# Computing the Action of the Generating Function of Bernoulli Polynomials on a Matrix with An Application to Non-local Boundary Value Problems 

Lidia Aceto • Luca Gemignani

June 4, 2024

#### Abstract

This paper deals with efficient numerical methods for computing the action of the generating function of Bernoulli polynomials, say $q(\tau, w)$, on a typically large sparse matrix. This problem occurs when solving some non-local boundary value problems. Methods based on the Fourier expansion of $q(\tau, w)$ have already been addressed in the scientific literature. The contribution of this paper is twofold. First, we place these methods in the classical framework of Krylov-Lanczos (polynomialrational) techniques for accelerating Fourier series. This allows us to apply the convergence results developed in this context to our function. Second, we design a new acceleration scheme. Some numerical results are presented to show the effectiveness of the proposed algorithms.

## 1 Introduction

In this work we are interested in the approximation of the function

$$
\begin{equation*}
q(\tau, w)=\frac{w e^{w \tau}}{e^{w}-1}, \quad w \in \mathbb{C} \backslash\{0, \pm 2 \pi \mathrm{i}, \pm 4 \pi \mathrm{i}, \ldots\} \tag{1.1}
\end{equation*}
$$

which acts on a typically large sparse matrix. As known, this function is the generating function of Bernoulli polynomials $B_{k}(\tau)$, i.e.

$$
\begin{equation*}
q(\tau, w)=\sum_{k=0}^{+\infty} B_{k}(\tau) \frac{w^{k}}{k!}, \tag{1.2}
\end{equation*}
$$

see e.g. [1], which are very important in various fields of mathematics and, in particular, are intimately connected to differential equations. For example, recall that in a finite-dimensional setting in [4] it is proved that for a given matrix $A \in \mathbb{R}^{s \times s}$ and a given vector $f \in \mathbb{R}^{s}$, the non-local boundary value problem (BVP)

$$
\begin{align*}
& \frac{\mathrm{d} \mathbf{u}}{\mathrm{~d} \tau}=A \mathbf{u}, \quad 0<\tau<1  \tag{1.3}\\
& \int_{0}^{1} \mathbf{u}(\tau) \mathrm{d} \tau=f \tag{1.4}
\end{align*}
$$

admits as unique solution

$$
\begin{equation*}
\mathbf{u}(\tau)=q(\tau, A) \boldsymbol{f} \tag{1.5}
\end{equation*}
$$

More general differential problems can also be reduced into the form (1.3), (1.4) by the application of semidiscretization-in-space schemes.

BVPs with special non-local boundary conditions are ubiquitous in applied sciences and engineering. Integral boundary conditions are encountered in various applications such as population dynamics, blood flow models, chemical engineering and cellular systems (see e.g. [7, 16] and the references given therein). Interestingly, such problems are also relevant in control theory for system identification, where the analysis goes back to the work of Bellmann [3].

Several numerical methods have been developed in [4|5] for evaluating the matrix function $q(\tau, A)$, when $A$ is large and possibly sparse. The approach based on (1.2) is unreliable since the formal series uniformly converges only within $|w|<2 \pi$. By using an ad-hoc technique for the convergence acceleration of a Fourier series, in [5] for $n \geq 0$ the following rational-trigonometric modification of (1.2) has been obtained

$$
\begin{equation*}
q(\tau, 2 \pi z)=\sum_{k=0}^{2 n+1} B_{k}(\tau) \frac{(2 \pi z)^{k}}{k!}+(-1)^{n} 2 z^{2 n+2} \sum_{k=1}^{+\infty} \frac{\cos (2 \pi k \tau)+\frac{z}{k} \sin (2 \pi k \tau)}{k^{2 n}\left(z^{2}+k^{2}\right)} \tag{1.6}
\end{equation*}
$$

Hence, by truncating the series on the right to a finite number of terms, say $N$, in the same work it has been proposed to consider the family of approximations given by

$$
\begin{equation*}
g_{n, N}(\tau, z):=\sum_{k=0}^{2 n+1} B_{k}(\tau) \frac{(2 \pi z)^{k}}{k!}+(-1)^{n} 2 z^{2 n+2} \sum_{k=1}^{N} \frac{\cos (2 \pi k \tau)+\frac{z}{k} \sin (2 \pi k \tau)}{k^{2 n}\left(z^{2}+k^{2}\right)} \tag{1.7}
\end{equation*}
$$

Although it has also been shown that the series on the right side of (1.6) converges uniformly to $q(\tau, 2 \pi z)$ on every set $\mathcal{K}_{1} \times \mathcal{K}_{2}$, with $\mathcal{K}_{1} \subset(0,1)$ and $\mathcal{K}_{2} \subset \mathbb{C} \backslash \pm i \mathbb{N}$ compact sets, both the residual estimates and the exact evaluations of the asymptotic error constants are still missing. Furthermore, although increasing the value of $n$ can bring great benefits to improve the convergence rate of (1.6), computing the
polynomial term of $g_{n, N}(\tau, A)$ can be prone to numerical instabilities whenever $A$ has eigenvalues of large magnitude [6].

This work aims to fill these gaps. The starting point is the derivation of the formula (1.6) in a more general framework for the development of acceleration methods for ordinary Fourier series, which in [17] is called the Krylov-Lanczos approximation, since this approach was originally proposed by Krylov [13] and Lanczos [14]. The term Krylov-Lanczos approximation denotes a class of methods for accelerating trigonometric series of a non-periodic function by polynomial corrections that represent discontinuities of the function and some of its first derivatives. A classical approach among these methods is the Lanczos representation of functions in terms of Bernoulli polynomials and trigonometric series [14.15]. It is shown that this approach, applied to the periodic extension of $q(\tau, w)$, leads to the expansion (1.6). The result allows us to adapt the techniques and tools developed in the general framework for the analysis of the function $q(\tau, w)$. Specifically, we derive estimates of the residual error in $L^{2}$-norm and for pointwise convergence in the regions $\mathcal{K}_{1}$ far from the discontinuities at the endpoints. Furthermore, we develop an alternative acceleration strategy for $\tau \in \mathcal{K}_{1}$ which replaces the polynomial term in (1.6) with a suitable rational function expressed in a convenient form as sum of ratios.

The paper is organized as follows. In Section 2 we derive the expansion formula (1.6) in the framework of Lanczos representation. In Section 3 we adjust known error estimates for the Lanczos approximation to the function $q(\tau, w)$ by devising a suitable scheme for evaluating the pointwise convergence in regions away from the discontinuities. In Section 4 we show that this scheme indeeed yields an effective acceleration scheme involving only the manipulation of rational functions. In Section 5]we illustrate the effectiveness of this scheme by numerical experiments related with the solution of a non-local BVP of type (1.3)-(1.4). Finally, conclusions and future work are drawn in Section 6 .

## 2 Lanczos Acceleration of Fourier Expansions

Suppose we set a value for $w$, since $q(\tau, w)$ is analytic over the unit interval, it can be expanded into Fourier series of $\tau$ and we get

$$
q(\tau, w)=\hat{c}_{0}+\sum_{k=1}^{+\infty}\left[\hat{c}_{k} \cos (2 \pi k \tau)+\hat{s}_{k} \sin (2 \pi k \tau)\right] ;
$$

the coefficients that occur in this series (Fourier coefficients) are given by

$$
\hat{c}_{0}=\int_{0}^{1} q_{\tau}(w) d \tau=1
$$

and through the real and imaginary parts of

$$
\hat{c}_{k}+\mathrm{i} \hat{\mathrm{~s}}_{k}=\int_{0}^{1} q_{\tau}(w) e^{\mathrm{i} 2 \pi k \tau} d \tau
$$

From the evaluation of the latter integral it therefore follows that

$$
\begin{equation*}
q(\tau, w)=1+2 w \sum_{k=1}^{+\infty}[w \cos (2 \pi k \tau)-k \sin (2 \pi k \tau)]\left(w^{2}+k^{2}\right)^{-1} \tag{2.8}
\end{equation*}
$$

Since $q(\tau, w)$ is non-periodic, the use of the Fourier series has a computational disadvantage, i.e. the series can converge very slowly.

In [5, Lemma 1], the authors developed methods to accelerate the convergence of (2.8) by using relations expressing Bernoulli polynomials by appropriate numerical series of sine and cosine. This led to the relationship given in (1.6).

In this section, a derivation of the so-called Lanczos representation for the function $q(\tau, w)$ is described. This involves expressing $q(\tau, w)$ in the form

$$
\begin{equation*}
q(\tau, w) \equiv g(\tau)=h_{p-1}(\tau)+f_{p}(\tau) \tag{2.9}
\end{equation*}
$$

where $h_{p-1}(\tau)$ is a polynomial of degree $(p-1)$ and $f_{p}(\tau)$ has Fourier coefficients with a decay of order $k^{-p}$ as $k \rightarrow+\infty$. Following the results reported in [15] pp. 82, 83], for any $p \geq 1$ we get

$$
\begin{align*}
h_{p-1}(\tau) & :=1+\sum_{k=1}^{p-1}\left[g^{(k-1)}(1)-g^{(k-1)}(0)\right] \frac{B_{k}(\tau)}{k!}  \tag{2.10}\\
f_{p}(\tau) & :=2 \sum_{k=1}^{+\infty}\left[c_{k} \cos (2 \pi k \tau)+s_{k} \sin (2 \pi k \tau)\right] \tag{2.11}
\end{align*}
$$

where $B_{k}(\cdot)$ is the k-th Bernoulli polynomial and the coefficients $c_{k}$ and $s_{k}$ are such that

$$
c_{k}+\mathrm{i} s_{k}=\frac{(-1)^{p}}{(2 \pi k \mathrm{i})^{p}} \int_{0}^{1} g^{(p)}(\tau)\left(e^{2 \pi k \mathrm{i} \tau}-1\right) d \tau
$$

cfr. [15, Eqs. (1.14) and (1.20)]. By direct calculation it is easily found that

$$
\begin{align*}
c_{k}+\mathrm{i} s_{k} & =\frac{(-1)^{p}}{(2 \pi k \mathrm{i})^{p}}\left(\frac{w^{p+1}}{e^{w}-1} \frac{e^{w+2 \pi k \mathrm{i}}-1}{w+2 \pi k \mathrm{i}}-w^{p}\right) \\
& =\frac{(-1)^{p}}{(2 \pi k \mathrm{i})^{p}} w^{p+1}\left(\frac{1}{w+2 \pi k \mathrm{i}}-\frac{1}{w}\right) \\
& =\frac{(-1)^{p}}{(2 \pi k)^{p}} w^{p+1}\left(\frac{w-2 \pi k \mathrm{i}}{w^{2}+(2 \pi k)^{2}}-\frac{1}{w}\right) \\
& =\frac{(-1)^{p+1}}{(2 \pi k)^{p-1} \mathrm{i}^{p}} w^{p} \frac{2 \pi k+w \mathrm{i}}{w^{2}+(2 \pi k)^{2}} \tag{2.12}
\end{align*}
$$

Consequently,

$$
c_{k}+\mathrm{i} s_{k}=\left\{\begin{array}{cl}
\frac{(-1)^{p / 2+1}}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}}+\mathrm{i} \frac{(-1)^{p / 2+1}}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}}, & p \text { even }  \tag{2.13}\\
\frac{(-1)^{(p+1) / 2}}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}}+\mathrm{i} \frac{(-1)^{(p+1) / 2}}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}}, & p \text { odd. }
\end{array}\right.
$$

In addition, observing that

$$
g^{(k-1)}(1)-g^{(k-1)}(0)=w^{k}
$$

and that $B_{0}(\tau)=1$, we can rewrite (see (2.10)

$$
\begin{aligned}
h_{p-1}(\tau) & =B_{0}(\tau)+\sum_{k=1}^{p-1} B_{k}(\tau) \frac{w^{k}}{k!} \\
& =\sum_{k=0}^{p-1} B_{k}(\tau) \frac{w^{k}}{k!}
\end{aligned}
$$

To establish whether the newly introduced Lanczos representation of $q(\tau, w)$ recovers the expression found in [5] and reported in (1.6), we set $p=2(n+1)$ and $w=(2 \pi z)$. Obviously,

$$
\begin{equation*}
h_{2 n+1}(\tau)=\sum_{k=0}^{2 n+1} B_{k}(\tau) \frac{(2 \pi z)^{k}}{k!} \tag{2.14}
\end{equation*}
$$

Concerning $f_{p}(\tau)$, from (2.13) we have that

$$
\begin{equation*}
f_{2 n+2}(\tau)=2 \sum_{k=1}^{+\infty}\left[c_{k} \cos (2 \pi k \tau)+s_{k} \sin (2 \pi k \tau)\right] \tag{2.15}
\end{equation*}
$$

with

$$
\begin{equation*}
c_{k}=\frac{(-1)^{n}}{k^{2 n}} \frac{z^{2 n+2}}{z^{2}+k^{2}}, \quad s_{k}=\frac{(-1)^{n}}{k^{2 n+1}} \frac{z^{2 n+3}}{z^{2}+k^{2}} \tag{2.16}
\end{equation*}
$$

Then, it is immediate to verify that the Lanczos representation

$$
q(\tau, w)=h_{2 n+1}(\tau)+f_{2 n+2}(\tau)
$$

agrees with (1.6).
Such concurrence is interesting from both a theoretical and a practical point of view. Indeed, it makes possible to adapt general results for the Lanczos representation of regular functions to the specific expansion (1.6) of $q(\tau, 2 \pi z)$. These results include error estimates and the design of alternative acceleration schemes. The corresponding adaptations for $q(\tau, w)$ are the subject of the next sections.

## 3 Error Estimate and Convergence

The connection between the function $q(\tau, w)$ and the Lanczos representations discussed in the previous section is now exploited to derive the error estimate and to perform a convergence analysis.

Denoting by

$$
f_{p, N}(\tau):=2 \sum_{k=1}^{N}\left[c_{k} \cos (2 \pi k \tau)+s_{k} \sin (2 \pi k \tau)\right]
$$

the truncation to the first $N$ terms of $f_{p}(\tau)$ (see (2.11) , we may approximate

$$
\begin{equation*}
q(\tau, w) \approx h_{p-1}(\tau)+f_{p, N}(\tau) . \tag{3.17}
\end{equation*}
$$

Then, we are able to provide an estimate for the error

$$
\begin{align*}
R_{p, N}(\tau, w) & :=q(\tau, w)-\left[h_{p-1}(\tau)+f_{p, N}(\tau)\right] \\
& =2 \sum_{k=N+1}^{+\infty}\left[c_{k} \cos (2 \pi k \tau)+s_{k} \sin (2 \pi k \tau)\right] \tag{3.18}
\end{align*}
$$

Theorem 1 For a given integer $p \geq 1$ the following estimate holds

$$
\begin{equation*}
\lim _{N \rightarrow+\infty} N^{p-1 / 2}\left\|R_{p, N}(\tau, w)\right\|_{2}=|w|^{p} \frac{1}{(2 \pi)^{p}} \frac{\sqrt{2}}{\sqrt{2 p-1}} \tag{3.19}
\end{equation*}
$$

where $\|\cdot\|_{2}$ is the $L^{2}$-norm.
Proof Following [?, Theorem 2.1] and using (2.12) we can write

$$
R_{p, N}(\tau, w)=\sum_{|k|>N} F_{-k} e^{-\mathrm{i} 2 \pi k \tau}
$$

with

$$
F_{-k}=c_{k}+\mathrm{i} s_{k} .
$$

Using the Parseval's identity, we get

$$
\begin{aligned}
\left\|R_{p, N}(\tau, w)\right\|_{2}^{2} & =\sum_{|k|>N}\left|F_{-k}\right|^{2} \\
& =\frac{1}{(2 \pi)^{2 p}}|w|^{2 p+2} \sum_{|k|>N} \frac{1}{k^{2 p}}\left|\frac{w-2 \pi k \mathrm{i}}{w^{2}+(2 \pi k)^{2}}-\frac{1}{w}\right|^{2} \\
& =\frac{1}{(2 \pi)^{2 p}}|w|^{2 p+2} \sum_{|k|>N} \frac{1}{k^{2 p}} \frac{(2 \pi k)^{2}}{w^{2}\left[w^{2}+(2 \pi k)^{2}\right]} \\
& \approx \frac{1}{(2 \pi)^{2 p}}|w|^{2 p} \sum_{|k|>N} \frac{1}{k^{2 p}} \\
& \approx \frac{1}{(2 \pi)^{2 p}}|w|^{2 p} \frac{2 N^{-2 p+1}}{2 p-1} .
\end{aligned}
$$

This concludes the proof.
Remark 1 It is worth noting in (3.19) the occurrence of the term $|w|^{p}$ which can be problematic for convergence in the $w$-domain. This observation is confirmed by many experimental results reported in [11] which indicate that the more is the size of $w$, the more is the number of terms of (1.6) needed to reach a prescribed accuracy.

| $z$ | 512 | 1024 | 2048 |
| :---: | :---: | :---: | :---: |
| 1 | 0.5327 | 0.5328 | 0.5319 |
| 0.1 | 0.5327 | 0.5328 | 0.5319 |
| 10 | 0.5327 | 0.5328 | 0.5319 |

Table 1: Values of the quantity $\Delta(N)$ given in (3.22) with $R_{1, N}(\tau, z)$ truncated at the first 2048 terms.

When $p=2(n+1)$ and $w=(2 \pi z)$, (3.17) coincides with (1.7). So, we can rewrite the approximation to $q(\tau, 2 \pi z)$ given in (1.7) as

$$
\begin{equation*}
g_{n, N}(\tau, z)=h_{2 n+1}(\tau)+f_{2 n+2, N}(\tau) \tag{3.20}
\end{equation*}
$$

Using these notation, we define the error as

$$
\begin{align*}
& R_{n, N}(\tau, z):=q(\tau, 2 \pi z)-g_{n, N}(\tau, z) \\
& =2 \sum_{k=N+1}^{+\infty}\left[\frac{(-1)^{n} z^{2 n+2}}{k^{2 n}\left(z^{2}+k^{2}\right)} \cos (2 \pi k \tau)+\frac{(-1)^{n} z^{2 n+3}}{k^{2 n+1}\left(z^{2}+k^{2}\right)} \sin (2 \pi k \tau)\right] . \tag{3.21}
\end{align*}
$$

From Theorem 1 it is immediate to deduce that

$$
\lim _{N \rightarrow+\infty} N^{2 n+3 / 2}\left\|R_{n, N}(\tau, z)\right\|_{2}=|z|^{2 n+2} \frac{\sqrt{2}}{\sqrt{4 n+3}}
$$

In Table 1 we show a numerical illustration of this result with $n=1$. For a given $z \in\{1,0.1,10\}$ and $N \in\{512,1024,2048\}$ we compute the quantity

$$
\begin{equation*}
\Delta(N)=\frac{N^{7 / 2}}{|z|^{4}}\left\|R_{1, N}(\tau, z)\right\|_{2} \tag{3.22}
\end{equation*}
$$

where $\left\|R_{1, N}(\tau, z)\right\|_{2}$ is estimated using the Mathematica function NIntegrate applied to the partial sum formed by the first 2048 terms of the expansion (3.21). Doubling the number of terms does not change the results. The integrands are highly oscillatory and Mathematica returns partial errors of order $10^{-3}$. As can be seen, for each $N$ considered the computed value $\Delta(N)$ is a good approximation of $\sqrt{2 / 7} \approx$ 0.5345 , independently of $z$.

To investigate pointwise convergence in regions away from the discontinuities at the endpoints of the interval $[0,1]$, we follow an approach that is based on the results of [12] and differs from the approach used in [5]. This approach avoids the use of Bernoulli polynomials by employing rational corrections of the error in order to accelerate its convergence toward zero. More precisely, we consider the first term in
(3.18) without considering a constant, namely (see (2.13))

$$
\begin{align*}
R_{p, N}^{(1)}(\tau, w) & := \begin{cases}\sum_{k=N+1}^{+\infty} \frac{1}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}} \cos (2 \pi k \tau), & p \text { even } \\
\sum_{k=N+1}^{+\infty} \frac{1}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}} \cos (2 \pi k \tau), & p \text { odd }\end{cases} \\
& \equiv \sum_{k=N+1}^{+\infty} \gamma_{k}^{(0)} \cos (2 \pi k \tau) \tag{3.23}
\end{align*}
$$

From the relation

$$
2 \cos (2 \pi k \tau) \cos (2 \pi \tau)=\cos (2 \pi(k+1) \tau)+\cos (2 \pi(k-1) \tau), \quad k \geq 1,
$$

it follows that

$$
\begin{aligned}
(2-2 \cos (2 \pi \tau)) R_{p, N}^{(1)}(\tau, w)= & \sum_{k=N+1}^{+\infty} 2 \gamma_{k}^{(0)} \cos (2 \pi k \tau) \\
& -\sum_{k=N+1}^{+\infty} \gamma_{k}^{(0)}[\cos (2 \pi(k+1) \tau)+\cos (2 \pi(k-1) \tau)] \\
= & \sum_{k=N+1}^{+\infty} 2 \gamma_{k}^{(0)} \cos (2 \pi k \tau) \\
& -\sum_{r=N+2}^{+\infty} \gamma_{r-1}^{(0)} \cos (2 \pi r \tau)-\sum_{s=N}^{+\infty} \gamma_{s+1}^{(0)} \cos (2 \pi s \tau)
\end{aligned}
$$

Therefore, we obtains that

$$
\begin{align*}
& (2-2 \cos (2 \pi \tau)) R_{p, N}^{(1)}(\tau, w)=\gamma_{N+1}^{(0)}[2 \cos (2 \pi(N+1) \tau)-\cos (2 \pi N \tau)] \\
& -\gamma_{N+2}^{(0)} \cos (2 \pi(N+1) \tau)+\sum_{k=N+2}^{+\infty} \gamma_{k}^{(1)} \cos (2 \pi k \tau) \tag{3.24}
\end{align*}
$$

with

$$
\begin{equation*}
\gamma_{k}^{(1)}=-\gamma_{k-1}^{(0)}+2 \gamma_{k}^{(0)}-\gamma_{k+1}^{(0)} . \tag{3.25}
\end{equation*}
$$

Notice that $-\gamma_{k}^{(1)}$ is the classical approximation of the second derivative of the function (see (3.23) and (2.13))

$$
f_{1}(x)= \begin{cases}\frac{1}{(2 \pi x)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi x)^{2}}, & p \text { even }  \tag{3.26}\\ \frac{1}{(2 \pi x)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi x)^{2}}, & p \text { odd }\end{cases}
$$

over the grid $x_{k}=k, k \geq N+2$. Since

$$
f_{1}^{\prime \prime}(x)=\left\{\begin{array}{cl}
\frac{\theta_{1}(p) w^{p} x^{4-p}}{\left(w^{2}+(2 \pi x)^{2}\right)^{3}}+\frac{\theta_{2}(p) w^{p} x^{2-p}}{\left(w^{2}+(2 \pi x)^{2}\right)^{2}}+\frac{\theta_{3}(p) w^{p} x^{-p}}{w^{2}+(2 \pi x)^{2}}, & p \text { even }  \tag{3.27}\\
\frac{\vartheta_{1}(p) w^{1+p} x^{3-p}}{\left(w^{2}+(2 \pi x)^{2}\right)^{3}}+\frac{\vartheta_{2}(p) w^{1+p} x^{1-p}}{\left(w^{2}+(2 \pi x)^{2}\right)^{2}}+\frac{\vartheta_{3}(p) w^{1+p} x^{-1-p}}{w^{2}+(2 \pi x)^{2}}, & p \text { odd }
\end{array}\right.
$$

from Taylor expansion we deduce that

$$
f_{1}^{\prime \prime}(k)+\gamma_{k}^{(1)}=-\frac{2 f_{1}^{\mathrm{iv}}\left(\xi_{k}\right)}{4!}, \quad k-1 \leq \xi_{k} \leq k+1
$$

which implies

$$
\gamma_{k}^{(1)}= \begin{cases}O\left(k^{-p-2}\right), & p \text { even }  \tag{3.28}\\ O\left(k^{-p-3}\right), & p \text { odd }\end{cases}
$$

Analogously, for the second term in 3.18 we have

$$
\begin{align*}
R_{p, N}^{(2)}(\tau, w) & := \begin{cases}\sum_{k=N+1}^{+\infty} \frac{1}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}} \sin (2 \pi k \tau), & p \text { even } \\
\sum_{k=N+1}^{+\infty} \frac{1}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}} \sin (2 \pi k \tau), & p \text { odd }\end{cases} \\
& \equiv \sum_{k=N+1}^{+\infty} \delta_{k}^{(0)} \sin (2 \pi k \tau) \tag{3.29}
\end{align*}
$$

Using the the formula

$$
2 \sin (2 \pi k \tau) \cos (2 \pi \tau)=\sin (2 \pi(k+1) \tau)+\sin (2 \pi(k-1) \tau), \quad k \geq 1
$$

we obtain that

$$
\begin{align*}
(2 & -2 \cos (2 \pi \tau)) R_{p, N}^{(2)}(\tau, w)=\delta_{N+1}^{(0)}[2 \sin (2 \pi(N+1) \tau)-\sin (2 \pi N \tau)] \\
& -\delta_{N+2}^{(0)} \sin (2 \pi(N+1) \tau)+\sum_{k=N+2}^{+\infty} \delta_{k}^{(1)} \sin (2 \pi k \tau) \tag{3.30}
\end{align*}
$$

with

$$
\begin{equation*}
\delta_{k}^{(1)}=-\delta_{k-1}^{(0)}+2 \delta_{k}^{(0)}-\delta_{k+1}^{(0)} \tag{3.31}
\end{equation*}
$$

Again, we observe that $-\delta_{k}^{(1)}$ is the classical approximation of the second derivative of the function

$$
f_{2}(x)= \begin{cases}\frac{1}{(2 \pi x)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi x)^{2}}, & p \text { even }  \tag{3.32}\\ \frac{1}{(2 \pi x)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi x)^{2}}, & p \text { odd }\end{cases}
$$

over the grid $x_{k}=k, k \geq N+2$. Notice that (3.26) coincides with (3.32) up to a change of parity of $p$. Hence, from (3.28) we find that

$$
\delta_{k}^{(1)}= \begin{cases}O\left(k^{-p-3}\right), & p \text { even }  \tag{3.33}\\ O\left(k^{-p-2}\right), & p \text { odd }\end{cases}
$$

In this way, we arrive at the following result which describes the behaviour of the error in the interior of the unit interval.

Theorem 2 For any $\tau \in(0,1)$, setting

$$
m= \begin{cases}p, & p \text { even }, \\ p+1, & p \text { odd }\end{cases}
$$

we have

$$
R_{p, N}(\tau, w)=\frac{(-1)^{\lceil(p+1) / 2\rceil}}{1-\cos (2 \pi \tau)} \Gamma_{p, N}(\tau, w)+o\left(N^{-m}\right), \quad N \rightarrow+\infty
$$

where $\lceil\cdot\rceil$ denotes the ceiling function and

$$
\Gamma_{p, N}(\tau, w)=\gamma_{N+1}^{(0)}[2 \cos (2 \pi(N+1) \tau)-\cos (2 \pi N \tau)]-\gamma_{N+2}^{(0)} \cos (2 \pi(N+1) \tau)
$$

Proof Using (3.23) and (3.29), the error in (3.18) can be written as

$$
\begin{equation*}
R_{p, N}(\tau, w)=(-1)^{\lceil(p+1) / 2\rceil} 2\left[R_{p, N}^{(1)}(\tau, w)+R_{p, N}^{(2)}(\tau, w)\right] . \tag{3.34}
\end{equation*}
$$

Then, taking into account the relations given in (3.24) and (3.30), and the estimates (3.28), (3.33) the result follows immediately.

## 4 Acceleration of Convergence

The results reported in Theorem 1 and Theorem 2 illustrate theoretically the acceleration capabilities of Lanczos approximation. However, the numerical results shown in [6] clearly indicate that the computation of the polynomial term in (1.6) can be prone to numerical instabilities. To circumvent this issue, in this section we investigate the design of different acceleration techniques for evaluating $q(\tau, w)$. Our starting point is the observation that the strategy devised in the previous section for the error analysis of the Lanczos representation can be applied from scratch to the expansion with $p=2$ or very small values of $p$.
Recalling that (see (3.23) and (3.29)

$$
\gamma_{k}^{(0)}=\left\{\begin{array}{l}
\frac{1}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}}, p \text { even, } \\
\frac{1}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}}, p \text { odd, }
\end{array}\right.
$$

$$
\delta_{k}^{(0)}= \begin{cases}\frac{1}{(2 \pi k)^{p-1}} \frac{w^{p+1}}{w^{2}+(2 \pi k)^{2}}, & p \text { even } \\ \frac{1}{(2 \pi k)^{p-2}} \frac{w^{p}}{w^{2}+(2 \pi k)^{2}}, & p \text { odd }\end{cases}
$$

and denoting by

$$
\Gamma_{1}^{(1)}:=\frac{\gamma_{N+1}^{(0)}[2 \cos (2 \pi(N+1) \tau)-\cos (2 \pi(N) \tau)]-\gamma_{N+2}^{(0)} \cos ((N+1) \tau)}{2-2 \cos (2 \pi \tau)}
$$

and

$$
\Delta_{1}^{(1)}:=\frac{\delta_{N+1}^{(0)}[2 \sin (2 \pi(N+1) \tau)-\sin (2 \pi(N) \tau)]-\delta_{N+2}^{(0)} \sin ((N+1) \tau)}{2-2 \cos (2 \pi \tau)}
$$

from (3.24) and (3.30) we find that for any $\tau \in(0,1)$ the error can be expressed as (see (3.34))

$$
\begin{aligned}
R_{p, N}(\tau, w) & =\frac{(-1)^{\lceil(p+1) / 2\rceil} 2}{2-2 \cos (2 \pi \tau)}\left[(2-2 \cos (2 \pi \tau)) R_{p, N}^{(1)}(\tau, w)+\right. \\
& \left.+(2-2 \cos (2 \pi \tau)) R_{p, N}^{(2)}(\tau, w)\right] \\
& =(-1)^{\lceil(p+1) / 2\rceil} 2\left(\Gamma_{1}^{(1)}+\Delta_{1}^{(1)}\right)+ \\
& +\frac{(-1)^{\lceil(p+1) / 2\rceil}}{2-2 \cos (2 \pi \tau)}\left(\sum_{k=N+2}^{+\infty} \gamma_{k}^{(1)} \cos (2 \pi k \tau)+\sum_{k=N+2}^{+\infty} \delta_{k}^{(1)} \sin (2 \pi k \tau)\right),
\end{aligned}
$$

with
$\gamma_{k}^{(j)}=-\gamma_{k-1}^{(j-1)}+2 \gamma_{k}^{(j-1)}-\gamma_{k+1}^{(j-1)}, \quad \delta_{k}^{(j)}=-\delta_{k-1}^{(j-1)}+2 \delta_{k}^{(j-1)}-\delta_{k+1}^{(j-1)}, \quad j \geq 1$.
The process can be iterated in order to accelerate the convergence of the two series in the left hand side of this relation by the multiplication by the factor $2-2 \cos (2 \pi \tau)$. In this way, by setting for an integer $\ell \geq 1$,
$\Gamma_{1}^{(\ell)}=\sum_{j=1}^{\ell} \frac{\gamma_{N+j}^{(j-1)}[2 \cos (2 \pi(N+j) \tau)-\cos (2 \pi(N+j-1) \tau)]-\gamma_{N+j+1}^{(j-1)} \cos ((N+j) \tau)}{(2-2 \cos (2 \pi \tau))^{j}}$
and
$\Delta_{1}^{(\ell)}=\sum_{j=1}^{\ell} \frac{\delta_{N+j}^{(j-1)}[2 \sin (2 \pi(N+j) \tau)-\sin (2 \pi(N+j-1) \tau)]-\delta_{N+j+1}^{(j-1)} \sin ((N+j) \tau)}{(2-2 \cos (2 \pi \tau))^{j}}$,
we find that

$$
R_{p, N}(t, w)=(-1)^{\lceil(p+1) / 2\rceil} 2\left(\Gamma_{1}^{(\ell)}+\Delta_{1}^{(\ell)}\right)+S_{p, N, \ell}(\tau, w), \quad \ell \geq 1
$$

or, equivalently,

$$
\begin{align*}
q(\tau, w) & =\left[h_{p-1}(\tau)+f_{p, N}(\tau)\right]+(-1)^{\lceil(p+1) / 2\rceil} 2\left(\Gamma_{1}^{(\ell)}+\Delta_{1}^{(\ell)}\right)+S_{p, N, \ell}(\tau, w) \\
& :=\mathcal{G}_{p, N, \ell}(\tau, w)+S_{p, N, \ell}(\tau, w), \quad \ell \geq 1 \tag{4.35}
\end{align*}
$$

Remark 2 At $\ell=0$ the approximation of $q(\tau, w)$ reduces to the approximation already given in (3.18) without acceleration, i.e.

$$
\mathcal{G}_{p, N, 0}(\tau, w)=h_{p-1}(\tau)+f_{p, N}(\tau)
$$

The error estimates for the residual $S_{p, N, \ell}(\tau, w)$ can be derived using the same arguments exploited in the proofs of Theorem 1 and Theorem[2] A global estimate of $\left\|S_{p, N, \ell}(\tau, w)\right\|_{2}$ can be obtained by introducing the penalty factors $\theta_{j}, 0<\theta_{j}<1$, as pursued in [17, 18]. In particular, the error analysis is extended by replacing the term $2-2 \cos (2 \pi \tau)$ with the modified form $2-2 \theta_{j} \cos (2 \pi \tau)$ for appropriate choices of such penalty factors. The overall process behaves similarly with the only modification being the use of weighted finite difference approximations for the second derivatives.

We have performed numerical experiments to test the effectiveness of the proposed acceleration technique. In Figure 1we illustrate this behavior by drawing the relative error function

$$
\operatorname{err}_{p, N, \ell}(\tau, w)=\frac{\left|q(\tau, w)-\mathcal{G}_{p, N, \ell}(\tau, w)\right|}{|q(\tau, w)|}, \quad-10 \leq w \leq 0,
$$

for $\tau \in\left\{2^{-3}, 2^{-7}\right\}$, by setting $N=100$, and for different values of $p$ and $\ell$. Our experiments indicate that the method performs quite well for $\tau$ away from the discontinuities and its effectiveness decreases as the value of $\tau$ approaches 0 . If $\tau=0$, to get reliable algorithm for approximating $q(0, w)$ we must combine our approach with a suitable numerical method for evaluating the exponential function. Indeed, we can rely on the identity

$$
\begin{equation*}
q(0, w)=q(1-\alpha, w) e^{w / \alpha}-w, \quad \alpha \in(0,1) . \tag{4.36}
\end{equation*}
$$

The resulting approach is considered for $\alpha=1 / 8$ in Figure 2 where the exponential function is computed using the Matlab built-in function exp. Another popular method for calculating the exponential is the rational approximation. This tool can be suitable for parallel computations [10]. For further experiments, we used the rational Chebyshev approximation $\mathcal{N}_{r}(\zeta) / \mathcal{D}_{r}(\zeta)$ from $e^{-\zeta}$ for $\zeta \in[0,+\infty)$, with $\mathcal{N}_{r}(\zeta)$ and $\mathcal{D}_{r}(\zeta)$ polynomials of degree $r$, where the coefficients of such polynomials up to degree $r=30$ are given in [8]. In this way, we obtain an approximation of $q(0, w)$, denoted as $u_{n, N, \ell, r, \alpha}(w)$ and defined by

$$
q(0, w) \approx u_{p, N, \ell, r, \alpha}(w):=\mathcal{G}_{p, N, \ell}(\alpha, w) \frac{\mathcal{N}_{r}(-w / \alpha)}{\mathcal{D}_{r}(-w / \alpha)}-w .
$$

Considering that the rational Chebyshev approximation of $e^{-\zeta}$ has uniform absolute error estimates of the form

$$
\sup _{\zeta \geq 0}\left|\frac{\mathcal{N}_{r}(\zeta)}{\mathcal{D}_{r}(\zeta)}-e^{-\zeta}\right| \simeq 10^{-r},
$$

Fig. 1: Plots of the relative error $\operatorname{err}_{p, N, \ell}(\tau, w)$ with $N=100$ and $p=2 n+2$. In (a)-(b): $\tau=2^{-3}$. In (c)-(d): $\tau=2^{-7}$.

Fig. 2: Plots of $\operatorname{err}_{p, N, \ell}(\tau, w)$ at $\tau=0$ generated by using formula (4.36) with $\alpha=1 / 8, N=100$ and $p=2 n+2$.

Fig. 3: Plots of the absolute error $\operatorname{err}_{p, N, \ell, r, \alpha}(w)$ with $N=100, r=13$ and $\alpha=1 / 8$.
cfr. [8], in Figure 3] we plot the absolute error function

$$
\operatorname{err}_{p, N, \ell, r, \alpha}(w)=\left|q(0, w)-u_{p, N, \ell, r, \alpha}(w)\right|, \quad-5000 \leq w \leq 0,
$$

with $N=100, r=13, \alpha=1 / 8$ and for different values of the parameters $p$ and $\ell$. As can be seen by comparing the pictures on the left with those on the right of the figure, the acceleration strategy proposed in this work ( $\ell=3$ in this example) is more robust than the technique without acceleration $(\ell=0)$ for large input values. To confirm this statement, in the next section we present the results of two numerical tests concerning the computation of $q(\tau, A) \boldsymbol{f}$ with $A \in \mathbb{R}^{s \times s}$ a matrix having a real spectrum located on the negative axis with many eigenvalues of large magnitude. Based on the above results, the use of the acceleration strategy can significantly influence the accuracy of the computation of $q(\tau, w)$.

## 5 Numerical Experiments

In this section we present some experiments starting from the differential problem

$$
\left\{\begin{array}{l}
u_{t}=u_{x x},  \tag{5.37}\\
u(0, t)=u(1, t)=0,
\end{array} \quad 0<x<1,0<t<t_{f},\right.
$$

with the non-local condition

$$
\begin{equation*}
\frac{1}{t_{f}} \int_{0}^{t_{f}} u(x, t) d t=f(x) \tag{5.38}
\end{equation*}
$$

As is well known, the numerical solution of such a non-local BVP can be derived by applying the classical method of lines [9]. Then one discretizes the one-dimensional operator

$$
\mathcal{L}=\frac{d^{2}}{d x^{2}}
$$

by using central differences over the grid of points in the interval $[0,1]$ and obtains a matrix $A=\left(a_{i, j}\right) \in \mathbb{R}^{s \times s}$. Thus, the problem (5.37)-(5.38) is reduced to a differential problem of the form (1.3)- 1.4). The derivation of the numerical solution of such a BVP therefore involves the computation of $q(t, A) f$, where $f$ is the vector with contains the evaluation of $f$ on the grid, cfr. (1.5). If we now use $\left\{x_{i}\right\}_{i=0}^{s+1}$, with $0=x_{0}<x_{1}<\cdots<x_{s}<x_{s+1}=1$, to denote the grid points on [0,1], the matrix $A=\left(a_{i, j}\right)$ has a tridiagonal structure with non-zero entries

$$
\begin{cases}a_{i, i}=-2 /\left(\left(x_{i+1}-x_{i}\right)\left(x_{i}-x_{i-1}\right)\right), & 1 \leq i \leq s  \tag{5.39}\\ a_{i+1, i}=2 /\left(\left(x_{i+1}-x_{i}\right)\left(x_{i+2}-x_{i}\right)\right), & 1 \leq i \leq s-1 \\ a_{i, i+1}=2 /\left(\left(x_{i+i}-x_{i}\right)\left(x_{i+1}-x_{i-1}\right)\right), & 1 \leq i \leq s-1\end{cases}
$$

When the grid is uniform with stepsize $h$, the matrix reduces to $A=\left(1 / h^{2}\right) T$ with $T$ the 1D Laplacian matrix. Note that small values of $h$ imply the presence of both large eigenvalues and a large norm of $A$. In light of the Theorem 1 the first is a critical fact for the convergence of the approximation 3.17). The second, however, can deteriorate the accuracy of the acceleration strategy. To illustrate these effects, we performed numerical experiments in which we compared for $p=2 n+2$ the approximation derived with (3.17) (for such $p$, (3.17) actually reduces to (3.20) with that in 4.35). As shown in the previous section the latter requires the incorporation of the corrective term $(-1)^{\lceil(p+1) / 2\rceil} 2\left(\Gamma_{1}^{(\ell)}+\Delta_{1}^{(\ell)}\right)$. The evaluation of this term boils down to the calculation of quantities

$$
\begin{equation*}
\gamma_{N+1}^{(0)}, \gamma_{N+2}^{(0)}, \gamma_{N+2}^{(1)}, \gamma_{N+3}^{(1)}, \ldots, \gamma_{N+\ell}^{(\ell-1)}, \gamma_{N+\ell+1}^{(\ell-1)} \tag{5.40}
\end{equation*}
$$

and

$$
\delta_{N+1}^{(0)}, \delta_{N+2}^{(0)}, \delta_{N+2}^{(1)}, \delta_{N+3}^{(1)}, \ldots, \delta_{N+\ell}^{(\ell-1)}, \delta_{N+\ell+1}^{(\ell-1)}
$$

All these quantities can be obtained from $\gamma_{N+j}^{(0)}$ and $\delta_{N+j}^{(0)}, 0 \leq j \leq 2 \ell$, through recurrence relations. Furthermore, $\delta_{N+j}^{(0)}$ is derived from $\gamma_{N+j}^{(0)}$ at the cost of additional matrix-by-vector multiplication. The next graph illustrates the computation of the required quantities in (5.40) when $\ell=3$.

Table 2: Test 1 - uniform grid

| Lanc | $\tau=1 / 12$ |  |  | $\tau=1 / 6$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $N_{n}$ | 2 | 3 | 4 | 2 | 3 | 4 |
| 50 | $4.4 e+07$ | $2.3 e+11$ | $1.3 e+15$ | $1.4 e+08$ | $6.6 e+11$ | $1.0 e+16$ |
| 100 | $2.0 e+06$ | $2.3 e+09$ | $5.8 e+14$ | $4.1 e+05$ | $1.1 e+09$ | $6.9 e+15$ |
| 200 | $3.7 e+04$ | $8.4 e+07$ | $5.8 e+14$ | $1.5 e+05$ | $5.8 e+08$ | $6.9 e+15$ |

| FastLanc | $\tau=1 / 12$ |  |  | $\tau=1 / 6$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2 | 3 | 4 | 2 | 3 | 4 |
| 50 | $3.3 e-04$ | $1.7 e-05$ | 1.7e-06 | $6.0 e-06$ | $5.6 e-07$ | $1.0 e-08$ |
| 100 | $2.1 e-05$ | $1.6 e-07$ | 1.5e-09 | $2.3 e-06$ | $4.1 e-10$ | $2.9 e-11$ |
| 200 | $4.6 e-07$ | $1.7 e-09$ | $1.0 e-11$ | $2.0 e-09$ | $5.3 e-11$ | $2.1 e-11$ |

Therefore, considering that the evaluation of $g_{n, N}(\tau, A) f$ essentially requires the solution of $N$ shifted linear systems of the form $\left(A^{2}+k^{2} I\right) \boldsymbol{x}=\boldsymbol{b}$ while the computation of $\mathcal{G}_{p, N, \ell}(\tau, A) \boldsymbol{f}$ requires solving $2 \ell$ additional systems, we conclude that for small values of $\ell$ both approximations are comparable in terms of computational cost.

In our numerical experiments we consider as exact solution $z=(\operatorname{expm}(A)-$ $\operatorname{eye}(s)) \backslash(\operatorname{expm}(\tau A) A \boldsymbol{f})$ derived using the MATLAB "backslash" operator and builtin function expm. We measure the error with

$$
\|y-z\|_{\infty}
$$

having indicated with $\boldsymbol{y}$ the approximate solution provided by one of the two approximations, i.e. $g_{n, N}(\tau, A) \boldsymbol{f}$ and $\mathcal{G}_{p, N, \ell}(\tau, A) \boldsymbol{f}$, with $p=2 n+2$. For short, we denote by

- Lanc: $\left\|g_{n, N}(\tau, A) \boldsymbol{f}-\boldsymbol{z}\right\|_{\infty}$
- FastLanc: $\left\|\mathcal{G}_{p, N, \ell}(\tau, A) \boldsymbol{f}-\boldsymbol{z}\right\|_{\infty}$

For the tridiagonal matrix $A \in \mathbb{R}^{64 \times 64}$ given in (5.39) and $f=$ ones $(64,1)$, our test suite consists of two experiments:

- Test 1: uniform grid with $1 / h^{2}=1000$;
- Test 2: not uniform grid with

$$
x_{0}=0, \quad x_{1}=0.01, \quad x_{i+1}=x_{i}+\sigma\left(x_{i}-x_{i-1}\right), i \geq 1, \sigma=1.005 .
$$

In Table 2 we report the errors provided by the two approximations on a uniform grid for $\tau=1 / 12,1 / 6$ and $p=2$ (i.e. $n=0$ ) when the acceleration is considered. Analogue comparisons for not uniform grid are reported in Table 3. These tables clearly highlight the robustness of the proposed acceleration scheme compared to the strategy based on the use of Lanczos approximation.

Table 3: Test 2 - not uniform grid

| Lanc | $\tau=1 / 12$ |  |  | $\tau=1 / 6$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $N_{n}$ | 2 | 3 | 4 | 2 | 3 | 4 |
| 50 | $3.5 e+12$ | $1.8 e+18$ | $7.1 e+23$ | $3.6 e+12$ | $1.5 e+18$ | $1.8 e+24$ |
| 100 | $1.7 e+11$ | $1.9 e+16$ | $2.1 e+23$ | $6.5 e+09$ | $2.5 e+15$ | $1.1 e+24$ |
| 200 | $2.6 e+09$ | $7.6 e+14$ | $2.1 e+23$ | $3.8 e+09$ | $1.6 e+15$ | $1.1 e+24$ |

| FastLanc |  | $\tau=1 / 12$ |  |  | $\tau=1 / 6$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\ell$ | 2 | 3 | 4 | 2 | 3 | 4 |  |
|  | $2.9 e-03$ | $1.5 e-04$ | $1.0 e-05$ | $1.5 e-05$ | $1.4 e-06$ | $2.7 e-08$ |  |
| 100 | $1.7 e-04$ | $1.4 e-06$ | $1.3 e-08$ | $5.9 e-06$ | $1.0 e-09$ | $1.1 e-10$ |  |
| 200 | $4.0 e-05$ | $1.5 e-08$ | $1.3 e-10$ | $4.7 e-09$ | $1.3 e-10$ | $1.1 e-10$ |  |

## 6 Conclusions and Future Work

In this paper we have derived the series expansion of the generating function of Bernoulli polynomials in the framework of the so-called Lanczos acceleration method of Fourier-trigonometric series of smooth non-periodic functions. This is a general method that involves the use of Bernoulli polynomials to accelerate convergence. Our derivation makes it possible to adapt the general error estimates provided for this method to the meromorphic function under consideration, namely the generating function of Bernoulli polynomials. Extensions of this method involving the use of rational functions are also investigated. In particular, we propose a cost-effective acceleration method based on the rational-trigonometric approximation of the residual of the Fourier series. Numerical experiments with finite difference discretizations of differential operators show that our proposed acceleration method outperforms the Lanczos approximation in terms of robustness and accuracy. Future work will focus on the development of an automatic procedure for the selection of the parameters necessary for the construction of the resulting approximations. Another interesting topic is the analysis of Fourier-Padé approximation methods of the residual. Such methods can be very effective when combined with efficient scaling and squaring techniques. The development of these methods for the calculation of $q(\tau, w)$ is still an ongoing research project.
