location variables in ψ . If $\sigma = \emptyset$ (and so ψ does not have any free trace variables), there is no need for communication between locations, and in fact a verdict can be obtained from ψ immediately. This verdict is the same as what is found in the centralized synthesis.

We observe that the case for $\sigma = \emptyset$ and $\operatorname{Cm}_{\sigma}(\psi) \Rightarrow v$ only applies when ψ is a Boolean combination of tt and ff. Thus, every closed formula φ on which we apply our synthesis 1. is trivial, *i.e.* φ is logically equivalent to tt or ff, or

2. is such that every subformula $\psi \in \mathsf{Qf}$ of φ is in the scope of a quantifier.

For non-trivial formulas, the $\sigma = \emptyset$ case for $DM_{\sigma}(\psi)$ never applies, and we can ignore it. The decentralized monitor for a closed formula φ is $DM_{\emptyset}(\varphi)$.

▶ Remark 4.7. In the first clause of the definition of the synthesis function for box formulas, it might seem superfluous to send a message also when the monitor observes some $b \neq a$. However, this is important to make sure monitors do not deadlock. To see this, consider a synthesis where that definition instead looks like

$$\mathrm{Dm}_{\sigma}^{\ell}([a_{\pi}]\psi) = \begin{cases} a.(!(\mathrm{rng}(\sigma) \setminus \{\ell\}), a).\mathrm{Dm}_{\sigma}^{\ell}(\psi) + \sum_{b \neq a} b.\mathrm{yes} & \text{if } \sigma(\pi) = \ell \\ \sum_{b \in \mathsf{Act}} b.(?\{\sigma(\pi)\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi) & \text{otherwise} \end{cases}$$

Consider Act = {a, b}, $\mathcal{L} = \{\ell, \ell'\}$ and some hypertrace T such that $T(\ell) = b.t_1$ and $T(\ell') = b.t_2$ for some traces t_1 and t_2 . Now consider $m \otimes n$, where $m = \text{Dm}_{\sigma}^{\ell}([a_{\pi}]\psi)$, $n = \text{Dm}_{\sigma}^{\ell}([a_{\pi'}]\psi')$, $\sigma(\pi) = \ell$ and $\sigma(\pi') = \ell'$. For $A(\ell) = A(\ell') = b \neq a$, we then get $m \xrightarrow{A(\ell)} \text{yes}$ and $n \xrightarrow{A(\ell')} (?\{\sigma(\pi')\}, a).\text{Dm}_{\sigma}^{\ell}(\psi')$, and monitor $\text{yes} \otimes (?\{\sigma(\pi')\}, a).\text{Dm}_{\sigma}^{\ell}(\psi')$ is stuck because the receive action of the monitor $(?\{\sigma(\pi')\}, a).\text{Dm}_{\sigma}^{\ell}(\psi')$ has no matching send. It is precisely to avoid these scenarios that we make sure that, for each sending transition, there is a corresponding receiving transition, and a monitor always sends the last action it read to all other locations in the range of the environment σ .

Soundness and violation completeness for the synthesis defined in Table 11 follow from Corollary 4.2 and 4.3 by using Theorem 4.6, once we prove the following key result:

▶ Theorem 4.8. The synthesis function DM defined in Table 11 is principled.

▶ **Example 4.9.** In order to highlight the inter-monitor communication, we consider the following formula $\varphi = \exists \pi. \exists \pi'. ([a_{\pi}] \text{ff} \land [b_{\pi'}] \text{ff})$ over $\mathcal{L} = \{1, 2\}$ and $\text{Act} = \{a, b\}$, which states that either both traces start with a, or neither does. By letting $\sigma = [\pi \mapsto \ell, \pi' \mapsto \ell']$, the synthesis for this property gives:

$$\mathrm{D}\mathsf{M}_{\emptyset}(\varphi) = \bigvee_{\ell,\ell' \in \mathcal{L}} \bigvee_{\ell'' \in \{\ell,\ell'\}} \left[\mathrm{D}\mathsf{m}_{\sigma}^{\ell''}([a_{\pi}]\mathsf{f}\mathsf{f} \land [b_{\pi'}]\mathsf{f}\mathsf{f}) \right]_{\ell''} \text{, where}$$

$$\mathsf{Dm}_{\sigma}^{\ell''}([a_{\pi}]\mathsf{ff} \land [b_{\pi'}]\mathsf{ff}) = \begin{cases} (a.(!\emptyset, a).\mathsf{no} + b.(!\emptyset, b).\mathsf{yes}) \otimes & \text{if } \ell = \ell' = \ell'' \\ (b.(!\emptyset, b).\mathsf{no} + a.(!\emptyset, a).\mathsf{yes}) & \text{if } \ell \neq \ell' \text{ and } \ell'' = \ell \\ (a.(!\{\ell'\}, a).\mathsf{no} + b.(!\{\ell'\}, b).\mathsf{yes}) \otimes & \text{if } \ell \neq \ell' \text{ and } \ell'' = \ell \\ (a.((?\{\ell'\}, b).\mathsf{no} + (?\{\ell'\}, a).\mathsf{yes}) + \\ b.((?\{\ell'\}, b).\mathsf{no} + (?\{\ell'\}, a).\mathsf{yes})) & \text{if } \ell \neq \ell' \text{ and } \ell'' = \ell' \\ b.((?\{\ell\}, a).\mathsf{no} + (?\{\ell\}, b).\mathsf{yes}) + & \text{if } \ell \neq \ell' \text{ and } \ell'' = \ell' \\ b.((?\{\ell\}, a).\mathsf{no} + (?\{\ell\}, b).\mathsf{yes})) & \otimes (b.(!\{\ell\}, b).\mathsf{no} + a.(!\{\ell\}, a).\mathsf{yes}) \end{cases}$$

▶ Remark 4.10. The decentralized monitor synthesis presented in Table 11 does not deal explicitly with formulas of the form $\langle a_{\pi} \rangle \psi$. However, it can be applied to those formulas using the observation that $\langle a_{\pi} \rangle \psi$ is logically equivalent to $[a_{\pi}]\psi \wedge \bigwedge_{b\neq a}[b_{\pi}]$ ff. To showcase this, we present an example of the decentralized synthesis applied on Wolper's property (which uses diamonds) in Appendix E where we also discuss how to optimize the decentralized monitor synthesis for diamond formulas.

XX:14 Centralized vs Decentralized Monitors for Hyperproperties

5 Conclusion

We provided two methods to synthesize monitors for hyperproperties expressed in fragments of Hyper-recHML. Our first synthesis constructs monitors that process hypertraces in a centralized manner and they are guaranteed to correctly detect all violations of the input formula, as long as it does not have a least fixed-point operator. Our second synthesis constructs monitors that operate in a decentralized manner and use communication to share relevant information between components. The decentralized synthesis comes with the same correctness guarantees as the centralized one, but for the additional restriction that the trace quantifiers do not appear inside any fixed-point operator.

This additional restriction, which is natural and often present in monitoring set-ups for hyperlogics, e.g. [4, 11, 16, 19, 24, 29], allows us to examine the intricacies of monitoring in a decentralized setting with monitor communication. More precisely, it allows us to fix the σ in the synthesis function, which in turn produces a static set of locations with which a monitor might want to communicate. Despite the restriction to PHyper-recHML, our synthesis covers properties not monitorable in hyperlogics considered in the literature, or not even expressible in previously proposed hyperlogics.

Of course, the picture is still incomplete: we have a centralized synthesis for an expressive fragment of the logic, whereas we have a decentralized synthesis for a more restricted fragment. It is not clear if this restriction is necessary; a different synthesis for a larger fragment might be obtained, for example by utilizing a different communication paradigm than the one based on multicast we have adopted in this study. A starting point to discover such a synthesis and prove its correctness can be the synthesis properties in Definition 4.5. To fully delineate the power of decentralized monitoring, a maximality result in the spirit of those presented in [2,3] is needed, which we intend to establish in the future.

We note that we have focused on detecting violations, but we can similarly synthesize monitors that detect all satisfying hypertraces for the respective dual fragments.

Related Work. In [24], Finkbeiner et al. investigate RV for HyperLTL [19] formulas w.r.t. three different input classes, namely the bounded sequential, the unbounded sequential and the parallel classes. They also develop a monitoring tool RVHyper [23] based on the sequential algorithms developed for these input classes. The parallel class is closest to our set-up, and consists in a *fixed* number of system executions that are processed in parallel.

Agrawal et al. [4] are the first to study RV for hyperproperties expressed in HyperLTL and give a semantic characterization for monitorable HyperLTL hyperproperties called k-safety; this is a natural extension of the universally Pnueli-Zaks definition of monitorability [3,37] to hyperproperties. In contrast to this work, we do not restrict ourselves to alternation-free formulas (see Section 2.1) and every monitorable formula considered by Agrawal et al. can be expressed in our monitorable fragment. Brett et al. [?] improve on Agrawal et al. by presenting an algorithm for monitoring the full alternation-free fragment of HyperLTL. They also highlight challenges that arise when monitoring arbitrary HyperLTL formulas, namely (i) quantifier alternations, (ii) inter-trace dependencies and (iii) relative ordering of events across traces. Our decentralized synthesis address (i) by bounding the number of traces to the number of locations, and (ii) and (iii) via synchronized multicasts.

Beutner et al. [8] study runtime monitoring for $HYPER^2LTL_{fp}$, a temporal logic that is interpreted over sets of *finite* traces of *equal length*. Unlike $HYPER^2LTL$ [7], $HYPER^2LTL_{fp}$ permits quantification under temporal operators, which is also similar to Hyper-recHML. In contrast to HyperLTL, $HYPER^2LTL_{fp}$ features second-order quantification over sets of finite traces and can express properties like common knowledge. In [29], Gustfeld et al. study automated analysis techniques for asynchronous hyperproperties and propose a novel automata-theoretic framework, the so-called alternating asynchronous parity automata, together with the fixed-point logic H_{μ} for expressing asynchronous hyperproperties. The logic H_{μ} shares commonalities to PHyper-recHML, but it only allows for prenex formulas; moreover, its semantics progresses asynchronously on each trace. Properties such as "an atomic proposition does not occur on a certain level in the tree (of traces)" is not expressible in their logic H_{μ} , but are expressible in our Hyper-recHML fragments. The main contributions of their paper are various but neither consider RV.

Chalupa and Henzinger [18] explore the potential of monitoring for hyperproperties using prefix transducers. They develop a transducer language called prefix expressions, give it an operational semantics over a hypertrace (reminiscent of the semantics in Section 4) and then implement it to assess the induced overheads. They show how transducers can use the writing capabilities as a method for monitor synchronization across traces, akin to the monitor communication and verdict aggregation of Section 4. Since transducers are, in principle, more powerful that passive monitors, additional guarantees are required to ensure that they do not interfere unnecessarily with system executions.

A Proofs for Expressiveness of Hyperlogics

▶ **Proposition 2.2.** *Hyper-recHML is more expressive than HyperLTL.*

Proof. To prove this it suffices to show there exists a property of hypertraces that can be formulated in Hyper-recHML but not in HyperLTL.

Assume now that a formula φ_{h-LTL} expresses exactly that there exits a trace in a hypertrace such that a holds on even positions. We can't trivially claim that this would be expressed with a single quantifier $\exists \pi$, but we know that over singleton hypertraces, say for $T = \{t_0\}, T \models \varphi_{h-LTL}$ iff $T \models \varphi_{h_e}$. However, since T contains only a single trace, we know that all the trace variables in φ_{h-LTL} must be mapped to t_0 . Consequently, all propositional variables that occur in φ_{h-LTL} are now interpreted to hold on the same trace. Therefore, for this variable mapping, we get an LTL formula which expresses exactly that the single trace (that all trace variables have been mapped to) satisfies Wolper's property.

Therefore, we can express the same formula in plain LTL, by replacing all propositional variables with non-trace quantified ones, and arrive at a contradiction.

Therefore the property "there exists a trace for which a holds on at least all even positions" is not expressible in HyperLTL, but is expressible in Hyper-recHML. This proves the strict inclusion of HyperLTL in Hyper-recHML.

▶ **Proposition 2.3.** *Hyper-recHML is more expressive than HyperCTL*.*

Proof. To prove this, we refer the reader to the work of Bozzelli, Maubert and Pinchinat [15], who show that the property "there is an $n \ge 0$ such that $a \ne t(n)$ for every $t \in T$ " is not expressible in HyperCTL^{*}. This property was also shown not to be expressible in HyperLTL by Finkbeiner and Zimmerman [25]. In our logic this property is expressible (over the set of actions $\{a, b\}$) with the formula:

$$\min x.((\forall \pi \langle b_{\pi} \rangle \mathsf{tt}) \lor (\forall \pi'([a_{\pi'}]x \land [b_{\pi'}]x)) .$$

Note that this formula can also be simplified. We choose to write it like this so that it is explicit that either all traces have b, or all traces take a step. However the following formulation is also valid, and only uses one quantifier:

$$\min x.((\forall \pi((\langle b_{\pi} \rangle \mathsf{tt}) \lor ([a_{\pi}]x \land [b_{\pi}]x)))$$

•

B Proofs for Soundness and Violation Completeness of Centralized Monitors

We start with proving soundness of the synthesis procedure, i.e. if the monitor for φ returns yes/no when run in parallel with a hypertrace T, then T belongs/doesn't belong to $[\![\varphi]\!]$. This is done in Theorem 3.2, whose proof requires a few preliminary lemmata.

We first show that centralized monitors never output the end verdict if they are $\mathsf{end}\text{-}\mathsf{free}$ themselves :

Lemma B.1. If m is an end-free monitor and $m \Rightarrow v$, then v = no or v = yes.

We link the semantics of a formula to the special case where the synthesized centralized monitor is a verdict, which we use in various subsequent proofs: ▶ Lemma B.2. If $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{yes}$, then for all ρ we have $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \operatorname{HTrc}_{\mathcal{L}}$; if $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{no}$, then $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \emptyset$ for all ρ .

Proof. We proceed by induction on φ . If $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{yes}$, then the definition of the synthesis function (see Table 5) yields the following base cases: $\varphi = \operatorname{tt}$, or $\varphi = (\pi = \pi')$ and $\sigma(\pi) = \sigma(\pi')$, or $\varphi = (\pi \neq \pi')$ and $\sigma(\pi) \neq \sigma(\pi')$. In all cases we immediately conclude that $\|\varphi\|_{\sigma}^{\rho} = \operatorname{HTrc}_{\mathcal{L}}$ for all ρ .

In the inductive cases we only need to consider $\mathcal{L} = \{\ell\}$ and $\varphi = \forall \pi.\varphi'$ or $\varphi = \exists \pi.\varphi'$ where $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \operatorname{yes}$ (because otherwise $\operatorname{Cm}_{\sigma}(\varphi) \neq \operatorname{yes}$). In both cases we obtain from the induction hypothesis that $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \varphi' \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho} = \operatorname{HTrc}_{\mathcal{L}}$.

The proof where $Cm_{\sigma}(\varphi) = no$ is similar.

We show that if synthesized monitors of two formulas are equal, then these two formulas must have the same semantics, which is used to prove Corollary B.6.

▶ Lemma B.3. Let φ and ψ be (possibly open) formulas. If $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma'}(\psi)$, then for all ρ we have $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \psi \rrbracket_{\sigma'}^{\rho}$.

Proof. We proceed by induction on φ . As a first base case we consider $\varphi = \text{tt}$. We then have $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{yes} = \operatorname{Cm}_{\sigma'}(\psi)$. We can immediately conclude that for all ρ we have $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \psi \rrbracket_{\sigma'}^{\rho}$ using Lemma B.2. The base cases for $\varphi = \operatorname{ff}$, $\varphi = (\pi = \pi')$ and $\varphi = (\pi \neq \pi')$ are similar.

The last base case is for $\varphi = x$ for x a recursion variable. Then $\operatorname{Cm}_{\sigma}(\varphi) = x = \operatorname{Cm}_{\sigma'}(\psi)$, from which we can conclude that $\psi = x$ or $\psi = Q_1 \dots Q_n \cdot \psi'$ for Q_i a universal or existential quantifier, $n \ge 1$, $\mathcal{L} = \{\ell\}$ and $\psi' = x$. In the first case it follows immediately that for all ρ we have $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \psi \rrbracket_{\sigma'}^{\rho}$. In the second case we obtain that $\llbracket \psi \rrbracket_{\sigma}^{\rho} = \llbracket \psi' \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho} = \rho(x) = \llbracket \varphi \rrbracket$. We now proceed with the inductive cases. We first consider $\varphi = [a_{\pi}]\varphi'$. Thus $\operatorname{Cm}_{\sigma}(\varphi) =$

We now proceed with the inductive cases. We first consider $\varphi = [a_{\pi}]\varphi'$. Thus $\operatorname{Cm}_{\sigma}(\varphi) = a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\varphi') + \sum_{b \neq a} b_{\sigma(\pi)}.\operatorname{yes} = \operatorname{Cm}_{\sigma'}(\psi)$. We distinguish two cases: either $\psi = [a_{\pi'}]\psi'$, $\sigma(\pi) = \sigma'(\pi')$ and $\operatorname{Cm}_{\sigma}(\varphi') = \operatorname{Cm}_{\sigma'}(\psi')$, or $\operatorname{Act} = \{a, b\}, \ \psi = \langle b_{\pi'} \rangle \psi', \ \sigma(\pi) = \sigma'(\pi'),$ $\operatorname{Cm}_{\sigma}(\varphi') = \operatorname{no}$ and $\operatorname{Cm}_{\sigma'}(\psi') = \operatorname{yes}$. In the first case we use the induction hypothesis to obtain that for all ρ we have $\llbracket \varphi' \rrbracket_{\sigma}^{\rho} = \llbracket \psi' \rrbracket_{\sigma'}^{\rho}$. The definition of the semantics gives the desired result immediately. In the second case, we use Lemma B.2 to obtain that for all ρ we have $\llbracket \varphi' \rrbracket_{\sigma}^{\rho} = \{T \mid hd(T)(\sigma(\pi)) = a \text{ implies } tl(T) \in \emptyset\} = \{T \mid hd(T)(\sigma'(\pi')) = b \land tl(T) \in \mathsf{HTrc}_{\mathcal{L}}\} = \llbracket \psi \rrbracket_{\sigma'}^{\rho}.$

The case for $\varphi = \langle a_{\pi} \rangle \varphi'$ is similar.

Next we consider $\varphi = \max x.\varphi'$. Hence, $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{rec} x.\operatorname{Cm}_{\sigma}(\varphi') = \operatorname{Cm}_{\sigma'}(\psi)$. From this we conclude that $\psi = \max x.\psi'$ and $\operatorname{Cm}_{\sigma}(\varphi') = \operatorname{Cm}_{\sigma'}(\psi')$ for some ψ' . We use the induction hypothesis to obtain that for all ρ we have $[\![\varphi']\!]_{\sigma}^{\rho} = [\![\psi']\!]_{\sigma'}^{\rho}$. We derive

$$[\![\max x.\varphi']\!]^{\rho}_{\sigma} = \bigcup \{S \mid S \subseteq [\![\varphi']\!]^{\rho[x \mapsto S]}_{\sigma} \} \stackrel{IH}{=} \bigcup \{S \mid S \subseteq [\![\psi']\!]^{\rho[x \mapsto S]}_{\sigma} \} = [\![\max x.\psi']\!]^{\rho}_{\sigma}$$

For the case where $\varphi = \varphi_1 \wedge \varphi_2$ and the case where $\varphi = \forall \pi. \varphi'$, we need an intermediary result:

If
$$\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma_1}(\varphi_1) \otimes \ldots \otimes \operatorname{Cm}_{\sigma_k}(\varphi_k)$$
 for $k \ge 2$, then $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \bigcap_{i=1}^{\kappa} \llbracket \varphi_i \rrbracket_{\sigma_i}^{\rho}$, for all ρ . (2)

We will prove this claim at the end, but first finish the main proof using this result. Consider $\varphi = \varphi_1 \wedge \varphi_2$. Hence, $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma}(\varphi_1) \otimes \operatorname{Cm}_{\sigma}(\varphi_2) = \operatorname{Cm}_{\sigma'}(\psi)$. We use intermediary result (2) to conclude. Now consider the case where $\varphi = \forall \pi. \varphi'$ and $|\mathcal{L}| = 1$: we get $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \operatorname{Cm}_{\sigma'}(\psi)$. From the induction hypothesis we obtain that for all ρ we have that $[\![\varphi']\!]_{\sigma[\pi \mapsto \ell]}^{\rho} = [\![\psi]\!]_{\sigma'}^{\rho}$. Since $\mathcal{L} = \{\ell\}$, we have for all ρ that

XX:20 Centralized vs Decentralized Monitors for Hyperproperties

 $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \varphi' \rrbracket_{\sigma [\pi \mapsto \ell]}^{\rho}$, and we are done. If $\mathcal{L} = \{\ell_1, \ldots, \ell_k\}$ for $k \ge 2$, we have that $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma [\pi \mapsto \ell_1]}(\varphi_1) \otimes \ldots \otimes \operatorname{Cm}_{\sigma [\pi \mapsto \ell_k]}(\varphi_k) = \operatorname{Cm}_{\sigma'}(\psi)$ and we use intermediary result (2) to conclude.

The case for $\varphi = \varphi_1 \lor \varphi_2$ and $\varphi = \exists \pi. \varphi'$ can be handled in a similar manner as the two previous cases, with an additional result dual to (2).

Now we prove claim (2) by induction on φ . Without loss of generality we can assume that for all $i \in \{1, \ldots, k\}$ we have that $\operatorname{Cm}_{\sigma_i}(\varphi_i) \neq m \otimes n$ for all m, n (we refer to this as maximality).

We distinguish the case where k = 2 or k > 2. If k = 2, we get from the synthesis function that φ is a conjunction or a universal formula. In case $\varphi = \varphi' \land \varphi''$, we obtain that $\operatorname{Cm}_{\sigma}(\varphi') \otimes \operatorname{Cm}_{\sigma}(\varphi'') = \operatorname{Cm}_{\sigma_1}(\varphi_1) \otimes \operatorname{Cm}_{\sigma_2}(\varphi_2)$. We use the induction hypothesis of the main proof to conclude that for all ρ we have $\llbracket \varphi' \rrbracket_{\sigma}^{\rho} = \llbracket \varphi_1 \rrbracket_{\sigma_1}^{\rho}$ and for all ρ we have $\llbracket \varphi'' \rrbracket_{\sigma}^{\rho} = \llbracket \varphi_2 \rrbracket_{\sigma_2}^{\rho}$. The desired result now follows immediately from the semantics:

$$\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \llbracket \varphi' \rrbracket_{\sigma}^{\rho} \cap \llbracket \varphi'' \rrbracket_{\sigma}^{\rho} \stackrel{IH}{=} \llbracket \varphi_1 \rrbracket_{\sigma_1}^{\rho} \cap \llbracket \varphi_2 \rrbracket_{\sigma_2}^{\rho}$$

The case where $\varphi = \forall \pi. \varphi'$ and k = 2 implies that $\mathcal{L} = \{\ell_1, \ell_2\}$ and it is handled similarly.

Then we treat the case where k > 2. From the synthesis function, we can again conclude that φ is a conjunction or a universal formula. The universal case is a complicated version of the conjunctive case, so we only threat the former. Let $\varphi = \forall \pi.\varphi'$ and $K = \{1, \ldots, k\}$. Then, $\operatorname{Cm}_{\sigma}(\varphi) = \otimes_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\psi \mapsto \ell]}(\varphi')$, and from our assumption of maximality of $\otimes_{i \in K} \operatorname{Cm}_{\sigma_i}(\varphi_i)$, there is a partition $(K_\ell)_{\ell \in \mathcal{L}}$, such that for every $\ell \in \mathcal{L}$, $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \otimes_{i \in K_\ell} \operatorname{Cm}_{\sigma_i}(\varphi_i)$. By the induction hypothesis, for all ρ we have that $\llbracket \varphi' \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho} = \bigcap_{i \in K_\ell} \llbracket \varphi_i \rrbracket_{\sigma_i}^{\rho}$ and we can conclude that $\llbracket \varphi \rrbracket_{\sigma}^{\rho} = \bigcap_{\ell \in \mathcal{L}} \llbracket \varphi' \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho} = \bigcap_{\ell \in \mathcal{L}} \bigcap_{i \in K_\ell} \llbracket \varphi_i \rrbracket_{\sigma_i}^{\rho}$.

The following immediate fact is used to prove in Lemma B.7, which shows soundness of synthesized monitors when they have not taken any transitions yet, and Lemma B.10:

► Corollary B.4. $[\max x.\psi]_{\sigma} = [\![\psi\{\max x.\psi/x\}]\!]_{\sigma}.$

Proof. Immediate, since we interpret recursive formulas as fixed points.

The next lemma shows that for any combination of synthesized parallel monitors, we can construct an equal synthesized monitor, and link their semantics. It is used in various lemmas below.

▶ Lemma B.5. Let $n = \operatorname{Cm}_{\sigma_1}(\varphi_1) \otimes \ldots \otimes \operatorname{Cm}_{\sigma_k}(\varphi_k)$ with $k \ge 1$. Then there exist σ, ψ such that $n = \operatorname{Cm}_{\sigma}(\psi)$ and $\llbracket \psi \rrbracket_{\sigma} = \bigcap_{i \in I} \llbracket \varphi_i \rrbracket_{\sigma_i}$. Similarly, if $n = \operatorname{Cm}_{\sigma_1}(\varphi_1) \oplus \ldots \oplus \operatorname{Cm}_{\sigma_k}(\varphi_k)$, there exist σ, ψ such that $n = \operatorname{Cm}_{\sigma}(\psi)$ and $\llbracket \psi \rrbracket_{\sigma} = \bigcup_{i \in I} \llbracket \varphi_i \rrbracket_{\sigma_i}$.

Proof. We only prove the case for \otimes , the case for \oplus is similar. We proceed by induction on k. The base case is trivial. For the inductive case we consider $n = \operatorname{Cm}_{\sigma_1}(\varphi_1) \otimes \operatorname{Cm}_{\sigma_2}(\varphi_2) \otimes \ldots \otimes \operatorname{Cm}_{\sigma_k}(\varphi_k)$, where we know from the induction hypothesis that there exist σ', ψ' such that $\operatorname{Cm}_{\sigma_2}(\varphi_2) \otimes \ldots \otimes \operatorname{Cm}_{\sigma_k}(\varphi_k) = \operatorname{Cm}_{\sigma'}(\psi')$ and $\llbracket \psi' \rrbracket_{\sigma'} = \bigcap_{i \in \{2, \ldots, k\}} \llbracket \varphi_i \rrbracket_{\sigma_i}$. Let π_1, \ldots, π_j be all the variables occuring in φ_1 . Let π'_1, \ldots, π'_j all be fresh variables not occuring in φ_1 or in ψ' . Lastly, let $\varphi'_1 = \varphi_1 \{\pi'_1/\pi_1\} \ldots \{\pi'_j/\pi_j\}$.

 $\begin{array}{lll} \text{Then} & \operatorname{Cm}_{\sigma_1}(\varphi_1) &= & \operatorname{Cm}_{\sigma'[\pi'_1 \mapsto \sigma_1(\pi_1)] \dots [\pi'_j \mapsto \sigma_1(\pi_j)]}(\varphi'_1) & \text{and} & \llbracket \varphi_1 \rrbracket_{\sigma_1} &= \\ \llbracket \varphi'_1 \rrbracket_{\sigma'[\pi'_1 \mapsto \sigma_1(\pi_1)] \dots [\pi'_j \mapsto \sigma_1(\pi_j)]}. & \text{Furthermore} & \operatorname{Cm}_{\sigma'}(\psi') &= & \operatorname{Cm}_{\sigma'[\pi'_1 \mapsto \sigma_1(\pi_1)] \dots [\pi'_j \mapsto \sigma_1(\pi_j)]}(\psi') \end{array}$

and $\llbracket \psi' \rrbracket_{\sigma'} = \llbracket \psi' \rrbracket_{\sigma'[\pi'_1 \mapsto \sigma_1(\pi_1)] \dots [\pi'_j \mapsto \sigma_1(\pi_j)]}$. Thus we can conclude that $n = \operatorname{Cm}_{\sigma'[\pi'_1 \mapsto \sigma_1(\pi_1)] \dots [\pi'_j \mapsto \sigma_1(\pi_j)]}(\varphi'_1 \wedge \psi')$. We also have that

$$\begin{split} & \left[\left[\varphi_1' \wedge \psi' \right]_{\sigma'[\pi_1' \mapsto \sigma_1(\pi_1)] \dots [\pi_j' \mapsto \sigma_1(\pi_j)]} \\ & = \left[\left[\varphi_1' \right]_{\sigma'[\pi_1' \mapsto \sigma_1(\pi_1)] \dots [\pi_j' \mapsto \sigma_1(\pi_j)]} \cap \left[\psi' \right]_{\sigma'[\pi_1' \mapsto \sigma_1(\pi_1)] \dots [\pi_j' \mapsto \sigma_1(\pi_j)]} \\ & = \left[\left[\varphi_1 \right]_{\sigma_1} \cap \left[\left[\psi' \right]_{\sigma'} \right]_{\sigma'} \\ & = \left[\left[\varphi_1 \right]_{\sigma_1} \cap \bigcap_{i \in \{2, \dots, k\}} \left[\left[\varphi_i \right]_{\sigma_i} = \bigcap_{i \in I} \left[\left[\varphi_i \right]_{\sigma_i} \right]_{\sigma_i} \end{split}$$

Then we obtain that for any synthesized monitor that is a combination of synthesized parallel monitors, we can relate the semantics of the corresponding formulas:

▶ Corollary B.6. For all φ and σ , if $\operatorname{Cm}_{\sigma}(\varphi) = m \odot n$, and there exist ψ_1, ψ_2 and σ_1, σ_2 such that $m = \operatorname{Cm}_{\sigma_1}(\psi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\psi_2)$, then $\llbracket \varphi \rrbracket_{\sigma} = \llbracket \psi_1 \rrbracket_{\sigma_1} \cap \llbracket \psi_2 \rrbracket_{\sigma_2}$ if $\odot = \otimes$, and $\llbracket \varphi \rrbracket_{\sigma} = \llbracket \psi_1 \rrbracket_{\sigma_1} \cup \llbracket \psi_2 \rrbracket_{\sigma_2}$ if $\odot = \oplus$.

Proof. This follows immediately from the synthesis definition, Lemma B.3 and Lemma B.5.

Now we can prove soundness of synthesized monitors when they have not taken any transitions yet:

▶ Lemma B.7. If $\operatorname{Cm}_{\sigma}(\varphi) \Rightarrow v$, then $\llbracket \varphi \rrbracket_{\sigma} = \operatorname{HTrc}_{\mathcal{L}}$, if $v = \operatorname{yes}$, and $\llbracket \varphi \rrbracket_{\sigma} = \emptyset$, if $v = \operatorname{no}$.

Proof. We proceed by induction on \Rightarrow .

The base is for $Cm_{\sigma}(\varphi) = v$: here the result immediately follows from Lemma B.1 and Lemma B.2.

For the first inductive case, we consider $\operatorname{Cm}_{\sigma}(\varphi) = m \oplus n \Rightarrow$ yes and $m \Rightarrow$ yes. From the synthesis function and possibly Lemma B.5 we conclude that there exist φ_1, φ_2 and σ_1, σ_2 such that $m = \operatorname{Cm}_{\sigma_1}(\varphi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\varphi_2)$. We apply the induction hypothesis to obtain that $\llbracket \varphi_1 \rrbracket_{\sigma_1} = \mathsf{HTrc}_{\mathcal{L}}$. The result then follows from Corollary B.6.

Let $\operatorname{Cm}_{\sigma}(\varphi) = m \otimes n \Rightarrow$ no and $m \Rightarrow$ no. From the synthesis function and possibly Lemma B.5 we conclude that there exist φ_1, φ_2 and σ_1, σ_2 such that $m = \operatorname{Cm}_{\sigma_1}(\varphi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\varphi_2)$. We apply the induction hypothesis to obtain that $\llbracket \varphi_1 \rrbracket_{\sigma_1} = \emptyset$. The result then follows from Corollary B.6.

The case for end can be skipped, as no formula is synthesized into monitors with end.

Let $\operatorname{Cm}_{\sigma}(\varphi) = m \otimes n \Rightarrow v$ because $m \Rightarrow \operatorname{yes}$ and $n \Rightarrow v$. From the synthesis function and possibly Lemma B.5 we conclude that there exist φ_1, φ_2 and σ_1, σ_2 such that $m = \operatorname{Cm}_{\sigma_1}(\varphi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\varphi_2)$. We can apply the induction hypothesis to obtain that $\llbracket \varphi_1 \rrbracket_{\sigma_1} = \operatorname{HTrc}_{\mathcal{L}}$ and as we know that $v \neq \operatorname{end}$, we also get that $\llbracket \varphi_1 \rrbracket_{\sigma_1} = \operatorname{HTrc}_{\mathcal{L}}$ if $v = \operatorname{yes}$ and $\llbracket \varphi_1 \rrbracket_{\sigma_1} = \emptyset$ if $v = \operatorname{no}$. The result then follows from Corollary B.6.

The case for $\operatorname{Cm}_{\sigma}(\varphi) = m \oplus n \Rightarrow v$ because $m \Rightarrow \operatorname{no}$ and $n \Rightarrow v$ is similar to the previous case.

Let $\operatorname{Cm}_{\sigma}(\varphi) = m + n \Rightarrow v$ because $m \Rightarrow v$. This case can be skipped, because, by the definition of the synthesis function, we know that neither $m \Rightarrow v$ nor $n \Rightarrow v$ can hold whenever $\operatorname{Cm}_{\sigma}(\varphi) = m + n$.

For the last inductive case, we consider $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{rec} x.m \Rightarrow v$ because $m\{\operatorname{rec} x.m/x\} \Rightarrow v$. By definition of the synthesis, we know that $\varphi = \max x.\psi$ and $m = \operatorname{Cm}_{\sigma}(\psi)$. Note

XX:22 Centralized vs Decentralized Monitors for Hyperproperties

that $\operatorname{Cm}_{\sigma}(\psi)\{\operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi)/_{x}\} = \operatorname{Cm}_{\sigma}(\psi\{\max x.\psi/_{x}\})$. From the induction hypothesis and Corollary B.4, we obtain that $\llbracket \varphi \rrbracket_{\sigma} = \llbracket \psi\{\max x.\psi/_{x}\}\rrbracket_{\sigma} = \emptyset$, if $v = \operatorname{no}$, and $\llbracket \varphi \rrbracket_{\sigma} = \llbracket \psi\{\max x.\psi/_{x}\}\rrbracket_{\sigma} = H\operatorname{Trc}_{\mathcal{L}}$, if $v = \operatorname{yes}$.

The following lemma is a basic fact regarding substitution, and we use it in various places throughout the paper.

▶ Lemma B.8. If $\operatorname{Cm}_{\sigma}(\varphi) = m$, $\operatorname{Cm}_{\sigma}(\psi) = n$, and the free location variables of ψ are not bound in φ , then $\operatorname{Cm}_{\sigma}(\varphi\{^{\psi}/_x\}) = m\{^n/_x\}$.

Proof. The proof is by induction on φ and the only interesting case is the one where $\varphi = \exists \pi. \varphi'$ or $\varphi = \forall \pi. \varphi'$. We describe the case for $\varphi = \exists \pi. \varphi'$, as the other one is dual.

In this case, $m = \operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma}(\exists \pi.\varphi') = \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi')$. By the induction hypothesis, $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi'\{{}^{\psi}/_x\}) = \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi')\{{}^{\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\psi)}/_x\}$. Since π does not appear free in ψ , $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\psi) = \operatorname{Cm}_{\sigma}(\psi) = n$. Therefore, $\operatorname{Cm}_{\sigma}(\varphi\{{}^{\psi}/_x\}) = \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi'\{{}^{\psi}/_x\}) = \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi')\{{}^{n}/_x\} = m\{{}^{n}/_x\}.$

The next lemma shows that synthesized monitors always transition to other synthesized monitors:

▶ Lemma B.9. If $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} m'$, then $m' = \operatorname{Cm}_{\sigma'}(\varphi')$ for some σ' and φ' .

Proof. We proceed by induction on \xrightarrow{A} . The interesting cases are the inductive cases. We first treat both inductive cases of the sum. If $\operatorname{Cm}_{\sigma}(\varphi) = m + n \xrightarrow{A} m'$, we have two cases: either $\varphi = [a_{\pi}]\psi$ or $\varphi = \langle a_{\pi}\rangle\psi$. We treat the case for $\varphi = [a_{\pi}]\psi$, the other case is similar. Thus we are in the case where $\operatorname{Cm}_{\sigma}(\varphi) = a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\psi) + \sum_{b\neq a} b_{\sigma(\pi)}.\operatorname{yes}$. This means that m' can be $\operatorname{Cm}_{\sigma}(\psi)$ or yes. In both cases we have obtained the required result.

If $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{rec} x.m \xrightarrow{A} m'$ because $m\{\operatorname{rec} x.m/x\} \xrightarrow{A} m'$, we know that $m = \operatorname{Cm}_{\sigma}(\psi)$ and $\varphi = \max x.\psi$. We use Lemma B.8 to conclude that $m\{\operatorname{rec} x.m/x\} = \operatorname{Cm}_{\sigma}(\psi\{\varphi/x\})$ (note that the free location variables of φ are not bound in ψ). Thus we can use the induction hypothesis to know that $m' = \operatorname{Cm}_{\sigma'}(\varphi')$ for some σ' and formula φ' .

If $\operatorname{Cm}_{\sigma}(\varphi) = m \odot n \xrightarrow{A} m' \odot n'$, from the synthesis function and possibly Lemma B.5 we obtain σ_1, σ_2 and ψ_1, ψ_2 such that $m = \operatorname{Cm}_{\sigma_1}(\psi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\psi_2)$. We then use the induction hypothesis to obtain σ'_1, σ'_2 and ψ'_1, ψ'_2 such that $m' = \operatorname{Cm}_{\sigma'_1}(\psi'_1)$ and $n' = \operatorname{Cm}_{\sigma'_2}(\psi'_2)$. The required result now follows from Lemma B.5.

The last result we need to prove soundness is the following, which essentially shows the relation between the hypertrace and the semantics of the formula are carried over through the instrumentation steps:

▶ Lemma B.10. Let $\operatorname{Cm}_{\sigma}(\varphi) \triangleright T \rightarrow \operatorname{Cm}_{\sigma'}(\varphi') \triangleright T'$. If $T' \notin \llbracket \varphi' \rrbracket_{\sigma'}$ then $T \notin \llbracket \varphi \rrbracket_{\sigma}$; if $T' \in \llbracket \varphi' \rrbracket_{\sigma'}$ then $T \in \llbracket \varphi \rrbracket_{\sigma}$.

Proof. From $\operatorname{Cm}_{\sigma}(\varphi) \triangleright T \to \operatorname{Cm}_{\sigma'}(\varphi') \triangleright T'$ we deduce that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$ and $T \xrightarrow{A} T'$. We proceed by induction on $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$.

In the first base case we have $Cm_{\sigma}(\varphi) = v = Cm_{\sigma'}(\varphi')$. The result follows immediately from Lemma B.2.

The cases where $\operatorname{Cm}_{\sigma}(\varphi) = a_{\ell}.m$ are not applicable, as the synthesis function cannot produce $a_{\ell}.m$ (being $|\operatorname{Act}| > 1$).

The first inductive case is for $Cm_{\sigma}(\varphi) = m + n$ and $Cm_{\sigma'}(\varphi') = m'$ or $Cm_{\sigma'}(\varphi') = n'$. We distinguish two cases.

- 1. $\varphi = [a_{\pi}]\psi$. Here we have two more cases:
 - a. $m' = \operatorname{Cm}_{\sigma}(\psi), \ m = a_{\sigma(\pi)}.m', \ \text{and} \ A(\sigma(\pi)) = a.$ Assume that $T' \notin \llbracket \psi \rrbracket_{\sigma}$. Then $T \notin \llbracket [a_{\pi}]\psi \rrbracket_{\sigma}$ follows immediately from the definitions. If we assume instead that $T' \in \llbracket \psi \rrbracket_{\sigma},$ we also know immediately that $T \in \llbracket [a_{\pi}]\psi \rrbracket_{\sigma}.$
 - **b.** $m' = \text{yes}, \ m = b_{\sigma(\pi)}.m'$ for $b \neq a$, and $A(\sigma(\pi)) \neq a$. It follows immediately that $T \in \llbracket [a_{\pi}]\psi \rrbracket_{\sigma}$ as $A(\sigma(\pi)) \neq a$, and that $T' \notin \llbracket \varphi' \rrbracket_{\sigma'}$ never holds.
- **2.** $\varphi = \langle a_{\pi} \rangle \psi$. Also here we have two more cases:
 - a. $m' = \operatorname{Cm}_{\sigma}(\psi), \ m = a_{\sigma(\pi)}.m'$, and $A(\sigma(\pi)) = a$. Assume that $T' \notin \llbracket \psi \rrbracket_{\sigma}$. Then $T \notin \llbracket \langle a_{\pi} \rangle \psi \rrbracket_{\sigma}$ follows immediately from the definitions. If we assume instead that $T' \in \llbracket \psi \rrbracket_{\sigma}$, we also know immediately that $T \in \llbracket \langle a_{\pi} \rangle \psi \rrbracket_{\sigma}$.
 - **b.** m' = no, $m = b_{\sigma(\pi)} \cdot m'$ for $b \neq a$, and $A(\sigma(\pi)) \neq a$. It follows immediately that $T \notin [\![\langle a_{\pi} \rangle \psi]\!]_{\sigma}$ as $A(\sigma(\pi)) \neq a$, and that $T' \in [\![\varphi']\!]_{\sigma'}$ never holds.

Consider $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{rec} x.m \xrightarrow{A} m'$. Then we have $\varphi = \max x.\psi$ and $m = \operatorname{Cm}_{\sigma}(\psi)$. We know $\operatorname{Cm}_{\sigma'}(\varphi') = m'$, and $\operatorname{Cm}_{\sigma}(\psi) \{ \operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi)/_x \} \xrightarrow{A} m'$. Assume that $T' \in \llbracket \varphi' \rrbracket_{\sigma'}$. Note that $\operatorname{Cm}_{\sigma}(\psi) \{ \operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi)/_x \} = \operatorname{Cm}_{\sigma}(\psi \{ \max x.\psi/_x \})$. From the induction hypothesis and Corollary B.4, we obtain that $T \in \llbracket \psi \{ \max x.\psi/_x \} \rrbracket_{\sigma} = \llbracket \varphi \rrbracket_{\sigma}$. The case for $T' \notin \llbracket \varphi' \rrbracket_{\sigma'}$ is similar.

Last we consider $\operatorname{Cm}_{\sigma}(\varphi) = m \odot n \xrightarrow{A} m' \odot n'$, because $m \xrightarrow{A} m'$, $n \xrightarrow{A} n'$, and $m' \odot n' = \operatorname{Cm}_{\sigma'}(\varphi')$. From Lemma B.5, we know that there exist ψ_1, ψ_2 and τ_1, τ_2 such that $m' = \operatorname{Cm}_{\tau_1}(\psi_1)$ and $n' = \operatorname{Cm}_{\tau_2}(\psi_2)$. Similarly, we obtain also that $m = \operatorname{Cm}_{\sigma_1}(\varphi_1)$ and $n = \operatorname{Cm}_{\sigma_2}(\varphi_2)$ for some φ_1, φ_2 and σ_1, σ_2 . We distinguish two cases.

1. $\odot = \otimes$. We assume $T' \in \llbracket \varphi' \rrbracket_{\sigma'}$. Then by Corollary B.6 we know that $T' \in \llbracket \psi_1 \rrbracket_{\tau_1}$ and $T' \in \llbracket \psi_2 \rrbracket_{\tau_2}$. From the induction hypothesis we get that $T \in \llbracket \varphi_1 \rrbracket_{\sigma_1}$ and $T \in \llbracket \varphi_2 \rrbracket_{\sigma_2}$. By Corollary B.6 we know that $T \in \llbracket \varphi \rrbracket_{\sigma}$.

If on the other hand we assume $T' \notin \llbracket \varphi' \rrbracket_{\sigma'}$, the argument is dual.

2. $\odot = \oplus$. We assume $T' \in \llbracket \varphi' \rrbracket_{\sigma'}$. Then by Corollary B.6 we know that $T' \in \llbracket \psi_1 \rrbracket_{\tau_1}$ or $T' \in \llbracket \psi_2 \rrbracket_{\tau_2}$. From the induction hypothesis we get that $T \in \llbracket \varphi_1 \rrbracket_{\sigma_1}$ or $T \in \llbracket \varphi_2 \rrbracket_{\sigma_2}$. By Corollary B.6 we know that $T \in \llbracket \varphi \rrbracket_{\sigma}$. The case for $T' \notin \llbracket \varphi' \rrbracket_{\sigma'}$ is dual.

▶ **Theorem 3.2** (Soundness). Let $\varphi \in Hyper-maxHML$ be a closed formula and $T \in \mathsf{HTrc}_{\mathcal{L}}$. If $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow^* \mathsf{no}$, then $T \notin \llbracket \varphi \rrbracket$; if $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow^* \mathsf{yes}$, then $T \in \llbracket \varphi \rrbracket$.

Proof. By definition, there exist an integer h > 0 and $m_1 \triangleright T_1, \ldots, m_h \triangleright T_h$ such that $m_1 = \operatorname{Cm}_{\emptyset}(\varphi), T_1 = T, m_i \triangleright T_i \mapsto m_{i+1} \triangleright T_{i+1}$ (for every $i = 1, \ldots, h-1$), and $m_h \triangleright T_h \mapsto v$. We proceed by induction on h. The base case holds because of Lemma B.7. The inductive case holds because of Lemma B.10, which can be applied because of Lemma B.9.

We now move to violation completeness, i.e. that all hypertraces that do not belong to $[\![\varphi]\!]$ are rejected by the monitor for φ . This is proved in Theorem 3.3, that requires two preliminary easy lemmata, whose proofs hold by definition of the operational semantics.

▶ Lemma B.11. If $m \triangleright T \rightarrow *$ no, then $(m_1 \otimes \ldots \otimes m_h \otimes m \otimes m_{h+1} \otimes \ldots \otimes m_k) \triangleright T \rightarrow *$ no, for every $m_1, \ldots, m_h, m_{h+1}, \ldots, m_k$.

▶ Lemma B.12. If $m_i \triangleright T \rightarrow^*$ no for every i = 1, ..., k, then $(m_1 \oplus ... \oplus m_k) \triangleright T \rightarrow^*$ no.

▶ **Theorem 3.3** (Violation Completeness). Let $\varphi \in Hyper-maxHML$ be a closed formula and $T \in \mathsf{HTrc}_{\mathcal{L}}$. If $T \notin \llbracket \varphi \rrbracket$, then $Cm_{\emptyset}(\varphi) \triangleright T \rightarrow *$ no.

XX:24 Centralized vs Decentralized Monitors for Hyperproperties

Proof. We assume that in φ every recursive variable x appears in the scope of a unique (max) fixed-point subformula of φ of the form $\texttt{fix}(x) \triangleq \max x.\psi$. Let \leq_{φ} be a partial order of the recursive variables in φ , such that $x \leq_{\varphi} y$ if fix(x) is a subformula of fix(y) in φ . We now define the closure $\texttt{cls}(\psi)$ of a subformula ψ of φ by induction on the number of the free recursion variables in ψ : if ψ is closed, then $\texttt{cls}(\psi) \triangleq \psi$; otherwise, $\texttt{cls}(\psi) \triangleq \texttt{cls}(\psi\{\texttt{fix}(x)/x\})$, where x is \leq_{φ} -minimal in ψ .

For each σ , let ρ_{σ} be such that $\rho_{\sigma}(x) = \{T \mid \operatorname{Cm}_{\sigma}(\operatorname{cls}(x)) \triangleright T \not\to^* \operatorname{no}\}$ for every x in its domain. By induction on the structure of ψ , we prove that:

for every (not necessarily closed) subformula ψ of φ , $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$ implies $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \to *$ no, for σ and ρ_{σ} such that $\operatorname{FVloc}(\psi) \subseteq \operatorname{dom}(\sigma)$ and $\operatorname{FVrec}(\psi) \subseteq \operatorname{dom}(\rho_{\sigma})$.

Clearly, the theorem is proved if we consider φ .

There are seven possible base cases:

- $\psi = \text{tt}$, or $\psi = (\pi = \pi')$ for $\sigma(\pi) = \sigma(\pi')$, or $\psi = (\pi \neq \pi')$ for $\sigma(\pi) \neq \sigma(\pi')$: in these cases, all *T*'s belong to $[\![\psi]\!]_{\sigma}^{\rho_{\sigma}}$, so there is nothing to prove.
- $\psi = \text{ff}$, or $\psi = (\pi = \pi')$ for $\sigma(\pi) \neq \sigma(\pi')$, or $\psi = (\pi \neq \pi')$ for $\sigma(\pi) = \sigma(\pi')$: in these cases, $\text{Cm}_{\sigma}(\psi) \triangleq$ no and the claim is then trivial.
- $\psi = x$: immediate from the definition of ρ_{σ} .

For the inductive step, we distinguish the outmost operator in ψ :

- $\psi = \psi_1 \land \psi_2$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$ if and only if $T \notin \llbracket \psi_i \rrbracket_{\sigma}^{\rho_{\sigma}}$, for some $i \in \{1, 2\}$. By inductive hypothesis, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi_i)) \triangleright T \to *$ no. By definition of $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi))$ and Lemma B.11, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \to *$ no.
- $\psi = \psi_1 \lor \psi_2$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$ if and only if $T \notin \llbracket \psi_i \rrbracket_{\sigma}^{\rho_{\sigma}}$, for $i \in \{1, 2\}$. By inductive hypothesis, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi_i)) \triangleright T \to *$ no. By definition of $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi))$ and Lemma B.12, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \to *$ no.
- $\psi = [a_{\pi}]\chi$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$ if and only if $hd(T)(\sigma(\pi)) = a$ and $tl(T) \notin \llbracket \chi \rrbracket_{\sigma}^{\rho_{\sigma}}$. By definition, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) = a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) + \sum_{b \neq a} b_{\sigma(\pi)}.\operatorname{yes}$; hence, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \to \operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) \triangleright tl(T)$. By inductive hypothesis, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) \triangleright tl(T) \to tl(T) \to tl(T)$ and we easily conclude.
- $\psi = \langle a_{\pi} \rangle \chi$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$ if and only if either $hd(T)(\sigma(\pi)) \neq a$ or $tl(T) \notin \llbracket \chi \rrbracket_{\sigma}^{\rho_{\sigma}}$. By definition, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) = a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) + \sum_{b \neq a} b_{\sigma(\pi)}.$ no. If $hd(T)(\sigma(\pi)) \neq a$, then $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \mapsto \mathsf{no} \triangleright tl(T)$ and we easily conclude. Otherwise, we work like in the previous case.
- $\psi = \forall \pi. \chi$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho}$ if and only if there exists $\ell \in \mathcal{L}$ such that $T \notin \llbracket \chi \rrbracket_{\sigma[\pi \mapsto \ell]}^{\rho}$. By inductive hypothesis, $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\operatorname{cls}(\chi)) \triangleright T \mapsto^*$ no. We conclude by definition of $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi))$ and Lemma B.11.
- $\psi = \exists \pi. \chi$: by definition of the semantics, $T \notin \llbracket \psi \rrbracket_{\sigma}^{\rho}$ if and only if for all $\ell \in \mathcal{L}$ it holds that $T \notin \llbracket \chi \rrbracket_{\sigma \llbracket \pi \mapsto \ell \rrbracket}^{\rho}$. By inductive hypothesis, $\operatorname{Cm}_{\sigma \llbracket \pi \mapsto \ell \rrbracket}(\operatorname{cls}(\chi)) \triangleright T \to^* \operatorname{no}$, for all ℓ . We conclude by definition of $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi))$ and Lemma B.12.
- $\psi = \max x.\chi$: we prove the contrapositive, i.e. that $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \not\to^*$ no implies that $T \in \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$. Let us consider $S \triangleq \{T' \mid \operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) \triangleright T' \not\to^*$ no}. We observe that $\rho_{\sigma}[x \mapsto S]$ satisfies the assumptions required by the inductive statement; so, the inductive hypothesis gives us that $S \subseteq \llbracket \chi \rrbracket_{\sigma}^{\rho_{\sigma}[x \mapsto S]}$, and therefore $S \subseteq \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$. By the definition of the monitor semantics, $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\psi)) \triangleright T \not\to^*$ no yields $\operatorname{Cm}_{\sigma}(\operatorname{cls}(\chi)) \triangleright T \not\to^*$ no, meaning that $T \in S$, and therefore $T \in \llbracket \psi \rrbracket_{\sigma}^{\rho_{\sigma}}$, which completes the proof.

C Proofs for Correct Synthesis of Decentralized Monitors

We now prove four facts concerning the instrumentation rules of weakly bisimilar monitors, which we use to prove Corollary C.2, which shows that centralized and decentralized monitors behaviorally agree.

▶ Lemma C.1. Let \mathcal{R} be a weak bisimulation relation such that $M\mathcal{R}m$. Then the following statements hold:

- 1. If there exists M' such that $M \triangleright T \rightarrow M' \triangleright T'$, then there exists m' such that $m \triangleright T \rightarrow m' \triangleright T'$ and $M' \mathcal{R}m'$.
- **2.** If there exists m' such that $m \triangleright T \rightarrow m' \triangleright T'$, then there exists M' such that $M \triangleright T \rightarrow M' \triangleright T'$ and $M' \mathcal{R}m'$.
- **3.** If $M \triangleright T \rightarrow v$ then $m \triangleright T \rightarrow v$.
- **4.** If $m \triangleright T \rightarrow v$ then $M \triangleright T \rightarrow^* v$.

Proof. For the first item, we assume that $M \triangleright T \rightarrowtail M' \triangleright T'$. Hence we have that $M \xrightarrow{A} M'$ and $T \xrightarrow{A} T'$ or $M \xrightarrow{\ell:(!G,\gamma)} M'$ and T = T'. In the first case, we use the definition of weak bisimulation to obtain that $m \xrightarrow{A} m'$ for $M'\mathcal{R}m'$, from which we conclude that $m \triangleright T \rightarrowtail m' \triangleright T'$. In the second case, we use the definition of weak bisimulation to obtain that $M'\mathcal{R}m$ and we also know that $m \triangleright T \rightarrowtail^* m \triangleright T$.

For the second item, we assume that $m \triangleright T \rightarrowtail m' \triangleright T'$. Hence we have that $m \xrightarrow{A} m'$ and $T \xrightarrow{A} T'$. From the definition of weak bisimulation, there exist M_1, M_2, M' such that $M \rightarrow M_1 \xrightarrow{A} M_2 \rightarrow M'$ and $M'\mathcal{R}m'$. Thus, we can conclude that $M \triangleright T \rightarrowtail^* M_1 \triangleright T$, $M_1 \triangleright T \rightarrowtail M_2 \triangleright T'$ and $M_2 \triangleright T' \rightarrowtail^* M' \triangleright T'$, from which we obtain that $M \triangleright T \rightarrowtail^* M' \triangleright T'$.

For the third item we assume that $M \triangleright T \rightarrow v$, from which we conclude that $M \Rrightarrow v$. From the definition of weak bisimulation we obtain immediately that $m \Rrightarrow v$ and thus $m \triangleright T \rightarrow v$.

For the fourth item we assume that $m \triangleright T \rightarrow v$, from which we conclude that $m \Rrightarrow v$. From the definition of weak bisimulation we obtain immediately that $M \rightarrow M'$ and $M' \Rrightarrow v$ and thus $M \triangleright T \rightarrow^* v$.

▶ Corollary C.2. Let \mathcal{R} be a weak bisimulation such that $M\mathcal{R}m$. Then, $M \triangleright T \rightarrowtail^* v$ if and only if $m \triangleright T \succ^* v$.

Proof. For the left to right direction, assume that $M \triangleright T \rightarrow * v$. By definition there exist an integer h > 0 and $M_1 \triangleright T_1, \ldots, M_h \triangleright T_h$ such that $M_1 = M$, $T_1 = T$, $M_i \triangleright T_i \rightarrow M_{i+1} \triangleright T_{i+1}$ (for every $i = 1, \ldots, h - 1$), and $M_h \triangleright T_h \rightarrow v$. We proceed by induction on h. The base case holds because of Lemma C.1 (Item 3). In the inductive step we use Lemma C.1 (Item 1) to obtain $m \triangleright T \rightarrow * m_2 \triangleright T_2$ for some m_2 and T_2 such that $M_2 \mathcal{R}m_2$. Then we can use the induction hypothesis to conclude that $m_2 \triangleright T_2 \rightarrow * v$. Thus, $m \triangleright T \rightarrow * v$.

For the right to left direction, the proof is identical but uses Lemma C.1 (Item 4) and Lemma C.1 (Item 2) instead.

From the Formula Convergence property, we can immediately derive an auxiliary property:

▶ Lemma C.3 (Uniqueness). If $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \rightarrow M_1$, M_1 cannot communicate, $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \rightarrow M_2$ and M_2 cannot communicate, then $M_1 = M_2$.

Proof. Indeed, since $\operatorname{Cm}_{\sigma}(\varphi)$ has a possible transition for every A, by Lemma B.9 we know that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$. By applying Formula Convergence twice, we obtain $M_1 = \mathcal{M}_{\sigma'}(\varphi') = M_2$.

XX:26 Centralized vs Decentralized Monitors for Hyperproperties

▶ **Theorem 4.6.** For every principled synthesis $\mathcal{M}_{-}(-)$, $\mathcal{R}_{\mathcal{M}}$ is a weak bisimulation.

Proof. To prove that $\mathcal{R}_{\mathcal{M}}$ is a weak bisimulation, we first consider a pair $(\mathcal{M}_{\sigma}(\varphi), \operatorname{Cm}_{\sigma}(\varphi)) \in \mathcal{R}_1$. The first condition of weak bisimulation holds because, from Processing-Communication Alternation and Reactivity, we conclude that $\mathcal{M}_{\sigma}(\varphi) \not\xrightarrow{c}$, and thus M = M'. Then the result follows from Verdict Agreement.

For the second condition of weak bisimulation, we assume that $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M$. Since $\operatorname{Cm}_{\sigma}(\varphi)$ has a possible transition for every A, by Lemma B.9 we know that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$ for some σ' and φ' . From Bounded Communication, we can use Formula Convergence to obtain that $M \to \mathcal{M}_{\sigma'}(\varphi')$. By definition, $M\mathcal{R}_2\operatorname{Cm}_{\sigma'}(\varphi')$ and this suffices to conclude.

The third condition of weak bisimulation is not relevant, as $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{c} \psi$ via Processing-Communication Alternation and Reactivity. To check the fourth condition, we assume that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$ (because of Lemma B.9, we know that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A}$ results in a monitor synthesized from a formula). Via Reactivity we conclude that $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M$ for some M. Then we can use Bounded Communication and Formula Convergence to derive that $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \to \mathcal{M}_{\sigma'}(\varphi')$. As $\mathcal{M}_{\sigma'}(\varphi')\mathcal{R}_1\operatorname{Cm}_{\sigma'}(\varphi')$, we can conclude.

Now consider a pair $(M', \operatorname{Cm}_{\sigma'}(\varphi')) \in \mathcal{R}_2$, with $\mathcal{M}_{\sigma}(\varphi) \xrightarrow{A} M \to M' \to \mathcal{M}_{\sigma'}(\varphi')$ for some σ, φ and M. To verify the first condition from left to right, we assume $M' \to M''$ and $M'' \Rrightarrow v$. Since $\operatorname{Cm}_{\sigma}(\varphi)$ has a possible transition for every A and Lemma B.9, we know that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma''}(\varphi'')$ for some σ'' and φ'' . Hence, we can use Bounded Communication and Formula Convergence to conclude that $M'' \to \mathcal{M}_{\sigma''}(\varphi'')$. Furthermore, we obtain from Uniqueness and Processing-Communication Alternation that $\mathcal{M}_{\sigma'}(\varphi') = \mathcal{M}_{\sigma''}(\varphi'')$. Then we apply Verdict Irrevocability to conclude that $\mathcal{M}_{\sigma'}(\varphi') \Rrightarrow v$. Finally, we can conclude using Verdict Agreement. For the right to left direction, we use Verdict Agreement to obtain that $\mathcal{M}_{\sigma'}(\varphi') \rightrightarrows v$, which immediately satisfies the first condition of weak bisimulation. For the second condition of weak bisimulation, we assume that $M' \xrightarrow{A'} M''$. From Processing-Communication Alternation, we conclude that $M' \xrightarrow{A'}$, and thus that $M' = \mathcal{M}_{\sigma'}(\varphi')$. This sends back to the second condition for pairs in \mathcal{R}_1 .

For the third condition, we assume that $M' \xrightarrow{c} M''$. Since $\operatorname{Cm}_{\sigma}(\varphi)$ has a possible transition for every A and Lemma B.9, we know that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma''}(\varphi'')$ for some σ'' and φ'' . Hence, we can use Bounded Communication and Formula Convergence to conclude that $M'' \rightarrow \mathcal{M}_{\sigma''}(\varphi'')$. Furthermore, we obtain from Uniqueness and Processing-Communication Alternation that $\mathcal{M}_{\sigma'}(\varphi') = \mathcal{M}_{\sigma''}(\varphi'')$. By definition, $(M'', \operatorname{Cm}_{\sigma'}(\varphi')) \in \mathcal{R}_2$ and this suffices to conclude.

To check the fourth condition, we assume that $\operatorname{Cm}_{\sigma'}(\varphi') \xrightarrow{A'} \operatorname{Cm}_{\sigma''}(\varphi'')$. Via Reactivity we conclude that $\mathcal{M}_{\sigma'}(\varphi') \xrightarrow{A'} M_1$. Then we use Bounded Communication and Formula Convergence to derive that $M_1 \to \mathcal{M}_{\sigma''}(\varphi'')$, resulting in $M' \to \mathcal{M}_{\sigma'}(\varphi') \xrightarrow{A'} M_1 \to \mathcal{M}_{\sigma''}(\varphi'')$, which concludes the proof.

D Proof of Theorem 4.8

The monitor $DM_{\sigma}(\psi)$ is well-defined for closed formulas because of the following lemma:

▶ Lemma D.1. If ψ has no free variables, then $Cm_{\sigma}(\psi) \Rightarrow v$ for some v.

Proof. The proof follows from induction on ψ , making use of the fact that all formulas are assumed to be guarded.

D.1 Proofs for Verdict Agreement of $dM_{-}(\cdot)$

We now prove the synthesis defined in Table 11 satisfies the properties in Definition 4.5, and in this section we treat Verdict Agreement.

This lemma is the equivalent of Lemma B.8 for $Dm_{\sigma}^{\ell}(-)$, and the proof is identical.

▶ Lemma D.2. If $Dm^{\ell}_{\sigma}(\varphi) = m$, $Dm^{\ell}_{\sigma}(\psi) = n$, and the free location variables of ψ are not bound in φ , then $Dm^{\ell}_{\sigma}(\varphi\{^{\psi}/_x\}) = m\{^n/_x\}$.

To relate verdicts of centralized and decentralized monitors, we need the following intermediary result:

▶ Lemma D.3. Let $\psi \in Qf$ and $\varphi \in PHyper$ -recHML.

1. If there exists $\ell \in \mathcal{L}$ for which $Dm_{\sigma}^{\ell}(\psi) = v$, then $Cm_{\sigma}(\psi) = v$.

2. If $\operatorname{Cm}_{\sigma}(\psi) = v$, then for all $\ell \in \mathcal{L}$ we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = v$.

Proof. For the first statement we only prove the case for v = yes, the case for v = no is dual. We observe that $\text{Dm}^{\ell}_{\sigma}(\psi) = \text{yes}$ implies the following: $\psi = \text{tt}, \ \psi = (\pi = \pi')$ and $\sigma(\pi) = \sigma(\pi')$, or $\psi = (\pi \neq \pi')$ and $\sigma(\pi) \neq \sigma(\pi')$. In all these cases we obtain immediately that $\text{Cm}_{\sigma}(\psi) = \text{yes}$.

The second statement we prove only for $v = \mathsf{no}$. We observe that $\mathsf{Cm}_{\sigma}(\psi) = \mathsf{no}$ implies that $\psi = \mathsf{ff}, \ \psi = (\pi = \pi') \text{ and } \sigma(\pi) \neq \sigma(\pi'), \text{ or } \psi = (\pi \neq \pi') \text{ and } \sigma(\pi) = \sigma(\pi')$ (by definition, ψ is quantifier-free). In all these cases we have that $\mathsf{Dm}_{\sigma}^{\ell}(\psi) = \mathsf{no}$, for all ℓ .

We first relate the verdicts of centralized and decentralized synthesized monitors for $\psi\text{-}\mathrm{formulas}.$

▶ Lemma D.4. Let σ be such that $\mathsf{FVloc}(\psi) \subseteq \mathsf{dom}(\sigma)$. If there exists $\ell \in \mathcal{L}$ such that $\mathsf{Dm}^{\ell}_{\sigma}(\psi) \Rightarrow v$, then $\mathsf{Cm}_{\sigma}(\psi) \Rightarrow v$. Dually, if $\mathsf{Cm}_{\sigma}(\psi) \Rightarrow v$, then for all $\ell \in \mathcal{L}$ we have $\mathsf{Dm}^{\ell}_{\sigma}(\psi) \Rightarrow v$.

Proof. First, observe that ψ is quantifier-free (by definition) and that the definition of $\operatorname{Cm}_{\sigma}(\psi)$ is the same as the definition of $\operatorname{Dm}_{\sigma}^{\ell}(\psi)$ except for the box modality. Hence, we only prove the first statement by induction on \Rightarrow , as the other proof is identical.

If $Dm^{\ell}_{\sigma}(\psi) = v \Rightarrow v$, the result follows immediately from Lemma D.3.

We can skip the case for end as a synthesized monitor never takes that shape. We can also skip the case for +: if $Dm_{\sigma}^{\ell}(\psi) = m + n$, this means that $\psi = [a_{\pi}]\psi'$ and from the synthesis function it follows that $Dm_{\sigma}^{\ell}(\psi)$ cannot evaluate to a verdict.

The first inductive case we consider is $Dm_{\sigma}^{\ell}(\psi) = m \otimes n \Rightarrow no$ because $m \Rightarrow no$. Thus $\psi = \psi_1 \wedge \psi_2$ and $Dm_{\sigma}^{\ell}(\psi_1) = m$. We use the induction hypothesis to derive that $Cm_{\sigma}(\psi_1) \Rightarrow no$ and thus $Cm_{\sigma}(\psi) \Rightarrow v$.

The case for $Dm_{\sigma}^{\ell}(\psi) = m \oplus n \Rightarrow$ yes because $m \Rightarrow$ yes. is dual.

Next we consider $Dm_{\sigma}^{\ell}(\psi) = m \otimes n \Rightarrow v$ because $m \Rightarrow yes$ and $n \Rightarrow v$. Thus $\psi = \psi_1 \wedge \psi_2$, $Dm_{\sigma}^{\ell}(\psi_1) = m$ and $Dm_{\sigma}^{\ell}(\psi_2) = n$. We use the induction hypothesis to derive that $Cm_{\sigma}(\psi_1) \Rightarrow$ yes and $Cm_{\sigma}(\psi_2) \Rightarrow v$, which concludes the proof.

The case for $Dm^{\ell}_{\sigma}(\psi) = m \oplus n \Rightarrow v$ because $m \Rightarrow no$ and $n \Rightarrow v$ is dual.

Last we consider the recursive case. We have $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{rec} x.m \Rightarrow v$ because $m\{\operatorname{rec} x.m/x\} \Rightarrow v$. Thus we obtain that $\psi = \max x.\psi'$ and $m = \operatorname{Dm}_{\sigma}^{\ell}(\psi')$. As $\operatorname{Dm}_{\sigma}^{\ell}(\psi')\{\operatorname{rec} x.\operatorname{Dm}_{\sigma}^{\ell}(\psi')/x\} = \operatorname{Dm}_{\sigma}^{\ell}(\psi'\{\max x.\psi'/x\})$ from Lemma D.2, we get that $\operatorname{Dm}_{\sigma}^{\ell}(\psi'\{\max x.\psi'/x\}) \Rightarrow v$. Via the induction hypothesis we obtain that $\operatorname{Cm}_{\sigma}(\psi'\{\max x.\psi'/x\}) \Rightarrow v$. Via $\operatorname{Cm}_{\sigma}(\psi')\{\operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi')/x\} = \operatorname{Cm}_{\sigma}(\psi'\{\max x.\psi'/x\})$ (Lemma B.8) this implies that $\operatorname{Cm}_{\sigma}(\psi')\{\operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi')/x\} \Rightarrow v$. The latter gives that $\operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi') = \operatorname{Cm}_{\sigma}(\psi) \Rightarrow v$.

The next lemma states a few basic facts about verdict evaluation in a centralized and decentralized setting. When $I = \emptyset$, we let $\bigvee_{i \in I} m_i = \mathsf{no} = \bigoplus_{i \in I} m_i$ and $\bigwedge_{i \in I} m_i = \mathsf{yes} = \bigotimes_{i \in I} m_i$.

▶ Lemma D.5. The same statements hold whenever \bigoplus is replaced by \bigvee and \bigotimes by \bigwedge .

- 1. $\bigoplus_{i \in I} m_i \Rightarrow yes \Leftrightarrow \exists i \in I.m_i \Rightarrow yes$
- 2. $\bigoplus_{i \in I} m_i \Rrightarrow$ no $\Leftrightarrow \forall i \in I.m_i \Rrightarrow$ no
- 3. $\bigotimes_{i \in I} m_i \Rightarrow \mathsf{yes} \Leftrightarrow \forall i \in I.m_i \Rightarrow \mathsf{yes}$
- 4. $\bigotimes_{i \in I} m_i \Rrightarrow$ no $\Leftrightarrow \exists i \in I.m_i \Rrightarrow$ no

Now we can relate verdicts for monitors synthesized from any formula in the centralized and decentralized setting:

▶ Lemma D.6. Let σ be such that $\mathsf{FVloc}(\psi) \subseteq \mathsf{dom}(\sigma)$, and $\varphi \in PHyper\text{-maxHML. } \mathsf{DM}_{\sigma}(\varphi) \Rightarrow v \Leftrightarrow \mathsf{Cm}_{\sigma}(\varphi) \Rightarrow v$.

Proof. The proof proceeds by induction on φ . From the synthesis functions we know that $v \neq \text{end}$. For the base case we consider $\varphi = \psi$. We distinguish when ψ has free variables or not. If $\mathsf{FVloc}(\psi) = \emptyset$, by our assumptions we know that ψ is trivial and therefore $\mathsf{Cm}_{\sigma}(()\psi) = v \Rightarrow v$ and $\mathsf{DM}_{\sigma}(\psi) = [v]_{\ell_0} \Rightarrow v$. If $\mathsf{FVloc}(\psi) \neq \emptyset$ and $v = \mathsf{no}$, we derive:

$$\begin{split} \mathrm{D}\mathsf{M}_{\sigma}(\psi) &= \bigvee_{\ell \in \mathsf{rng}(\sigma)} [\mathrm{Dm}_{\sigma}^{\ell}(\psi)]_{\ell} \Rrightarrow \mathsf{no} & (\mathsf{FVloc}(\psi) = \mathsf{dom}(\sigma)) \\ \Leftrightarrow \forall \ell \in \mathsf{rng}(\sigma).[\mathrm{Dm}_{\sigma}^{\ell}(\psi)]_{\ell} \Rrightarrow \mathsf{no} & (\mathrm{Lemma} \ \mathrm{D.5}) \\ \Leftrightarrow \forall \ell \in \mathsf{rng}(\sigma).\mathrm{Dm}_{\sigma}^{\ell}(\psi) \Rrightarrow \mathsf{no} & (\mathrm{Lemma} \ \mathrm{D.4}) \end{split}$$

If v = yes:

$$\begin{split} \mathrm{D}\mathsf{M}_{\sigma}(\psi) &= \bigvee_{\ell \in \mathsf{rng}(\sigma)} [\mathrm{D}\mathsf{m}_{\sigma}^{\ell}(\psi)]_{\ell} \Rrightarrow \mathsf{yes} \\ &\Leftrightarrow \exists \ell \in \mathsf{rng}(\sigma). [\mathrm{D}\mathsf{m}_{\sigma}^{\ell}(\psi)]_{\ell} \Rrightarrow \mathsf{yes} \\ &\Leftrightarrow \exists \ell \in \mathsf{rng}(\sigma). \mathrm{D}\mathsf{m}_{\sigma}^{\ell}(\psi) \Rrightarrow \mathsf{yes} \\ &\Leftrightarrow \mathrm{C}\mathsf{m}_{\sigma}(\psi) \Rrightarrow \mathsf{yes} \end{split} \tag{Lemma D.5}$$

For the inductive step we first consider the case for $\exists \pi. \varphi$. If v = yes, we derive

$$DM_{\sigma}(\exists \pi.\varphi) = \bigvee_{\ell \in \mathcal{L}} DM_{\sigma[\pi \mapsto \ell]}(\varphi) \Rightarrow \text{yes}$$

$$\Leftrightarrow \exists \ell \in \mathcal{L}.DM_{\sigma[\pi \mapsto \ell]}(\varphi) \Rightarrow \text{yes} \qquad (\text{Lemma D.5})$$

$$\stackrel{IH}{\Leftrightarrow} \exists \ell \in \mathcal{L}.Cm_{\sigma[\pi \mapsto \ell]}(\varphi) \Rightarrow \text{yes}$$

$$\Leftrightarrow \bigoplus_{\ell \in \mathcal{L}} Cm_{\sigma[\pi \mapsto \ell]}(\varphi) = Cm_{\sigma}(\exists \pi.\varphi) \Rightarrow \text{yes} \qquad (\text{Lemma D.5})$$

The case for v = no is dual. The cases for $\forall \pi.\varphi, \varphi_1 \land \varphi_2$ and $\varphi_1 \lor \varphi_2$ are similar.

D.2 Proofs for Reactivity of $dM_{-}(\cdot)$

▶ Lemma D.7. For all $\varphi \in PHyper\text{-maxHML}$, A and environment σ , $DM_{\sigma}(\varphi) \xrightarrow{A} M$ for some $M \in DMon$.

Proof. We proceed by induction on $DM_{\sigma}(\varphi)$ and the proof is trivial for all the inductive cases. So we only treat the base case, where $\varphi = \psi \in Qf$ has no free formula variables. We prove that $Dm_{\sigma}^{\ell}(\psi)$ is reactive by induction on the well-founded ordering \prec over formulas that is defined thus: $\psi \prec \psi'$ iff

- 1. the number of top-level fixed-point operators in ψ is smaller than the number of top-level fixed-point operators in ψ' or
- **2.** that number is the same and ψ is a sub-formula of ψ' .

We proceed by a case analysis on the form of ψ .

- If $Dm^{\ell}_{\sigma}(\psi)$ is a verdict, then the claim follows immediately because $v \xrightarrow{a} v$ holds for each a.
- If $\psi = [a_{\pi}]\psi'$ for some a, π and ψ' , then $Dm_{\sigma}^{\ell}(\psi)$ is reactive by construction.
- If ψ = ψ₁ ∨ ψ₂, then Dm^ℓ_σ(ψ) = Dm^ℓ_σ(ψ₁) ⊕ Dm^ℓ_σ(ψ₂). Since ψ₁ ≺ ψ and ψ₂ ≺ ψ both hold, the inductive hypothesis yields that Dm^ℓ_σ(ψ₁) and Dm^ℓ_σ(ψ₂) are reactive. Reactivity of Dm^ℓ_σ(ψ) = Dm^ℓ_σ(ψ₁) ⊕ Dm^ℓ_σ(ψ₂) follows immediately from the operational rules for ⊕.
 The proof for the case that ψ = ψ₁ ∧ ψ₂ is identical to the one above.
- = Finally, we deal with the recursive case. Fix some action a. In order to show that $\mathrm{Dm}_{\sigma}^{\ell}(\max x.\psi) = \mathrm{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{a} m$ for some $m \in \mathrm{LMon}$, we argue as follows. Since formulas are guarded, $\psi\{\max x.\psi/x\} \prec \max x.\psi$. Therefore, the induction hypothesis yields that $\mathrm{Dm}_{\sigma}^{\ell}(\psi\{\max x.\psi/x\}) \xrightarrow{a} m$ for some m. By Lemma D.2, we have that $\mathrm{Dm}_{\sigma}^{\ell}(\psi)\{\operatorname{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi)/x\} = \mathrm{Dm}_{\sigma}^{\ell}(\psi\{\max x.\psi/x\})$, which concludes the proof using the rule giving the operational semantics of recursive monitors.

This completes the proof for the base case and we are done.

◀

D.3 Proofs for Bounded Communication of $dM_{-}(\cdot)$

We first show the existence of a finite communication path to a monitor that cannot communicate, and then argue that this monitor is unique.

To this end, we first show that $DM_{\sigma}(\varphi)$ cannot communicate.

▶ Lemma D.8. For all φ, σ it holds that for all $[m]_{\ell} \in DM_{\sigma}(\varphi)$, we have $m \xrightarrow{C}{\rightarrow}$ for all $c \in \{(!G, \gamma), (?\ell, \gamma) \mid G \subseteq \mathcal{L}, \ell \in \mathcal{L}, \gamma \in \mathsf{Con}\}.$

Proof. The statement follows from a straightforward induction on φ and the following claim: for all ℓ, ψ, σ and $c \in \{(!G, \gamma), (?\ell, \gamma) \mid G \subseteq \mathcal{L}, \ell \in \mathcal{L}, \gamma \in \mathsf{Con}\}$, it holds that $\mathrm{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{c}$. We prove this claim by showing that, if $m \xrightarrow{c} n$, then $m \neq \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ for all σ, ψ, ℓ by induction on \xrightarrow{c} . For the base case, we consider m = c.m' and we conclude immediately from the synthesis function that $c.m' \neq \mathrm{Dm}_{\sigma}^{\ell}(\psi)$, for all σ, ψ, ℓ .

For the first inductive step we consider $m = m_1 + m_2 \xrightarrow{c} n$ with $m_1 \xrightarrow{c} n$ or $m_2 \xrightarrow{c} n$. For $\mathrm{Dm}_{\sigma}^{\ell}(\psi)$ to be of the shape $m_1 + m_2$, we need $\psi = [a_{\pi}]\psi'$, and it is immediate that $\mathrm{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{c} f$ for all σ, ℓ, ψ . Hence, $m_1 + m_2 \neq \mathrm{Dm}_{\sigma}^{\ell}(\psi)$.

Next we consider $m = \operatorname{rec} x.m' \stackrel{c}{\sim} n$ because $m' \{ \operatorname{rec} x.m'/_x \} \stackrel{c}{\rightarrow} n$. From the induction hypothesis we obtain that $m' \{ \operatorname{rec} x.m'/_x \} \neq \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ for all ℓ, σ, ψ . Suppose that $m = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ for some ℓ, σ, ψ . Then $\psi = \max x.\psi'$ and $m' = \mathrm{Dm}_{\sigma}^{\ell}(\psi')$, which means that we know from the induction hypothesis that $\mathrm{Dm}_{\sigma}^{\ell}(\psi') \{ \operatorname{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi')/_x \} \neq \mathrm{Dm}_{\sigma'}^{\ell'}(\psi')$ for all ℓ', σ', ψ' . From Lemma D.2 we know that $\mathrm{Dm}_{\sigma}^{\ell}(\psi') \{ \operatorname{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi')/_x \} = \mathrm{Dm}_{\sigma}^{\ell}(\psi' \{ \max x.\psi'/_x \})$, thus we have reached a contradiction. Hence, $m \neq \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ for all ℓ, σ, ψ .

Let $m_1 \otimes m_2 \xrightarrow{c} n_1 \otimes m_2$ because $m_1 \xrightarrow{c} n_1$. From the induction hypothesis we obtain that $m_1 \neq \text{Dm}_{\sigma}^{\ell}(\psi)$ for all ℓ, σ, ψ , and thus that $m_1 \otimes m_2 \neq \text{Dm}_{\sigma}^{\ell}(\psi)$ for all ℓ, σ, ψ . The case for $m_1 \oplus m_2$ is the same.

XX:30 Centralized vs Decentralized Monitors for Hyperproperties

The case for $m_1 \odot m_2 \xrightarrow{(?\ell,\gamma)} n_1 \odot n_2$ because $m_1 \xrightarrow{(?\ell,\gamma)} n_1$ and $m_2 \xrightarrow{(?\ell,\gamma)} n_2$ is the same as the previous case.

Before proving Bounded Communication, we develop some tools that are used in many of the proofs to follow.

As most results in this work concern monitors that are reached in a run from a synthesized decentralized monitor, it is convenient to capture this in a definition.

▶ **Definition D.9.** We say that a monitor M is A-derived if for all $[m]_{\ell} \in M$ there exist ψ, σ, m' such that $Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m' \rightarrow m$. A monitor M is action-derived if there exists an A such that M is A-derived. We call a local monitor m action-derived/A-derived for ℓ if $[m]_{\ell}$ is action-derived/A-derived.

We define a syntactic characterization of the kinds of monitors that are action-derived. This provides us with a convenient inductive proof principle.

▶ **Definition D.10.** The class of relevant local monitors is defined for $\psi, \psi_a \in Qf$ by the grammar:

$$m ::= \operatorname{Dm}_{\sigma}^{\ell}(\psi) \quad | \ (!G,a).\operatorname{Dm}_{\sigma}^{\ell}(\psi) \quad | \ \sum_{a \in \operatorname{Act}} (?\{\ell'\},a).\operatorname{Dm}_{\sigma}^{\ell}(\psi_a) \ | \quad m \otimes m \ | \quad m \oplus m.$$

The class of relevant communicating monitors is then defined with the following grammar:

 $M::= \ [m]_\ell \ | \ M \wedge M \ | \ M \vee M,$

where m is a relevant local monitor and $\ell \in \mathcal{L}$. When it is clear from the context if a monitor is a relevant local monitor or a relevant communicating monitor, we will simply call it a relevant monitor, or say that a monitor is relevant.

The class of relevant (local) monitors is closed under transitions:

▶ Lemma D.11. Let M and m be a relevant communicating monitor and a relevant local monitor, respectively, and $M \xrightarrow{\lambda} M'$ and $m \xrightarrow{\lambda} m'$. Then, M' and m' are, respectively a relevant communicating monitor and a relevant local monitor.

Proof. The proof proceeds by induction on $\xrightarrow{\lambda}$. The proof for $M \xrightarrow{\lambda} M'$ follows directly from the result for m'. For $m \xrightarrow{\lambda} m'$ the only interesting case is for $m = \text{Dm}^{\ell}_{\sigma}(\psi)$, which is a base case. If $\lambda \in \text{Com}$, then the proof is trivial, as $\text{Dm}^{\ell}_{\sigma}(\psi)$ cannot communicate (Lemma D.8). Now assume that $\lambda = a \in \text{Act}$. From the synthesis function and our assumption that $|\text{Act}| \geq 2$, we observe that $\text{Dm}^{\ell}_{\sigma}(\psi) = a.m'$ never occurs, and this case can be excluded. The case where $\text{Dm}^{\ell}_{\sigma}(\psi) = m' = v$ is trivial.

When $Dm_{\sigma}^{\ell}(\psi) = n_1 + n_2$ and $n_1 \xrightarrow{a} m'$, ψ must be of the form $[a'_{\pi}]\psi'$, so

$$\mathrm{Dm}_{\sigma}^{\ell}(\psi) = a'.(!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell\}, a').\mathrm{Dm}_{\sigma}^{\ell}(\psi') + \sum_{b \neq a'} b.(!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell\}, b).\mathsf{yes}, b \in \mathbb{C}$$

or

$$\mathrm{Dm}^\ell_\sigma(\psi) = \sum_{b \in \mathsf{Act}} b. \big((?\{\sigma(\pi)\}, a'). \mathrm{Dm}^\ell_\sigma(\psi') + \sum_{b \neq a'} (?\{\sigma(\pi)\}, b). \mathsf{yes} \big)$$

In both cases it is immediate that m' is a relevant monitor, regardless of whether a = a' or $a \neq a'$.

Next we consider the case for $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = m = m_1 \otimes m_2$ (the case for \oplus is identical) and $m' = m'_1 \otimes m'_2$. Hence, $\psi = \psi_1 \wedge \psi_2$ and $m_1 = \operatorname{Dm}_{\sigma}^{\ell}(\psi_1) \xrightarrow{a} m'_1$ and $m_2 = \operatorname{Dm}_{\sigma}^{\ell}(\psi_2) \xrightarrow{a} m'_2$. From the induction hypothesis it follows that m'_1 and m'_2 are relevant monitors, making $m' = m'_1 \otimes m'_2$ a relevant monitor.

Last we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{rec} x.n \xrightarrow{a} m'$ because $n\{\operatorname{rec} x.n/x\} \xrightarrow{a} m'$. Thus we obtain that $\psi = \max x.\psi'$ and $n = \operatorname{Dm}_{\sigma}^{\ell}(\psi')$. As $\operatorname{Dm}_{\sigma}^{\ell}(\psi')\{\operatorname{rec} x.\operatorname{Dm}_{\sigma}^{\ell}(\psi')/x\} = \operatorname{Dm}_{\sigma}^{\ell}(\psi'\{\max x.\psi'/x\})$ (Lemma D.2), we use the induction hypothesis to obtain that m' is relevant.

The relevant monitors can be used to prove properties of action-derived monitors, because of the following:

▶ Lemma D.12. Every action-derived monitor M is relevant.

Proof. Straightforward from Lemma D.11.

◀

Now we proceed with a string of lemmas that are all stating basic facts regarding communication, and are used in many of the lemmas that follow. We start with three basic facts regarding receiving and sending of messages for action-derived local monitors. The first item states that local monitors can never receive the same message from the same sender twice in a chain of consecutive communications. Next, it states that if a monitor cannot receive a certain message from some sender, then it cannot receive that message in the future after taking only communication transitions. Lastly, it shows monitors only send the action they last read.

▶ Lemma D.13. Let $m \in LMon$ be A-derived for ℓ . Then:

1. If
$$m \xrightarrow{(?\ell',\gamma)} n$$
, then $n \xrightarrow{(?\ell',\gamma)}$.
2. If $m \xrightarrow{(?\ell',\gamma)}$ and $m \rightarrow n$, then $n \xrightarrow{(?\ell',\gamma)}$.
3. If $m \xrightarrow{(!G,\gamma)} n$, then $\gamma = A(\ell)$.

Proof. We prove the first two items for relevant local monitors, which is sufficient because m is a relevant local monitor via Lemma D.12. We proceed by induction on the structure of m.

If $m = \text{Dm}_{\sigma}^{\ell}(\psi)$, then *m* cannot communicate (Lemma D.8). Hence, the premise of the first item is not satisfied, and in the second item we get n = m, making the statement trivially true.

Next we consider $m = (!G, a).Dm_{\sigma}^{\ell}(\psi)$. Again, the premise of the first item is not satisfied. For the second item, n = m or $n = Dm_{\sigma}^{\ell}(\psi)$. The result follows immediately from the premise of the lemma or Lemma D.8.

If $m = \sum_{a \in \mathsf{Act}} (?\{\ell''\}, a) . \mathsf{Dm}^{\ell}_{\sigma}(\psi_a)$, both items follow immediately from Lemma D.8.

Let $m = m_1 \otimes m_2$ with m_1, m_2 relevant monitors. For the first statement, we derive two cases from $m_1 \otimes m_2 \xrightarrow{(?\ell',\gamma)} n$.

- 1. $n = n_1 \otimes n_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} n_1$ and $m_2 \xrightarrow{(?\ell',\gamma)} n_2$. The induction hypothesis gives that $n_1 \xrightarrow{(?\ell',\gamma)}$ and $n_2 \xrightarrow{(?\ell',\gamma)}$. Hence, $n \xrightarrow{(?\ell',\gamma)}$.
- 2. $n = n_1 \otimes m_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} n_1$ and $m_2 \xrightarrow{(?\ell',\gamma)}$. From the induction hypothesis we get that $n_1 \xrightarrow{(?\ell',\gamma)}$. Hence, $n = n_1 \otimes m_2 \xrightarrow{(?\ell',\gamma)}$.

For the second statement we derive from $m_1 \otimes m_2 \xrightarrow{(?\ell'_j\gamma)}$ that $m_1 \xrightarrow{(?\ell'_j\gamma)}$ and $m_2 \xrightarrow{(?\ell'_j\gamma)}$. Furthermore, we know that $n = n_1 \otimes n_2$ such that $m_1 \rightarrow n_1$ and $m_2 \rightarrow n_2$. From the induction hypothesis we obtain that $n_1 \xrightarrow{(?\ell'_j\gamma)}$ and $n_2 \xrightarrow{(?\ell'_j\gamma)}$. Hence, $n \xrightarrow{(?\ell'_j\gamma)}$.

The case for \oplus is identical to the one for \otimes and, therefore, we omit it.

XX:32 Centralized vs Decentralized Monitors for Hyperproperties

For the third item we proceed by induction on $\operatorname{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m'$ (we know σ, ψ and m' exist because m is A-derived for ℓ). For the first case we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = a.m'$. From the synthesis function and our assumption that $|\operatorname{Act}| \geq 2$, we observe that this never occurs.

When $Dm_{\sigma}^{\ell}(\psi) = m_1 + m_2$ and $m_1 \xrightarrow{A(\ell)} m'$, ψ must be of the form $[a_{\pi}]\psi'$, so

$$\mathrm{Dm}_{\sigma}^{\ell}(\psi) = a.(!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi') + \sum_{b \neq a} b.(!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell\}, b).\mathsf{yes},$$

or

$$\mathrm{Dm}_{\sigma}^{\ell}(\psi) = \sum_{b \in \mathsf{Act}} b.((?\{\sigma(\pi)\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi') + \sum_{b \neq a} (?\{\sigma(\pi)\}, b).\mathsf{yes}).$$

It is immediate that $\gamma = A(\ell)$ in $m \xrightarrow{(!G,\gamma)} n$.

Next we consider the case for $\mathsf{Dm}_{\sigma}^{\ell}(\psi) = m_1'' \otimes m_2''$ and $m' = m_1' \otimes m_2'$. Hence, $\psi = \psi_1 \wedge \psi_2$ and $m_1'' = \mathsf{Dm}_{\sigma}^{\ell}(\psi_1) \xrightarrow{A(\ell)} m_1'$ and $m_2'' = \mathsf{Dm}_{\sigma}^{\ell}(\psi_2) \xrightarrow{A(\ell)} m_2'$. Let $m = m_1 \otimes m_2$, and we know that $m_1' \to m_1$ and $m_2' \to m_2$. We assume without loss of generality that $n = n_1 \otimes m_2$ and $m_1 \xrightarrow{(!G,\gamma)} n_1$. From the induction hypothesis it follows immediately that $\gamma = A(\ell)$.

The case for \oplus is identical to the one for \otimes and, therefore, we omit it.

Last we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{rec} x.n \xrightarrow{A(\ell)} m'$ because $n\{\operatorname{rec} x.n/x\} \xrightarrow{A(\ell)} m'$. Thus we obtain that $\psi = \max x.\psi'$ and $n = \operatorname{Dm}_{\sigma}^{\ell}(\psi')$. As $\operatorname{Dm}_{\sigma}^{\ell}(\psi')\{\operatorname{rec} x.\operatorname{Dm}_{\sigma}^{\ell}(\psi')/x\} = \operatorname{Dm}_{\sigma}^{\ell}(\psi'\{\max x.\psi'/x\})$ (Lemma D.2), we use the induction hypothesis to obtain the desired result.

We generalize the third property from Lemma D.13 to communicating monitors: if an action-derived monitor M can take a communicating transition, the message it sends is always the last action taken by the location of the sender:

▶ Lemma D.14. Let $M \in \mathsf{DMon}$ be A-derived. If $M \xrightarrow{\ell:(!G,\gamma)} N$, then $\gamma = A(\ell)$.

Proof. The result follows immediately from induction on $\xrightarrow{\ell:(!G,\gamma)}$, where for the base case we make use of Lemma D.13: in the base case we consider $M = [m]_{\ell}$, $N = [n]_{\ell}$ and $m \xrightarrow{(!G,\gamma)} n$. Via Lemma D.13 we derive that $\gamma = A(\ell)$. The inductive step follows immediately from the induction hypothesis.

Lemma D.13 and Lemma D.14 are used in many of the proofs that follow throughout this appendix.

Before proceeding with lemmas that are all used to prove Lemma D.27, we state a few other basic properties, that are used in a variety of proofs.

Lemma D.27 uses a 'commutativity' property for communicating monitors (Lemma D.25), and this is based on five similar results for local monitors (Lemma D.15-Lemma D.19), that are in addition used in a variety of other lemmas.

The following lemma shows that, if action-derived local monitors can both send and receive a message, the order in which this happens does not matter.

▶ Lemma D.15. Let $m \in \text{LMon}$ be a relevant local monitor, $m \xrightarrow{(!G,\gamma)} m_1$ and $m \xrightarrow{(?\ell',\gamma')} m_2$ for some $\ell' \in \mathcal{L}$. Then, $m_1 \xrightarrow{(?\ell',\gamma')} m_3$ and $m_2 \xrightarrow{(!G,\gamma)} m_3$ for some m_3 .

Proof. We proceed by induction on m.

In all of the base cases, namely $m = Dm_{\sigma}^{\ell}(\psi)$, $m = (!G, a).Dm_{\sigma}^{\ell}(\psi)$ and $m = \sum_{a \in Act} (?\{\ell''\}, a).Dm_{\sigma}^{\ell}(\psi_a)$, the premise of the lemma is not satisfied. For $m = Dm_{\sigma}^{\ell}(\psi)$ we conclude this from Lemma D.8.

Let $m = n_1 \otimes n_2$ with n_1, n_2 relevant monitors. From $m \xrightarrow{(!G,\gamma)} m_1$ we derive w.l.o.g. that $m_1 = x_1 \otimes n_2$ and $n_1 \xrightarrow{(!G,\gamma)} x_1$. From $m \xrightarrow{(?\ell',\gamma')} m_2$ we derive three cases.

- 1. $m_2 = y_1 \otimes y_2$ such that $n_1 \xrightarrow{(?\ell',\gamma')} y_1$ and $n_2 \xrightarrow{(?\ell',\gamma')} y_2$. From the induction hypothesis we derive that $x_1 \xrightarrow{(?\ell',\gamma')} z$ and $y_1 \xrightarrow{(!G,\gamma)} z$. Thus $x_1 \otimes n_2 \xrightarrow{(?\ell',\gamma')} z \otimes y_2$ and $y_1 \otimes y_2 \xrightarrow{(!G,\gamma)} z \otimes y_2$, which concludes the proof.
- 2. $m_2 = y_1 \otimes n_2$ such that $n_1 \xrightarrow{(?\ell',\gamma')} y_1$ and $n_2 \xrightarrow{(?\ell',\gamma')} z_1$. From the induction hypothesis we derive $x_1 \xrightarrow{(?\ell',\gamma')} z$ and $y_1 \xrightarrow{(!G,\gamma)} z$. Thus $x_1 \otimes n_2 \xrightarrow{(?\ell',\gamma')} z \otimes n_2$ and $y_1 \otimes n_2 \xrightarrow{(!G,\gamma)} z \otimes n_2$, which concludes the proof.
- **3.** $m_2 = n_1 \otimes y_2$ such that $n_1 \xrightarrow{(?\ell', \gamma')}$ and $n_2 \xrightarrow{(?\ell', \gamma')} y_2$. We obtain that $n_1 \otimes y_2 \xrightarrow{(!G, \gamma)} x_1 \otimes y_2$ and $x_1 \otimes n_2 \xrightarrow{(?\ell', \gamma')} x_1 \otimes y_2$, where we use Lemma D.13 to conclude that $x_1 \xrightarrow{(?\ell', \gamma')}$ from $n_1 \xrightarrow{(?\ell', \gamma')}$.

The case for \oplus is identical to the one for \otimes and, therefore, we omit it.

The next lemma proves uniqueness of reached states after a receiving transition.

▶ Lemma D.16. Let $m \in \text{LMon}$ be a relevant local monitor, $m \xrightarrow{(?\ell',\gamma)} n_1$ and $m \xrightarrow{(?\ell',\gamma)} n_2$. Then we have $n_1 = n_2$.

Proof. We proceed by induction on m. In two of the base cases, namely $m = \text{Dm}_{\sigma}^{\ell}(\psi)$ and $m = (!G, a).\text{Dm}_{\sigma}^{\ell}(\psi)$, the premise of the lemma is not satisfied. For $m = \text{Dm}_{\sigma}^{\ell}(\psi)$ we conclude this from Lemma D.8. For the base case where $m = \sum_{a \in \text{Act}} (?\{\ell''\}, a).\text{Dm}_{\sigma}^{\ell}(\psi_a)$, we can conclude because there is only one entry in the sum for each combination of ℓ'' and a.

Let $m = m_1 \otimes m_2$ with m_1 , m_2 relevant monitors (the case for \oplus is identical to the one for \otimes and, therefore, we omit it). From $m \xrightarrow{(?\ell',\gamma)} n_1$ we derive two cases.

- 1. $n_1 = z_1 \otimes z_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} z_1$ and $m_2 \xrightarrow{(?\ell',\gamma)} z_2$. From $m \xrightarrow{(?\ell',\gamma)} n_2$ we derive two more cases.
 - **a.** $n_2 = w_1 \otimes w_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} w_1$ and $m_2 \xrightarrow{(?\ell',\gamma)} w_2$. From the induction hypothesis we conclude that $z_1 = w_1$ and $z_2 = w_2$, and thus that $n_1 = n_2$.
 - **b.** $n_2 = w_1 \otimes m_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} w_1$ and $m_2 \xrightarrow{(?\ell',\gamma)}$. This is a contradiction with $m_2 \xrightarrow{(?\ell',\gamma)} z_2$.
- 2. $n_1 = z_1 \otimes m_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} z_1$ and $m_2 \xrightarrow{(?\ell',\gamma)} b$. We then conclude from $m \xrightarrow{(?\ell',\gamma)} n_2$ that $n_2 = w_1 \otimes m_2$ such that $m_1 \xrightarrow{(?\ell',\gamma)} w_1$. From the induction hypothesis we conclude that $w_1 = z_1$ and thus that $n_1 = z_1 \otimes m_2 = w_1 \otimes m_2 = n_2$.

The next lemma states that if a monitor can receive a message from two different senders, the order in which this happens does not matter.

▶ Lemma D.17. Let $m \in \text{LMon}$ be a relevant local monitor. $m \xrightarrow{(?\ell_1,\gamma_1)} m_1$ and $m \xrightarrow{(?\ell_2,\gamma_2)} m_2$, where $\ell_1 \neq \ell_2$. Then, $m_1 \xrightarrow{(?\ell_2,\gamma_2)} m_3$ and $m_2 \xrightarrow{(?\ell_1,\gamma_1)} m_3$, for some m_3 .

Proof. We proceed by induction on m. In all of the base cases, namely $m = \text{Dm}_{\sigma}^{\ell}(\psi)$, $m = (!G, a).\text{Dm}_{\sigma}^{\ell}(\psi)$ and $m = \sum_{a \in \text{Act}} (?\{\ell'\}, a).\text{Dm}_{\sigma}^{\ell}(\psi_a)$, the premise of the lemma is not satisfied. For $m = \text{Dm}_{\sigma}^{\ell}(\psi)$ we conclude this from Lemma D.8.

◀

Let $m = y_1 \otimes y_2$ with y_1, y_2 relevant monitors. From $m \xrightarrow{(?\ell_1,\gamma_1)} m_1$ and $m \xrightarrow{(?\ell_2,\gamma_2)} m_2$, wlog we derive the following four cases.

1. $m_1 = z_1 \otimes z_2$ and $m_2 = w_1 \otimes w_2$, where

$$y_1 \xrightarrow{(?\ell_1,\gamma_1)} z_1 \tag{3}$$

$$y_2 \xrightarrow{(?\ell_1,\gamma_1)} z_2 \tag{4}$$

$$y_1 \xrightarrow{(:t_2, \gamma_2)} w_1$$
, and (5)

$$y_2 \xrightarrow{(\ell_2, \gamma_2)} w_2.$$
 (6)

From the induction hypothesis on Equations (3) and (5), and on Equations (4) and (6), $z_1 \xrightarrow{(?\ell_2,\gamma_2)} r_1$ and $w_1 \xrightarrow{(?\ell_1,\gamma_1)} r_1$, for some r_1 ; and $z_2 \xrightarrow{(?\ell_2,\gamma_2)} r_2$ and $w_2 \xrightarrow{(?\ell_1,\gamma_1)} r_2$, for some r_2 . We conclude that $m_1 \xrightarrow{(?\ell_2,\gamma_2)} r_1 \otimes r_2$ and $m_2 \xrightarrow{(?\ell_1,\gamma_1)} r_1 \otimes r_2$.

2. $m_1 = z_1 \otimes z_2$ and $m_2 = w_1 \otimes y_2$, where Equations (3) to (5) hold, and

$$y_2 \xrightarrow{(?\ell_2,\gamma_2)}$$
. (7)

From the induction hypothesis on Equations (3) and (5), we get that

$$z_1 \xrightarrow{(\ell_2, \gamma_2)} r_1$$
 and (8)

$$w_1 \xrightarrow{(?\ell_1,\gamma_1)} r_1,$$
 (9)

for some r_1 . Lemma D.13 and Equation (7) yield that $z_2 \xrightarrow{(?\ell_2,\gamma_2)}$, and therefore from Equation (8) we get that $m_1 = z_1 \otimes z_2 \xrightarrow{(?\ell_2,\gamma_2)} r_1 \otimes z_2$; finally, Equations (4) and (9) yield $m_2 = w_1 \otimes y_2 \xrightarrow{(?\ell_1,\gamma_1)} r_1 \otimes z_2$.

3. $m_1 = z_1 \otimes y_2$ and $m_2 = w_1 \otimes y_2$, where Equations (3), (5) and (7) hold, and

$$y_2 \xrightarrow{(?\ell_1,\gamma_1)}$$
 . (10)

From the induction hypothesis on Equations (3) and (5), we get Equations (8) and (9), for some r_1 , which together with Equations (7) and (10) yield $m_1 = z_1 \otimes y_2 \xrightarrow{(?\ell_2,\gamma_2)} r_1 \otimes y_2$ and $m_2 = w_1 \otimes y_2 \xrightarrow{(?\ell_1,\gamma_1)} r_1 \otimes y_2$.

4. $m_1 = z_1 \otimes y_2$ and $m_2 = y_1 \otimes w_2$, where Equations (3), (6) and (10) hold, and

$$y_1 \xrightarrow{(?\ell_2; \hat{j}'^2)}$$
 (11)

Lemma D.13 with Equations (3) and (11), and Equations (6) and (10) yield that $z_1 \xrightarrow{(?\ell_2,\gamma_2)}$ and $w_2 \xrightarrow{(?\ell_1,\gamma_1)}$ respectively, and therefore from Equations (3) and (6) we get that $m_1 = z_1 \otimes y_2 \xrightarrow{(?\ell_2,\gamma_2)} z_1 \otimes z_2$ and $m_2 = y_1 \otimes w_2 \xrightarrow{(?\ell_1,\gamma_1)} z_1 \otimes z_2$. The case for \oplus is identical to the one for \otimes and, therefore, we omit it.

The following lemma shows that if action-derived local monitors can send two different messages, the order in which this happens does not matter.

▶ Lemma D.18. Let *m* be a relevant local monitor, $m \xrightarrow{(!G,\gamma)} m_2$ and $m \xrightarrow{(!G',\gamma')} m_3$ for some $G, G' \subseteq \mathcal{L}$ such that $G \neq G'$ or $\gamma \neq \gamma'$. Then $m_2 \xrightarrow{(!G',\gamma')} m_4$ and $m_3 \xrightarrow{(!G,\gamma)} m_4$.

Proof. We proceed by induction on m. The base case for $m = Dm_{\sigma}^{\ell}(\psi)$ follows from Lemma D.8; for the other base cases (i.e., $m = (!G, a).Dm_{\sigma}^{\ell}(\psi)$ and m = $\sum_{a \in \mathsf{Act}} (?\{\ell'\}, a).\mathsf{Dm}^{\ell}_{\sigma}(\psi_a)),$ the premise of the lemma is not satisfied.

Let $m = n_1 \otimes n_2$ (the case for \oplus is identical) with n_1 , n_2 relevant monitors. From $m \xrightarrow{(!G,\gamma)} m_2$ we derive w.l.o.g. that $m_2 = x_1 \otimes n_2$ and $n_1 \xrightarrow{(!G,\gamma)} x_1$. From $m \xrightarrow{(!G',\gamma')} m_3$ we derive two cases.

- 1. $m_3 = y_1 \otimes n_2$ such that $n_1 \xrightarrow{(!G',\gamma')} y_1$. From the induction hypothesis we derive that $x_1 \xrightarrow{(!G',\gamma')} z$ and $y_1 \xrightarrow{(!G,\gamma)} z$. Thus $x_1 \otimes n_2 \xrightarrow{(!G',\gamma')} z \otimes n_2$ and $y_1 \otimes n_2 \xrightarrow{(!G,\gamma)} z \otimes n_2$, which concludes the proof.
- 2. $m_3 = n_1 \otimes y_2$ such that $n_2 \xrightarrow{(!G',\gamma')} y_2$. We obtain that $n_1 \otimes y_2 \xrightarrow{(!G,\gamma)} x_1 \otimes y_2$ and $x_1 \otimes n_2 \xrightarrow{(!G',\gamma')} x_1 \otimes y_2.$

The following lemma is the version of Lemma D.16 for sending.

▶ Lemma D.19. Let m be a relevant local monitor, $m \xrightarrow{(!G,\gamma)} n_1$ and $m \xrightarrow{(!G,\gamma)} n_2$. Then we have $n_1 = n_2$, or $n_1 \xrightarrow{(!G,\gamma)} z$ and $n_2 \xrightarrow{(!G,\gamma)} z$

Proof. We proceed by induction on m. If $m = (!G, a).Dm^{\ell}_{\sigma}(\psi)$, it is immediate that $n_1 = n_2$.

If $m = Dm_{\sigma}^{\ell}(\psi)$ or $m = \sum_{a \in Act} (?\{\ell'\}, a).Dm_{\sigma}^{\ell}(\psi_a)$, the premise of the lemma is not satisfied. Let $m = y_1 \otimes y_2$ (the case for \oplus is identical) with y_1, y_2 relevant monitors. From $m \xrightarrow{(!G,\gamma)} n_1$ we derive that $n_1 = z_1 \otimes y_2$ such that $y_1 \xrightarrow{(!G,\gamma)} z_1$. From $m \xrightarrow{(!G,\gamma)} n_2$ we derive two cases.

- 1. $n_2 = w_1 \otimes y_2$ such that $y_1 \xrightarrow{(!G,\gamma)} w_1$. From the induction hypothesis we conclude that $z_1 = w_1$ and thus that $n_1 = n_2$, or $w_1 \xrightarrow{(!G,\gamma)} r$ and $z_1 \xrightarrow{(!G,\gamma)} r$. In the latter case we derive that $n_1 = z_1 \otimes y_2 \xrightarrow{(!G,\gamma)} r \otimes y_2$ and $n_2 = w_1 \otimes y_2 \xrightarrow{(!G,\gamma)} r \otimes y_2$. **2.** $n_2 = y_1 \otimes w_2$ such that $y_2 \xrightarrow{(!G,\gamma)} w_2$. In that case we derive that $n_1 = z_1 \otimes y_2 \xrightarrow{(!G,\gamma)} z_1 \otimes w_2$
- and $n_2 = y_1 \otimes w_2 \xrightarrow{(!G,\gamma)} z_1 \otimes w_2.$

Before we continue on the path to proving Lemma D.27, we show how to formally capture the state of a decentralized monitor after taking a receiving transition, for which we only need Lemma D.16. This is used in various places later on in the proofs. In what follows we use $M[[m]_{\ell}/[n]_{\ell}]$ as notation for replacing $[n]_{\ell}$ in $M \in \mathsf{DMon}$ with $[m]_{\ell}$ (the operation does not change M in case $[n]_{\ell}$ does not occur in M).

▶ Lemma D.20. Let $M, N \in \mathsf{DMon}$ be action-derived monitors, $M \xrightarrow{G : (?\ell, \gamma)} N$, and $\{[m_i]_{\ell_s} \mid l_{\ell_s} \in \mathcal{N}\}$ $1 \leq i \leq k$ = { $[m]_{\ell'} \in M$ }. For each $1 \leq i \leq k$, let n_i be m_i , when $\ell_i \notin G$ or $m_i \xrightarrow{(?\ell,\gamma)}$, and be such that $m_i \xrightarrow{(?\ell,\gamma)} n_i$, otherwise. Then, $M[n_1/m_1] \cdots [n_k/m_k] = N$.

Proof. Lemma D.16 yields that each n_i is uniquely defined. Then, the lemma follows immediately from induction on $\overset{G:(?\ell,\gamma)}{\longrightarrow}$.

These properties for local monitors can then be used to show an important feature of action-derived monitors: when they communicate, the order of communication does not matter. More concretely, regardless of the order in which communication steps are executed, the state reached where no more communication can take place is unique (Lemma D.27).

Lemma D.21-Lemma D.24 are used to prove Lemma D.25, which is a 'commutativity' property for communication steps of action-derived monitors. This result, together with

Centralized vs Decentralized Monitors for Hyperproperties **XX:36**

Lemma D.26, then leads to Lemma D.27, which captures that the order of communication does not matter: regardless of in what order the communication steps are executed, the state where no more communication can take place, is equivalent.

▶ Lemma D.21. Let $M \in \mathsf{DMon}$ be action-derived. If $M \xrightarrow{G : (?\ell, \gamma)} N$, then $N \xrightarrow{G : (?\ell, \gamma)} N$.

Proof. We proceed by induction on $M \xrightarrow{G: (?\ell, \gamma)} N$. In the first base case we consider $M = [m]_{\ell'}, N = [n]_{\ell'}, \ell' \in G$, and $m \xrightarrow{(?\ell,\gamma)} n$. Via Lemma D.13, which we can apply because M is action-derived, we obtain that $n \xrightarrow{(?\ell_{\gamma}\gamma)}$. Hence, $[n]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} [n]_{\ell'}$. In the second and third base case we consider $M = [m]_{\ell'} = N$, and thus we are done immediately. In the inductive case we consider $M = M_1 \otimes M_2$ (the case for $M = M_1 \oplus M_2$ is identical), $N = N_1 \otimes N_2, M_1 \xrightarrow{G: (?\ell, \gamma)} N_1 \text{ and } M_2 \xrightarrow{G: (?\ell, \gamma)} N_2.$ From the induction hypothesis we get that $N_1 \xrightarrow{G: (?\ell, \gamma)} N_1$ and $N_2 \xrightarrow{G: (?\ell, \gamma)} N_2$, and thus that $N = N_1 \otimes N_2 \xrightarrow{G: (?\ell, \gamma)} N_1 \otimes N_2.$

► Lemma D.22. Let $M \in \mathsf{DMon}$ be A-derived. Let $M \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} N_1$ and $M \xrightarrow{G_2 : (?\ell_2, A(\ell_2))}$ $N_2. Then N_1 \xrightarrow{G_2 : (?\ell_2 A(\ell_2))} N_3 and N_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} N_3, or N_1 = N_2.$

Proof. We proceed by induction on $M \xrightarrow{G_1: (?\ell_1, A(\ell_1))} N_1$. In the first base case we consider $M = [m]_{\ell}, N_1 = [n_1]_{\ell}, \ell \in G_1$, and $m \xrightarrow{(?\ell_1, A(\ell_1))} n_1$. We distinguish two cases:

- 1. $N_2 = [n_2]_{\ell}, m \xrightarrow{(?\ell_2, A(\ell_2))} n_2, \ell \in G_2$. Since *M* is action-derived, we can use Lemma D.17
 - to obtain two further cases: **a.** $\ell_1 \neq \ell_2$ and $n_1 \xrightarrow{(?\ell_2, A(\ell_2))} q$ and $n_2 \xrightarrow{(?\ell_1, A(\ell_1))} q$. Hence, $N_1 = [n_1]_{\ell} \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} [q]_{\ell}$ and $N_2 = [n_2]_{\ell} \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} [q]_{\ell}$.
 - **b.** $\ell_1 = \ell_2$. Via Lemma D.16 we conclude that $n_1 = n_2$ and thus that $N_1 = N_2$.
- 2. $N_2 = [m]_\ell$ and $\ell \notin G_2$ or $m \xrightarrow{(?\ell_2, A(\ell_2))}$. Via Lemma D.13 we obtain that $\ell \notin G_2$ or $n_1 \xrightarrow{(?\ell_2, A(\ell_2))}$. Hence, $N_1 = [n_1]_\ell \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} [n_1]_\ell = N_1$. Since $N_2 = M$, we know that $N_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} N_1$, which concludes the proof.

For the next two base cases we consider $N_1 = [m]_{\ell}$ and $\ell \notin G_1$ or $m \xrightarrow{(?\ell_1, A(\ell_1))}$. We distinguish two cases:

- 1. $N_2 = [n_2]_\ell$, $m \xrightarrow{(?\ell_2, A(\ell_2))} n_2$, $\ell \in G_2$. Via Lemma D.13 we obtain that $\ell \notin G_1$ or $n_2 \xrightarrow{(?\ell_1, A(\ell_1))}$. Hence, $N_2 = [n_2]_\ell \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} [n_2]_\ell = N_2$. Since $N_1 = M$, we know that $N_1 \xrightarrow{G_2: (?\ell_2, A(\ell_2))} N_2$, which concludes the proof.
- 2. $N_2 = [m]_{\ell}$ and $\ell \notin G_2$ or $m \xrightarrow{(?\ell_2, A(\ell_2))}$. Hence, $M = N_2 = N_1$, and we are done immediately.

For the inductive step, we let $M = M_1 \otimes M_2$ (the case where $M = M_1 \oplus M_2$ is identical), $N_1 = O_1 \otimes O_2, M_1 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} O_1 \text{ and } M_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} O_2.$ This implies that $N_2 = O_3 \otimes O_4$, with $M_1 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_3$ and $M_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_4.$ We apply the induction hypothesis to $M_1 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} O_1$ to obtain two cases: 1. $O_1 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q_1$ and $O_3 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} Q_1$. We apply the induction hypothesis to

- - $M_{2} \xrightarrow{G_{1}:(?\ell_{1},A(\ell_{1}))} O_{2} \text{ to obtain two more cases:}$ a. $O_{2} \xrightarrow{G_{2}:(?\ell_{2},A(\ell_{2}))} Q_{2} \text{ and } O_{4} \xrightarrow{G_{1}:(?\ell_{1},A(\ell_{1}))} Q_{2}.$ Hence, $O_{1} \otimes O_{2} \xrightarrow{G_{2}:(?\ell_{2},A(\ell_{2}))} Q_{1} \otimes Q_{2}$ and $O_{3} \otimes O_{4} \xrightarrow{G_{1}:(?\ell_{1},A(\ell_{1}))} Q_{1} \otimes Q_{2},$ which concludes the proof.
 - **b.** $O_2 = O_4$. We apply Lemma D.21 to $M_2 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} O_4$ to conclude that $O_4 \xrightarrow{G_2: (?\ell_2, A(\ell_2))} O_4$. Similarly, we apply Lemma D.21 to $M_2 \xrightarrow{G_1: (?\ell_1, A(\ell_1))} O_2$ to

conclude that $O_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} O_2$. Then $O_1 \otimes O_2 = O_1 \otimes O_4 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q_1 \otimes O_4$ and $O_3 \otimes O_4 = O_3 \otimes O_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} Q_1 \otimes O_2 = Q_1 \otimes O_4$, which concludes the proof.

- 2. $O_1 = O_3$. We apply the induction hypothesis to $M_2 \xrightarrow{G_1 : (?\ell_1, A(\ell_1))} O_2$ to obtain two more cases:
 - cases: a. $O_2 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} Q_2$ and $O_4 \xrightarrow{G_1:(?\ell_1, A(\ell_1))} Q_2$. We apply Lemma D.21 to $M_1 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} O_3$ to conclude that $O_3 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} O_3$. Similarly, we apply Lemma D.21 to $M_1 \xrightarrow{G_1:(?\ell_1, A(\ell_1))} O_1$ to conclude that $O_1 \xrightarrow{G_1:(?\ell_1, A(\ell_1))} O_1$. Then $O_1 \otimes O_2 = O_3 \otimes O_2 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} O_3 \otimes Q_2$ and $O_3 \otimes O_4 = O_1 \otimes O_4 \xrightarrow{G_1:(?\ell_1, A(\ell_1))} O_1 \otimes O_1 \otimes O_2 = O_3 \otimes Q_2$, which concludes the proof.
 - **b.** $O_2 = O_4$. Then we immediately have $N_1 = N_2$.

▶ Lemma D.23. Let $M \in \mathsf{DMon}$ be action-derived. If $M \xrightarrow{G : (?\ell, \gamma)} N_1$ and $M \xrightarrow{G : (?\ell, \gamma)} N_2$, then $N_1 = N_2$.

Proof. We proceed by induction on $M \xrightarrow{G: (?\ell, \gamma)} N_1$. In the first base case we consider $M = [m]_{\ell'}, N_1 = [n_1]_{\ell'}, \ell' \in G$, and $m \xrightarrow{(?\ell, \gamma)} n_1$. We distinguish two cases:

- 1. $N_2 = [n_2]_{\ell'}, m \xrightarrow{(?\ell,\gamma)} n_2$. We apply Lemma D.16 (*M* is action-derived) to conclude that $n_2 = n_1$, and thus $N_1 = N_2$.
- **2.** $N_2 = [m]_{\ell'}$ and $m \xrightarrow{(?\ell,\gamma)}$ or $\ell' \notin G$. This is a contradiction with $m \xrightarrow{(?\ell,\gamma)} n_1$ and $\ell' \in G$, thus we can exclude this case.

In the second and third base case we consider $M = [m]_{\ell'} = N_1$, and $\ell' \notin G$ or $m \xrightarrow{(?\ell,\gamma)}$. We distinguish two cases:

1. $N_2 = [n_2]_{\ell'}, m \xrightarrow{(?\ell,\gamma)} n_2, \ell' \in G$. This is a contradiction with $m \xrightarrow{(?\ell,\gamma)}$ or $\ell' \notin G$. Hence we can exclude this case.

2. $N_2 = [m]_{\ell'}$ and $\ell' \notin G$ or $m \xrightarrow{(?\ell,\gamma)}$. Hence, $M = N_2 = N_1$, and we are done immediately. In the inductive case we consider $M = M_1 \otimes M_2$ (the case for $M = M_1 \oplus M_2$ is identical), $N_1 = O_1 \otimes O_2$, $M_1 \xrightarrow{G : (?\ell,\gamma)} O_1$ and $M_2 \xrightarrow{G : (?\ell,\gamma)} O_2$. This implies that $N_2 = O_3 \otimes O_4$, with $M_1 \xrightarrow{G : (?\ell,\gamma)} O_3$ and $M_2 \xrightarrow{G : (?\ell,\gamma)} O_4$. We apply the induction hypothesis twice to obtain that $O_1 = O_3$ and $O_2 = O_4$, and thus $N_1 = N_2$.

► Lemma D.24. Let $M \in \mathsf{DMon}$ be action-derived. Let $M \xrightarrow{\ell_1:(!G_1,\gamma_1)} N_1$ and $M \xrightarrow{G_2:(?\ell_2, A(\ell_2))} N_2$. Then there exists N_3 such that $N_1 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} N_3$ and $N_2 \xrightarrow{\ell_1:(!G_1,\gamma_1)} N_3$.

Proof. We proceed by induction on $M \xrightarrow{\ell_1:(!G_1,\gamma_1)} N_1$. In the base case we consider $M = [m]_{\ell_1}$, $N_1 = [n_1]_{\ell_1}$ and $m \xrightarrow{(!G_1,\gamma_1)} n_1$. We distinguish two cases based on $M \xrightarrow{G_2:(?\ell_2, A(\ell_2))} N_2$:

- 1. $N_2 = [n_2]_{\ell_1}, m \xrightarrow{(?\ell_2, A(\ell_2))} n_2$, and $\ell_1 \in G_2$. Hence, we can apply Lemma D.15 to obtain that there exists m_1 such that $n_1 \xrightarrow{(?\ell_2, A(\ell_2))} m_1$ and $n_2 \xrightarrow{(!G_1, \gamma_1)} m_1$. Hence, $N_2 \xrightarrow{\ell_1:(!G_1, \gamma_1)} [m_1]_{\ell_1}$ and $N_1 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} [m_1]_{\ell_1}$.
- 2. $N_2 = [m]_{\ell_1}$ and $\ell_1 \notin G_2$ or $m \xrightarrow{(?\ell_2, A(\ell_2))}$. As $M = N_2$, we have $N_2 \xrightarrow{\ell_1:(!G_1, \gamma_1)} N_1$. Via Lemma D.13 and $m \xrightarrow{(!G_1, \gamma_1)} n_1$ we obtain that $\ell_1 \notin G_2$ or $n_1 \xrightarrow{(?\ell_2, A(\ell_2))}$. Hence, $N_1 \xrightarrow{G_2:(?\ell_2, A(\ell_2))} N_1$, which concludes the proof.

For the inductive case we consider $M = M_1 \otimes M_2$ (the case for $M = M_1 \oplus M_2$ is identical), $N_1 = O_1 \otimes O_2, M_1 \xrightarrow{\ell_1:(!G_1,\gamma_1)} O_1 \text{ and } M_2 \xrightarrow{G_1:(!\ell_1,\gamma_1)} O_2$. We deduce that $N_2 = O_3 \otimes O_4$, with $M_1 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_3$ and $M_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_4$. We use the induction hypothesis to conclude that there exists Q such that $O_1 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q$ and $O_3 \xrightarrow{\ell_1 : (!G_1, \gamma_1)} Q$. Since $M \xrightarrow{\ell_1 : (!G_1, \gamma_1)} N_1$, we know that $\gamma_1 = A(\ell_1)$ (Lemma D.14). Hence, we can apply Lemma D.22 on $M_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} O_2$ and $M_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_4$:

- 1. $O_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q'$ and $O_4 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} Q'$. Hence, $N_1 = O_1 \otimes O_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q \otimes Q'$ and $N_2 = O_3 \otimes O_4 \xrightarrow{\ell_1 : (!G_1, \gamma_1)} Q \otimes Q'$.
- 2. $O_2 = O_4$. We apply Lemma D.21 to $M_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} O_2$ and $M_2 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_4$ to conclude that $O_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} O_2$ and $O_4 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} O_4$. Hence, $N_1 = O_1 \otimes O_2 = O_1 \otimes O_4 \xrightarrow{G_2 : (?\ell_2, A(\ell_2))} Q \otimes O_4$ and $N_2 = O_3 \otimes O_4 = O_3 \otimes O_2 \xrightarrow{\ell_1 : (!G_1, \gamma_1)} Q \otimes O_2 = Q \otimes O_4$.

▶ Lemma D.25. Let $M \in \mathsf{DMon}$ be action-derived. Let $M \xrightarrow{c_1} M_1$ and $M \xrightarrow{c_2} M_2$. Then, either $M_1 \xrightarrow{c_2} N$ and $M_2 \xrightarrow{c_1} N$, or $c_1 = c_2$ and $M_1 = M_2$.

Proof. We proceed by induction on $M \xrightarrow{c_1} M_1$. Let $c_1 = \ell_1 : (!G_1, \gamma_1)$ and $c_2 = \ell_2 : (!G_2, \gamma_2)$. In the base case we consider $M = [m]_{\ell_1}$, $M_1 = [m']_{\ell_1}$ and $m \xrightarrow{(!G_1, \gamma_1)} m'$. Thus we know that $M_2 = [m'']_{\ell_1}$, $\ell_1 = \ell_2$ and $m \xrightarrow{(!G_2, \gamma_2)} m''$. We distinguish two cases:

- 1. $G_1 \neq G_2$ or $\gamma_1 \neq \gamma_2$. Then we apply Lemma D.18 to obtain that $m' \xrightarrow{(!G_2,\gamma_2)} n$ and $m'' \xrightarrow{(!G_1,\gamma_1)} n$. Hence, $M_1 \xrightarrow{c_2} [n]_{\ell_1}$ and $M_2 \xrightarrow{c_1} [n]_{\ell_1}$.
- 2. $G_1 = G_2$ and $\gamma_1 = \gamma_2$. We apply Lemma D.19 to obtain that $m' \xrightarrow{(!G_2,\gamma_2)} n$ and $m'' \xrightarrow{(!G_1,\gamma_1)} n$, or that m' = m''. In the former case we conclude similar as for the first item. In the latter case we get immediately that $M_1 = M_2$ and $c_1 = c_2$.

For the inductive case we consider $M = N_1 \otimes N_2$ (the case for $M = N_1 \oplus N_2$ is identical), $M_1 = N'_1 \otimes N'_2$, $N_1 \xrightarrow{c_1} N'_1$ and $N_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} N'_2$. We distinguish two cases.

- 1. $M_2 = O_1 \otimes O_2$, with $N_1 \xrightarrow{c_2} O_1$ and $N_2 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} O_2$. We obtain two further cases from the induction hypothesis applied to N_1 :
 - a. $N'_1 \xrightarrow{c_2} Q$ and $O_1 \xrightarrow{c_1} Q$. Since $M \xrightarrow{c_1} M_1$ and $M \xrightarrow{c_2} M_2$, we obtain via Lemma D.14 that $\gamma_1 = A(\ell_1)$ and $\gamma_2 = A(\ell_2)$. Thus we can apply Lemma D.22 to $N_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} N'_2$ and $N_2 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} O_2$ to obtain two further cases:
 - i. $N'_2 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} Q'$ and $O_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} Q'$. Hence $N'_1 \otimes N'_2 \xrightarrow{c_2} Q \otimes Q'$ and $O_1 \otimes O_2 \xrightarrow{c_1} Q \otimes Q'$, which concludes the proof.
 - ii. $N'_2 = O_2$. We obtain from Lemma D.21 that $O_2 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} O_2$ and $N'_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} N'_2$. Hence, $N'_1 \otimes N'_2 = N'_1 \otimes O_2 \xrightarrow{c_2} Q \otimes O_2$ and $O_1 \otimes O_2 = O_1 \otimes N'_2 \xrightarrow{c_1} Q \otimes N'_2 = Q \otimes O_2$.
 - **b.** $N'_1 = O_1$ and $c_1 = c_2$. Since $c_1 = c_2$, we obtain from Lemma D.23 that $N'_2 = O_2$. Hence, $M_1 = M_2$ and we can conclude.
- 2. $M_2 = O_1 \otimes O_2$, with $N_1 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} O_1$ and $N_2 \xrightarrow{c_2} O_2$. Via Lemma D.24 (applied twice, to N_1 and N_2 , which we can do because, like before, $\gamma_1 = A(\ell_1)$ and $\gamma_2 = A(\ell_2)$) we obtain that $N'_1 \xrightarrow{G_2 : (?\ell_2, \gamma_2)} Q$ and $O_1 \xrightarrow{c_1} Q$, and $N'_2 \xrightarrow{c_2} Q'$ and $O_2 \xrightarrow{G_1 : (?\ell_1, \gamma_1)} Q'$. Hence, $N'_1 \otimes N'_2 \xrightarrow{c_2} Q \otimes Q'$ and $O_1 \otimes O_2 \xrightarrow{c_1} Q \otimes Q'$, which concludes the proof.
- ▶ Lemma D.26. If $DM_{\sigma}(\varphi) \xrightarrow{A} M \to M' \to N \xrightarrow{c}$ for all c and $M' \xrightarrow{c} M''$, then $M'' \to N$.

Proof. We proceed by induction on the length of $M' \to N$. In the base case we consider M' = N. As N cannot send messages, we then also have M' = M'', and the desired result follows. In the inductive step we consider $M' \xrightarrow{c'} M_1 \to N$. Let $c = \ell : (!G, \gamma)$ and $c' = \ell' : (!G', \gamma')$. Via Lemma D.25 we obtain that there exists N' such that $M_1 \xrightarrow{c} N'$ and $M'' \xrightarrow{c'} N'$ or $M'' = M_1$. In the latter case we can conclude immediately because $M_1 \to N$. In the former case we use the induction hypothesis to obtain that $N' \to N$ from which we can conclude because $M'' \xrightarrow{c'} N'$.

▶ Lemma D.27. If $DM_{\sigma}(\varphi) \xrightarrow{A} M \to M' \to N \xrightarrow{c}$ for all c and $M' \to M''$, then $M'' \to N$.

Proof. We proceed by induction on the length of $M' \to M''$. If the length is 0, then M' = M'' and we are done immediately. Otherwise we consider $M' \xrightarrow{c} M_1 \to M''$ with $c = \ell : (!G, \gamma)$. Via Lemma D.26 we conclude that $M_1 \to N$. From the induction hypothesis we then obtain that $M'' \to N$.

Lemma D.27 is used in the proof of Bounded Communication and Formula Convergence.

The next three lemmas are used to prove Lemma D.47, Lemma D.35, Lemma D.36 and Lemma D.56. They describe 'correct' communication paths of local monitors, where 'correct' means that the local monitors only take receiving transitions that correspond to messages containing the last action of the sender. Lemma D.28 shows that in correct communication paths, the order of communication does not matter for the final destination (when no sending and receiving can take place). Lemma D.29 is a direct generalization of Lemma D.28, and is the equivalent of Lemma D.27 on the level of local monitors. Lemma D.30 is used to show those correct communication paths can be combined when multiple local monitors are put in parallel, which is used in Lemma D.47 and Lemma D.56.

We first define formally what is such a correct communication path. Let $m \Rightarrow_A m'$ denote the existence of an integer h > 0 and of h monitors m_1, \ldots, m_h and communication actions c_1, \ldots, c_{h-1} such that $m_1 = m$, $m_h = m'$, $m_i \xrightarrow{c_i} m_{i+1}$ for every $i = 1, \ldots, h-1$ and if $c_i = (?\ell, \gamma)$, then $\gamma = A(\ell)$. Hence, \Rightarrow_A is the same as \rightarrow but with the extra constraint on actions of kind $(?\ell, \gamma)$.

▶ **Lemma D.28.** Let *m* be a relevant local monitor and $m \Rightarrow_A m' \xrightarrow{q}$ for all *c*. Let $m \xrightarrow{(?\ell', A(\ell'))} n$ for some $\ell' \in \mathcal{L}$ or $m \xrightarrow{(!G, \gamma)} n$ for some $G \subseteq \mathcal{L}$. Then $n \Rightarrow_A m'$.

Proof. Let $m \Rightarrow_A m'$ in h steps. We proceed by induction on h. In the base case we consider m = m', and as m' cannot communicate, the premise of the lemma is not satisfied. Now suppose that $m \stackrel{c_1}{\longrightarrow} m_1 \Rightarrow_A m'$ with $c_1 = (!G, \gamma)$ or $c_1 = (?\ell'', A(\ell'))$ for some $\ell'' \in \mathcal{L}$, and $m \stackrel{(?\ell', A(\ell'))}{\longrightarrow} n$. We distinguish two cases, depending on the form of c_1 :

- 1. $c_1 = (!G, \gamma)$. We use Lemma D.15 to obtain that $m_1 \xrightarrow{(?\ell', A(\ell'))} z$ and $n \xrightarrow{c_1} z$. Hence, $m_1 \Rightarrow_A m'$ in h-1 steps, and $m_1 \xrightarrow{(?\ell', A(\ell'))} z$. We apply the induction hypothesis to obtain that $z \Rightarrow_A m'$, from which we can conclude because $n \xrightarrow{c_1} z$.
- 2. $c_1 = (?\ell'', A(\ell''))$ for some $\ell'' \in \mathcal{L}$. Via Lemma D.17, we get that either $m_1 \xrightarrow{(?\ell', A(\ell'))} z$ and $n \xrightarrow{c_1} z$, in which case we proceed in the same way as in the previous case, or we get that $\ell' = \ell''$. In the latter case, we use Lemma D.16 to derive that $m_1 = n$, in which case we can conclude because $m_1 \Rightarrow_A m'$.

Now we consider $m \xrightarrow{c_1} m_1 \Rightarrow_A m'$ with $c_1 = (!G', \gamma')$ or $c_1 = (?\ell'', A(\ell''))$ for some $\ell'' \in \mathcal{L}$, and $m \xrightarrow{(!G,\gamma)} n$. We again distinguish two cases:

XX:40 Centralized vs Decentralized Monitors for Hyperproperties

- 1. $c_1 = (!G', \gamma')$. If $G \neq G'$ or $\gamma \neq \gamma'$, then we use Lemma D.18 to obtain that $m_1 \xrightarrow{(!G,\gamma)} z$ and $n \xrightarrow{c_1} z$. Hence, $m_1 \Rightarrow_A m'$ in h - 1 steps, and $m_1 \xrightarrow{(!G,\gamma)} z$. We apply the induction hypothesis to obtain that $z \Rightarrow_A m'$, from which we can conclude because $n \xrightarrow{c_1} z$. If G = G' and $\gamma = \gamma'$, we obtain from Lemma D.19 that $m_1 = n$, in which case we can conclude, or that $m_1 \xrightarrow{(!G,\gamma)} z$ and $n \xrightarrow{(!G,\gamma)} z$ and we can proceed as before.
- **2.** $c_1 = (?\ell'', A(\ell''))$ for some $\ell'' \in \mathcal{L}$. Via Lemma D.15, we get that $m_1 \xrightarrow{(!G,\gamma)} z$ and $n \xrightarrow{c_1} z$; we then proceed in the same way as in the previous case.

We can extend the previous lemma to a more general statement:

▶ Lemma D.29. Let *m* be a relevant local monitor, $m \Rightarrow_A m' \xrightarrow{c}{\not\rightarrow}$ for all *c* and $m \Rightarrow_A n$. Then $n \Rightarrow_A m'$.

Proof. Let $m \Rightarrow_A n$ in h steps. We prove the lemma by induction on h. In the base case we consider n = m, in which case we are done immediately. For the inductive step, we consider $m \xrightarrow{c_1} z \Rightarrow_A n$ for $c_1 = (!G, \gamma)$ or $c_1 = (?\ell', A(\ell'))$, where $z \Rightarrow_A n$ in h-1 steps. Via Lemma D.28, we can conclude that $z \Rightarrow_A m'$. From the induction hypothesis we conclude that $n \Rightarrow_A m'$.

▶ Lemma D.30. Let m_1^1 and m_1^2 be relevant local monitors, $m_1^1 \Rightarrow_A n_1 \xrightarrow{c}{\not\rightarrow}$ for all c, and $m_1^2 \Rightarrow_A n_2 \xrightarrow{c}{\not\rightarrow}$. Then $m_1^1 \otimes m_1^2 \Rightarrow_A n_1 \otimes n_2$ and $m_2^1 \oplus m_2^2 \Rightarrow_A n_1 \oplus n_2$.

Proof. The proof is identical for \oplus and \otimes , so we just treat the former case. Let $m_1^1 \Rightarrow_A n_1$ in h steps. We proceed by induction on h. In the base case we have $m_1^1 = n_1$. Since n_1 cannot communicate, we get that $m_1^1 \oplus m_1^2 \Rightarrow_A m_1^1 \oplus n_2 = n_1 \oplus n_2$.

In the inductive step we consider $m_1^1 \xrightarrow{c_1} x_1 \Rightarrow_A n_1$ with $c_1 = (!G, \gamma)$ or $c_1 = (?\ell', A(\ell'))$ for some $\ell' \in \mathcal{L}$. We distinguish three cases.

- 1. If $c_1 = (!G, \gamma)$, then $m_1^1 \oplus m_1^2 \xrightarrow{c_1} x_1 \oplus m_1^2$. We obtain from the induction hypothesis that $x_1 \oplus m_1^2 \Rightarrow_A n_1 \oplus n_2$, which concludes the proof.
- **2.** $c_1 = (?\ell', A(\ell'))$ and $m_1^2 \xrightarrow{(?\ell', A(\ell'))}$. In this case $m_1^1 \oplus m_1^2 \xrightarrow{c_1} x_1 \oplus m_1^2$, and we continue as in the previous case.
- **3.** $c_1 = (?\ell', A(\ell'))$ and $m_1^2 \xrightarrow{c_1} x_2$. Thus we have $m_1^2 \Rightarrow_A n_2$ and $m_1^2 \xrightarrow{(?\ell', A(\ell'))} x_2$, which means we can apply Lemma D.28 to conclude that $x_2 \Rightarrow_A n_2$. We can then apply the induction hypothesis to conclude that $x_1 \oplus x_2 \Rightarrow_A n_1 \oplus n_2$. Together with $m_1^1 \oplus m_1^2 \xrightarrow{c_1} x_1 \oplus x_2$, this concludes the proof.

The following lemma shows that for every receiving transition in a monitor m that is reached from a monitor synthesized from some $\psi \in Qf$, there exists a corresponding sending transition in another local monitor reached from a synthesized local monitor for ψ located at a different location.

▶ Lemma D.31. Let $Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m \rightarrow m_1$ and $m_1 \xrightarrow{(?\ell',\gamma)} m'$. Then $\ell' \in rng(\sigma)$, $\ell' \neq \ell$, and there are n, n' and G' such that $Dm_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} n \xrightarrow{(!G',A(\ell'))} n'$ and $\ell \in G'$.

Proof. We proceed by induction on $\xrightarrow{A(\ell)}$. In case $Dm_{\sigma}^{\ell}(\psi) = v$, the premise of the lemma is never satisfied. We do not consider the case where $Dm_{\sigma}^{\ell}(\psi) = a.m$, as this cannot occur in the synthesis function (because of our assumption that $|Act| \geq 2$).

For the first inductive case we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = x_1 + x_2 \xrightarrow{A(\ell)} m$, because $x_1 \xrightarrow{A(\ell)} m$ or $x_2 \xrightarrow{A(\ell)} m$. Hence, $\psi = [a_{\pi}]\psi'$. As $m_1 \xrightarrow{(?\ell',\gamma)} m'$, we know that $\sigma(\pi) = \ell' \neq \ell$. Thus, from the synthesis function, we immediately have that $\ell' \in \operatorname{rng}(\sigma)$ and $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} n$ such that $n \xrightarrow{(!G',A(\ell'))} n'$ with $\ell \in G'$.

Next we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = x_1 \otimes x_2 \xrightarrow{A(\ell)} y_1 \otimes y_2 \rightarrow z_1 \otimes z_2$ because $x_1 \xrightarrow{A(\ell)} y_1$ and $x_2 \xrightarrow{A(\ell)} y_2$. From the synthesis function we know that $x_1 = Dm_{\sigma}^{\ell}(\psi_1)$ and $x_2 = Dm_{\sigma}^{\ell}(\psi_2)$ for formulas ψ_1, ψ_2 such that $\psi = \psi_1 \land \psi_2$. We also know $y_1 \rightarrow z_1$ and $y_2 \rightarrow z_2$. If $z_1 \otimes z_2 \xrightarrow{(?\ell',\gamma)} m'$, then either $m' = w_1 \otimes w_2$ for $z_1 \xrightarrow{(?\ell',\gamma)} w_1$ and $z_2 \xrightarrow{(?\ell',\gamma)} w_2$ or w.l.o.g. $m' = w_1 \otimes z_2$ for $z_1 \xrightarrow{(?\ell',\gamma)} w_1$ and $z_2 \xrightarrow{(?\ell',\gamma)}$. In the first case we obtain from the induction hypothesis that $\ell' \in \operatorname{rng}(\sigma)$ such that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi_1) \xrightarrow{A(\ell')} o_1, o_1 \xrightarrow{(!G'_1, A(\ell'))} o'_1 \text{ and } \ell \in G'_1 \text{ and } \operatorname{Dm}_{\sigma}^{\ell'}(\psi_2) \xrightarrow{A(\ell')} o_2,$ $o_2 \xrightarrow{(!G'_2, A(\ell'))} o'_2 \text{ and } \ell \in G'_2.$ Hence, $\operatorname{Dm}^{\ell'}_{\sigma}(\psi_1 \wedge \psi_2) = \operatorname{Dm}^{\ell'}_{\sigma}(\psi_1) \otimes \operatorname{Dm}^{\ell'}_{\sigma}(\psi_2) \xrightarrow{A(\ell')} o_1 \otimes o_2$ and $o_1 \otimes o_2 \xrightarrow{(!G'_1, A(\ell'))} o'_1 \otimes o_2$ with $\ell \in G'_1$, which concludes the proof.

In the second case we obtain from the induction hypothesis that $\ell' \in \operatorname{rng}(\sigma)$ such that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi_1) \xrightarrow{A(\ell')} o, o \xrightarrow{(!G',A(\ell'))} o'$ and $\ell \in G'$. It is immediate from the synthesis function that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi_2) \xrightarrow{A(\ell')} o_2$ for some monitor o_2 . Thus we have $\operatorname{Dm}_{\sigma}^{\ell'}(\psi_1 \wedge \psi_2) =$ $\operatorname{Dm}_{\sigma}^{\ell'}(\psi_1) \otimes \operatorname{Dm}_{\sigma}^{\ell'}(\psi_2) \xrightarrow{A(\ell')} o \otimes o_2 \text{ and } o \otimes o_2 \xrightarrow{(!G',A(\ell'))} o' \otimes o_2 \text{ with } \ell \in G', \text{ which concludes}$ the proof.

The case for $m_1 \oplus m_2 \xrightarrow{A(\ell)} n_1 \oplus n_2$ is similar.

Last we consider $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{rec} x.x_1 \xrightarrow{A(\ell)} m$ because $x_1\{\operatorname{rec} x.x_1/x\} \xrightarrow{A(\ell)} m$. Thus we obtain that $\psi = \max x.\psi'$ and $x_1 = \operatorname{Dm}_{\sigma}^{\ell}(\psi')$. As $\operatorname{Dm}_{\sigma}^{\ell}(\psi')\{\operatorname{rec} x.\operatorname{Dm}_{\sigma}^{\ell}(\psi')/x\} =$ $Dm_{\sigma}^{\ell}(\psi'\{\max x.\psi'/x\})$ (Lemma D.2), we use the induction hypothesis to obtain that $\ell' \in \operatorname{rng}(\sigma)$ such that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi'\{\max x.\psi'/x\}) \xrightarrow{A(\ell')} n, n \xrightarrow{(!G',A(\ell'))} n'$ and $\ell \in G'$. Via $\operatorname{Dm}_{\sigma}^{\ell'}(\psi)\{\operatorname{rec} x.\operatorname{Dm}_{\sigma}^{\ell'}(\psi)/x\} = \operatorname{Dm}_{\sigma}^{\ell'}(\psi'\{\operatorname{max} x.\psi'/x\})$ we get that $\operatorname{Dm}_{\sigma}^{\ell'}(\operatorname{max} x.\psi') =$ rec $x.\mathrm{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} n$, which concludes the proof.

The next lemma is only used to prove Lemma D.33. It captures that a communicating monitor never makes a choice between a send and a receive, so if M_1 (in the lemma below) can send with some transition c, and reach M_2 , it cannot have reached M_2 by receiving some message (intuitively because the send from c is still present if M_1 takes a receiving transition, and it is not present in M_2). Instead, if a monitor can both send and receive, this must be because multiple monitors are connected in parallel, either locally with \otimes/\oplus or as communicating monitors via \vee / \wedge .

Lemma D.32. Let m_1 , M_1 be action-derived monitors.

- 1. If $m_1 \xrightarrow{(!G,\gamma)} m_2$ and $m_1 \xrightarrow{(?G,\gamma)} m_3$, then $m_2 \neq m_3$. 2. If $M_1 \xrightarrow{\ell:(!G,\gamma)} M_2$ and $M_1 \xrightarrow{G:(?\ell,\gamma)} M_3$, then $M_2 \neq M_3$.

Proof. We define a function *cc* from relevant (local) monitors to natural numbers recursively, for arbitrary σ, ℓ, ψ :

- $\quad = \quad cc(\mathrm{Dm}^{\ell}_{\sigma}(\psi)) = cc(\sum_{a \in \mathsf{Act}}(?\{\ell'\}, a).\mathrm{Dm}^{\ell}_{\sigma}(\psi_a)) = 0;$
- $cc((!G, a).Dm_{\sigma}^{\ell}(\psi)) = 1;$
- $cc(m_1 \odot m_2) = cc(m_1) + cc(m_2)$, where \odot denotes either \oplus or \otimes ;
- $cc([m]_{\ell}) = cc(m);$ and
- $cc(M \diamond N) = cc(M) + cc(N)$, where \diamond denotes either \land or \lor .

We prove that, if $m_1 \xrightarrow{(!G,\gamma)} m_2$, then $cc(m_2) < cc(m_1)$. We prove this result for relevant local monitors, which is sufficient because m_1 is a relevant local monitor via

XX:42 Centralized vs Decentralized Monitors for Hyperproperties

Lemma D.12. We proceed by induction on m_1 . The base case $m_1 = (!G, \gamma).\mathrm{Dm}_{\sigma}^{\ell}(\psi)$ entails that $m_2 = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$, and thus $cc(m_2) = 0 < 1 = cc((!G, \gamma).\mathrm{Dm}_{\sigma}^{\ell}(\psi))$. If $m_1 = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ or $m_1 = \sum_{a \in \mathsf{Act}} (?\{\ell'\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi_a)$, then $m_1 \xrightarrow{(!G,\gamma)} m_2$ does not hold (via Lemma D.8 for $m_1 = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$).

If $m_1 = m \odot m'$ with m, m' relevant monitors, the result follows immediately from the definition of cc and the inductive hypothesis.

To complete the proof of the first statement, we now prove that, if $m_1 \xrightarrow{(?G,\gamma)} m_3$, then $cc(m_1) = cc(m_3)$, again by induction on the structure of m_1 as a relevant monitor. The base cases $m_1 = (!G, \gamma).\mathrm{Dm}_{\sigma}^{\ell}(\psi)$ and $m_1 = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$ entail that $m_1 \xrightarrow{(?G,\gamma)} m_3$ does not hold. If $m_1 = \sum_{a \in \mathsf{Act}} (?\{\ell'\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi_a)$, then, $m_3 = \mathrm{Dm}_{\sigma}^{\ell}(\psi_a)$ for some ψ_a , and therefore $cc(m_1) = cc(m_3) = 0$. The cases for $m_1 = m \odot m'$ are straightforward from the inductive hypothesis.

For the second statement, we first prove that, if $M_1 \xrightarrow{G: (?\ell, \gamma)} M_3$, then $cc(M_1) = cc(M_3)$. The proof is by straightforward induction on $M_1 \xrightarrow{G: (?\ell, \gamma)} M_3$, using the fact that $cc(m_1) = cc(m_3)$, if $m_1 \xrightarrow{(?G, \gamma)} m_3$, which we proved above. Then, it suffices to prove that $cc(M_1) > cc(M_2)$ when $M_1 \xrightarrow{\ell: (!G, \gamma)} M_2$, which can be done by straightforward induction on $M_1 \xrightarrow{\ell: (!G, \gamma)} M_2$.

From the previous lemma we can then conclude that if M_1 reaches M_2 by a sending transition, and we combine M_1 with another monitor N_1 that transitions to M_2 composed with N_2 , N_1 must have taken a receiving step. This is useful for Lemma D.41 and Lemma D.35, which are in turn used to prove Lemma D.46, Lemma D.47 and Lemma D.57.

▶ Lemma D.33. Let M_1 be action-derived, $M_1 \xrightarrow{\ell:(!G,\gamma)} M_2$ and $M_1 \diamond N_1 \xrightarrow{\ell:(!G,\gamma)} M_2 \diamond N_2$. Then, $N_1 \xrightarrow{G:(?\ell,\gamma)} N_2$.

Proof. From the semantics and $M_1 \diamond N_1 \xrightarrow{\ell:(!G,\gamma)} M_2 \diamond N_2$, we obtain that $M_1 \xrightarrow{\ell:(!G,\gamma)} M_2$ and $N_1 \xrightarrow{G:(?\ell,\gamma)} N_2$, or $N_1 \xrightarrow{\ell:(!G,\gamma)} N_2$ and $M_1 \xrightarrow{G:(?\ell,\gamma)} M_2$. In the first case we are done with the proof immediately. In the second case we derive a contradiction from Lemma D.32: $M_1 \xrightarrow{\ell:(!G,\gamma)} M_2$ and $M_1 \xrightarrow{G:(?\ell,\gamma)} M_2$. Hence, $N_1 \xrightarrow{G:(?\ell,\gamma)} N_2$.

This lemma states that action transitions are deterministic for synthesized monitors, and is used in the proof of Lemma D.35.

▶ Lemma D.34. If $Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m$ and $Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} n$, then m = n.

Proof. We proceed by induction on $\xrightarrow{A(\ell)}$. The interesting cases are the inductive ones. We first treat both inductive cases of the sum. If $\text{Dm}_{\sigma}^{\ell}(\psi) = m_1 + m_2 \xrightarrow{A(\ell)} m$, $\psi = [a_{\pi}]\psi'$ for some a, π and ψ' . As there is only one possible transition for each $a \in \text{Act}$, we have obtained the required result.

If $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{rec} x.m_1 \xrightarrow{A(\ell)} m$ because $m_1\{\operatorname{rec} x.m_1/x\} \xrightarrow{A(\ell)} m$, we know that $m_1 = \operatorname{Dm}_{\sigma}^{\ell}(\psi')$ and $\psi = \max x.\psi'$, and $m_1\{\operatorname{rec} x.m_1/x\} \xrightarrow{A(\ell)} n$. We use Lemma D.2 to conclude that $m_1\{\operatorname{rec} x.m_1/x\} = \operatorname{Dm}_{\sigma}^{\ell}(\psi'\{\psi/x\})\sigma$ (note that the free location-variables of ψ are not bound in ψ'). Thus we can use the induction hypothesis to know that m = n.

If $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = m_1 \odot m_2 \xrightarrow{A(\ell)} m_3 \odot m_4 = m$, we know from the synthesis definition that either $\psi = \psi_1 \land \psi_2$ or $\psi = \psi_1 \lor \psi_2$ for some ψ_1 and ψ_2 such that $m_1 = \operatorname{Dm}_{\sigma}^{\ell}(\psi_1)$ and $m_2 \text{Dm}^{\ell}_{\sigma}(\psi_2)$. Hence, $\text{Dm}^{\ell}_{\sigma}(\psi_1) \xrightarrow{A(\ell)} m_3$ and $\text{Dm}^{\ell}_{\sigma}(\psi_2) \xrightarrow{A(\ell)} m_4$. Similarly, we know that $n = n_1 \odot n_2$ for some n_1, n_2 , and $\operatorname{Dm}^{\ell}_{\sigma}(\psi_1) \xrightarrow{A(\ell)} n_1$ and $\operatorname{Dm}^{\ell}_{\sigma}(\psi_2) \xrightarrow{A(\ell)} n_2$. We use the induction hypothesis to conclude that $m_3 = n_1$ and $m_4 = n_2$, from which we derive that m = n.

In what follows we need to specify a condition on a group of local monitors who all take some 'correct' set of communication transitions (correct as in following the restrictions in \Rightarrow_A). This condition is used in later proofs, and it states that the reached states in the group of local monitors will no longer take receiving transitions that match a sending transition that occured on one of the local communication paths. Let $\ell_1, \ldots, \ell_k \in \mathcal{L}$ and $m_1,\ldots,m_k,n_1,\ldots,n_k$ be monitors. We write $m_i \stackrel{\ell_i}{\xrightarrow{}}_{i=1}^k n_i$ if, for every $i \leq k$, there exists

an integer $h_i > 0$ and h_i monitors $m_i^1, \ldots, m_i^{h_i}$ such that $m_i = m_i^1, m_i^{h_i} = n_i, m_i^j \xrightarrow{c_i^j} m_i^{j+1}$ for every $j = 1, \ldots, h_i - 1$ and

- 1. if $c_i^j = (?\ell, \gamma)$ for some γ and ℓ , then $\gamma = A(\ell)$; 2. if $c_i^j = (!G, \gamma)$ for some $i \leq k, j \leq h_i, G$ and γ , then, for every $i' \neq i, \ell_{i'} \in G$ implies that $n_{i'} \xrightarrow{(?\ell_i,\gamma)}$

Essentially, $m_i \stackrel{\ell_i}{\xrightarrow{}} _{i=1}^k n_i$ amounts to saying that, for every $i \leq k, m_i \Rightarrow_A n_i$ plus condition 2 above

The next lemma is used in the proof of Lemma D.36. It proves that local monitors that 'accidentally' receive messages from another local monitor's communication transitions are such that they cannot take any more receiving transitions matching those accidental messages. This captures the intuition that a local monitor always takes all receiving transitions that match a message at once, and no new receiving transitions appear for a local monitor when it is taking a chain of consecutive communication transitions.

Important in the proof is Lemma D.31: in \Rightarrow_A local monitors can send and receive freely, but in \rightarrow between decentralized monitors, communication is always initiated by a sender. Therefore, all receiving transitions that need to happen, need to be initiated by some sending transition.

▶ Lemma D.35. Let $Dm^{\ell}_{\sigma}(\psi) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_A n_{\ell} \Rightarrow_A y_{\ell}$ and y_{ℓ} cannot communicate for all $\ell \in \operatorname{rng}(\sigma) = \{1, \dots, k\}$ such that $m_{\ell} \stackrel{\ell}{\Rightarrow}_{\ell=1}^{k} n_{\ell}$. Then, for some $\ell \in \{1, \dots, k\}$, there exist q_1, \ldots, q_k , such that $\bigvee_{\ell'=1}^k [n_{\ell'}]_{\ell'} \to \bigvee_{\ell'=1}^k [q_{\ell'}]_{\ell'}$, $n_{\ell'} \stackrel{\ell'}{\to} \sum_{\ell'=1}^k q_{\ell'}$, and $q_\ell = y_\ell$.

Proof. Let $n_{\ell} \Rightarrow_A y_{\ell}$ in h_{ℓ} steps. We proceed by induction h_{ℓ} . In the base case, we consider $n_{\ell} = y_{\ell}$. Then we have $\bigvee_{\ell'=1}^k [n_{\ell'}]_{\ell'} = \bigvee_{\ell'=1}^k [q_{\ell'}]_{\ell'}$, where $n_{\ell'} \stackrel{\ell'}{\xrightarrow{k}}_{\ell'=1}^k q_{\ell'}$ and $q_{\ell} = y_{\ell}$, and the lemma follows.

In the inductive step we consider the cases where $n_{\ell} \xrightarrow{c_1} w_{\ell} \Rightarrow_A y_{\ell}$ with $c_1 = (!G, \gamma)$ or $c_1 = (?\ell_1, A(\ell_1))$ for some $\ell_1 \in \mathcal{L}$:

1. Case $c_1 = (!G, \gamma)$: In this case, without loss of generality, we assume that $\ell = k$. Then, $\bigvee_{\ell'=1}^{k} [n_{\ell'}]_{\ell'} = \bigvee_{\ell'=1}^{k-1} [n_{\ell'}]_{\ell'} \vee [n_{\ell}]_{\ell} \xrightarrow{\ell:(!G,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell}]_{\ell}, \text{ where } \bigvee_{\ell'=1}^{k-1} [n_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [n_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [n_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \vee [w_{\ell'}]_{\ell'} \text{ where } \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(?\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(\ell,\gamma)} \bigvee_{\ell'=1}^{k-1} [w_{\ell'}]_{\ell'} \xrightarrow{G:(\ell,\gamma)} (w_{\ell'}]_{\ell'} \xrightarrow{G:(\ell,\gamma)} (w_{\ell'}]_{\ell$

We now argue that $m_{\ell'} \stackrel{\ell'}{\Rightarrow}_{\ell'=1}^k w_{\ell'}$. For each $\ell' \in \operatorname{rng}(\sigma)$, we have $m_{\ell'} \Rightarrow_A n_{\ell'}$, and we assume in $g_{\ell'}$ steps. Then, via Lemma D.13, we know that $\gamma = A(\ell)$, and thus for $\ell' \neq \ell$ we obtain via Lemma D.20 that $n_{\ell'} \xrightarrow{(?\ell, A(\ell))} w_{\ell'}$ or $n_{\ell'} = w_{\ell'}$. From this we conclude that $m_{\ell'} \Rightarrow_A w_{\ell'}$ for each $\ell' \in \operatorname{rng}(\sigma)$ in $f_{\ell'} = g_{\ell'}$ or $f_{\ell'} = g_{\ell'} + 1$ steps; and if

XX:44 Centralized vs Decentralized Monitors for Hyperproperties

$$\begin{split} f_{\ell'} &= g_{\ell'} + 1, \text{ then } c_{\ell'}^{g_{\ell'}+1} = (?\ell, A(\ell)) \text{ if } \ell' \neq \ell \text{ and } c_{\ell'}^{g_{\ell'}+1} = c_1 \text{ otherwise. For the second condition of } m_{\ell'} \frac{\ell'}{A} k_{\ell'=1}^k w_{\ell'}, \text{ let } \ell' \leq k \text{ such that } m_{\ell'} \Rightarrow_A w_{\ell'} \text{ in } f_{\ell'} \text{ steps, let } i \leq f_{\ell'} \text{ and } c_{\ell'}^i = (!G', \gamma'). \text{ Now take some } \ell'' \in G' \cap \operatorname{rng}(\sigma) \text{ with } \ell'' \neq \ell', \text{ and we have to show that } w_{\ell''} \xrightarrow{(?\ell', \gamma')}. \text{ If } i \leq g_{\ell'}, \text{ then we know immediately that } n_{\ell''} \xrightarrow{(?\ell', \gamma')} \text{ from } m_{\ell'} \frac{\ell'}{A} k_{\ell'=1}^k n_{\ell'}. \end{split}$$
Via Lemma D.13, we can conclude that $w_{\ell''} \xrightarrow{(?\ell', \gamma')}. \text{ If } i = g_{\ell'} + 1, \text{ then we have reasoned above that } \ell' = \ell, G' = G \text{ and } \gamma' = \gamma. \text{ Furthermore, we know that } n_{\ell''} \xrightarrow{(?\ell', \gamma)} w_{\ell''}, \text{ or } n_{\ell''} = w_{\ell''} \text{ and } n_{\ell''} \xrightarrow{(?\ell', \gamma)}. \text{ In both cases we derive (via Lemma D.13) that } w_{\ell''} \xrightarrow{(?\ell', \gamma)}. \text{ Therefore, we conclude that } m_{\ell'} \frac{\ell'}{A} k_{\ell'=1}^k w_{\ell'}. \end{split}$

We have for all $\ell' \in \operatorname{rng}(\sigma)$ that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} m_{\ell'} \Rightarrow_A w_{\ell'} \Rightarrow_A y_{\ell'}$ because of Lemma D.28. Since $m_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} w_{\ell'}$, we can apply the induction hypothesis to obtain that $\bigvee_{\ell'=1}^{k} [w_{\ell'}]_{\ell'} \rightarrow \bigvee_{\ell'=1}^{k} [q_{\ell'}]_{\ell'}$ with $w_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} q_{\ell'}$ and $q_{\ell} = y_{\ell}$. Then we can show that $n_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} q_{\ell'}$ for $q_{\ell} = y_{\ell}$: $m_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} w_{\ell'}$ and $w_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} q_{\ell'}$ immediately yield the first condition for $n_{\ell'} \xrightarrow{\ell'}_{A} \stackrel{k'}{\ell'=1} q_{\ell'}$; and they yield the second condition by using Lemma D.13.

2. Case $c_1 = (?\ell_1, A(\ell_1))$: We obtain from Lemma D.31 that $\ell \neq \ell_1 \in \operatorname{rng}(\sigma)$ and $\operatorname{Dm}_{\sigma}^{\ell_1}(\psi) \xrightarrow{A(\ell_1)} x_{\ell_1} \xrightarrow{(!G', A(\ell_1))} z_{\ell_1}$ for some $G' \subseteq \mathcal{L}$, where $\ell \in G'$. From Lemma D.34, $x_{\ell_1} = m_{\ell_1}$. As $m_{\ell'} \xrightarrow{\ell'}_{A} \underset{\ell'=1}{\overset{k}{\to}} n_{\ell'}, m_{\ell_1} \Rightarrow_A n_{\ell_1}$ with the same transitions, and by Lemma D.18 and Lemma D.15, we obtain that $n_{\ell_1} \xrightarrow{(!G', A(\ell_1))} w_{\ell_1}$ if $m_{\ell_1} \Rightarrow_A n_{\ell_1}$ does not include any transitions labeled by $(!G', A(\ell_1))$. If such a transition does exist, from $m_{\ell'} \xrightarrow{\ell'}_{A} \underset{\ell'=1}{\overset{k}{\to}} n_{\ell'}$, we get that $n_{\ell'} \xrightarrow{(?\ell_1, A(\ell_1))}$ for all $\ell' \neq \ell_1$ and $\ell' \in \operatorname{rng}(\sigma) \cap G'$. This is a contradiction with $n_{\ell} \xrightarrow{c_1} w_{\ell}$ (note that $\ell \in G'$). Hence, we have $n_{\ell_1} \xrightarrow{(!G', A(\ell_1))} w_{\ell_1}$. We derive

$$\bigvee_{\ell' \in \operatorname{rng}(\sigma) \setminus \{\ell, \ell_1\}} [n_{\ell'}]_{\ell'} \vee [n_\ell]_\ell \vee [n_{\ell_1}]_{\ell_1} \xrightarrow{\ell_1: (!G', A(\ell_1))} \bigvee_{\ell' \in \operatorname{rng}(\sigma) \setminus \{\ell, \ell_1\}} [w_{\ell'}]_{\ell'} \vee [w_\ell]_\ell \vee [w_{\ell_1}]_{\ell_1},$$

where

$$\bigvee_{\ell' \in \mathsf{rng}(\sigma) \setminus \{\ell_1\}} [n_{\ell'}]_{\ell'} \xrightarrow{G' : (?\ell_1, A(\ell_1))} \bigvee_{\ell' \in \mathsf{rng}(\sigma) \setminus \{\ell_1\}} [w_{\ell'}]_{\ell}$$

via Lemma D.33. We can now argue that $m_{\ell'} \stackrel{\ell'}{\xrightarrow{A}} _{\ell'=1}^k w_{\ell'}$ in a similar manner as above. As $w_{\ell'} \Rightarrow_A y_{\ell'}$ for all $\ell' \in \operatorname{rng}(\sigma)$ via Lemma D.29, we can apply the induction hypothesis to obtain

$$\bigvee_{\ell' \in \mathsf{rng}(\sigma) \setminus \{\ell, \ell_1\}} [w_{\ell'}]_{\ell'} \vee [w_{\ell}]_{\ell} \vee [w_{\ell_1}]_{\ell_1} \to \bigvee_{\ell' \in \mathsf{rng}(\sigma) \setminus \{\ell\}} [q_{\ell'}]_{\ell'} \vee [y_{\ell}]_{\ell}$$

with $w_{\ell'} \stackrel{\ell'}{\xrightarrow{k}}{}_{\ell'=1}^k q_{\ell'}$. Lastly we can argue that $n_{\ell'} \stackrel{\ell'}{\xrightarrow{k}}{}_{\ell'=1}^k q_{\ell'}$ in a similar manner as before.

The next lemma is important for Lemma D.47 and Lemma D.57 (part of the lemmas for Formula Convergence). It is actually stronger than what is needed for Lemma D.47, as we just need that $\bigvee_{\ell \in \mathsf{rng}(\sigma)} [n_\ell]_\ell$ (in the lemma below) transitions to some monitor that cannot comunicate, and it does not exactly need to be $\bigvee_{\ell \in \mathsf{rng}(\sigma)} [y_\ell]_\ell$. However, that is needed for

Lemma D.57, so we present the stronger statement already here. The lemma shows that local monitors can be combined and, even if their communications 'accidentally' influence one another, the same final state (where no communication can take place) is reached. It also shows another important property: in \Rightarrow_A local monitors can send and receive freely, but in \rightarrow between decentralized monitors, communication is always initiated by a sender. This lemma captures that all the receiving transitions a local monitor can do before it reaches a state that cannot communicate, are triggered by sending actions present in other local monitors located at locations found in the range of σ .

▶ Lemma D.36. Let
$$Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_{A} n_{\ell} \Rightarrow_{A} y_{\ell}$$
 and y_{ℓ} cannot communicate for all $\ell \in rng(\sigma) = \{1, \ldots, k\}$ such that $m_{i} \stackrel{i}{\Rightarrow}_{k=1}^{k} n_{i}$. Then $\bigvee_{\ell \in rng(\sigma)} [n_{\ell}]_{\ell} \rightarrow \bigvee_{\ell \in rng(\sigma)} [y_{\ell}]_{\ell}$.

Proof. We proceed by induction on the size of the range of σ . If the range is empty, the result is trivial. In the inductive step, we pick some $1 \in \operatorname{rng}(\sigma)$. Via Lemma D.35 we obtain that $\bigvee_{\ell \in \operatorname{rng}(\sigma)} [n_\ell]_\ell \to \bigvee_{\ell \in \operatorname{rng}(\sigma) \setminus \{1\}} [q_\ell]_\ell \lor [y_1]_1$ such that $n_i \stackrel{i \to k}{\Rightarrow}_{i=1} q_i$ with $q_1 = y_1$. For all $\ell \in \operatorname{rng}(\sigma) \setminus \{1\}$ we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi) \stackrel{A(\ell)}{\longrightarrow} m_\ell \Rightarrow_A n_\ell \Rightarrow_A y_\ell$, and $n_\ell \Rightarrow_A q_\ell$, which means we can apply Lemma D.29 to conclude that $q_\ell \Rightarrow_A y_\ell$. From this we derive that $\operatorname{Dm}_{\sigma}^{\ell}(\psi) \stackrel{A(\ell)}{\longrightarrow} m_\ell \Rightarrow_A q_\ell \Rightarrow_A q_\ell \Rightarrow_A y_\ell$ for all $\ell \in \operatorname{rng}(\sigma)$. It remains to show that $m_i \stackrel{i}{\Rightarrow}_{i=1}^k q_i$ with $q_\ell = y_1$.

For each $i \in \operatorname{rng}(\sigma)$, we have $m_i \Rightarrow_A n_i \Rightarrow_A q_i$, and thus $m_i \Rightarrow_A q_i$, which we assume happens in h_i steps. Let $h_i = f_i + g_i$ where $m_i \Rightarrow_A n_i$ in f_i steps and $n_i \Rightarrow_A q_i$ in g_i steps. For the second condition of $m_i \xrightarrow{i}_{A} k_{i=1}^k q_i$, take $i \in \operatorname{rng}(\sigma)$, $j \leq h_i$ and $c_i^j = (!G, \gamma)$. Then take $i' \in G \cap \operatorname{rng}(\sigma)$ with $i \neq i'$, and we have to show that $q_{i'} \xrightarrow{(?i,\gamma)}$. If $j \leq f_i$, then from $m_i \xrightarrow{i}_{A} k_{i=1}^k n_i$, we obtain that $n_{i'} \xrightarrow{(?i,\gamma)}$, and subsequently that $q_{i'} \xrightarrow{(?i,\gamma)}$ via Lemma D.13. On the other hand, if $j > f_i$, the result follows from $n_i \xrightarrow{i}_{A} k_{i=1}^k q_i$.

We obtain from the induction hypothesis that $\bigvee_{\ell \in \operatorname{rng}(\sigma) \setminus \{1\}} [q_\ell]_\ell \to \bigvee_{\ell \in \operatorname{rng}(\sigma) \setminus \{1\}} [y_\ell]_\ell$. Hence, $\bigvee_{\ell \in \operatorname{rng}(\sigma)} [n_\ell]_\ell \to \bigvee_{\ell \in \operatorname{rng}(\sigma) \setminus \{1\}} [q_\ell]_\ell \lor [y_1]_1 \to \bigvee_{\ell \in \operatorname{rng}(\sigma)} [y_\ell]_\ell$. In the last step we use that y_1 cannot communicate and therefore does not change anymore.

Another important feature that we need for Bounded Communication and Formula Convergence is the following: if different monitors influence each other via communication when combined (so a decentralized monitor is combined with another monitor and all of a sudden a local monitor in the decentralized system receives messages that it did not receive before), this makes no difference on the states the monitors reach when no more communication can take place.

We first set up a definition that helps us with two things. First, it allows us to describe what a decentralized monitor M looks like if it is combined via \vee or \wedge with another decentralized monitor, and then transitions according to a communication path of that other monitor. In other words, M will change state when the other monitor sends messages that local monitors in M can receive, and we formally capture what M looks like after these changes. Second, this definition will allow us to prove that influences from another monitor captured via Definition D.37 do not affect the final outcome (when no more communication takes place). These two elements then lead to Lemma D.46, where the different monitors in a join will send messages that 'accidentally' reach the others and it is shown this is not a problem. Lemma D.46 is used to prove Lemma D.47 (Bounded Communication) and Lemma D.61 (Formula Convergence). To this end, we define a set L of monitors that can all take the same receiving transition. Definition D.37 defines this set properly, and Lemma D.38 proves three general facts about this set.

▶ Definition D.37. Let $H \subseteq \mathcal{L}$ and $M \in \mathsf{DMon}$. Let $L = \{[m_1]_{\ell_1}, \ldots, [m_k]_{\ell_k}\}$. We say that L is a set of recipients for $H : (?\ell', \gamma)$ if for all $j \in \{1, \ldots, k\}$:

- 1. $\ell_j \in H$, and
- 2. $m_j \xrightarrow{(?\ell',\gamma)} n_j$ for some $n_j \in \mathsf{LMon}$.
- We call a set L an M-cover for $H:(?\ell',\gamma)$ if
- 1. L is a set of recipients for $H : (?\ell', \gamma)$,
- **2.** every $[m]_{\ell} \in L$ is action-derived, and
- **3.** if $[m]_{\ell} \in M$, $\ell \in H$ and $m \to m' \xrightarrow{(?\ell',\gamma)} n$, then $[m']_{\ell} \in L$.

▶ Lemma D.38. Let $H \subseteq \mathcal{L}$ and $M \in \mathsf{DMon}$ with M action-derived. Let $L = \{[m_1]_{\ell_1}, \ldots, [m_k]_{\ell_k}\}$ be an M-cover for $H : (?\ell, \gamma)$.

- $1. If M = [m]_{\ell'} \notin L, and M \xrightarrow{\ell': (!G, \gamma)} N \text{ or } M \xrightarrow{G: (?\ell'', \gamma)} N, then N = [n]_{\ell'} \notin L.$
- **2.** If $M \xrightarrow{G:(?\ell',\gamma)} N$, then L is also an N-cover for $H:(?\ell,\gamma)$.
- **3.** If $M \xrightarrow{\ell':(!G,\gamma)} N$, then L is also an N-cover for $H: (?\ell, \gamma)$.

Proof. For the first item, we observe that $N = [n]_{\ell'}$, where

m = n; or $m \xrightarrow{(?\ell'',\gamma)} n \text{ or};$ $m \xrightarrow{(!G,\gamma)} n.$

In the first case we know immediately that $[n]_{\ell'} = [m]_{\ell'} \notin L$. In the other two cases, because L is an M-cover, either $\ell' \notin H$, or $m \xrightarrow{(?\ell, \gamma)}$. Via Lemma D.13 this implies that $\ell' \notin H$ or $n \xrightarrow{(?\ell, \gamma)}$. In both cases we know that $[n]_{\ell'} \notin L$.

For the second item, we proceed by induction on $\overset{G:(?\ell',\gamma)}{\longrightarrow}$. For the base case, we get that $M = [m]_{\ell''}, N = [n]_{\ell''}, \ell'' \in G$, and m = n or $m \xrightarrow{(?\ell,\gamma)} n$. Suppose that $n \to z_1 \xrightarrow{(?\ell,\gamma)} z_2$ and $\ell'' \in H$. Then, we also know that $m \to z_1 \xrightarrow{(?\ell,\gamma)} z_2$; as $[m]_{\ell''} = M$, because L is an M-cover, we obtain that $[z_1]_{\ell''} \in L$, yielding that L is an N-cover. For the inductive case we consider $M = M_1 \lor M_2$ (the case for $M = M_1 \land M_2$ is identical), $N = N_1 \lor N_2$ and $M_1 \xrightarrow{G:(?\ell',\gamma)} N_1$ and $M_2 \xrightarrow{G:(?\ell',\gamma)} N_2$. Since L is an M-cover, it is also an M_1 -cover and an M_2 -cover. It then follows immediately from the induction hypothesis that L is an N_1 -cover and an N_2 -cover, and thus an N-cover.

For the third item, we proceed by induction on $\frac{\ell':(!G,\gamma)}{\cdots}$. For the base case we get that $M = [m]_{\ell'}, N = [n]_{\ell'}, \text{ and } m \xrightarrow{(!G,\gamma)} n$. Suppose that $n \to z_1 \xrightarrow{(?\ell,\gamma)} z_2$. Then, we also know that $m \to z_1 \xrightarrow{(?\ell,\gamma)} z_2$; as $[m]_{\ell'} = M$, because L is an M-cover, we obtain that $[z_1]_{\ell'} \in L$, yielding that L is an N-cover. For the inductive case we consider $M = M_1 \lor M_2$ (the case for $M = M_1 \land M_2$ is identical), $N = N_1 \lor N_2$ and $M_1 \xrightarrow{\ell':(!G,\gamma)} N_1$ and $M_2 \xrightarrow{G:(?\ell',\gamma)} N_2$. Since L is an M-cover, it is also an M_1 -cover and an M_2 -cover. It then follows immediately from the induction hypothesis and the previous item that L is an N_1 -cover and an N_2 -cover, and thus an N-cover.

In what follows it is useful to describe the state of a monitor M after receiving the message corresponding to L. To do this formally, we observe the following:

▶ Lemma D.39. Let L be an M-cover for $H: (?\ell, \gamma)$. For every $[m]_{\ell'} \in L$, if $m \xrightarrow{(?\ell, \gamma)} m_1$ and $m \xrightarrow{(?\ell, \gamma)} m_2$, then $m_1 = m_2$ and $[m_1]_{\ell} \notin L$.

Proof. The lemma follows immediately from Lemmas D.13 and D.16.

◄

With this lemma, we can then define what M after L is:

▶ Definition D.40. Let $L = \{[m_1]_{\ell_1}, \ldots, [m_k]_{\ell_k}\}$ be an *M*-cover for H : c and, for each $i \leq k$, let n_i be the unique monitor (by Lemma D.39) such that $m_i \xrightarrow{c} n_i$. We define $M[L] = M[[n_1]_{\ell_1}/[m_1]_{\ell_1}] \ldots [[n_k]_{\ell_k}/[m_k]_{\ell_k}].$

We can now use Definitions D.37 and D.40 and Lemma D.38 to prove we can describe a monitor that 'accidentally' receives messages from another monitor's communication transitions very precisely. This is then used to prove Lemma D.46.

▶ Lemma D.41. Let $M_1, M_2 \in \mathsf{DMon}$, where each M_i is A-derived. Let

$$M_1^1 \xrightarrow{c_1} M_1^2 \xrightarrow{c_2} \dots \xrightarrow{c_{n-1}} M_1^n,$$

where $M_1^1 = M_1$ and n > 0. Furthermore, let

$$M_1^1 \vee M_2^1 \xrightarrow{c_1} M_1^2 \vee M_2^2 \xrightarrow{c_2} \dots \xrightarrow{c_{n-1}} M_1^n \vee M_2^n,$$

where $M_2^1 = M_2$, and $c_i = \ell_i : (!G_i, A(\ell_i))$ for every $i \in \{1, \ldots, n-1\}$. Then, for every $i \in \{1, \ldots, n-1\}$ there exists an M_2 -cover L_i for $G_i : (?\ell_i, A(\ell_i))$, such that, for each $i, M_2[L_1] \ldots [L_i] = M_2^{i+1}$.

Proof. We proceed by induction on n. If n = 1, then the lemma holds vacuously. Otherwise, we have

$$M_1^1 \vee M_2^1 \xrightarrow{c_1} M_1^2 \vee M_2^2 \xrightarrow{c_2} \dots \xrightarrow{c_{n-2}} M_1^{n-1} \vee M_2^{n-1} \xrightarrow{c_{n-1}} M_1^n \vee M_2^n.$$

The induction hypothesis tells us that there exist L_1, \ldots, L_{n-2} such that, for each $i \in \{1, \ldots, n-2\}$, L_i is an M_2 -cover for $G_i : (?\ell_i, A(\ell_i))$, and $M_2[L_1] \cdots [L_i] = M_2^{i+1}$. Let

$$L_{n-1} = \{ [m']_{\ell} \mid \ell \in G_{n-1} \text{ and } \exists [m]_{\ell} \in M_2. \ m \to m' \xrightarrow{(?\ell_{n-1}, A(\ell_{n-1}))} m'' \}.$$

Then, L_{n-1} is an M_2 -cover for G_{n-1} : $(?\ell_{n-1}, A(\ell_{n-1}))$ by Definition D.37, and also an M_2^i -cover for G_{n-1} : $(?\ell_{n-1}, A(\ell_{n-1}))$ by Lemmas D.33 and D.38.

What is left to show is that $M_2[L_1]\cdots [L_{n-2}][L_{n-1}] = M_2^n$. We can conclude this from the induction hypothesis if we show that $M_2^{n-1}[L_{n-1}] = M_2^n$. Via Lemma D.33 we conclude that $M_2^{n-1} \xrightarrow{G_{n-1} : (\ell_{n-1}, \gamma_{n-1})} M_2^n$. Let $\{[m_i]_{\ell'_i} \mid 1 \leq i \leq k\} = \{[m]_\ell \in M_2^{n-1}\}$. For each $1 \leq i \leq k$, let m'_i be m_i , when $\ell_i \notin G_{n-1}$ or $m_i \xrightarrow{(?\ell_{n-1}, \gamma_{n-1})}$, or be such that $m_i \xrightarrow{(?\ell_{n-1}, \gamma_{n-1})} m'_i$, otherwise. Then, $M[L_{n-1}] = M_2^{n-1}[m'_1/m_1]\cdots [m'_k/m_k] = M_2^n$, by Lemma D.20.

Lemma D.42 and Lemma D.43 are used to prove Lemma D.44, and they state some basic facts of behavior of M[L] w.r.t. the behavior of M.

▶ Lemma D.42. Let $M \in \mathsf{DMon}$, $H \subseteq \mathcal{L}$, M be A-derived, and L be an M-cover for $H : (?\ell', A(\ell'))$. If $M \xrightarrow{G : (?q, A(q))} N$, for some $q \in \mathcal{L}$, then $M[L] \xrightarrow{G : (?q, A(q))} N[L]$.

XX:48 Centralized vs Decentralized Monitors for Hyperproperties

Proof. We proceed by induction on $\xrightarrow{G:(?q,A(q))}$. In the first base case we consider $M = [m]_{\ell}$, $N = [n]_{\ell}$, $\ell \in G$ and $m \xrightarrow{(?q,A(q))} n$. If $[m]_{\ell} \notin L$, then $[n]_{\ell} \notin L$ via Lemma D.38. Hence, M = M[L] and N = N[L], which concludes the proof. Otherwise we have that $M[L] = [m_1]_{\ell}$ with $m \xrightarrow{(?\ell',A(\ell'))} m_1$ and $\ell \in H$. We distinguish two cases:

- 1. $q \neq \ell'$. We then apply Lemma D.17 on m: $n \xrightarrow{(?\ell', A(\ell'))} n_1$ and $m_1 \xrightarrow{(?q, A(q))} n_1$. From this we derive that $M[L] = [m_1]_\ell \xrightarrow{G: (?q, A(q))} [n_1]_\ell$. Since L is an M-cover, it is also an N-cover via Lemma D.38. Thus, from $n \xrightarrow{(?\ell', A(\ell'))} n_1$ we obtain that $N = [n]_\ell \in L$. Hence, from $n \xrightarrow{(?\ell', A(\ell'))} n_1$ and via Lemma D.39, we get $N[L] = [n_1]_\ell$ and $M[L] = [m_1]_\ell \xrightarrow{G: (?q, A(q))} [n_1]_\ell = N[L]$.
- 2. $q = \ell'$. Then, $A(q) = A(\ell')$, and, via Lemma D.16, we obtain that $m_1 = n$, and thus that $M[L] = [m_1]_{\ell} = [n]_{\ell} = N$. From $m \xrightarrow{(?\ell', A(\ell'))} m_1$ and Lemma D.13, we conclude that $m_1 \xrightarrow{(?\ell', A(\ell'))}$. Using $q = \ell'$ and $m_1 = n$, we get that $n \xrightarrow{(?q, A(q))}$. Similarly, we have $n \xrightarrow{(?\ell', A(\ell'))}$, which implies that $[n]_{\ell} \notin L$, and therefore N = N[L]. From $n \xrightarrow{(?q, A(q))}$ we derive that $M[L] = [n]_{\ell} \xrightarrow{G:(?q, A(q))} [n]_{\ell} = N = N[L]$, which is what we wanted to show.

In the second base case, we consider $M = [m]_{\ell}$, $N = [m]_{\ell}$, and $m \xrightarrow{(?q,A(q))}$. If M = M[L] then $[m]_{\ell} \notin L$ by Lemma D.39, and thus also N = N[L], which concludes the proof. Otherwise we have that $M[L] = [m_1]_{\ell}$ with $m \xrightarrow{(?\ell',A(\ell'))} m_1$ and $\ell \in H$. We know that M = N, so M[L] = N[L]. We know that $m \xrightarrow{(?q,A(q))}$ and, via Lemma D.13, that $m_1 \xrightarrow{(?q,A(q))}$. We can conclude that $M[L] = [m_1]_{\ell} \xrightarrow{G:(?q,A(q))} [m_1]_{\ell} = N[L]$.

In the third base case we consider $M = [m]_{\ell}$, $N = [m]_{\ell}$ and $\ell \notin G$. If M = M[L] then $[m]_{\ell} \notin L$, and thus also N = N[L], which concludes the proof. Otherwise we have that $M[L] = [m_1]_{\ell}$ with $m \xrightarrow{(?\ell', A(\ell'))} m_1$ and $\ell \in H$. We know that M = N, so M[L] = N[L]. Since $\ell \notin G$, we can conclude that $M[L] = [m_1]_{\ell} \xrightarrow{G: (?q, A(q))} [m_1]_{\ell} = N[L]$.

For the inductive step, we consider $M = M_1 \lor M_2$ (the case for $M_1 \land M_2$ is the same), $N = N_1 \lor N_2$, $M_1 \xrightarrow{G:(?q, A(q))} N_1$, and $M_2 \xrightarrow{G:(?q, A(q))} N_2$. For M_1 and M_2 it holds immediately that they are A-derived. Similarly, the same set L is immediately an M_1 -cover and an M_2 -cover. Thus we can apply the induction hypothesis to obtain that $M_1[L] \xrightarrow{G:(?q, A(q))} N_1[L]$, and $M_2[L] \xrightarrow{G:(?q, A(q))} N_2[L]$. From this, we derive $M[L] = M_1[L] \lor M_2[L] \xrightarrow{G:(?q, A(q))} N_1[L]$, $N_1[L] \lor N_2[L] = N[L]$.

▶ Lemma D.43. Let $M \in \mathsf{DMon}$, $H \subseteq \mathcal{L}$, M be A-derived and L be an M-cover for $H : (?\ell', A(\ell'))$. If $M \xrightarrow{\ell:(!G,\gamma)} N$, then $M[L] \xrightarrow{\ell:(!G,\gamma)} N[L]$.

Proof. The proof proceeds by induction on $\xrightarrow{\ell:(!G,\gamma)}$. For the base case, we consider $M = [m]_{\ell}$, $N = [n]_{\ell}$ and $m \xrightarrow{(!G,\gamma)} n$. If M = M[L] then also N = N[L] via Lemma D.38, and the proof is done immediately. Otherwise, we must have that $M[L] = [m]_{\ell}[[m_1]_{\ell}/[m]_{\ell}] = [m_1]_{\ell}$ for $m \xrightarrow{(?\ell',A(\ell'))} m_1$ and $\ell \in H$. From Lemma D.15 we get $n \xrightarrow{(?\ell',A(\ell'))} n_1$ and $m_1 \xrightarrow{(!G,\gamma)} n_1$. Since L is an M-cover, we know it is also an N-cover (Lemma D.38) and therefore $[n]_{\ell} \in L$. Then we obtain from $n \xrightarrow{(?\ell',A(\ell'))} n_1$ and Lemma D.39 that $N[L] = [n_1]_{\ell}$; hence, $M[L] = [m_1]_{\ell} \xrightarrow{\ell:(!G,\gamma)} [n_1]_{\ell} = N[L]$.

For the inductive step we consider $M = M_1 \vee M_2$ (the case for \wedge is identical), $N = N_1 \vee N_2$, $M_1 \xrightarrow{\ell:(!G,\gamma)} N_1$, and $M_2 \xrightarrow{G:(?\ell,\gamma)} N_2$. We have that $M[L] = M_1[L] \vee M_2[L]$. It is immediate that M_1 and M_2 are A-derived, and that L is an M_1 -cover and an M_2 -cover. Thus, we can apply the induction hypothesis to obtain that $M_1[L] \xrightarrow{\ell:(!G,\gamma)} N_1[L]$. From Lemma D.14, we know that $\gamma = A(\ell)$. Since we have $M_2 \xrightarrow{G:(?\ell, A(\ell))} N_2$, we can apply Lemma D.42 to get $M_2[L] \xrightarrow{G:(?\ell, A(\ell))} N_2[L]$. Thus $M[L] = M_1[L] \lor M_2[L] \xrightarrow{\ell:(!G,\gamma)} N_1[L] \lor N_2[L] = N[L]$.

This lemma captures the following. Intuitively, $M_i[L]$ is the state of M_i after receiving the message corresponding to L. This can be understood as M_i receiving messages from some other decentralized monitor (as what happens in Lemma D.46). The lemma then states that even if M_i receives at any point some messages from another decentralized monitor, the same state is reached when no more communication can take place. It is used to prove Lemma D.45.

▶ Lemma D.44. Let $M_1 \in \mathsf{DMon}$, $H \subseteq \mathcal{L}$, M_1 be action-derived, and

$$M_1 \xrightarrow{c_1} M_2 \xrightarrow{c_2} \dots \xrightarrow{c_{n-1}} M_n \xrightarrow{c_n} N$$

for all $n \ge 1$ such that N cannot communicate (Definition 4.4). Let $s \le i \le n$ and L be an M_s -cover for $H: (?\ell, A(\ell))$. Then,

$$M_i[L] \xrightarrow{c_i} M_{i+1}[L] \xrightarrow{c_{i+1}} \dots \xrightarrow{c_{n-1}} M_n[L] \xrightarrow{c_n} N.$$

Proof. We prove this by induction on n-i. For the base case we consider $i = n \ge 1$. Thus we know that $M_n \xrightarrow{c_n} N$, and we need to prove that $M_n[L] \xrightarrow{c_n} N[L]$. We know that L is an M_n -cover, by Lemma D.38. Hence, we can apply Lemma D.43 to conclude that $M_n[L] \xrightarrow{c_n} N[L]$. Since N cannot communicate by assumption, we know that N[L] = N.

In the inductive step we obtain from the induction hypothesis that $M_{i+1}[L] \xrightarrow{c_{i+1}} \dots \xrightarrow{c_{n-1}} M_n[L] \xrightarrow{c_n} N$. Then we apply Lemma D.43 to conclude that $M_i[L] \xrightarrow{c_i} M_{i+1}[L]$, which completes the proof.

We can generalize the previous result to include a union of L's. This lemma is a cornerstone used to prove Lemma D.46 (together with Lemma D.41).

▶ Lemma D.45. Let $H \subseteq \mathcal{L}$, $M_1 \in \mathsf{DMon}$, M_1 be action-derived, and

$$M_1 \xrightarrow{c_1} M_2 \xrightarrow{c_2} \dots \xrightarrow{c_{n-1}} M_n \xrightarrow{c_n} N$$

for all $n \ge 1$ such that N cannot communicate (Definition 4.4). Let $s \le i \le n$ and $L = (L_i)_{i \in I}$ with $I = \{1, \ldots, q\}$ such that, for all $i \in I$, L_i is an M_s -cover for $H^i : (?\ell^i, A(\ell^i))$. Let $M_i[L] = M_i[L_1] \ldots [L_q]$, for all $s \le i \le n$. Then,

 $M_i[L] \xrightarrow{c_i} M_{i+1}[L] \xrightarrow{c_{i+1}} \dots \xrightarrow{c_{n-1}} M_n[L] \xrightarrow{c_n} N.$

Proof. We proceed by induction on *I*. If $I = \emptyset$, the result is trivial. In the inductive step, we obtain from the induction hypothesis that

$$M_i[L_1]\dots[L_{q-1}] \xrightarrow{c_i} M_{i+1}[L_1]\dots[L_{q-1}] \xrightarrow{c_{i+1}} \dots \xrightarrow{c_{n-1}} M_n[L_1]\dots[L_{q-1}] \xrightarrow{c_n} N.$$

If we show that L_q is a cover for $M_i[L_1] \dots [L_{q-1}]$, the result follows immediately from Lemma D.44. Take $[m]_{\ell} \in M_i[L_1] \dots [L_{q-1}]$ with $\ell \in H_q$ such that $m \to m' \xrightarrow{(?\ell^q, A(\ell^q))} n$. Hence, we know that there exists $[m_1]_{\ell} \in M_i$ such that $m_1 \to m$, and thus also $m_1 \to m'$. As L_q is an M_s -cover, it is also an M_i -cover via Lemma D.38. Hence, we obtain that $[m']_{\ell} \in L_q$, as desired.

XX:50 Centralized vs Decentralized Monitors for Hyperproperties

The next lemma is actually stronger than what is needed for Bounded Communication (for Bounded Communication it is sufficient that $\bigvee_{\ell \in \mathcal{L}} M_{\ell}$ in the lemma below can transition to some decentralized monitor that cannot communicate, and it does not exactly need to be $\bigvee_{\ell \in \mathcal{L}} N_{\ell}$). However, for Formula Convergence we need the lemma in its strong version, so we prove only that one.

We have shown in Lemma D.41 that we can describe monitors 'accidentally' receiving messages from other monitors in such a way, that we can use Lemma D.45 to conclude that even if a monitor received some accidental messages from another decentralized monitor, the same state is reached when no more communication can take place:

▶ Lemma D.46. If for all $\ell \in \mathcal{L} = \{1, \ldots, k\}$ we have $\mathsf{DM}_{\sigma_{\ell}}(\varphi_{\ell}) \xrightarrow{A} M_{\ell} \to N_{\ell}$ and N_{ℓ} cannot communicate according to Definition 4.4, then $\bigvee_{\ell \in \mathcal{L}} M_{\ell} \to \bigvee_{\ell \in \mathcal{L}} N_{\ell}$ and $\bigwedge_{\ell \in \mathcal{L}} M_{\ell} \to \bigwedge_{\ell \in \mathcal{L}} N_{\ell}$.

Proof. Proof by induction on k and we only treat the case for \bigvee . In case k = 1, we are done immediately. If $\mathcal{L} = \{1, \ldots, k+1\}$, let $M_1 \xrightarrow{c_1} M_1^2 \xrightarrow{c_2} \ldots \xrightarrow{c_n} N_1$ for $n \ge 0$. Then $\bigvee_{\ell \in \mathcal{L}} M_\ell \xrightarrow{c_1} \ldots \xrightarrow{c_n} N_1 \lor N$. Let $c_j = \ell_j : (!G_j, A(\ell_j))$ (via Lemma D.14) for all $j \in \{1, \ldots, n\}$. Via Lemma D.41, we obtain that there exist L_1, \ldots, L_n such that, for each $j \in \{1, \ldots, n\}$, L_j is a $(\bigvee_{\ell=2}^k M_\ell)$ -cover for $G_j : (?\ell_j, A(\ell_j))$, and

$$\bigvee_{\ell=2}^{\ell=k} M_{\ell}[L_1] \dots [L_n] = N.$$

From the induction hypothesis, we know that $\bigvee_{\ell=2}^{k} M_{\ell} \to \bigvee_{\ell=2}^{k} N_{\ell}$. Thus, we can apply Lemma D.45 to conclude that $N \to \bigvee_{\ell=2}^{k} N_{\ell}$.

From $\bigvee_{\ell \in \mathcal{L}} M_\ell \rightarrow N_1 \lor N$ we can conclude. Here we use that N_1 cannot take any communication steps and therefore does not change anymore.

We can now finally prove Bounded Communication:

▶ Lemma D.47. For every $DM_{\sigma}(\varphi) \xrightarrow{A} M \rightarrow M'$, there exists M'' such that $M' \rightarrow M''$ and M'' cannot communicate.

Proof. We proceed by induction on φ . The base case is for $\varphi \in Qf$. Hence, $DM_{\sigma}(\varphi) = \bigvee_{\ell \in \mathsf{rng}(\sigma)} [Dm_{\sigma}^{\ell}(\varphi)]_{\ell} \xrightarrow{A} \bigvee_{\ell \in \mathsf{rng}(\sigma)} [m_{\ell}]_{\ell} = M$ and $M \to \bigvee_{\ell \in \mathsf{rng}(\sigma)} [n_{\ell}]_{\ell} = M'$. We observe here that $m_{\ell} \Rightarrow_{A} n_{\ell}$, because we know from the semantics that for any receive $\xrightarrow{(?\ell',\gamma)}$ in the path $m_{\ell} \to n_{\ell}$, there exists ℓ' such that $m_{\ell'} \to m'_{\ell'}$ and $m'_{\ell'} \xrightarrow{(!G,\gamma)}$ with $\ell \in G$ and via Lemma D.13 that $\gamma = A(\ell')$.

As n_{ℓ} is a relevant local monitor, we prove for n_{ℓ} by induction on the structure of relevant local monitors that there exists n'_{ℓ} such that $n_{\ell} \Rightarrow_A n'_{\ell}$ and $n'_{\ell} \stackrel{c}{\not\sim}$ for all c. The first two base cases $(n_{\ell} = \text{Dm}_{\sigma}^{\ell}(\psi) \text{ and } n_{\ell} = (!G, a).\text{Dm}_{\sigma}^{\ell}(\psi))$ are trivial because of Lemma D.8. For the third base case, $n_{\ell} = \sum_{a \in \text{Act}} (?\{\ell'\}, a).\text{Dm}_{\sigma}^{\ell}(\psi_a)$, we observe that there is some $a \in \text{Act}$ such that $a = A(\ell')$, and we take that transition. For the inductive cases we proceed as follows. We let $n_{\ell} = n_1 \odot n_2$, and from the inductive hypothesis we get that $n_1 \Rightarrow_A m_1$ and $n_2 \Rightarrow_A m_2$ such that $m_1 \stackrel{c}{\rightarrow}$ and $m_2 \stackrel{c}{\not\sim}$ for all c. Via Lemma D.30, we derive that $n_1 \odot n_2 \Rightarrow_A m_1 \odot m_2$. It is immediate that $m_1 \odot m_2 \stackrel{c}{\not\sim}$ for all c.

Hence, any $n_{\ell} \Rightarrow_A n'_{\ell}$, such that $n'_{\ell} \stackrel{c}{\not\sim}$ for all c. From this we derive that $\mathrm{Dm}^{\ell}_{\sigma}(\psi) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_A n'_{\ell}$ for all $\ell \in \mathrm{rng}(\sigma)$. We can then apply Lemma D.36 (with $m_{\ell} = n_{\ell}$ in the statement of the lemma) to conclude that $\bigvee_{\ell \in \mathrm{rng}(\sigma)} [m_{\ell}]_{\ell} \rightarrow \bigvee_{\ell \in \mathrm{rng}(\sigma)} [n'_{\ell}]_{\ell}$. It is immediate

that $\bigvee_{\ell \in \mathsf{rng}(\sigma)} [n'_{\ell}]_{\ell} \xrightarrow{c}$ for all c. We apply Lemma D.27 to derive that $M' \to \bigvee_{\ell \in \mathsf{rng}(\sigma)} [n'_{\ell}]_{\ell}$, which concludes the proof.

We only treat one of the inductive cases, the others are similar. Let $\varphi = \exists \pi. \varphi'$. Then $\mathrm{DM}_{\sigma}(\varphi') = \bigvee_{\ell \in \mathcal{L}} \mathrm{DM}_{\sigma[\pi \mapsto \ell]}(\varphi') \xrightarrow{A} \bigvee_{\ell \in \mathcal{L}} M_{\ell} = M$. From the induction hypothesis we obtain that $M_{\ell} \to N_{\ell}$ such that N_{ℓ} cannot communicate. We apply Lemma D.46 and conclude that $M \to \bigvee_{\ell \in \mathcal{L}} N_{\ell}$. Then we can use Lemma D.27 to derive that $M' \to \bigvee_{\ell \in \mathcal{L}} N_{\ell}$, which concludes the proof.

D.4 Proofs for Verdict Irrevocability of $dM_{-}(\cdot)$

We start by proving Verdict Irrevocability at the level of local monitors.

▶ Lemma D.48. Let m be a relevant local monitor. If $m \xrightarrow{c} n$ and $m \Rightarrow v$, then $n \Rightarrow v$.

Proof. We proceed by induction on m.

For the base case, if $m = \text{Dm}_{\sigma}^{\ell}(\psi)$, we conclude from Lemma D.8; if $m = (!G, a).\text{Dm}_{\sigma}^{\ell}(\psi)$ or $m = \sum_{a \in \text{Act}} (?\{\ell'\}, a).\text{Dm}_{\sigma}^{\ell}(\psi_a)$, the premise of the lemma is not satisfied.

For the inductive step, let $m = n_1 \otimes n_2$ with n_1, n_2 relevant monitors; from $m \Rightarrow v$ we derive two cases (by Lemma B.1, we obtain that $v \neq \text{end}$ and we can thus exclude that case): 1. $n_1 \Rightarrow \text{no}$ and v = no. From $m \stackrel{c}{\rightarrow} n$ we derive another five cases, where we let $n = o_1 \otimes o_2$:

- a. $c = (!G, \gamma), n_1 \xrightarrow{c} o_1$ and $n_2 = o_2$. We use the induction hypothesis to obtain that $o_1 \Rightarrow \mathsf{no}$. Then $o_1 \otimes o_2 \Rightarrow \mathsf{no}$ follows immediately.
- **b.** $c = (!G, \gamma), n_2 \xrightarrow{c} o_2$ and $n_1 = o_1$. Hence, $o_1 \Rightarrow no$ and $o_1 \otimes o_2 \Rightarrow no$ follows immediately.
- **c.** $c = (?\ell', \gamma), n_1 \xrightarrow{(?\ell', \gamma)} o_1$ and $n_2 \xrightarrow{(?\ell', \gamma)} o_2$. This case is the same as item (a).
- **d.** $c = (?\ell', \gamma), n_1 \xrightarrow{(?\ell', \gamma)} o_1, o_2 = n_2 \text{ and } n_2 \xrightarrow{(?\ell', \gamma)}$. This case is the same as item (a). **e.** $c = (?\ell', \gamma), n_2 \xrightarrow{(?\ell', \gamma)} o_2, o_1 = n_1 \text{ and } n_1 \xrightarrow{(?\ell', \gamma)}$. This case is the same as item (b).
- **e.** $c = (1, 7), n_2 \longrightarrow o_2, o_1 = n_1$ and $n_1 \longrightarrow c_2$. This case is the same as item (b). **2.** $n_1 \Rightarrow$ yes and $n_2 \Rightarrow v$. From $m \stackrel{c}{\rightarrow} n$ we derive another five cases, where we let $n = o_1 \otimes o_2$:
- **a.** $c = (!G, \gamma), n_1 \xrightarrow{c} o_1$ and $n_2 = o_2$. We use the induction hypothesis to obtain that $o_1 \Rightarrow$ yes. Since $n_2 = o_2$, we have $o_2 \Rightarrow v$. Then $o_1 \otimes o_2 \Rightarrow v$ follows immediately.
 - **b.** $c = (!G, \gamma), n_2 \xrightarrow{c} o_2$ and $n_1 = o_1$. Hence, $o_1 \Rightarrow$ yes and from the induction hypothesis we get $o_2 \Rightarrow v$, from which we can conclude.
 - **c.** $c = (?\ell', \gamma), n_1 \xrightarrow{(?\ell', \gamma)} o_1$ and $n_2 \xrightarrow{(?\ell', \gamma)} o_2$. From the induction hypothesis we conclude that $o_1 \Rightarrow \text{yes}$ and $o_2 \Rightarrow v$, from which we can conclude.
 - **d.** $c = (?\ell', \gamma), n_1 \xrightarrow{(?\ell', \gamma)} o_1, o_2 = n_2 \text{ and } n_2 \xrightarrow{(?\ell', \gamma)}$. This case is the same as item (a). **e.** $c = (?\ell', \gamma), n_2 \xrightarrow{(?\ell', \gamma)} o_2, o_1 = n_1 \text{ and } n_1 \xrightarrow{(?\ell', \gamma)}$. This case is the same as item (b).

The case for \oplus is similar to the one for \otimes and, therefore, we omit it.

•

Next we show that the verdict is not end:

▶ Lemma D.49. Let $M \in \mathsf{DMon}$ be action-derived. If $M \Rightarrow v$, then $v \neq \mathsf{end}$.

Proof. This follows immediately from a simple induction on \Rightarrow and Lemma B.1.

Then we prove that the verdict carries over receiving transitions:

▶ Lemma D.50. Let $M \in \mathsf{DMon}$ be action-derived. If $M \xrightarrow{G : (?\ell, \gamma)} N$ and $M \Rightarrow v$, then $N \Rightarrow v$.

XX:52 Centralized vs Decentralized Monitors for Hyperproperties

Proof. We proceed by induction on $M \xrightarrow{G: (?\ell, \gamma)} N$. For the first base case, we consider $M = [m]_{\ell'}, N = [n]_{\ell'}$ and $m \xrightarrow{(?\ell, \gamma)} n$: $M \Rightarrow v$ implies that $m \Rightarrow v$, and (via Lemma D.48) we can conclude $n \Rightarrow v$, thus $N \Rightarrow v$. In the other two base cases, we have M = N and the result follows immediately.

For the inductive step we consider $M = M_1 \otimes M_2$ (the case for $M = M_1 \oplus M_2$ is similar), $N = N_1 \otimes N_2, M_1 \xrightarrow{G: (?\ell, \gamma)} N_1$ and $M_2 \xrightarrow{G: (?\ell, \gamma)} N_2$. From $M_1 \otimes M_2 \Rightarrow v$ we distinguish two cases, where we use Lemma D.49 to exclude the case for v = end:

- 1. $M_1 \Rightarrow$ yes and $M_2 \Rightarrow v$, From the induction hypothesis we get $N_1 \Rightarrow$ yes and $N_2 \Rightarrow v$. We immediately obtain that $N_1 \otimes N_2 \Rightarrow v$ according to the transition rules for \Rightarrow .
- 2. $M_1 \Rightarrow no, v = no$. We use the induction hypothesis to obtain that $N_1 \Rightarrow no$, and the result follows immediately.

Then we can prove that verdicts propagate if we take just one communication transition: We first prove Verdict Irrevocability for just one communication step:

▶ Lemma D.51. Let $M \in \mathsf{DMon}$ be action-derived. If $M \xrightarrow{c} N$ and $M \Rightarrow v$, then $N \Rightarrow v$.

Proof. We proceed by induction on $M \xrightarrow{c} N$. Let $c = \ell : (!G, \gamma)$. For the base case, we consider $M = [m]_{\ell}$, $N = [n]_{\ell}$ and $m \xrightarrow{(!G,\gamma)} n$: $M \Rightarrow v$ implies that $m \Rightarrow v$ and (via Lemma D.48) we can conclude $n \Rightarrow v$, hence $N \Rightarrow v$.

For the inductive step, we consider $M = M_1 \otimes M_2$ (the case for $M = M_1 \oplus M_2$ is similar), $N = N_1 \otimes N_2, M_1 \xrightarrow{c} N_1$ and $M_2 \xrightarrow{G: (?\ell, \gamma)} N_2$. From $M_1 \otimes M_2 \Longrightarrow v$ we distinguish four cases, where we use Lemma D.49 to exclude the case for v = end:

- 1. $M_1 \Rightarrow no, v = no$. We use the induction hypothesis to obtain that $N_1 \Rightarrow no$, and the result follows.
- 2. $M_2 \Rightarrow no, v = no$. We use Lemma D.50 to derive that $N_2 \Rightarrow no$, which concludes the proof.
- **3.** $M_1 \Rightarrow$ yes, $M_2 \Rightarrow v$. We use the induction hypothesis to obtain that $N_1 \Rightarrow$ yes and Lemma D.50 to derive that $N_2 \Rightarrow v$, and the result follows.
- **4.** $M_2 \Rightarrow$ yes, $M_1 \Rightarrow v$. Same as the previous case.

Verdict Irrevocability then follows via straightforward induction:

▶ Lemma D.52. If $DM_{\sigma}(\varphi) \xrightarrow{A} M_1 \rightarrow M_2 \rightarrow M$ and $M_2 \Rightarrow v$, then $M \Rightarrow v$.

Proof. We proceed by induction on the number of transitions in $M_2 \rightarrow M$. In the base case we consider $M_2 = M$, in which case the result follows trivially. In the inductive step we consider $M_2 \xrightarrow{c} N \rightarrow M$. Via Lemma D.51 we get that $N \Rightarrow v$, and the result then follows from the induction hypothesis.

D.5 Proofs for Processing-Communication Alternation of $dM_{-}(\cdot)$

We showed the first item of Processing-Communication Alternation in Lemma D.8.

For the second item of Processing-Communiation Alternation in Definition 4.5, we actually prove the contrapositive, because this simplifies the inductive proofs. We first show the result for local monitors:

▶ Lemma D.53. Let $Dm^{\ell}_{\sigma}(\psi) \xrightarrow{A(\ell)} m' \rightarrow m \xrightarrow{A'(\ell)} n$. Then $m \xrightarrow{c}$ for all c.

Proof. We prove this lemma for relevant local monitors, which is sufficient because m is a relevant local monitor via Lemma D.12. We proceed by induction on m.

In two of the base cases, namely $m = (!G, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi)$ and $m = \sum_{a \in \mathsf{Act}} (?\{\ell''\}, a).\mathrm{Dm}_{\sigma}^{\ell}(\psi_a)$, the premise of the lemma is not satisfied. In the other base case, $m = \mathrm{Dm}_{\sigma}^{\ell}(\psi)$, the result follows from Lemma D.8.

Let $m = m_1 \otimes m_2$ with m_1 , m_2 relevant monitors. The case for $m = m_1 \oplus m_2$ is identical, and therefore omitted. We derive from $m_1 \otimes m_2 \xrightarrow{A'(\ell)} n$ that $n = n_1 \otimes n_2$, $m_1 \xrightarrow{A'(\ell)} n_1$ and $m_2 \xrightarrow{A'(\ell)} n_2$. Hence, we can apply the induction hypothesis to obtain that $m_1 \xrightarrow{c}$ and $m_2 \xrightarrow{c'}$, from which we conclude that $m \xrightarrow{c'}$.

Then we show the contrapositive of Processing-Communication Alternation. The proof is a straightforward induction on \xrightarrow{A} using Lemma D.53:

▶ Lemma D.54. Let $M \in \mathsf{DMon}$ be action-derived. If $M \xrightarrow{A} N$, then $M \xrightarrow{c} for all c$.

Proof. We proceed by induction on \xrightarrow{A} . For the first base case, we consider $M = [m]_{\ell}$, $N = [n]_{\ell}$, $m \xrightarrow{a} n$ and $A(\ell) = a$. We use Lemma D.53 to conclude that $m \xrightarrow{c}$, from which we obtain that $M \xrightarrow{c}$. For the second base case, we consider $M = [m]_{\ell}$, and by assumption $m \xrightarrow{c}$. For the inductive step, we consider $M = M_1 \odot M_2$, $N = N_1 \odot N_2$, $M_1 \xrightarrow{A} N_1$ and $M_2 \xrightarrow{A} N_2$. From the induction hypothesis it follows that $M_1 \xrightarrow{c}$ and $M_2 \xrightarrow{c}$, so immediately we obtain that $M \xrightarrow{c}$.

D.6 Proofs for Formula Convergence of $dM_{-}(\cdot)$

We start with a lemma that only relies on Lemma D.3, and captures a basic equality between synthesized centralized monitors and synthesized decentralized local monitors. It is used in the proof of Lemma D.59 and Lemma D.56.

▶ Lemma D.55. If $Cm_{\sigma}(\psi) = Cm_{\sigma'}(\psi')$, then $Dm_{\sigma}^{\ell}(\psi) = Dm_{\sigma'}^{\ell}(\psi')$, for all $\ell \in \mathcal{L}$.

Proof. We proceed by induction on ψ . As a first base case, we consider $\psi = \text{tt}$. We then have $\operatorname{Cm}_{\sigma}(\psi) = \operatorname{yes} = \operatorname{Cm}_{\sigma'}(\psi')$. Via Lemma D.3 we conclude that, for all $\ell \in \mathcal{L}$, we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{yes} = \operatorname{Dm}_{\sigma'}^{\ell}(\psi')$. The base cases for $\psi = \operatorname{ff}$, $\psi = (\pi = \pi')$ and $\psi = (\pi \neq \pi')$ are similar.

The last base case is for $\psi = x$, for x a recursion variable. Then $\operatorname{Cm}_{\sigma}(\psi) = x = \operatorname{Cm}_{\sigma'}(\psi')$, from which we can conclude that $\psi = x$. Immediately it follows that, for all $\ell \in \mathcal{L}$, $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = x = \operatorname{Dm}_{\sigma'}^{\ell}(\psi')$.

We now proceed with the inductive cases. We first consider $\psi = [a_{\pi}]\psi_1$. Thus $\operatorname{Cm}_{\sigma}(\psi) = a_{\sigma(\pi)}.\operatorname{Cm}_{\sigma}(\psi_1) + \sum_{b \neq a} b_{\sigma(\pi)}.\operatorname{yes} = \operatorname{Cm}_{\sigma}(\psi')$. Thus $\psi' = [a_{\pi'}]\psi_2$, $\sigma(\pi) = \sigma'(\pi')$ and $\operatorname{Cm}_{\sigma}(\psi_1) = \operatorname{Cm}_{\sigma'}(\psi_2)$. We use the induction hypothesis to obtain that for all $\ell \in \mathcal{L}$ we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi_1) = \operatorname{Dm}_{\sigma'}^{\ell}(\psi_2)$. We distinguish two cases for any $\ell \in \mathcal{L}$:

- 1. If $\sigma(\pi) = \ell$, then also $\sigma'(\pi') = \sigma(\pi) = \ell$, and $\operatorname{Dm}_{\sigma}^{\ell}(\psi) = \operatorname{Dm}_{\sigma}^{\ell}([a_{\pi}]\psi_1) = a.(!\{\sigma(\pi'') : \sigma(\pi'') \neq \ell\}, a).\operatorname{Dm}_{\sigma}^{\ell}(\psi_1) + \sum_{b\neq a} b.(!\{\sigma(\pi'') : \sigma(\pi'') \neq \ell\}, b).$ yes and $\operatorname{Dm}_{\sigma'}^{\ell}(\psi') = \operatorname{Dm}_{\sigma'}^{\ell}([a_{\pi'}]\psi_2) = a.(!\{\sigma(\pi'') : \sigma(\pi'') \neq \ell\}, a).\operatorname{Dm}_{\sigma'}^{\ell}(\psi_2) + \sum_{b\neq a} b.(!\{\sigma(\pi'') : \sigma(\pi') \neq \ell\}, b).$ yes. Using the induction hypothesis, we have obtained the required result.
- 2. If $\sigma(\pi) \neq \ell$, then also $\sigma'(\pi') \neq \ell$, and the result follows in a similar manner from the induction hypothesis.

Next we consider $\psi = \max x.\psi_1$. Hence, $\operatorname{Cm}_{\sigma}(\psi) = \operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi_1) = \operatorname{Cm}_{\sigma'}(\psi')$. From this we conclude that $\psi' = \max x.\psi_2$ and $\operatorname{Cm}_{\sigma}(\psi_1) = \operatorname{Cm}_{\sigma'}(\psi_2)$. We use the induction hypothesis to obtain that, for all $\ell \in \mathcal{L}$, we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi_1) = \operatorname{Dm}_{\sigma'}^{\ell}(\psi_2)$. We derive with the induction

Centralized vs Decentralized Monitors for Hyperproperties **XX**:54

hypothesis that, for all $\ell \in \mathcal{L}$, $\mathrm{Dm}_{\sigma}^{\ell}(\max x.\psi_1) = \mathrm{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi_1) = \mathrm{rec} x.\mathrm{Dm}_{\sigma'}^{\ell}(\psi_2) =$ $\mathrm{Dm}_{\sigma'}^{\ell}(\max x.\psi_2) = \mathrm{Dm}_{\sigma'}^{\ell}(\psi').$

Consider $\psi = \psi_1 \wedge \psi_2$. Hence, $\operatorname{Cm}_{\sigma}(\psi) = \operatorname{Cm}_{\sigma}(\psi_1) \otimes \operatorname{Cm}_{\sigma}(\psi_2) = \operatorname{Cm}_{\sigma'}(\psi')$, with $\psi' = \psi'_1 \wedge \psi'_2$, $\operatorname{Cm}_{\sigma}(\psi_1) = \operatorname{Cm}_{\sigma'}(\psi'_1)$ and $\operatorname{Cm}_{\sigma}(\psi_2) = \operatorname{Cm}_{\sigma'}(\psi'_2)$. The result follows immediately from the induction hypothesis. The case for $\psi = \psi \lor \psi_2$ can be handled in a similar manner.

To prove Formula Convergence for quantifier free formulas, we need the following result. Informally, it captures part of the weak bisimulation on the level of local monitors.

▶ Lemma D.56. Let $\psi \in Qf$. If $Cm_{\sigma}(\psi) \xrightarrow{A} Cm_{\sigma}(\psi')$ then for all $\ell \in \mathcal{L}$ we have $Dm_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)}$ $m_{\ell} \Rightarrow_A Dm_{\sigma}^{\ell}(\psi').$

Proof. We proceed by induction on \xrightarrow{A} for central monitors. In case $\operatorname{Cm}_{\sigma}(\psi) = v = \operatorname{Cm}_{\sigma}(\psi')$, we get via Lemma D.3 that for all $\ell \in \mathcal{L}$ we have $Dm_{\sigma}^{\ell}(\psi) = v$ and $Dm_{\sigma}^{\ell}(\psi') = v$. Thus we can conclude as $v \xrightarrow{A(\ell)} v \Rightarrow_A v$ for any $A(\ell)$.

We do not consider the cases with $Cm_{\sigma}(\psi) = a_{\ell}.m$, because this cannot occur (because of our assumption that $|\mathsf{Act}| \ge 2$).

Let $\operatorname{Cm}_{\sigma}(\psi) = m + n \xrightarrow{A} \operatorname{Cm}_{\sigma}(\psi')$ because $m \xrightarrow{A} \operatorname{Cm}_{\sigma}(\psi')$ or $n \xrightarrow{A} \operatorname{Cm}_{\sigma}(\psi')$. Hence,

- $\psi = [a_{\pi}]\psi'', m = a_{\sigma(\pi)}.Cm_{\sigma}(\psi''), \text{ and } n = \sum_{b \neq a} b_{\sigma(\pi)}.yes.$ We distinguish two cases. **1.** $A(\ell) = a$ and $\sigma(\pi) = \ell$. This entails that $Cm_{\sigma}(\psi') = Cm_{\sigma}(\psi'')$. Let $\ell' \in \mathcal{L}$. If $\ell' = \ell$, we have $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} (!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell'\}, a)$. $\operatorname{Dm}_{\sigma}^{\ell'}(\psi'')$; and if $\ell' \neq \ell$ we have $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} (?\{\ell\}, a) \cdot \operatorname{Dm}_{\sigma}^{\ell'}(\psi'') + \sum_{b \neq a} (?\{\ell\}, b) \cdot \operatorname{yes}$. Thus in both situations we can conclude that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} n_{\ell'} \xrightarrow{c} \operatorname{Dm}_{\sigma}^{\ell'}(\psi'')$, where $\gamma = A(\ell)$ whenever $c = (?\ell, \gamma)$. From Lemma D.55 and $\operatorname{Cm}_{\sigma}(\psi') = \operatorname{Cm}_{\sigma}(\psi'')$, we obtain that, for all $\ell \in \mathcal{L}$, $\operatorname{Dm}_{\sigma}^{\ell}(\psi') = \operatorname{Dm}_{\sigma}^{\ell}(\psi'')$, which concludes the proof.
- 2. $A(\ell) = b, a \neq b$ and $\sigma(\pi) = \ell$. This entails that $\operatorname{Cm}_{\sigma}(\psi') = \operatorname{yes}$. We use Lemma D.3 to conclude that, for all ℓ , we have $Dm_{\sigma}^{\ell}(\psi') = yes$. Let $\ell' \in \mathcal{L}$. If $\ell' = \ell$, we have $\mathrm{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} (!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell'\}, b).\mathsf{yes} = (!\{\sigma(\pi') \mid \sigma(\pi') \neq \ell\}, b).\mathrm{Dm}_{\sigma}^{\ell'}(\psi'); b)$ and if $\ell' \neq \ell$, we have $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} (?\{\ell\}, a) \cdot \operatorname{Dm}_{\sigma}^{\ell'}(\psi'') + \sum_{b \neq a} (?\{\ell\}, b) \cdot \operatorname{yes} =$ $(?\{\ell\}, a).\mathrm{Dm}_{\sigma}^{\ell'}(\psi'') + \sum_{b \neq a} (?\{\ell\}, b).\mathrm{Dm}_{\sigma}^{\ell'}(\psi')$. Thus in both situations we can conclude that $\operatorname{Dm}_{\sigma}^{\ell'}(\psi) \xrightarrow{A(\ell')} n_{\ell'} \xrightarrow{c} \operatorname{Dm}_{\sigma}^{\ell'}(\psi')$ and $\gamma = A(\ell)$ whenever $c = (?\ell, \gamma)$.

Next we consider the recursive case: $\operatorname{Cm}_{\sigma}(\psi) = \operatorname{rec} x.m \xrightarrow{A} \operatorname{Cm}_{\sigma}(\psi')$ because $m\{\operatorname{rec} x.m/x\} \xrightarrow{A} \operatorname{Cm}_{\sigma}(\psi')$. Thus we obtain that $\psi = \max x.\psi_1$ and $m = \operatorname{Cm}_{\sigma}(\psi_1)$. As $\operatorname{Cm}_{\sigma}(\psi_1)\{\operatorname{rec} x.\operatorname{Cm}_{\sigma}(\psi_1)/x\} = \operatorname{Cm}_{\sigma}(\psi_1\{\max x.\psi_1/x\})$ (Lemma B.8), we use the induction hypothesis to obtain that, for all ℓ , we have $\mathrm{Dm}_{\sigma}^{\ell}(\psi_1\{\max x.\psi_1/x\}) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_A \mathrm{Dm}_{\sigma}^{\ell}(\psi')$. Using that $\mathrm{Dm}_{\sigma}^{\ell}(\psi_1)\{\operatorname{rec} x.\mathrm{Dm}_{\sigma}^{\ell}(\psi_1)/x\} = \mathrm{Dm}_{\sigma}^{\ell}(\psi_1\{\max x.\psi_1/x\})$ (Lemma D.2), we get that $\mathrm{Dm}_{\sigma}^{\ell}(\psi_1)\{\stackrel{\mathrm{rec }x.\mathrm{Dm}_{\sigma}^{\ell}(\psi_1)}{/}_x\}\xrightarrow{A(\ell)} m_{\ell} \Rightarrow_A \mathrm{Dm}_{\sigma}^{\ell}(\psi'). \text{ This implies that } \mathrm{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_A \mathrm{Dm}_{\sigma}^{\ell}(\psi').$ $\mathrm{Dm}^{\ell}_{\sigma}(\psi').$

Lastly we consider $\operatorname{Cm}_{\sigma}(\psi) = m \otimes n \xrightarrow{A} m' \otimes n'$ because $m \xrightarrow{A} m'$ and $n \xrightarrow{A} n'$. The case where $\operatorname{Cm}_{\sigma}(\psi) = m \oplus n$ is dual. As ψ is quantifier-free, we get that $\psi = \psi_1 \wedge \psi_2$, $m = \operatorname{Cm}_{\sigma}(\psi_1)$ and $n = \operatorname{Cm}_{\sigma}(\psi_2)$. We also get $\psi' = \psi'_1 \wedge \psi'_2$, $m' = \operatorname{Cm}_{\sigma}(\psi'_1)$ and $n' = \operatorname{Cm}_{\sigma}(\psi'_2)$. From the induction hypothesis we obtain that, for all ℓ , we have $\operatorname{Dm}_{\sigma}^{\ell}(\psi_1) \xrightarrow{A(\ell)} m_{\ell}^1 \Rightarrow_A \operatorname{Dm}_{\sigma}^{\ell}(\psi_1')$ and $\operatorname{Dm}_{\sigma}^{\ell}(\psi_2) \xrightarrow{A(\ell)} m_{\ell}^2 \Rightarrow_A \operatorname{Dm}_{\sigma}^{\ell}(\psi_2')$. Thus, for all ℓ , we have that $\operatorname{Dm}_{\sigma}^{\ell}(\psi_1 \wedge \psi_2) \xrightarrow{A(\ell)} m_{\ell}^1 \otimes m_{\ell}^2$ and via Lemma D.30 we get $m_{\ell}^2 \otimes m_{\ell}^2 \Rightarrow_A \mathrm{Dm}_{\sigma}^{\ell}(\psi_1') \otimes \mathrm{Dm}_{\sigma}^{\ell}(\psi_2')$, which concludes the proof.

XX:55

Then we can prove Formula Convergence for $\psi \in Qf$:

▶ Lemma D.57. Let $\psi \in Qf$. If $DM_{\sigma}(\psi) \xrightarrow{A} M \rightarrow M'$, M' cannot communicate, and $Cm_{\sigma}(\psi) \xrightarrow{A} Cm_{\sigma}(\psi')$ for some formula ψ' , then $M' = DM_{\sigma}(\psi')$.

Proof. Lemma D.56 tells us that $\operatorname{Dm}_{\sigma}^{\ell}(\psi) \xrightarrow{A(\ell)} m_{\ell} \Rightarrow_{A} \operatorname{Dm}_{\sigma}^{\ell}(\psi')$, for all $\ell \in \mathcal{L}$. Thus we know that $\operatorname{DM}_{\sigma}(\psi) = \bigvee_{\ell \in \operatorname{rng}(\sigma)} [\operatorname{Dm}_{\sigma}^{\ell}(\psi)]_{\ell} \xrightarrow{A} \bigvee_{\ell \in \operatorname{rng}(\sigma)} [m_{\ell}]_{\ell}$ and because $\operatorname{Dm}_{\sigma}^{\ell}(\psi') \xrightarrow{C} \mathcal{H}$ for all c via Lemma D.8, we can use Lemma D.36 (with $n_{\ell} = m_{\ell}$) to obtain that $\bigvee_{\ell \in \operatorname{rng}(\sigma)} [m_{\ell}]_{\ell} \rightarrow \bigvee_{\ell \in \operatorname{rng}(\sigma)} [\operatorname{Dm}_{\sigma}^{\ell}(\psi')]_{\ell} = \operatorname{DM}_{\sigma}(\psi')$. Via Lemma D.8, we know that $\operatorname{DM}_{\sigma}(\psi')$ cannot communicate. Hence, we apply Lemma D.27 to derive that $M' \rightarrow \operatorname{DM}_{\sigma}(\psi')$. Since M' cannot communicate by assumption, we get that $M' = \operatorname{DM}_{\sigma}(\psi)$.

Then we show a result for the synthesis function in the centralized setting specifically for ψ -formulas, which differs from Lemma B.9 because σ remains constant. This allows us to prove the base case in the proof for Formula Convergence (Lemma D.61) via Lemma D.57.

▶ Lemma D.58. If $\operatorname{Cm}_{\sigma}(\psi) \xrightarrow{A} m'$, then $m' = \operatorname{Cm}_{\sigma}(\psi')$ for some ψ' .

Proof. The proof is a simplified version of the proof for Lemma B.9.

The next lemma is used to prove Lemma D.60, which in turn is used in the final steps of proving Formula Convergence.

▶ Lemma D.59. If
$$Cm_{\sigma}(\varphi) = Cm_{\sigma'}(\varphi')$$
 and $\mathcal{L} = \{\ell\}$, then $DM_{\sigma}(\varphi) = DM_{\sigma'}(\varphi')$.

Proof. We proceed by induction on φ . In the base case we consider $\varphi \in Qf$. Hence, via Lemma D.55 we have $\mathsf{DM}_{\sigma}(\varphi) = \bigvee_{\ell \in \mathsf{rng}(\sigma)} [\mathsf{Dm}_{\sigma}^{\ell}(\varphi)]_{\ell} = [\mathsf{Dm}_{\sigma}^{\ell}(\varphi)]_{\ell} = [\mathsf{Dm}_{\sigma'}^{\ell}(\varphi')]_{\ell} = \mathsf{DM}_{\sigma'}(\varphi')$. We now treat the inductive case for $\varphi = \exists \pi.\varphi'$. Then we have $\mathsf{Cm}_{\sigma}(\varphi) = \mathsf{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \mathsf{Cm}_{\sigma'}(\varphi')$. From the induction hypothesis we derive that $\mathsf{DM}_{\sigma[\pi \mapsto \ell]}(\varphi') = \mathsf{DM}_{\varphi'}(\sigma')$, which proves the claim. Next consider $\varphi = \varphi_1 \land \varphi_2$. Hence, $\mathsf{Cm}_{\sigma}(\varphi) = \mathsf{Cm}_{\sigma}(\varphi_1) \otimes \mathsf{Cm}_{\sigma}(\varphi_2) = \mathsf{Cm}_{\sigma'}(\varphi')$. As $\mathcal{L} = \{\ell\}$, we know that $\varphi' = \varphi'_1 \land \varphi'_2$ with $\mathsf{Cm}_{\sigma}(\varphi_1) = \mathsf{Cm}_{\sigma'}(\varphi'_1)$ and $\mathsf{Cm}_{\sigma}(\varphi_2) = \mathsf{Cm}_{\sigma'}(\varphi'_2)$. From the induction hypothesis we conclude that $\mathsf{DM}_{\sigma}(\varphi_1) = \mathsf{DM}_{\sigma'}(\varphi'_1)$ and $\mathsf{DM}_{\sigma}(\varphi_2) = \mathsf{DM}_{\sigma'}(\varphi'_2)$. The result now follows: $\mathsf{DM}_{\sigma}(\varphi) = \mathsf{DM}_{\sigma}(\varphi_1) \land \mathsf{DM}_{\sigma}(\varphi_2) = \mathsf{DM}_{\sigma'}(\varphi')$.

▶ Lemma D.60. If $Cm_{\sigma}(\varphi) = \bigoplus_{i \in I} Cm_{\sigma_i}(\varphi_i)$, then $DM_{\sigma}(\varphi) = \bigvee_{i \in I} DM_{\sigma_i}(\varphi_i)$.

Proof. We assume that $\bigoplus_{i \in I} \operatorname{Cm}_{\sigma_i}(\varphi_i)$ is maximal, in that no $\operatorname{Cm}_{\sigma_i}(\varphi_i)$ is of the form $m_1 \oplus m_2$. If $\mathcal{L} = \{\ell\}$, we proceed by induction on φ .

If φ is such that |I| = 1, then we have $Cm_{\sigma}(\varphi) = Cm_{\sigma_i}(\varphi_i)$ and the result follows from Lemma D.59.

If $\varphi = \exists \pi \varphi'$, then $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \bigoplus_{i \in I} \operatorname{Cm}_{\sigma_i}(\varphi_i)$. By the induction hypothesis, $\operatorname{DM}_{\sigma}(\varphi) = \operatorname{DM}_{\sigma[\pi \mapsto \ell]}(\varphi') = \bigvee_{i \in I} \operatorname{DM}_{\sigma_i}(\varphi_i)$, which concludes this case.

If $\varphi = \varphi_1 \vee \varphi_2$, then $\operatorname{Cm}_{\sigma}(\varphi) = \operatorname{Cm}_{\sigma}(\varphi_1) \oplus \operatorname{Cm}_{\sigma}(\varphi_2) = \bigoplus_{i \in I} \operatorname{Cm}_{\varphi_i}(\sigma_i)$. Then, there is some $J \subsetneq I$, such that $\operatorname{Cm}_{\sigma}(\varphi_1) = \bigoplus_{i \in J} \operatorname{Cm}_{\sigma_i}(\varphi_i)$ and $\operatorname{Cm}_{\sigma}(\varphi_2) = \bigoplus_{i \in I \setminus J} \operatorname{Cm}_{\sigma_i}(\varphi_i)$. By the induction hypothesis, $\operatorname{DM}_{\sigma}(\varphi_1) = \bigvee_{i \in J} \operatorname{DM}_{\varphi_i}(\sigma_i)$ and $\operatorname{DM}_{\sigma}(\varphi_2) = \bigvee_{i \in I \setminus J} \operatorname{DM}_{\varphi_i}(\sigma_i)$, and therefore $\operatorname{DM}_{\sigma}(\varphi) = \operatorname{DM}_{\sigma}(\varphi_1) \vee \operatorname{DM}_{\sigma}(\varphi_2) = \bigvee_{i \in I} \operatorname{DM}_{\sigma_i}(\varphi_i)$.

We now assume $|\mathcal{L}| > 1$ and proceed by induction on φ . From the synthesis function, we can conclude that φ is a disjunction or an existential formula. In case $\varphi = \varphi_1 \lor \varphi_2$, we obtain that there exists $J \subsetneq I$ such that $\operatorname{Cm}_{\sigma}(\varphi_1) = \bigoplus_{\ell \in J} \operatorname{Cm}_{\sigma_{\ell}}(\varphi_{\ell})$ and $\operatorname{Cm}_{\sigma}(\varphi_2) = \bigoplus_{\ell \in J} \operatorname{Cm}_{\sigma_{\ell}}(\varphi_{\ell})$. From the induction hypothesis it follows that $\operatorname{DM}_{\sigma}(\varphi_1) = \bigvee_{\ell \in J} \operatorname{Cm}_{\sigma_{\ell}}(\varphi_{\ell})$

XX:56 Centralized vs Decentralized Monitors for Hyperproperties

and $DM_{\sigma}(\varphi_1) = \bigvee_{\ell \in I \setminus \{J\}} Cm_{\sigma_{\ell}}(\varphi_{\ell})$. The result then follows from the fact that $DM_{\sigma}(\varphi) = DM_{\sigma}(\varphi_1) \vee DM_{\sigma}(\varphi_2)$.

Now consider $\varphi = \exists \pi.\varphi'$. Then, $\operatorname{Cm}_{\sigma}(\varphi) = \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi')$, and from our assumption of the maximality of $\bigoplus_{i \in I} \operatorname{Cm}_{\sigma_i}(\varphi_i)$, there is a partition $(I_{\ell})_{\ell \in \mathcal{L}}$ of I, such that for every $\ell \in \mathcal{L}$, $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi') = \bigoplus_{i \in I_{\ell}} \operatorname{Cm}_{\sigma_i}(\varphi_i)$. By the induction hypothesis, for every $\ell \in \mathcal{L}$, $\operatorname{DM}_{\sigma[\pi \mapsto \ell]}(\varphi') = \bigvee_{i \in I_{\ell}} \operatorname{DM}_{\sigma_i}(\varphi_i)$ and we can conclude that $\operatorname{DM}_{\sigma}(\varphi) = \bigvee_{\ell \in \mathcal{L}} \operatorname{DM}_{\sigma[\pi \mapsto \ell]}(\varphi') =$ $\bigvee_{\ell \in \mathcal{L}} \bigvee_{i \in I_{\ell}} \operatorname{DM}_{\sigma_i}(\varphi_i) = \bigvee_{i \in I} \operatorname{DM}_{\sigma_i}(\varphi_i)$.

Then we can prove Formula Convergence:

▶ Lemma D.61. If $DM_{\sigma}(\varphi) \xrightarrow{A} M \rightarrow M'$, M' cannot communicate, and $Cm_{\sigma}(\varphi) \xrightarrow{A} Cm_{\sigma'}(\varphi')$ for some formula φ' and environment σ' , then $M' = DM_{\sigma'}(\varphi')$.

Proof. We proceed by induction on φ . The case for ψ follows from Lemma D.57, where we know that $\sigma' = \sigma$ because of Lemma D.58. We start with the inductive case for $\exists \pi.\varphi$. We assume that $\mathsf{DM}_{\sigma}(\exists \pi.\varphi) = \bigvee_{\ell \in \mathcal{L}} \mathsf{DM}_{\sigma[\pi \mapsto \ell]}(\varphi) \xrightarrow{A} M \to M'$. Thus $M = \bigvee_{\ell \in \mathcal{L}} M_{\ell}$ and $\mathsf{DM}_{\sigma[\pi \mapsto \ell]}(\varphi) \xrightarrow{A} M_{\ell}$, for each ℓ . Via Bounded Communication we obtain that for all ℓ there exists N_{ℓ} such that $M_{\ell} \to N_{\ell}$ and N_{ℓ} cannot communicate (Definition 4.4). We apply Lemma D.46 and conclude that $M \to \bigvee_{\ell \in \mathcal{L}} N_{\ell}$. Then we can use Lemma D.27 to derive that $\bigvee_{\ell \in \mathcal{L}} N_{\ell} \to M'$, which implies that $\bigvee_{\ell \in \mathcal{L}} N_{\ell} = M'$ because $\bigvee_{\ell \in \mathcal{L}} N_{\ell}$ cannot send messages.

From the assumption that $\operatorname{Cm}_{\sigma}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma'}(\varphi')$, we obtain that $\operatorname{Cm}_{\sigma}(\exists \pi.\varphi) \xrightarrow{A} \bigoplus_{\ell \in \mathcal{L}} \operatorname{Cm}_{\sigma_{\ell}}(\varphi_{\ell})$ and $\operatorname{Cm}_{\sigma[\pi \mapsto \ell]}(\varphi) \xrightarrow{A} \operatorname{Cm}_{\sigma_{\ell}}(\varphi_{\ell})$. From $M_{\ell} \to N_{\ell}$ and the induction hypothesis we can then conclude that $N_{\ell} = \operatorname{DM}_{\sigma_{\ell}}(\varphi_{\ell})$. Hence, $M' = \bigvee_{\ell \in \mathcal{L}} \operatorname{DM}_{\sigma_{\ell}}(\varphi_{\ell})$. We conclude via Lemma D.60.

The cases for $\forall \pi.\varphi, \varphi_1 \land \varphi_2$ and $\varphi_1 \lor \varphi_2$ are similar.

E On the Decentralized Synthesis of Diamonds

The decentralized monitor synthesis presented in Table 11 does not deal explicitly with formulas in Qf of the form $\langle a_{\pi} \rangle \psi$. However, it can be applied to those formulas using the observation that $\langle a_{\pi} \rangle \psi$ is logically equivalent to

$$[a_{\pi}]\psi \wedge \bigwedge_{b \neq a} [b_{\pi}] \text{ff} .$$

$$\tag{12}$$

The following example shows the resulting decentralized monitor synthesis at work.

▶ **Example E.1.** Let us consider Wolper's property φ_{h_e} from (1); for the sake of clarity, we will be denoting it as $\exists \pi. \psi$, with

$$\psi = \max x.(\psi_1 \wedge \psi_2)$$
 $\psi_1 = [a_\pi]\langle a_\pi \rangle x$ $\psi_2 = [b_\pi]\langle a_\pi \rangle x$

Let $\mathcal{L} = \{1, 2\}$ and $\mathsf{Act} = \{a, b\}$. The synthesis is applied thus:

$$\mathrm{D}\mathsf{M}_{\emptyset}(\varphi) = \bigvee_{\ell \in \mathcal{L}} \left[\mathrm{rec} \ x. \left(m_{[\pi \mapsto \ell]}^{\ell}(\psi_1) \otimes m_{[\pi \mapsto \ell]}^{\ell}(\psi_2) \right) \right]_{\ell}$$

with

$$\begin{array}{lll} m^{\ell}_{[\pi \mapsto \ell]}(\psi_1) &=& a.(!\emptyset, a).m^{\ell}_{[\pi \mapsto \ell]}(\langle a_{\pi} \rangle x) + b.(!\emptyset, b).\mathsf{yes} \\ m^{\ell}_{[\pi \mapsto \ell]}(\psi_2) &=& b.(!\emptyset, b).m^{\ell}_{[\pi \mapsto \ell]}(\langle a_{\pi} \rangle x) + a.(!\emptyset, a).\mathsf{yes} \end{array}$$

and

$$m^{\ell}_{[\pi \mapsto \ell]}(\langle a_{\pi} \rangle x) = (a.(!\emptyset, a).x + b.(!\emptyset, b).\mathsf{yes}) \otimes (b.(!\emptyset, b).\mathsf{no} + a.(!\emptyset, a).\mathsf{yes})$$
(13)

As the above example indicates, a decentralized monitor synthesis for formulas of the form $\langle a_{\pi} \rangle \psi$ that is based on rewriting them as in (12) leads to monitors with a high degree of parallelism (in the above example such degree was quite reduced because, for simplicity, we assumed to have just two actions – but in general |Act| - 1 parallel ands are required). In alternative, one could define a decentralized monitor synthesis directly for formulas of the form $\langle a_{\pi} \rangle \psi$ as follows:

$$m_{\sigma}^{\ell}(\langle a_{\pi}\rangle\psi) = \begin{cases} a.(!(\operatorname{rng}(\sigma)\backslash\{\ell\}), a).\operatorname{Dm}_{\sigma}^{\ell}(\psi) + \sum_{b\neq a} b.(!(\operatorname{rng}(\sigma)\backslash\{\ell\}), b).\operatorname{no} & \text{if } \sigma(\pi) = \ell \\ \\ \sum_{b\in\operatorname{Act}} b.\left((?\{\sigma(\pi)\}, a).\operatorname{Dm}_{\sigma}^{\ell}(\psi) + \sum_{b\neq a}(?\{\sigma(\pi)\}, b).\operatorname{no}\right) & \text{otherwise} \end{cases}$$

(that is essentially the synthesis for box formulas of Table 11 with no in place of yes). With this explicit rule for diamonds, (13) simply reduces to:

$$m^\ell_{[\pi\mapsto\ell]}(\langle a_\pi
angle x)=a.(!\emptyset,a).x+b.(!\emptyset,b).$$
no

In particular, the synthesized monitor for diamond now contains no occurrence of any parallel operator.
