

Which exceptional low-dimensional projections of a Gaussian point cloud can be found in polynomial time?

Andrea Montanari* and Kangjie Zhou†

June 6, 2024

Abstract

Given d -dimensional standard Gaussian vectors $\mathbf{x}_1, \dots, \mathbf{x}_n$, we consider the set of all empirical distributions of its m -dimensional projections, for m a fixed constant. Diaconis and Freedman [DF84] proved that, if $n/d \rightarrow \infty$, all such distributions converge to the standard Gaussian distribution. In contrast, we study the proportional asymptotics, whereby $n, d \rightarrow \infty$ with $n/d \rightarrow \alpha \in (0, \infty)$. In this case, the projection of the data points along a typical random subspace is again Gaussian, but the set $\mathcal{F}_{m,\alpha}$ of all probability distributions that are asymptotically feasible as m -dimensional projections contains non-Gaussian distributions corresponding to exceptional subspaces.

Non-rigorous methods from statistical physics yield an indirect characterization of $\mathcal{F}_{m,\alpha}$ in terms of a generalized Parisi formula. Motivated by the goal of putting this formula on a rigorous basis, and to understand whether these projections can be found efficiently, we study the subset $\mathcal{F}_{m,\alpha}^{\text{alg}} \subseteq \mathcal{F}_{m,\alpha}$ of distributions that can be realized by a class of iterative algorithms. We prove that this set is characterized by a certain stochastic optimal control problem, and obtain a dual characterization of this problem in terms of a variational principle that extends Parisi's formula.

As a byproduct, we obtain computationally achievable values for a class of random optimization problems including ‘generalized spherical perceptron’ models.

1 Introduction

Let $(\mathbf{x}_i)_{i \leq n} \sim_{\text{i.i.d.}} \mathbf{N}(\mathbf{0}, \mathbf{I}_d)$ be independent standard Gaussian vectors and denote by $\mathbf{X} \in \mathbb{R}^{n \times d}$ the matrix with rows \mathbf{x}_i^\top for $i \in [n]$. We are interested in characterizing the set of low-dimensional empirical distributions of this “Gaussian cloud”, in the proportional asymptotics whereby $n, d \rightarrow \infty$ with $n/d \rightarrow \alpha \in (0, \infty)$. Namely, fixing $m \geq 1$, we define¹:

$$\mathcal{F}_{m,\alpha} := \left\{ P \in \mathcal{P}(\mathbb{R}^m) : \exists \mathbf{W} = \mathbf{W}_n(\mathbf{X}, \omega), \text{ s.t. } \mathbf{W}^\top \mathbf{W} = \mathbf{I}_m, \right. \\ \left. \frac{1}{n} \sum_{i=1}^n \delta_{\mathbf{W}^\top \mathbf{x}_i} \xrightarrow{w} P \text{ in probability} \right\}, \quad (1)$$

¹Here and below $\mathcal{P}(\mathbb{R}^m)$ denotes the set of probability distributions on \mathbb{R}^m .

where ω represents some additional randomness independent of \mathbf{X} (for the purpose of this paper, we can take ω to be uniformly random on $[0, 1]$). In words, this is the set of probability distributions on \mathbb{R}^m that can be approximated by the empirical distribution of the projections $\{\mathbf{W}^\top \mathbf{x}_i\}_{i \leq n}$ for \mathbf{W} any $d \times m$ orthogonal matrix. By general arguments (cf. [MZ22, Lemma E.8]), the set $\mathcal{F}_{m,\alpha}$ is closed under weak convergence.

This feasible set $\mathcal{F}_{m,\alpha}$ was first studied in theoretical statistics as a null model for projection pursuit [FT74, Fri87]. In particular, Diaconis and Freedman [DF84] established that²

$$\lim_{\alpha \rightarrow \infty} \sup_{P \in \mathcal{F}_{m,\alpha}} d_{\text{KS}}(P, \mathbf{N}(0, 1)) = 0, \quad (2)$$

with d_{KS} denoting the Kolmogorov-Smirnov distance. Later, Bickel, Kur and Nadler [BKN18] first attempted to characterize the feasible set $\mathcal{F}_{m,\alpha}$ under the proportional limit, and obtains certain upper and lower bounds in terms of the second moment of the target distribution, as well as the Kolmogorov-Smirnov distance between the target distribution and standard Gaussian measure. Tighter inner and outer bounds on $\mathcal{F}_{m,\alpha}$ (and generalizations of this set) were established in the recent paper [MZ22], together with applications to supervised learning problems.

The structure of the feasible set $\mathcal{F}_{m,\alpha}$ is directly related to the asymptotics of random optimization problems of the form

$$\text{maximize } \frac{1}{n} \sum_{i=1}^n h(\mathbf{W}^\top \mathbf{x}_i), \quad \text{subject to } \mathbf{W} \in O(d, m), \quad (3)$$

where we denote by $O(d, m)$ the set of $d \times m$ orthogonal matrices.

A simple and yet not fully understood example of the type (3) is provided by the so-called spherical perceptron problem. Given data $\{(y_i, \bar{\mathbf{x}}_i)\}_{i \leq n} \sim_{\text{i.i.d.}} \text{Unif}(\{+1, -1\}) \otimes \mathbf{N}(\mathbf{0}, \mathbf{I}_d)$ and a parameter $\kappa \in \mathbb{R}$, we would like to find a vector $\mathbf{w} \in \mathbb{R}^d$, $\|\mathbf{w}\|_2 = 1$ such that $y_i \langle \mathbf{w}, \bar{\mathbf{x}}_i \rangle \geq \kappa$ for all $i \leq n$. This is known in machine learning as a linear classifier with margin κ for the data $\{(y_i, \bar{\mathbf{x}}_i)\}_{i \leq n}$, see [SSBD14] for further background.

For $\kappa \geq 0$, an explicit threshold $\alpha_*(\kappa)$ is known such that a κ -margin classifier \mathbf{w} exists with high probability if $n/d \rightarrow \alpha < \alpha_*(\kappa)$, and does not exist if $n/d \rightarrow \alpha > \alpha_*(\kappa)$ [Gar88, ST03, Sto13]. On the other hand, such a phase transition has not been established for $\kappa < 0$. Franz and Parisi used non-rigorous spin glass techniques to derive a conjectured threshold in [FP16, FSU19]. The further speculated that the structure of near optima of this problem is related to dense ‘disordered’ sphere packings in high dimension [PUZ20]. Upper and lower bounds $\alpha_{\text{UB}}(\kappa)$, $\alpha_{\text{LB}}(\kappa)$ on the phase transition threshold of the spherical perceptron for $\kappa < 0$, as well as efficient algorithms to find a solution were recently studied in [MZZ24, EAS22].

The negative spherical perceptron problem can be rephrased as a question about the value of an optimization problem of the form (3), with $m = 1$. Defining $\mathbf{x}_i = y_i \bar{\mathbf{x}}_i$ and taking $h_\kappa(t) = \min(t - \kappa, 0)$, we are led to consider the optimization problem

$$\text{maximize } \frac{1}{n} \sum_{i=1}^n h_\kappa(\langle \mathbf{w}, \mathbf{x}_i \rangle), \quad \text{subject to } \mathbf{w} \in \mathbb{S}^{d-1}, \quad (4)$$

where \mathbb{S}^{d-1} denotes the d -dimensional unit sphere. A κ -margin solution exists if and only if the value of this problem is zero.

²Strictly speaking, the theorem of [DF84] applies to $n, d \rightarrow \infty$, with $n/d \rightarrow \infty$ at any rate, but the treatment given there can be adapted to yield the claimed limit.

Proposition 4.1 in [MZ22] implies that for any $h \in C_b(\mathbb{R}^m)$ (the set of all bounded continuous functions on \mathbb{R}^m):

$$\text{p-lim inf}_{n,d \rightarrow \infty} \max_{\mathbf{W} \in O(d,m)} \frac{1}{n} \sum_{i=1}^n h(\mathbf{W}^\top \mathbf{x}_i) = \sup_{P \in \mathcal{F}_{m,\alpha}} \left\{ \int_{\mathbb{R}^m} h(\mathbf{z}) P(d\mathbf{z}) \right\} =: \mathcal{V}_{m,\alpha}(h). \quad (5)$$

Therefore, characterizing the feasible set $\mathcal{F}_{m,\alpha}$ would allow us to determine $\mathcal{V}_{m,\alpha}(h)$, the asymptotics of the global maximum for all problems of the form (3).

Vice versa, determining $\mathcal{V}_{m,\alpha}(h)$ for all $h \in C_b(\mathbb{R}^m)$ provides a complete characterization of $\text{conv}(\mathcal{F}_{m,\alpha})$, the convex hull of $\mathcal{F}_{m,\alpha}$, as a consequence of the following duality theorem. This is an application of the Hahn-Banach theorem and we defer its proof to Appendix A.

Theorem 1.1. *Denote by $\mathcal{P}(\mathbb{R}^m)$ the set of all probability distributions on \mathbb{R}^m . Assume $E \subset \mathcal{P}(\mathbb{R}^m)$ is convex and closed under weak limit. Then, for any $\mu \in \mathcal{P}(\mathbb{R}^m)$, $\mu \in E$ if and only if for any $h \in C_b(\mathbb{R}^m)$,*

$$\int_{\mathbb{R}^m} h d\mu \leq \sup_{\nu \in E} \left\{ \int_{\mathbb{R}^m} h d\nu \right\}. \quad (6)$$

Throughout the paper, we will often move between $\mathcal{F}_{m,\alpha}$ and its dual $\mathcal{V}_{m,\alpha}(\cdot)$, which is a functional on $C_b(\mathbb{R}^m)$.

The main result of this paper is to provide a Parisi-type formula for a subset of $\mathcal{F}_{m,\alpha}$ that can be realized via polynomial-time computable projections, namely

$$\mathcal{F}_{m,\alpha}^{\text{alg}} := \left\{ P \in \mathcal{P}(\mathbb{R}^m) : \exists \mathbf{W} = \mathbf{W}_n(\mathbf{X}, \omega) \text{ polytime computable, s.t.} \right. \quad (7)$$

$$\left. \mathbf{W}^\top \mathbf{W} = I_m, \frac{1}{n} \sum_{i=1}^n \delta_{\mathbf{W}^\top \mathbf{x}_i} \xrightarrow{w} P \text{ in probability} \right\}.$$

More explicitly, $\mathbf{W}_n(\mathbf{X}, \omega)$ is ‘polytime computable’ means that there exists an algorithm, accepting (\mathbf{X}, ω) (or its finite-precision approximation) as input and computing $\mathbf{W}_n(\mathbf{X}, \omega)$ in time polynomial in n, d . In what follows, we will describe a class of efficient algorithms for computing $\mathbf{W}_n(\mathbf{X}, \omega)$, and characterize the resulting set of computationally feasible distributions, thus providing an inner bound on $\mathcal{F}_{m,\alpha}^{\text{alg}}$. These algorithms are a version of the incremental approximate message passing (IAMP) algorithms that have been recently developed to optimize the Hamiltonians of mean-field spin glasses [Mon19, EAMS21]. Recent work by Huang and Sellke [HS22, HS24] proves that—in the spin glass context—IAMP algorithms are optimal within the broader class of Lipschitz algorithms. This provides rigorous evidence for the expectation that the class of IAMP algorithms characterize the fundamental computational limit of the random optimization problem (3), and related ones.

The main contributions of this paper are as follows.

Section 2 provides further background, by deriving a general prediction for $\mathcal{V}_{m,\alpha}(h)$ using non-rigorous techniques from spin glass theory. The resulting prediction takes the form of a generalized Parisi formula. This conjecture is a useful benchmark as well as a motivation for our theory.

In Section 3, we present our main results, namely:

1. We characterize a set of probability distributions that can be realized via m -dimensional polynomial-time computable projections (Theorem 3.1), which provides an inner bound on $\mathcal{F}_{m,\alpha}^{\text{alg}}$. By analogy with previous results in spin glass theory, we expect this inner bound to be tight in some cases.

As mentioned above, our inner bound is based on computing the projection matrix $\mathbf{W} = \mathbf{W}_n(\mathbf{X}, \omega)$ via an IAMP algorithm, and we denote the resulting set of distributions by

$\mathcal{F}_{m,\alpha}^{\text{AMP}} \subseteq \mathcal{F}_{m,\alpha}^{\text{alg}}$. The set of probability distributions in $\mathcal{F}_{m,\alpha}^{\text{AMP}}$ are represented as the laws of a certain class of stochastic integrals.

2. Using this stochastic integral representation, it is immediate to derive a lower bound on

$$\mathcal{V}_{1,\alpha}^{\text{alg}}(h) := \sup_{P \in \mathcal{F}_{1,\alpha}^{\text{alg}}} \int_{\mathbb{R}} h(z) P(dz)$$

for general $h \in C_b(\mathbb{R})$. We will denote this lower bound by $\mathcal{V}_{1,\alpha}^{\text{AMP}}(h)$ (Theorem 3.2).

In particular, for any $\varepsilon > 0$, there exists an IAMP algorithm returning $\widehat{\mathbf{w}}_n^{\text{AMP}}$, such that

$$\frac{1}{n} \sum_{i=1}^n h(\langle \widehat{\mathbf{w}}_n^{\text{AMP}}, \mathbf{x}_i \rangle) \geq \mathcal{V}_{1,\alpha}^{\text{AMP}}(h) - \varepsilon$$

with probability converging to 1 as $n, d \rightarrow \infty$, with $n/d \rightarrow \alpha$.

3. The formula for $\mathcal{V}_{1,\alpha}^{\text{AMP}}(h)$ takes the form of a stochastic optimal control problem. We use a duality argument to derive a Parisi-type formula for $\mathcal{V}_{1,\alpha}^{\text{AMP}}(h)$, which takes the form of a variational principle over a suitable function space (Theorem 3.3). This variational principle turns out to be closely related to the conjectured formula for $\mathcal{V}_{1,\alpha}(h)$, which we derive using the replica method in Section 2.

For the first two results, we generalize techniques developed in the context of spin glasses in [Mon19, EAMS21]. However, the third point (deriving a Parisi-type formula via duality) poses significant new challenges. The approach followed in previous work was to establish an Hamilton-Jacobi-Bellman (HJB) equation for the value of the stochastic optimal control problem, and then show that the latter is equivalent to the Parisi-type PDE via Legendre-Fenchel duality. While we follow a similar route, we need to consider a more general class of optimal control problems, corresponding to more general initializations for the HJB equation. As a consequence, we lack a priori convexity estimates on the solution of the HJB equation and establishing that the latter is indeed well posed requires a novel proof.

Proofs of our main results are presented in Section 4 and Section 5. Section 4 describes the IAMP algorithm and presents the proof of our general feasibility theorem, i.e., Theorem 3.1. Section 5 present the proof of the Parisi-type formula, namely Theorem 3.3. Several technical elements of these proofs are deferred to the appendices.

Concurrent work. After this work was first presented (as part of the Ph.D. thesis of the second author), we became aware that partially overlapping results had been obtained independently by Brice Huang, Mark Sellke, and Nike Sun [HSS24]. These authors also consider the Ising case and obtain hardness results for Lipschitz algorithms.

Notations

We will follow the convention of using boldface letters for matrices or vectors whose dimensions diverge as $n, d \rightarrow \infty$, and normal fonts otherwise. We denote the standard scalar product between two vectors \mathbf{u}, \mathbf{v} by $\langle \mathbf{u}, \mathbf{v} \rangle$, and the matrix scalar product by $\langle \mathbf{A}, \mathbf{B} \rangle = \text{Tr}(\mathbf{A}^\top \mathbf{B})$. We use $\|\cdot\|_2$ to denote the Euclidean norm of a vector. We use $\|\cdot\|_{L^p}$ to denote the standard L^p norm of a function for $p \in [1, +\infty]$.

We denote by \mathbb{S}_+^m the convex cone of $m \times m$ positive semi-definite matrices. For $d \geq m$, we denote by $O(d, m)$ the set of all $d \times m$ orthogonal matrices. For a subset S in a topological space, we denote by $\text{cl } S$ its closure. For $p \geq 1$, we denote by $C^k(\mathbb{R}^p)$ the collection of all functions that have continuous k -th derivatives in \mathbb{R}^p . We also denote by $C_b(\mathbb{R}^p)$ the set of all bounded continuous functions on \mathbb{R}^p , and by $C_c^\infty(\mathbb{R}^p)$ the set of all infinitely differentiable functions with compact supports. We use $\mathcal{P}(\mathbb{R}^p)$ to denote the set of all probability measures on \mathbb{R}^p equipped with the topology of weak convergence, unless otherwise stated.

For a function h , we denote by $\text{conc}(h)$ the (upper) concave envelope of h . Namely, $\text{conc}(h)$ is the pointwise minimum of all concave functions that dominate h . For $l, k \geq 1$, and a differentiable mapping $F : \mathbb{R}^k \rightarrow \mathbb{R}^l$, we denote by $J_F \in \mathbb{R}^{l \times k}$ the Jacobian matrix of F , namely for $x \in \mathbb{R}^k$: $J_F(x)_{ij} = \partial F_i / \partial x_j$. We occasionally use J_F as a shorthand for $J_F(x)$ whenever the variable x is clear from the context. We say that a function $\psi : \mathbb{R}^p \rightarrow \mathbb{R}$ is pseudo-Lipschitz if there exists a constant C such that, for all $x, y \in \mathbb{R}^p$,

$$|\psi(x) - \psi(y)| \leq C(1 + \|x\|_2 + \|y\|_2)\|x - y\|_2.$$

Let $\{B_t\}_{t \in [0,1]}$ be an m -dimensional standard Brownian motion, and let $\{\mathcal{F}_t\}_{t \in [0,1]}$ be its canonical filtration. For $s \leq t$, we denote by $D[s, t]$ the space of all admissible controls on the interval $[s, t]$, i.e., the collection of all progressively measurable processes $\{\Phi_r\}_{s \leq r \leq t}$ satisfying

$$\sigma(\Phi_r) \subset \mathcal{F}_r, \quad \forall r \in [s, t], \quad \text{and} \quad \mathbb{E} \left[\int_s^t \Phi_r \Phi_r^\top dr \right] < \infty. \quad (8)$$

2 Conjectures from statistical physics

This section will be devoted to the prediction of the feasible set $\mathcal{F}_{m,\alpha}$ using physicists' replica method. Based on the duality between $\mathcal{F}_{m,\alpha}$ and $\mathcal{V}_{m,\alpha}(\cdot)$, we will state the general prediction for $\mathcal{V}_{m,\alpha}(h)$ in the following conjecture, with detailed calculations deferred to Appendix B. Recall that $\mathcal{V}_{m,\alpha}(h)$ is defined in Eq. (5).

Conjecture 2.1 (Replica prediction for $\mathcal{V}_{m,\alpha}(h)$). *For any fixed $h \in C_b(\mathbb{R}^m)$, almost surely*

$$\lim_{n \rightarrow \infty} \max_{\mathbf{W} \in O(d, m)} \frac{1}{n} \sum_{i=1}^n h(\mathbf{W}^\top \mathbf{x}_i) = \mathcal{V}_{m,\alpha}(h), \quad (9)$$

$$\mathcal{V}_{m,\alpha}(h) = \inf_{(\mu, M, C) \in \mathcal{U} \times \mathcal{J}_m \times \mathbb{S}_+^m} \mathbf{F}_m(\mu, M, C). \quad (10)$$

In the above display, the m -dimensional Parisi functional $\mathbf{F}_m : \mathcal{U} \times \mathcal{J}_m \times \mathbb{S}_+^m \rightarrow \mathbb{R}$ is defined as

$$\mathbf{F}_m(\mu, M, C) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \text{Tr} \left(M(t) \left(C + \int_t^1 \mu(s) M(s) ds \right)^{-1} \right) dt, \quad (11)$$

where $f_\mu : [0, 1] \times \mathbb{R}^m \rightarrow \mathbb{R}$ solves the m -dimensional Parisi PDE:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) \langle \nabla_x f_\mu(t, x), M(t) \nabla_x f_\mu(t, x) \rangle + \frac{1}{2} \text{Tr} (M(t) \nabla_x^2 f_\mu(t, x)) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}^m} \left\{ h(x + u) - \frac{1}{2} \langle u, C^{-1} u \rangle \right\}, \end{aligned} \quad (12)$$

\mathbb{S}_+^m denotes the set of $m \times m$ positive definite matrices, and

$$\mathcal{I}_m := \left\{ M : [0, 1) \rightarrow \mathbb{S}_+^m : \int_0^1 M(t) dt = I_m \right\}, \quad (13)$$

$$\mathcal{U} := \left\{ \mu : [0, 1) \rightarrow \mathbb{R}_{\geq 0} : \mu \text{ non-decreasing, } \int_0^1 \mu(t) dt < \infty \right\}. \quad (14)$$

Remark 1 (Replica prediction for $\mathcal{V}_{1,\alpha}(h)$). The formulas in Conjecture 2.1 can be significantly simplified for the case $m = 1$. In this case, $M(t) = r(t)$ is a non-negative function on $[0, 1]$ satisfying $\int_0^1 r(t) dt = 1$, and $C = c$ is a positive scalar. We then have

$$F_1(\mu, r, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{r(t) dt}{c + \int_t^1 \mu(s) r(s) ds},$$

where f_μ solves the PDE

$$\begin{aligned} \partial_s f_\mu(s, x) + \frac{1}{2} r(t) (\mu(s) \partial_x f_\mu(s, x)^2 + \partial_x^2 f_\mu(s, x)) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \quad (15)$$

Examples of this formula in the literature sometimes use a different parametrization of the time variable. Namely, they use the change of variable $s \mapsto t(s) = \int_0^s r(u) du$. Under this change, we recast $f_\mu(s, x)$ as $f_\mu(t, x)$ and $\mu(s)$ as $\mu(t)$. The Parisi PDE then reads

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) \partial_x f_\mu(t, x)^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \quad (16)$$

Further, the Parisi functional reduces to

$$F_1(\mu, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dq}{c + \int_q^1 \mu(u) du}. \quad (17)$$

Notice that the reduced Parisi functional does not depend on r any more. The replica prediction for $\mathcal{V}_{1,\alpha}(h)$ then becomes

$$\lim_{n \rightarrow \infty} \max_{\mathbf{w} \in \mathbb{S}^{d-1}} \frac{1}{n} \sum_{i=1}^n h(\langle \mathbf{w}, \mathbf{x}_i \rangle) = \mathcal{V}_{1,\alpha}(h) = \inf_{(\mu, c) \in \mathcal{U} \times \mathbb{R}_{>0}} F_1(\mu, c). \quad (18)$$

In the following sections, we will drop the subscript “1” and use $F(\mu, c)$ instead of $F_1(\mu, c)$.

3 Main results

In this section, we present our main results regarding $\mathcal{F}_{m,\alpha}^{\text{alg}}$, the set of computationally feasible probability distributions in $\mathcal{F}_{m,\alpha}$. In Section 3.1, we describe the class of IAMP algorithms to be analyzed. Section 3.2 presents the characterization of the set of probability distributions in $\mathcal{F}_{m,\alpha}^{\text{alg}}$ that can be realized using our algorithm. Section 3.3 then states our main achievability result for $\mathcal{V}_{m,\alpha}^{\text{alg}}(\cdot)$. Finally, in Section 3.4 we establish the extended Parisi variational principle for $\mathcal{V}_{1,\alpha}^{\text{alg}}(\cdot)$.

3.1 Overview of the algorithm

We give a brief description of our two-stage AMP algorithm. For further background information and discussion, we refer to Section 4. In this and the next section, we will work with a slightly more general model than the one described in the introduction, whereby each data point consists of a pair (\mathbf{x}_i, y_i) with $\mathbf{x}_i \in \mathbb{R}^d$ and $y_i \in \mathbb{R}$. We introduce this generalization in view of its applications to supervised learning problems, to be developed in future work.

We now state our assumptions on this model below.

Assumption 3.1. $\{(\mathbf{x}_i, y_i)\}_{i \in [n]}$ are i.i.d. data such that for each $i \in [n]$, $y_i \sim P_Y$ is independent of $\mathbf{x}_i \sim \mathcal{N}(\mathbf{0}, \mathbf{I}_d)$, where $P_Y \in \mathcal{P}(\mathbb{R})$ is a sub-Gaussian distribution.

In this more general setting, we are interested in the joint empirical distribution of $\{(y_i, \mathbf{W}^\top \mathbf{x}_i)\}_{1 \leq i \leq n}$. The definition of $\mathcal{F}_{m,\alpha}^{\text{alg}}$ is then generalized accordingly:

$$\mathcal{F}_{m,\alpha}^{\text{alg}} := \left\{ P \in \mathcal{P}(\mathbb{R} \times \mathbb{R}^m) : \exists \mathbf{W} = \mathbf{W}_n(\mathbf{X}, \mathbf{y}, \omega) \text{ polytime computable, s.t.} \right. \quad (19)$$

$$\left. \mathbf{W}^\top \mathbf{W} = \mathbf{I}_m, \frac{1}{n} \sum_{i=1}^n \delta_{(y_i, \mathbf{W}^\top \mathbf{x}_i)} \xrightarrow{w} P \text{ in probability} \right\}.$$

Our algorithm has two stages: The first stage consists of T_1 iterations with fixed step size, followed by an incremental stage of T_2 iterations with small step sizes, where T_1 and T_2 are two positive integers to be determined.

The first stage of our algorithm consists of T_1 identical AMP iterations: for $t = 0, \dots, T_1 - 1$, we update $\mathbf{V}^t \in \mathbb{R}^{n \times m}$, $\mathbf{W}^t \in \mathbb{R}^{d \times m}$, using:

$$\mathbf{W}^{t+1} = \frac{1}{\sqrt{n}} \mathbf{X}^\top F(\mathbf{V}^t; \mathbf{y}) - \mathbf{W}^t K_t^\top, \quad (20)$$

$$\mathbf{V}^t = \frac{1}{\sqrt{n}} \mathbf{X} \mathbf{W}^t - \frac{d}{n} F(\mathbf{V}^{t-1}; \mathbf{y}). \quad (21)$$

Here $F : \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^m$ is understood to be applied row-wise. Namely, for $\mathbf{V} \in \mathbb{R}^{n \times m}$ (with rows \mathbf{v}_i), $\mathbf{y} \in \mathbb{R}^n$ (with entries y_i), $F(\mathbf{V}; \mathbf{y}) \in \mathbb{R}^{n \times m}$ is the matrix whose i -th row is $F(\mathbf{v}_i; y_i)$. Further, the Onsager correction term $K_t \in \mathbb{R}^{m \times m}$ is given by

$$K_t = \frac{1}{n} \sum_{i=1}^n \frac{\partial F}{\partial \mathbf{v}^t}(\mathbf{v}_i^t; y_i). \quad (22)$$

We will show (using general tools from the analysis of AMP algorithms) that, in the limit of large T_1 after $n, d \rightarrow \infty$, this iteration converges to an approximate fixed point of some non-linear function, which will be the starting point of the second stage of our algorithm.

In the second stage, we allow each iterate to depend on all previous ones. Denote $\mathbf{W}^{\leq t} = (\mathbf{W}^s)_{1 \leq s \leq t}$ and $\mathbf{V}^{\leq t} = (\mathbf{V}^s)_{1 \leq s \leq t}$. We iterate, for $T_1 \leq t < T_1 + T_2$:

$$\mathbf{W}^{t+1} = \frac{1}{\sqrt{n}} \mathbf{X}^\top F_t(\mathbf{V}^{\leq t}; \mathbf{y}) - \sum_{s=1}^t G_s(\mathbf{W}^{\leq s}) K_{t,s}^\top, \quad (23)$$

$$\mathbf{V}^t = \frac{1}{\sqrt{n}} \mathbf{X} G_t(\mathbf{W}^{\leq t}) - \sum_{s=1}^t F_{s-1}(\mathbf{V}^{\leq s-1}; \mathbf{y}) D_{t,s}^\top, \quad (24)$$

where

$$K_{t,s} = \frac{1}{n} \sum_{i=1}^n \frac{\partial F_t}{\partial \mathbf{v}^s} (\mathbf{v}_i^1, \dots, \mathbf{v}_i^t; y_i), \quad D_{t,s} = \frac{1}{n} \sum_{i=1}^d \frac{\partial G_t}{\partial \mathbf{w}^s} (\mathbf{w}_i^1, \dots, \mathbf{w}_i^t), \quad t \geq s.$$

As before, we will overload the notations and let F_t and G_t operate on its argument matrices row-wise. We further assume that F_t and G_t take the following specific structure:

$$F_t(\mathbf{v}^1, \dots, \mathbf{v}^t; y) = \mathbf{v}^t \Phi_{t-1}(\mathbf{v}^1, \dots, \mathbf{v}^{t-1}; y), \quad (25)$$

$$G_t(\mathbf{w}^1, \dots, \mathbf{w}^t) = \mathbf{w}^t \Psi_{t-1}(\mathbf{w}^1, \dots, \mathbf{w}^{t-1}), \quad (26)$$

where Φ_{t-1} and Ψ_{t-1} are matrix-valued mapping that satisfy certain moment constraints from the state evolution of AMP. The second stage of our algorithm involves T_2 iterations with the above choices of F_t and G_t .

Finally, the output of our two-stage AMP algorithm will be a weighted average of \mathbf{W}^{T_1} and the incremental AMP iterations in the second stage. To be concrete, we will show that

$$\text{p-lim}_{n,d \rightarrow \infty} \frac{1}{n} (\mathbf{W}^{T_1})^\top \mathbf{W}^{T_1} = Q, \quad (27)$$

where $Q \in \mathbb{S}_+^m$ is a deterministic $m \times m$ matrix satisfying $Q \preceq I_m$, which will be characterized in the following sections. For any such Q , let $Q_{T_1+1}, \dots, Q_{T_1+T_2}$ be T_2 deterministic $m \times m$ matrices such that

$$\sum_{t=T_1+1}^{T_1+T_2} Q_t^\top Q_t = I_m - Q,$$

we then compute

$$\mathbf{W}_Q = \frac{1}{\sqrt{n}} \mathbf{W}^{T_1} + \frac{1}{\sqrt{n}} \sum_{t=T_1+1}^{T_1+T_2} G_t(\mathbf{W}^{\leq t}) Q_t.$$

We set the final output of our algorithm to be $\widehat{\mathbf{W}}_n^{\text{AMP}} = \mathbf{W}_Q (\mathbf{W}_Q^\top \mathbf{W}_Q)^{-1/2}$, which is guaranteed to be a $d \times m$ orthogonal matrix. The set of (α, m) -feasible distributions achieved by our algorithm will be studied in the next section.

3.2 A set of computationally feasible distributions

We begin with stating our AMP achievability result for general m , and then simplify our formulas to the special case $m = 1$.

Definition 1. Let $Q \in \mathbb{S}_+^m$ be such that $0 \preceq Q \preceq I_m$, and $V^0 \sim \mathcal{N}(0, Q)$ be independent of $Y \sim P_Y$. We say that $F : \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^m$ is a Q -contraction for (V^0, Y) , if

$$\alpha \mathbb{E} \left[F(V^0, Y) F(V^0, Y)^\top \right] = Q, \quad (28)$$

and there exists some $S \in \mathbb{S}_+^m \setminus \{0\}$, such that

$$\alpha \mathbb{E} \left[J_F(V^0, Y)^\top S J_F(V^0, Y) \right] \preceq S, \quad (29)$$

where J_F denotes the Jacobian matrix of F with respect to the first variable.

Theorem 3.1 (Inner bound for $\mathcal{F}_{m,\alpha}^{\text{alg}}$). *Let $Q \in \mathbb{S}_+^m$ be such that $0 \preceq Q \preceq I_m$, and $V^0 \sim \mathbf{N}(0, Q)$ be independent of $Y \sim P_Y$. Assume that F is a Q -contraction for (V^0, Y) . Let $(B_t)_{0 \leq t \leq 1}$ be an m -dimensional standard Brownian motion independent of (V^0, Y) . Define the filtration $\{\mathcal{F}_t\}$ by*

$$\mathcal{F}_t = \sigma(V^0, Y, (B_s)_{0 \leq s \leq t}), \quad 0 \leq t \leq 1.$$

Assume $Q(t) \in L^2([0, 1] \rightarrow \mathbb{R}^{m \times m})$ satisfy

$$\int_0^1 Q(t) Q(t)^\top dt = I_m - Q,$$

and $\{\Phi_t\}_{0 \leq t \leq 1}$ is an $m \times m$ matrix-valued progressively measurable stochastic process with respect to the filtration $\{\mathcal{F}_t\}_{0 \leq t \leq 1}$, satisfying

$$\mathbb{E} [\Phi_t \Phi_t^\top] \preceq \frac{I_m}{\alpha}, \quad \forall 0 \leq t \leq 1.$$

Then, we have that $\text{Law}(Y, U) \in \mathcal{F}_{m,\alpha}^{\text{alg}}$, where

$$U = V^0 + F(V^0, Y) + \int_0^1 Q(t) (I_m + \Phi_t) dB_t.$$

We obtain the following feasibility result for the case $m = 1$ in the unsupervised setting. Notice that in this case, we can eliminate the matrix-valued function $t \mapsto Q(t)$ by a time reparametrization. See Section 5.2 for details.

Corollary 3.1 (Inner bound for $\mathcal{F}_{1,\alpha}^{\text{alg}}$, unsupervised setting). *Let $q \in [0, 1]$, $v \sim \mathbf{N}(0, q)$ and assume that $F : \mathbb{R} \rightarrow \mathbb{R}$ satisfies*

$$\mathbb{E} [F(v)^2] = \frac{q}{\alpha}, \quad \mathbb{E} [F'(v)^2] \leq \frac{1}{\alpha}. \quad (30)$$

Define the filtration $\mathcal{F}_t = \sigma(v, (B_s)_{0 \leq s \leq t})$ for $t \in [0, 1]$, with $(B_t)_{t \in [0, 1]}$ a standard Brownian motion independent of v . Let $(\phi_t)_{q \leq t \leq 1}$ be a real-valued progressively measurable process with respect to $\{\mathcal{F}_t\}_{q \leq t \leq 1}$. Then $\text{Law}(U) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$, where

$$U = v + F(v) + \int_q^1 (1 + \phi_t) dB_t.$$

The proof of Theorem 3.1 is deferred to Section 4, where we will also describe in greater details the two-stage AMP algorithm utilized for proving it.

3.3 Dual value $\mathcal{V}_{1,\alpha}^{\text{alg}}(h)$ and stochastic optimal control

From now on we will focus on the case $m = 1$. We fix a function $h : \mathbb{R} \rightarrow \mathbb{R}$ and consider the problem of maximizing the Hamiltonian

$$H_{n,d}(\mathbf{w}) := \frac{1}{n} \sum_{i=1}^n h(\langle \mathbf{x}_i, \mathbf{w} \rangle), \quad \mathbf{w} \in \mathbb{S}^{d-1}.$$

We will characterize the optimal value achieved by AMP algorithms of the type described in the previous section. For this purpose, we define

$$\begin{aligned} \mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h) &:= \sup_{f, \phi} \mathbb{E}_{v \sim \mathcal{N}(0, q)} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) \right], \\ \text{subject to } \mathbb{E}[F(v)^2] &= \frac{q}{\alpha}, \mathbb{E}[F'(v)^2] \leq \frac{1}{\alpha}, \text{ and } \mathbb{E}[\phi_t^2] \leq \frac{1}{\alpha}, \forall t \in [0, 1]. \end{aligned} \quad (31)$$

Note that for any fixed choice of q and F , this is a stochastic optimal control problem for the control process $\{\phi_t\}_{t \in [q, 1]}$ on the time interval $[q, 1]$. As a direct consequence of Corollary 3.1, the following theorem characterizes the asymptotic maximum achieved by our two-stage AMP algorithm, in terms of $\mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h)$.

Theorem 3.2 (Optimal value of $H_{n,d}(\mathbf{w})$ achieved by AMP algorithms). *For any $h : \mathbb{R} \rightarrow \mathbb{R}$ Lipschitz continuous and bounded from above, the followings hold.*

- (a) Upper bound. *Let $\hat{\mathbf{w}}_n^{\text{AMP}}$ be the output of any AMP algorithm as defined in Section 3.1, with an arbitrary choice of the nonlinearities satisfying technical assumptions in Sections 3.1 and 3.2. Then, almost surely,*

$$\lim_{n \rightarrow \infty} H_{n,d}(\hat{\mathbf{w}}_n^{\text{AMP}}) \leq \mathcal{V}_{1,\alpha}^{\text{AMP}}(h) := \sup_{q \in [0, 1]} \mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h). \quad (32)$$

- (b) Achievability. *For any $\varepsilon > 0$, there exists a two-stage AMP algorithm such that, almost surely,*

$$\lim_{n \rightarrow \infty} H_{n,d}(\hat{\mathbf{w}}_n^{\text{AMP}}) \geq \mathcal{V}_{1,\alpha}^{\text{AMP}}(h) - \varepsilon. \quad (33)$$

Of course, since AMP is a polynomial-time algorithm, the last theorem implies that

$$\mathcal{V}_{1,\alpha}^{\text{alg}}(h) \geq \mathcal{V}_{1,\alpha}^{\text{AMP}}(h). \quad (34)$$

3.4 Hamilton-Jacobi-Bellman equation and Parisi-type formula

We will now develop a variational principle that is dual to the stochastic optimal control problem of Eq. (31). The resulting formula is closely related to the Parisi variational principle, that we derived heuristically in Section 2 (note that the Parisi formula for $m = 1$ is in Remark 1).

We begin with defining two relevant function spaces.

Definition 2 (Space of functional order parameters). *Define*

$$\mathcal{L} := \left\{ (\mu, c) \in L^1[0, 1] \times \mathbb{R}_{>0} : \mu|_{[0, t]} \in L^\infty[0, t] \text{ and } c + \int_t^1 \mu(s) ds > 0 \text{ for all } t \in [0, 1] \right\}, \quad (35)$$

and let

$$\mathcal{L}_\# := \left\{ \gamma : [0, 1] \rightarrow \mathbb{R}_{>0} \text{ absolutely continuous} : (\mu, c) \in \mathcal{L} \text{ for } \mu = \gamma'/\gamma^2, c = 1/\gamma(1) \right\}. \quad (36)$$

Further, for any $q \in [0, 1]$, define

$$\mathcal{L}(q) = \{(\mu, c) \in \mathcal{L} : \mu(t) = 0, \forall t \in [0, q]\} \quad (37)$$

and

$$\mathcal{L}_\#(q) = \{\gamma \in \mathcal{L}_\# : \gamma|_{[0, q]} \text{ is constant}\}. \quad (38)$$

Then, we see that $\gamma \in \mathcal{L}_\#(q)$ if and only if $(\mu, c) \in \mathcal{L}(q)$ with $(\mu, c) = (\gamma'/\gamma^2, 1/\gamma(1))$.

We are now ready to state our main result establishing a Parisi-type variational principle for the stochastic optimal control problem (31). Recall the Parisi functional of Eq. (17) (we drop the subscript 1 for notational simplicity):

$$F(\mu, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds},$$

where f_μ is the solution to the partial differential equation (16), which we copy here for the reader's convenience:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) \partial_x f_\mu(t, x)^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \tag{39}$$

We also define

$$\overline{\mathcal{V}}_{1,\alpha}^{\text{AMP}}(q; h) := \sup_{\substack{\alpha \mathbb{E}[F(v)^2] \leq q \\ \mathbb{E}[\phi_t^2] \leq 1/\alpha}} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) \right].$$

Note that this differs from the definition of $\mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h)$ in that the equality constraint $\alpha \mathbb{E}[F(v)^2] = q$ is replaced by an inequality one, and we drop the constraint $\alpha \mathbb{E}[F'(v)^2] \leq 1$. As a consequence, we always have $\overline{\mathcal{V}}_{1,\alpha}^{\text{AMP}}(q; h) \geq \mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h)$.

Theorem 3.3. *Assume $h \in C^2(\mathbb{R})$ is Lipschitz continuous and bounded from above. Then the followings hold.*

- (a) Variational formula. Fix $q \in [0, 1)$ and $v \sim \mathcal{N}(0, q)$. For any $\gamma \in \mathcal{L}_\#(q)$ and $(\mu, c) \in \mathcal{L}(q)$ satisfying $\mu = \gamma'/\gamma^2$ and $c = 1/\gamma(1)$, we have:

$$F(\mu, c) = \sup_{F, \phi} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt - \frac{\gamma(q)}{2} \left(F(v)^2 - \frac{q}{\alpha} \right) \right]. \tag{40}$$

- (b) Weak duality. For any $q \in [0, 1)$, we have

$$\mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h) \leq \overline{\mathcal{V}}_{1,\alpha}^{\text{AMP}}(q; h) \leq \inf_{(\mu, c) \in \mathcal{L}(q)} F(\mu, c). \tag{41}$$

- (c) Strong duality. Fix $q \in [0, 1)$, and assume there exists $(\mu_*, c_*) \in \mathcal{L}(q)$ such that

$$F(\mu_*, c_*) = \inf_{(\mu, c) \in \mathcal{L}(q)} F(\mu, c).$$

Then there exists a feasible pair (F^*, ϕ^*) that satisfies

$$\alpha \mathbb{E}[F^*(v)^2] = q, \quad \alpha \mathbb{E}[(F^*)'(v)^2] \leq 1, \quad \mathbb{E}[(\phi_t^*)^2] \leq \frac{1}{\alpha}, \quad \forall t \in [q, 1], \tag{42}$$

such that

$$F(\mu_*, c_*) = \mathbb{E} \left[h \left(v + F^*(v) + \int_q^1 (1 + \phi_t^*) dB_t \right) \right] = \mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h). \tag{43}$$

Further, (F^*, ϕ^*) is efficiently computable given access to (μ_*, c_*) .

In particular, under the conditions at point (c), we have the dual characterization

$$\mathcal{V}_{1,\alpha}^{\text{AMP}}(q; h) = \inf_{(\mu, c) \in \mathcal{L}(q)} F(\mu, c). \quad (44)$$

The proof of Theorem 3.3 is presented in Section 5.3, with technical legwork (constructing a solution to the Parisi PDE, verification argument, and computing first-order variation of the Parisi functional) deferred to Appendix E.

4 Incremental AMP algorithm: Proof of Theorem 3.1

This section will be devoted to establishing our general two-stage AMP algorithm and the proof of Theorem 3.1, with proofs of auxiliary results deferred to Appendix C.

For future applications, we will prove several technical results under a more general data distribution, whereby $\{(y_i, \mathbf{x}_i)\}_{i \leq n}$ are i.i.d. pairs but y_i is dependent on \mathbf{x}_i . Namely, we assume $\mathbf{x}_i \sim \mathbf{N}(\mathbf{0}, \mathbf{I}_d)$ as above and

$$y_i = \varphi(\mathbf{V}^\top \mathbf{x}_i; \varepsilon_i), \quad \forall i \in [n]. \quad (45)$$

Using vector notation, we will write $\mathbf{y} = \varphi(\mathbf{X}\mathbf{V}; \boldsymbol{\varepsilon})$, where φ is understood to act on its arguments row-wise. Here the noise vector $\boldsymbol{\varepsilon} = (\varepsilon_i)_{i \in [n]}$ is independent of \mathbf{X} , $\varepsilon_i \sim_{\text{i.i.d.}} P_\varepsilon \in \mathcal{P}(\mathbb{R})$, and $\varphi : \mathbb{R}^k \rightarrow \mathbb{R}$ is a deterministic link function. Finally, $\mathbf{V} \in \mathbb{R}^{d \times k}$ is a deterministic matrix (in fact, a sequence of such matrices with d diverging with n). We assume that the y_i 's are sub-Gaussian with sub-Gaussian norm of order one. Note that the case of y_i independent of \mathbf{x}_i is recovered if we choose φ dependent uniquely on its second argument, i.e., with an abuse of notation, $y_i = \varphi(\varepsilon_i)$. We will refer to this as the case of “pure noise labels” or “purely random labels”.

Lemma 4.1. *Without loss of generality, we can assume that the empirical distribution of the rows of $\sqrt{n}\mathbf{V}$ converges in W_2 distance (and hence weakly) to $P_V = \mathbf{N}(0, \alpha I_k)$ as $n, d \rightarrow \infty$.*

Proof. First of all, we can assume $\mathbf{V} \in O(d, k)$ (the set of $d \times k$ orthogonal matrices) by eventually adjusting φ . Now for any fixed $\mathbf{V} \in O(d, k)$, let \mathbf{R} be a uniformly random orthogonal matrix of size $d \times d$, namely \mathbf{R} is sampled from the uniform probability measure on $O(d, d)$. Then, we know that $\mathbf{X}\mathbf{V} = \mathbf{X}\mathbf{R}^\top \mathbf{R}\mathbf{V}$, which leads to

$$\mathbf{y} = \varphi(\mathbf{X}\mathbf{V}; \boldsymbol{\varepsilon}) = \varphi(\mathbf{X}\mathbf{R}^\top \mathbf{R}\mathbf{V}; \boldsymbol{\varepsilon}).$$

Using rotational invariance of standard Gaussian measure and the uniform measure on $O(d, k)$, we know that the empirical distribution of the rows of $\sqrt{n}\mathbf{R}\mathbf{V}$ weakly converges to $P_V = \mathbf{N}(0, \alpha I_k)$ almost surely, and that $\mathbf{X}\mathbf{R}^\top \stackrel{d}{=} \mathbf{X}$ is independent of $\mathbf{R}\mathbf{V}$. Therefore, recasting $\mathbf{X}\mathbf{R}^\top$ as \mathbf{X} and $\mathbf{R}\mathbf{V}$ as \mathbf{V} , we can apply the general AMP algorithm to the pair (\mathbf{X}, \mathbf{y}) and assume without loss of generality that the empirical distribution of the rows of $\sqrt{n}\mathbf{V}$ weakly converges to $P_V = \mathbf{N}(0, \alpha I_k)$ as $n, d \rightarrow \infty$. \square

4.1 Approximate message passing

Following [BM11, JM13, CMW20], we define the general AMP algorithm as an iterative procedure which generates two sequences of matrices $\{\mathbf{W}^t\}_{t \geq 1} \subset \mathbb{R}^{d \times m}$ and $\{\mathbf{V}^t\}_{t \geq 1} \subset \mathbb{R}^{n \times m}$ according to:

$$\mathbf{W}^{t+1} = \frac{1}{\sqrt{n}} \mathbf{X}^\top F_t(\mathbf{V}^{\leq t}; \mathbf{y}) - \sum_{s=1}^t G_s(\mathbf{W}^{\leq s}) K_{t,s}^\top, \quad (46)$$

$$\mathbf{V}^t = \frac{1}{\sqrt{n}} \mathbf{X} G_t(\mathbf{W}^{\leq t}) - \sum_{s=1}^t F_{s-1}(\mathbf{V}^{\leq s-1}; \mathbf{y}) D_{t,s}^\top, \quad (47)$$

where $\mathbf{W}^1 = \mathbf{X}^\top F_0(\mathbf{y})/\sqrt{n}$, and $\{F_t : \mathbb{R}^{mt+1} \rightarrow \mathbb{R}^m\}_{t \geq 0}$ and $\{G_t : \mathbb{R}^{mt} \rightarrow \mathbb{R}^m\}_{t \geq 1}$ are two sequences of Lipschitz functions. Moreover, we let $\mathbf{W}^{\leq t} = (\mathbf{W}^s)_{1 \leq s \leq t}$, $\mathbf{V}^{\leq t} = (\mathbf{V}^s)_{1 \leq s \leq t}$, and adopt the convention that the Lipschitz functions G_t and F_t apply row-wise to their arguments. The Onsager correction terms are defined as

$$D_{t,s} = \frac{1}{n} \sum_{i=1}^d \frac{\partial G_t}{\partial \mathbf{w}^s}(\mathbf{w}_i^1, \dots, \mathbf{w}_i^t), \quad K_{t,s} = \frac{1}{n} \sum_{i=1}^n \frac{\partial F_t}{\partial \mathbf{v}^s}(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t; y_i), \quad (48)$$

where \mathbf{w}_i^s is the i -th row of \mathbf{W}^s and \mathbf{v}_i^s is the i -th row of \mathbf{V}^s , respectively.

Remark 2. We will refer to the matrices in Eq (48) as ‘‘Onsager coefficients’’. The population version of these coefficients are used in some of the earlier literature, whereby the empirical average over i is replaced by an expectation over the asymptotic distributions of the \mathbf{w}_i^t ’s and \mathbf{v}_i^t ’s. By an induction argument in [JM13], the high-dimensional asymptotics of these two versions of this algorithm are the same.

As $n, d \rightarrow \infty$ and $n/d \rightarrow \alpha$, for any fixed $t \in \mathbb{N}$, the limiting joint distribution of the first t AMP iterates is exactly characterized by the following proposition.

Proposition 4.2 (State evolution of AMP). *Denote $\bar{\mathbf{Z}}_{\leq t} := (\bar{\mathbf{Z}}_1, \dots, \bar{\mathbf{Z}}_t)$ and $\mathbf{Z}_{\leq t} := (Z_1, \dots, Z_t)$ where each $Z_t, \bar{\mathbf{Z}}_t \in \mathbb{R}^m$. The joint distributions of the random variables $(\bar{\mathbf{Z}}_{\leq t}, Y) \in \mathbb{R}^{mt+1}$ and $(\mathbf{Z}_{\leq t}, V) \in \mathbb{R}^{mt+k}$ are defined as follows (note that $\bar{\mathbf{Z}}_0 \in \mathbb{R}^k$): Both $(\bar{\mathbf{Z}}_0, \bar{\mathbf{Z}}_{\leq t})$ and $\mathbf{Z}_{\leq t}$ are multivariate normal with zero mean, and their covariance structures are specified via the following recursion: (note that the Z_t ’s and $\bar{\mathbf{Z}}_t$ ’s are row vectors)*

$$\begin{aligned} \mathbb{E}[\bar{\mathbf{Z}}_i^\top \bar{\mathbf{Z}}_j] &= \frac{1}{\alpha} \mathbb{E}[G_i(V\mu_{\leq i} + Z_{\leq i})^\top G_j(V\mu_{\leq j} + Z_{\leq j})], \quad i, j \geq 1, \\ \mathbb{E}[\bar{\mathbf{Z}}_i^\top \bar{\mathbf{Z}}_0] &= \frac{1}{\alpha} \mathbb{E}[G_i(V\mu_{\leq i} + Z_{\leq i})^\top V], \quad \mathbb{E}[\bar{\mathbf{Z}}_0^\top \bar{\mathbf{Z}}_0] = \frac{1}{\alpha} \mathbb{E}[V^\top V], \quad i \geq 1, \\ \mathbb{E}[\mathbf{Z}_i^\top \mathbf{Z}_j] &= \mathbb{E}[F_{i-1}(\bar{\mathbf{Z}}_{\leq i-1}; Y)^\top F_{j-1}(\bar{\mathbf{Z}}_{\leq j-1}; Y)], \quad i, j \geq 1, \\ Y &= \varphi(\bar{\mathbf{Z}}_0; \varepsilon), \quad \mu_{t+1} = \mathbb{E}\left[\frac{\partial F_t}{\partial \bar{\mathbf{Z}}_0}(\bar{\mathbf{Z}}_{\leq t}; \varphi(\bar{\mathbf{Z}}_0; \varepsilon))\right]. \end{aligned} \quad (49)$$

Here, $V \sim P_V$ is independent of $(Z_i)_{i \geq 1}$, and $\varepsilon \sim P_\varepsilon$ is independent of $(\bar{\mathbf{Z}}_i)_{i \geq 0}$. Under this specification, we know that

$$\text{p-lim}_{n \rightarrow \infty} D_{t,s} = \frac{1}{\alpha} \mathbb{E}\left[\frac{\partial G_t}{\partial \mathbf{w}^s}(V\mu_{\leq t} + Z_{\leq t})\right], \quad \text{p-lim}_{n \rightarrow \infty} K_{t,s} = \mathbb{E}\left[\frac{\partial F_t}{\partial \mathbf{v}^s}(\bar{\mathbf{Z}}_{\leq t}; Y)\right]. \quad (50)$$

Furthermore, for any pseudo-Lipschitz functions ψ_1, ψ_2 , we have almost surely

$$\lim_{n \rightarrow \infty} \frac{1}{d} \sum_{i=1}^d \psi_1(\mathbf{w}_i^1, \dots, \mathbf{w}_i^t, \mathbf{v}_i) = \mathbb{E}[\psi_1(V\mu_{\leq t} + Z_{\leq t}, V)], \quad (51)$$

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \psi_2(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t, y_i) = \mathbb{E}[\psi_2(\bar{Z}_{\leq t}, Y)], \quad (52)$$

as $n, d \rightarrow \infty$ and $n/d \rightarrow \alpha$.

Proof. This can be deduced from the results in [JM13, CMW20, MW22]. \square

Remark 3. As mentioned in the introduction, we allow the algorithm that computes the projection matrix \mathbf{W} to be randomized. In the framework of Proposition 4.2, randomization can be implemented by letting the functions F_t depend on an additional random variable. Namely, $F_t(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t; y_i)$ is replaced by $F_t(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t; y_i, \omega_i)$ with $(\omega_i)_{i \geq 1} \sim_{\text{i.i.d.}} \text{Unif}([0, 1])$. For simplicity of notation, we will leave this dependence implicit. Expectations in the state evolution equations are understood to be taken with respect to these random variables as well.

Corollary 4.3. *The empirical distribution of $(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t, y_i)_{1 \leq i \leq n}$ almost surely weakly converges to the law of $(\bar{Z}_{\leq t}, Y)$. Similarly, the empirical distribution of $(\mathbf{w}_i^1, \dots, \mathbf{w}_i^t, \mathbf{v}_i)_{1 \leq i \leq d}$ almost surely weakly converges to the law of $(V\mu_{\leq t} + Z_{\leq t}, V)$.*

Proof. We only prove the first part as the second part is exactly identical. Following the notation of [BPR06], we denote by ν_n the empirical distribution of $(\mathbf{v}_i^{\leq t}, y_i)_{1 \leq i \leq n} = (\mathbf{v}_i^1, \dots, \mathbf{v}_i^t, y_i)_{1 \leq i \leq n}$ and by ν the law of $(\bar{Z}_{\leq t}, Y)$. Since for each u , the function $f_u(x) = \exp(i\langle u, x \rangle)$ is bounded Lipschitz, we know from Eq. (51) that

$$\mathbb{P}\left(\lim_{n \rightarrow \infty} \nu_n(f_u) = \nu(f_u)\right) = 1, \quad \forall u \in \mathbb{R}^{mt+1}.$$

Applying Theorem 2.6 in [BPR06] implies that $\nu_n \Rightarrow \nu$ with probability one. \square

Remark 4. If the labels $\{y_i\}_{i \in [n]}$ are purely random, then $\varphi(\bar{Z}_0; \varepsilon)$ has no dependence on \bar{Z}_0 , and consequently $\mu_t \equiv 0$. The state evolution can thus be simplified to

$$\lim_{n \rightarrow \infty} \frac{1}{d} \sum_{i=1}^d \psi_1(\mathbf{w}_i^1, \dots, \mathbf{w}_i^t) = \mathbb{E}[\psi_1(Z_{\leq t})], \quad (53)$$

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \psi_2(\mathbf{v}_i^1, \dots, \mathbf{v}_i^t, y_i) = \mathbb{E}[\psi_2(\bar{Z}_{\leq t}, Y)], \quad (54)$$

where Y is independent of $(\bar{Z}_i)_{i \geq 1}$, and for $i, j \geq 1$,

$$\begin{aligned} \mathbb{E}[\bar{Z}_i^\top \bar{Z}_j] &= \frac{1}{\alpha} \mathbb{E}[G_i(Z_{\leq i})^\top G_j(Z_{\leq j})], \\ \mathbb{E}[Z_i^\top Z_j] &= \mathbb{E}[F_{i-1}(\bar{Z}_{\leq i-1}; Y)^\top F_{j-1}(\bar{Z}_{\leq j-1}; Y)]. \end{aligned} \quad (55)$$

4.2 First stage: Fixed-point AMP

In this section, we present the first stage of our general two-stage AMP algorithm, which consists of several identical AMP iterations that finally converges to a fixed point of the state evolution equations (49), which will be the starting point of the pure incremental part in the second stage.

Since the aim of this stage is just to get an initialization with non-zero mean, we will take some simple choices for the functions $\{F_t\}_{t \geq 0}$ and $\{G_t\}_{t \geq 1}$. To be specific, we set all F_t with $t \geq 1$ to be F , which only depends on $(\mathbf{V}^t; \mathbf{y})$, and all G_t to be the identity mapping on \mathbf{W}^t . Consequently, $D_t = (d/n)I_m$ and the AMP iterations reduce to

$$\mathbf{W}^{t+1} = \frac{1}{\sqrt{n}} \mathbf{X}^\top F(\mathbf{V}^t; \mathbf{y}) - \mathbf{W}^t K_t^\top, \quad (56)$$

$$\mathbf{V}^t = \frac{1}{\sqrt{n}} \mathbf{X} \mathbf{W}^t - \frac{d}{n} F(\mathbf{V}^{t-1}; \mathbf{y}), \quad (57)$$

where we still have $\mathbf{W}^1 = \mathbf{X}^\top F_0(\mathbf{y})/\sqrt{n}$, and

$$K_t = \frac{1}{n} \sum_{i=1}^n \frac{\partial F}{\partial \mathbf{v}^t}(\mathbf{v}_i^t; y_i) \quad (58)$$

are the Onsager terms. With this simple choice, the state evolution equations (49) reduce to

$$\begin{aligned} \mathbb{E} [\bar{Z}_i^\top \bar{Z}_j] &= \mu_i^\top \mu_j + \frac{1}{\alpha} \mathbb{E} [Z_i^\top Z_j], \quad i, j \geq 1, \\ \mathbb{E} [\bar{Z}_i^\top \bar{Z}_0] &= \mu_i^\top, \quad \mathbb{E} [\bar{Z}_0^\top \bar{Z}_0] = I_k, \quad i \geq 1, \\ \mathbb{E} [Z_1^\top Z_1] &= \mathbb{E} [F_0(Y)^\top F_0(Y)], \\ \mathbb{E} [Z_i^\top Z_1] &= \mathbb{E} [F(\bar{Z}_{i-1}; Y)^\top F_0(Y)], \quad i \geq 2, \\ \mathbb{E} [Z_i^\top Z_j] &= \mathbb{E} [F(\bar{Z}_{i-1}; Y)^\top F(\bar{Z}_{j-1}; Y)], \quad i, j \geq 2, \\ Y &= \varphi(\bar{Z}_0; \varepsilon), \quad \mu_1 = \mathbb{E} \left[\frac{\partial F_0}{\partial \bar{z}_0}(\varphi(\bar{Z}_0; \varepsilon)) \right], \\ \mu_{t+1} &= \mathbb{E} \left[\frac{\partial F}{\partial \bar{z}_0}(\bar{Z}_t; \varphi(\bar{Z}_0; \varepsilon)) \right], \quad t \geq 1. \end{aligned} \quad (59)$$

We will make the following assumption on the non-linearity F :

Assumption 4.1. *There exists two matrix-valued parameters $\mu \in \mathbb{R}^{k \times m}$ and $Q \in \mathbb{S}_+^m$, such that*

1. (μ, Q) is a solution to the following system of equations:

$$\mu = \mathbb{E}_{(\mu, Q)} \left[\frac{\partial F}{\partial \bar{z}_0}(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon)) \right], \quad (60)$$

$$Q = \mu^\top \mu + \frac{1}{\alpha} \mathbb{E}_{(\mu, Q)} \left[F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon)) \right], \quad (61)$$

where $\mathbb{E}_{(\mu, Q)}$ represents the expectation taken under $(\bar{Z}, \bar{Z}_0)^\top \sim \mathcal{N}\left(0, \begin{bmatrix} Q & \mu^\top \\ \mu & I_k \end{bmatrix}\right)$, independent of $\varepsilon \sim P_\varepsilon$.

2. Further, there exists a differentiable function F_0 satisfying

$$\mu = \mathbb{E} \left[\frac{\partial F_0}{\partial \bar{z}_0} (\varphi(\bar{Z}_0; \varepsilon)) \right], \quad Q = \mu^\top \mu + \frac{1}{\alpha} \mathbb{E} \left[F_0(\varphi(\bar{Z}_0; \varepsilon))^\top F_0(\varphi(\bar{Z}_0; \varepsilon)) \right]. \quad (62)$$

Remark 5. For general F , there is no guarantee that there exists (μ, Q) and F_0 satisfying Assumption 4.1. However, we will soon restrict ourselves to a specific setting (the pure noise case) where the existence of (μ, Q) and F_0 is guaranteed.

Lemma 4.4. Under Assumption 4.1, we have for all $t \geq 1$,

$$\mathbb{E} [\bar{Z}_t^\top \bar{Z}_0] = \mu^\top, \quad \mathbb{E} [\bar{Z}_t^\top \bar{Z}_t] = Q. \quad (63)$$

Proof. We prove by induction. For $t = 1$, the conclusion follows automatically from point 2 in Assumption 4.1 and Eq. (59). Now assume the conclusion holds for t . For $t + 1$, we have

$$\mathbb{E} [\bar{Z}_{t+1}^\top \bar{Z}_0] = \mu_{t+1}^\top = \mathbb{E} \left[\frac{\partial F}{\partial \bar{z}_0} (\bar{Z}_t; \varphi(\bar{Z}_0; \varepsilon)) \right]^\top = \mu^\top,$$

which follows from our induction hypothesis and point 1 in Assumption 4.1. Further,

$$\begin{aligned} \mathbb{E} [\bar{Z}_{t+1}^\top \bar{Z}_{t+1}] &= \mu_{t+1}^\top \mu_{t+1} + \frac{1}{\alpha} \mathbb{E} [Z_{t+1}^\top Z_{t+1}] \\ &= \mu^\top \mu + \frac{1}{\alpha} \mathbb{E} [F(\bar{Z}_t; \varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}_t; \varphi(\bar{Z}_0; \varepsilon))] \\ &= \mu^\top \mu + \frac{1}{\alpha} \mathbb{E}_{(\mu, Q)} [F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon))] = Q. \end{aligned}$$

This completes the proof. \square

The state evolution equations (59) can thus be further simplified:

$$\begin{aligned} \mathbb{E} [\bar{Z}_0^\top \bar{Z}_0] &= I_k, \quad \mathbb{E} [\bar{Z}_i^\top \bar{Z}_0] = \mu^\top, \quad \mathbb{E} [\bar{Z}_i^\top \bar{Z}_i] = Q, \quad i \geq 1, \\ \mathbb{E} [\bar{Z}_i^\top \bar{Z}_j] &= \mu^\top \mu + \frac{1}{\alpha} \mathbb{E} [Z_i^\top Z_j], \quad i, j \geq 1, \\ \mathbb{E} [Z_1^\top Z_1] &= \mathbb{E} [F_0(\varphi(\bar{Z}_0; \varepsilon))^\top F_0(\varphi(\bar{Z}_0; \varepsilon))], \\ \mathbb{E} [Z_i^\top Z_1] &= \mathbb{E} [F(\bar{Z}_{i-1}; \varphi(\bar{Z}_0; \varepsilon))^\top F_0(\varphi(\bar{Z}_0; \varepsilon))], \quad i \geq 2, \\ \mathbb{E} [Z_i^\top Z_j] &= \mathbb{E} [F(\bar{Z}_{i-1}; \varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}_{j-1}; \varphi(\bar{Z}_0; \varepsilon))], \quad i, j \geq 2. \end{aligned} \quad (64)$$

Fix $T_1 \in \mathbb{N}_+$, we will take $\mathbf{W}_F = \mathbf{W}^{T_1} / \sqrt{n}$ as the output of this fixed-point AMP stage. By state evolution, we have

$$\begin{aligned} \mathbf{W}_F^\top \mathbf{W}_F &= \frac{1}{n} (\mathbf{W}^{T_1})^\top \mathbf{W}^{T_1} = \frac{1}{n} \sum_{i=1}^d (\mathbf{w}_i^{T_1})^\top \mathbf{w}_i^{T_1} \\ &\rightarrow \frac{1}{\alpha} \mathbb{E} [(V\mu + Z_{T_1})^\top (V\mu + Z_{T_1})] = \mu^\top \mu + \frac{1}{\alpha} \mathbb{E} [Z_{T_1}^\top Z_{T_1}] \\ &= \mathbb{E} [\bar{Z}_{T_1}^\top \bar{Z}_{T_1}] = Q \text{ in probability as } n \rightarrow \infty. \end{aligned}$$

Further, we compute the limiting empirical joint distribution of the labels \mathbf{y} and the projected covariates $\mathbf{X}\mathbf{W}_F = \mathbf{X}\mathbf{W}^{T_1}/\sqrt{n}$. According to the generalized AMP iteration equations and Proposition 4.2, we obtain that

$$\mathbf{X}\mathbf{W}_F = \frac{1}{\sqrt{n}}\mathbf{X}\mathbf{W}^{T_1} = \mathbf{V}^{T_1} + F(\mathbf{V}^{T_1-1}; \mathbf{y})D_{T_1}^\top = \mathbf{V}^{T_1} + \frac{d}{n}F(\mathbf{V}^{T_1-1}; \mathbf{y}).$$

As a consequence,

$$\begin{aligned} \frac{1}{n} \sum_{i=1}^n \delta_{(y_i, (\mathbf{X}\mathbf{W}_F)_i)} &\xrightarrow{w} \text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) \right) \\ &= \text{Law} \left(\varphi(\bar{Z}_0; \varepsilon), \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; \varphi(\bar{Z}_0; \varepsilon)) \right), \end{aligned}$$

where we have

$$\mathbb{E} \left[F(\bar{Z}_{T_1-1}; \varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}_{T_1-1}; \varphi(\bar{Z}_0; \varepsilon)) \right] = \mathbb{E} \left[Z_{T_1}^\top Z_{T_1} \right] = \alpha \left(Q - \mu^\top \mu \right).$$

In the next section, we establish that in the pure noise case, and under suitable conditions on F_0 and F , we have $\lim_{t \rightarrow \infty} \mathbb{E}[\|\bar{Z}_t - \bar{Z}_{t-1}\|_2^2] = 0$. Therefore, one can take the limit $T_1 \rightarrow \infty$, see Proposition 4.6 for details.

4.2.1 Pure noise labels

In this section, we specialize our general results to the case of pure noise labels, namely $\mathbf{y} = \varphi(\varepsilon)$ is independent of \mathbf{X} . Under this setting, we see that in the AMP state evolution $Y = \varphi(\varepsilon)$ does not depend on \bar{Z}_0 , and Eq. (59) implies $\mu_t = 0$ for all $t \geq 1$. Further, point 2 of Assumption 4.1 is verified by the following lemma.

Lemma 4.5. *For any function F and $Q \in \mathbb{S}_+^m$, there exists a differentiable F_0 such that*

$$\mathbb{E} \left[F_0(\varphi(\varepsilon))^\top F_0(\varphi(\varepsilon)) \right] = \alpha Q, \quad \mathbb{E} \left[F(\bar{Z}_1; \varphi(\varepsilon))^\top F_0(\varphi(\varepsilon)) \right] = 0. \quad (65)$$

Proof. Recall that by Remark 3, we have implicitly $F_0(\varphi(\varepsilon)) = F_0(\varphi(\varepsilon), \omega)$ where $\omega \sim \text{Unif}([0, 1])$ encodes additional randomness. We can therefore choose F_0 to be a function that depends uniquely on ω , while F being independent of ω , and it is clear that we can construct $F_0(\omega)$ to be, for instance, a zero-mean Gaussian vector with the claimed covariance. \square

From now on, we will choose F such that F/α is a Q -contraction for (\bar{Z}, Y) where $\bar{Z} \sim \mathbf{N}(0, Q)$ is independent of Y , as per Definition 1. This implies that

$$\mathbb{E} \left[F(\bar{Z}, Y) F(\bar{Z}, Y)^\top \right] = \alpha Q, \quad (66)$$

and there exists some $S \in \mathbb{S}_+^m \setminus \{0\}$, such that

$$\mathbb{E} \left[J_F(\bar{Z}, Y)^\top S J_F(\bar{Z}, Y) \right] \preceq \alpha S, \quad (67)$$

which verifies point 1 of Assumption 4.1. Now, choosing F_0 as in Lemma 4.5 and \mathbf{W}_F the same as before, we deduce that

$$\begin{aligned} \frac{1}{n} \sum_{i=1}^n \delta_{(y_i, (\mathbf{X}\mathbf{W}_F)_i)} &\xrightarrow{w} \text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) \right) \\ &= \text{Law} \left(\varphi(\varepsilon), \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; \varphi(\varepsilon)) \right), \end{aligned}$$

where

$$\mathbb{E} \left[F \left(\overline{Z}_{T_1-1}; \varphi(\varepsilon) \right)^\top F \left(\overline{Z}_{T_1-1}; \varphi(\varepsilon) \right) \right] = \mathbb{E} \left[Z_{T_1}^\top Z_{T_1} \right] = \alpha Q. \quad (68)$$

To characterize this limiting joint distribution, we need to compute $\mathbb{E}[\overline{Z}_{T_1}^\top \overline{Z}_{T_1-1}]$. Define $C_t = \mathbb{E}[\overline{Z}_{t+1}^\top \overline{Z}_t]$, then we have

$$C_1 = \frac{1}{\alpha} \mathbb{E} \left[Z_2^\top Z_1 \right] = \frac{1}{\alpha} \mathbb{E} \left[F \left(\overline{Z}_1; \varphi(\varepsilon) \right)^\top F_0 \left(\varphi(\varepsilon) \right) \right] = 0,$$

and the recurrence relation

$$C_{t+1} = \frac{1}{\alpha} \mathbb{E} \left[F \left(\overline{Z}_{t+1}; \varphi(\varepsilon) \right)^\top F \left(\overline{Z}_t; \varphi(\varepsilon) \right) \right]. \quad (69)$$

Note that the right hand side of the above equation only depends on $C_t = \mathbb{E}[\overline{Z}_{t+1}^\top \overline{Z}_t]$, since we always have $\mathbb{E}[\overline{Z}_{t+1}^\top \overline{Z}_{t+1}] = \mathbb{E}[\overline{Z}_t^\top \overline{Z}_t] = Q$. Now we define for $C \in \mathbb{S}_+^m$ with $0 \preceq C \preceq Q$:

$$\psi(C) = \frac{1}{\alpha} \mathbb{E}_{(C,Q)} \left[F \left(\overline{Z}; \varphi(\varepsilon) \right)^\top F \left(\overline{Z}'; \varphi(\varepsilon) \right) \right], \quad (70)$$

where $\mathbb{E}_{(C,Q)}$ denotes the expectation taken under $(\overline{Z}, \overline{Z}')^\top \sim \mathcal{N} \left(0, \begin{bmatrix} Q & C \\ C & Q \end{bmatrix} \right)$, independent of ε . We then know that $\psi(Q) = Q$, and $C_{t+1} = \psi(C_t)$. The proposition below establishes that as $t \rightarrow \infty$, C_t converges to Q , the unique fixed point of ψ :

Proposition 4.6. $\lim_{t \rightarrow \infty} C_t = Q$.

Remark 6. If $m = 1$, the requirement on F reduces to

$$\mathbb{E}_{v^0 \sim \mathcal{N}(0,q)} \left[F(v^0; \varphi(\varepsilon))^2 \right] = \alpha q, \quad \mathbb{E}_{v^0 \sim \mathcal{N}(0,q)} \left[\partial_{v^0} F(v^0; \varphi(\varepsilon))^2 \right] \leq \alpha. \quad (71)$$

As a consequence, we know that

$$\text{Law} \left(\varphi(\varepsilon), \overline{Z}_{T_1} + \frac{1}{\alpha} F \left(\overline{Z}_{T_1-1}; \varphi(\varepsilon) \right) \right)$$

is arbitrarily close to

$$\text{Law} \left(\varphi(\varepsilon), \overline{Z} + \frac{1}{\alpha} F \left(\overline{Z}; \varphi(\varepsilon) \right) \right), \quad \overline{Z} \sim \mathcal{N}(0, Q)$$

in W_2 distance for sufficiently large T_1 .

4.3 Second stage: Incremental AMP

In this section we describe the second stage of our algorithm, which is an incremental AMP (IAMP) procedure first introduced in [Mon19]. We will see that the asymptotics of this incremental stage admit a stochastic integral representation under a suitable scaling limit.

For this IAMP stage, the non-linear functions $\{F_t\}_{t \geq T_1}$ and $\{G_t\}_{t \geq T_1+1}$ are chosen to satisfy the following assumption:

Assumption 4.2. Consider the random variables $((V^t)_{t \geq 1}, Y)$ and $((W^t)_{t \geq 1}, V)$ defined as follows:

$$\begin{aligned} (V^t)_{1 \leq t \leq T_1} &= (\bar{Z}_t)_{1 \leq t \leq T_1}, \quad Y = \varphi(\bar{Z}_0; \varepsilon), \quad \bar{Z}_0 \sim \mathbf{N}(0, I_k), \quad \varepsilon \sim P_\varepsilon, \quad \bar{Z}_0 \perp \varepsilon, \\ (V^t)_{t \geq T_1+1} &\sim_{\text{i.i.d.}} \mathbf{N}(0, I_m), \quad (V^t)_{t \geq T_1+1} \perp ((V^t)_{1 \leq t \leq T_1}, Y), \\ (W^t)_{1 \leq t \leq T_1} &= (Z_t)_{1 \leq t \leq T_1}, \quad V \perp (W^t)_{t \geq 1}, \quad V \sim P_V, \\ (W^t)_{t \geq T_1+1} &\sim_{\text{i.i.d.}} \mathbf{N}(0, I_m), \quad (W^t)_{t \geq T_1+1} \perp ((W^t)_{1 \leq t \leq T_1}, V). \end{aligned} \quad (72)$$

We impose the following second moment constraints on $\{F_t\}_{t \geq T_1}$ and $\{G_t\}_{t \geq T_1+1}$:

1. F_{T_1} is only a function of $Y = \varphi(\bar{Z}_0; \varepsilon)$ with $\mathbb{E}[F_{T_1}(Y)^\top F_{T_1}(Y)] = I_m$, G_{T_1+1} is only a function of $V\mu_{T_1+1} + W^{T_1+1}$ with

$$\mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1}) \right] = \alpha I_m. \quad (73)$$

Further, for $\mu_{T_1+1} = \mathbb{E}[\partial_{\bar{Z}_0} F_{T_1}(\varphi(\bar{Z}_0; \varepsilon))]$, we require

$$\mathbb{E}_{(\mu, Q)} \left[F_{T_1}(\varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon)) \right] = 0, \quad (74)$$

$$\mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top V \right] = 0. \quad (75)$$

2. The functions $\{F_t\}_{t \geq T_1+1}$ and $\{G_t\}_{t \geq T_1+2}$ have the form:

$$F_t(V^{\leq t}, Y) = V^t \Phi_{t-1}(V^{\leq t-1}, Y), \quad G_t(W^{\leq t}) = W^t \Psi_{t-1}(W^{\leq t-1}),$$

where Φ_{t-1} and Ψ_{t-1} are $m \times m$ matrix-valued functions satisfying

$$\begin{aligned} \mathbb{E} \left[\Phi_{t-1}(V^{\leq t-1}, Y)^\top \Phi_{t-1}(V^{\leq t-1}, Y) \right] &= I_m, \\ \mathbb{E} \left[\Psi_{t-1}((V\mu_s + W^s)_{1 \leq s \leq T_1+1}, (W^s)_{T_1+2 \leq s \leq t-1})^\top \Psi_{t-1}((V\mu_s + W^s)_{1 \leq s \leq T_1+1}, (W^s)_{T_1+2 \leq s \leq t-1}) \right] &= \alpha I_m. \end{aligned} \quad (76)$$

Proposition 4.7. Under Assumption 4.2, we have $(Z_t)_{t \geq T_1+1} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$ is independent of $((Z_t)_{1 \leq t \leq T_1}, V)$, and $(\bar{Z}_t)_{t \geq T_1+1} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$ is independent of $((\bar{Z}_t)_{1 \leq t \leq T_1}, Y)$.

Now we construct the weight matrix \mathbf{W}_I from the IAMP iterations. Fix a positive integer T_2 , and let Q_1, \dots, Q_{T_2} be T_2 non-random $m \times m$ matrices such that $\sum_{t=1}^{T_2} Q_t^\top Q_t = I_m - Q$. We then define

$$\mathbf{W}_I = \frac{1}{\sqrt{n}} \sum_{t=1}^{T_2} G_{T_1+t+1}(\mathbf{W}^{\leq T_1+t+1}) Q_t$$

as the output of the IAMP stage. The final output of our two-stage algorithm is constructed as follows. Recall that the fixed-point stage outputs

$$\mathbf{W}_F = \frac{1}{\sqrt{n}} \mathbf{W}^{T_1}.$$

We combine \mathbf{W}_F and \mathbf{W}_I by letting $\mathbf{W}_Q = \mathbf{W}_F + \mathbf{W}_I$, and setting $\mathbf{W} = \mathbf{W}_Q(\mathbf{W}_Q^\top \mathbf{W}_Q)^{-1/2}$ to be the final output of our algorithm. By definition, it is easy to see that $\mathbf{W} \in O(d, m)$, as we required in the definition of (α, m) -feasibility. Next it suffices to figure out the limiting empirical distribution of the rows of $(\mathbf{y}, \mathbf{X}\mathbf{W})$, which is characterized by the following:

Theorem 4.1. *Let Assumption 4.2 hold, and further assume that for all $t \geq 0$, F_t is continuous, and for all $t \geq 1$, G_t and its partial derivatives are all pseudo-Lipschitz of order 2. Let the weight matrix \mathbf{W} be constructed as above, then we have almost surely,*

$$\frac{1}{n} \sum_{i=1}^n \delta_{(y_i, (\mathbf{X}\mathbf{W})_i)} \xrightarrow{w} \text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right)$$

as $n \rightarrow \infty$, where $Y = \varphi(\bar{Z}_0; \varepsilon)$,

$$A_t = \frac{1}{\alpha} \mathbb{E} [\Psi_{T_1+t} (V \mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})], \quad 1 \leq t \leq T_2,$$

and the joint distributions of $(Z_{\leq T_1+T_2+1}, V)$ and $(\bar{Z}_{\leq T_1+T_2+1}, Y)$ are specified in Assumption 4.2. Moreover, for any sequence of $m \times m$ matrices $(A_t)_{1 \leq t \leq T_2}$ satisfying $A_t^\top A_t \preceq I_m/\alpha$, and functions $(F_{T_1+t})_{1 \leq t \leq T_2}$ satisfying Assumption 4.2 (not necessarily to be continuous),

$$\text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right)$$

is an (α, m) -feasible probability distribution in $\mathcal{F}_{m, \alpha}^{\text{alg}}$.

4.3.1 Pure noise labels

Here we specialize our general results to the case of the y_i 's being purely random labels, namely $\mathbf{y} = \varphi(\varepsilon)$ is independent of \mathbf{X} . Under this setting, our requirements on the IAMP functions $\{F_t\}_{t \geq T_1}$ and $\{G_t\}_{t \geq T_1+1}$ simplify to the following:

Assumption 4.3. *Consider the random variables $((V^t)_{t \geq 1}, Y)$ and $(W^t)_{t \geq 1}$ defined as follows:*

$$\begin{aligned} (V^t)_{1 \leq t \leq T_1} &= (\bar{Z}_t)_{1 \leq t \leq T_1}, \quad Y = \varphi(\varepsilon), \quad \varepsilon \sim P_\varepsilon, \\ (V^t)_{t \geq T_1+1} &\sim \text{i.i.d. } \mathbf{N}(0, I_m), \quad (V^t)_{t \geq T_1+1} \perp ((V^t)_{1 \leq t \leq T_1}, Y), \\ (W^t)_{1 \leq t \leq T_1} &= (Z_t)_{1 \leq t \leq T_1}, \\ (W^t)_{t \geq T_1+1} &\sim \text{i.i.d. } \mathbf{N}(0, I_m), \quad (W^t)_{t \geq T_1+1} \perp (W^t)_{1 \leq t \leq T_1}. \end{aligned} \tag{77}$$

We impose the following second moment constraints on $\{F_t\}_{t \geq T_1}$ and $\{G_t\}_{t \geq T_1+1}$:

1. F_{T_1} is only a function of $Y = \varphi(\varepsilon)$ with $\mathbb{E}[F_{T_1}(Y)^\top F_{T_1}(Y)] = I_m$, G_{T_1+1} is only a function of W^{T_1+1} with

$$\mathbb{E} \left[G_{T_1+1} (W^{T_1+1})^\top G_{T_1+1} (W^{T_1+1}) \right] = \alpha I_m. \tag{78}$$

Further, we require

$$\mathbb{E}_Q \left[F_{T_1}(\varphi(\varepsilon))^\top F(\bar{Z}; \varphi(\varepsilon)) \right] = 0. \tag{79}$$

2. The functions $\{F_t\}_{t \geq T_1+1}$ and $\{G_t\}_{t \geq T_1+2}$ have the form:

$$F_t(V^{\leq t}, Y) = V^t \Phi_{t-1}(V^{\leq t-1}, Y), \quad G_t(W^{\leq t}) = W^t \Psi_{t-1}(W^{\leq t-1}),$$

where Φ_{t-1} and Ψ_{t-1} are $m \times m$ matrix-valued functions satisfying

$$\begin{aligned} \mathbb{E} \left[\Phi_{t-1}(V^{\leq t-1}, Y)^\top \Phi_{t-1}(V^{\leq t-1}, Y) \right] &= I_m, \\ \mathbb{E} \left[\Psi_{t-1}(W^{\leq t-1})^\top \Psi_{t-1}(W^{\leq t-1}) \right] &= \alpha I_m. \end{aligned} \tag{80}$$

Based on Assumption 4.3, the state evolution for IAMP is specified as follows:

Proposition 4.8. *For any fixed function F and $Q \in \mathbb{S}_+^m$, there exists F_{T_1} and G_{T_1+1} satisfying part 1 of Assumption 4.3. Further, under Assumption 4.3, we have $(Z_t)_{t \geq T_1+1} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$ is independent of $(Z_t)_{1 \leq t \leq T_1}$, and $(\bar{Z}_t)_{t \geq T_1+1} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$ is independent of $((\bar{Z}_t)_{1 \leq t \leq T_1}, Y)$.*

Proof. Similar to the proof of Proposition 4.7. \square

Using an analogous argument as that in the proof of Theorem 4.1, we can show that for any sequence of $m \times m$ matrices $(A_t)_{1 \leq t \leq T_2}$ satisfying $A_t^\top A_t \preceq I_m/\alpha$, and functions $(F_{T_1+t})_{1 \leq t \leq T_2}$ satisfying Assumption 4.3 (not necessarily to be continuous),

$$\text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right)$$

is in $\mathcal{F}_{m,\alpha}^{\text{alg}}$, where we recall that $\sum_{t=1}^{T_2} Q_t^\top Q_t = I_m - Q$. Let us denote

$$U = \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t.$$

Then, according to our choice of F_t and G_t for IAMP,

$$U = \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + \bar{Z}_{T_1+t} \Phi_{T_1+t-1}(\bar{Z}_{\leq T_1+t-1}, Y) A_t) Q_t,$$

where the constraints read

$$\begin{aligned} \mathbb{E} \left[\Phi_{T_1+t-1}(\bar{Z}_{\leq T_1+t-1}, Y)^\top \Phi_{T_1+t-1}(\bar{Z}_{\leq T_1+t-1}, Y) \right] &= I_m, \quad \forall t \geq 1, \\ A_t^\top A_t &\preceq \frac{I_m}{\alpha}, \quad \forall t \geq 1, \quad \text{and} \quad \sum_{t=1}^{T_2} Q_t^\top Q_t = I_m - Q. \end{aligned}$$

For future convenience, we denote $V^t = \bar{Z}_{T_1+t}$ for $t \geq 1$, and choose Φ_{T_1+t-1} as a function of $(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y)$, i.e.,

$$\Phi_{T_1+t-1}(\bar{Z}_{\leq T_1+t-1}, Y) = \Phi_{T_1+t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y). \quad (81)$$

We further recast $\Phi_{T_1+t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y) A_t$ as $\Phi_{t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y)$ for all $t \geq 1$, so that the constraints can be rewritten as

$$\mathbb{E} \left[\Phi_{t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y)^\top \Phi_{t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y) \right] \preceq \frac{I_m}{\alpha}, \quad \forall t \geq 1, \quad (82)$$

and

$$U = \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (V^{t+1} + V^t \Phi_{t-1}(V^{\leq t-1}, \bar{Z}_{T_1-1}, Y)) Q_t.$$

According to the discussion in Section 4.2.1, we know that as $T_1 \rightarrow \infty$,

$$U \rightarrow \bar{Z} + \frac{1}{\alpha} F(\bar{Z}; Y) + \sum_{t=1}^{T_2} (V^{t+1} + V^t \Phi_{t-1}(V^{\leq t-1}, \bar{Z}, Y)) Q_t,$$

where $\bar{Z} \sim \mathbf{N}(0, Q)$ is independent of $(V^t)_{t \geq 1}$. For notational simplicity, we recast \bar{Z} as V^0 and T_2 as T , thus leading to the following theorem:

Theorem 4.2. For any $T \in \mathbb{N}_+$, let $(V^t)_{1 \leq t \leq T} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$ be independent of (V^0, Y) with $V^0 \perp Y$, $V^0 \sim \mathbf{N}(0, Q)$, $Y = \varphi(\varepsilon)$, $\varepsilon \sim P_\varepsilon$. Further, assume that F/α is a Q -contraction for (V^0, Y) as per Definition 1. Define

$$U = V^0 + \frac{1}{\alpha} F(V^0; Y) + \sum_{t=1}^T (V^{t+1} + V^t \Phi_{t-1}(V^{\leq t-1}, V^0, Y)) Q_t, \quad (83)$$

where

$$\mathbb{E} \left[\Phi_{t-1}(V^{\leq t-1}, V^0, Y)^\top \Phi_{t-1}(V^{\leq t-1}, V^0, Y) \right] \preceq \frac{I_m}{\alpha}, \quad \forall t \geq 1, \quad \sum_{t=1}^T Q_t^\top Q_t = I_m - Q.$$

Then, we have $\text{Law}(Y, U) \in \mathcal{F}_{m, \alpha}^{\text{alg}}$.

4.4 Stochastic integral representation

In this section we take the scaling limit for the feasible distribution described in Theorem 4.2, yielding a stochastic integral representation for IAMP-feasible probability measures. For ease of exposition we only consider the case $m = 1$, as the proof for general $m \geq 2$ follows similarly.

For $m = 1$, Eq. (83) can be rewritten as (recast $F(v^0, Y)/\alpha$ as $F(v^0, Y)$)

$$\begin{aligned} U &= v^0 + F(v^0, Y) + \sum_{t=1}^T q_t (v^{t+1} + \phi_{t-1}(v^{\leq t-1}, v^0, Y) v^t), \\ \mathbb{E} [F(v^0, Y)^2] &= \frac{q}{\alpha}, \quad \mathbb{E} [\partial_{v^0} F(v^0, Y)^2] \leq \frac{1}{\alpha}, \\ \mathbb{E} [\phi_{t-1}(v^{\leq t-1}, v^0, Y)^2] &\leq \frac{1}{\alpha}, \quad \forall t \geq 1, \quad \sum_{t=1}^T q_t^2 = 1 - q. \end{aligned}$$

where $(v^t)_{1 \leq t \leq T} \sim_{\text{i.i.d.}} \mathbf{N}(0, 1)$, independent of $v^0 \sim \mathbf{N}(0, q)$ and $Y = \varphi(\varepsilon)$, $\varepsilon \sim P_\varepsilon$. We first show that the Itô integral with respect to a family of simple adapted processes can be approximated by the U defined above in L^2 distance to arbitrary accuracy.

Lemma 4.9. Let $(B_t)_{0 \leq t \leq 1}$ be a standard Brownian motion. Define the filtration $\{\mathcal{F}_t\}_{0 \leq t \leq 1}$ by

$$\mathcal{F}_t = \sigma(v^0, Y, (B_s)_{0 \leq s \leq t}), \quad 0 \leq t \leq 1,$$

where $v^0 \sim \mathbf{N}(0, q)$ is independent of Y and $(B_t)_{0 \leq t \leq 1}$. Assume $0 = t_0 < t_1 < \dots < t_n = 1$ is an arbitrary discretization of $[0, 1]$, $\{q(t_j)\}_{0 \leq j \leq n-1}$ is a sequence of scalars satisfying

$$\sum_{j=0}^{n-1} q(t_j)^2 (t_{j+1} - t_j) = 1 - q,$$

$\{\phi_{t_j}\}_{0 \leq j \leq n-1}$ is a sequence of random variables adapted to $\{\mathcal{F}_{t_j}\}_{0 \leq j \leq n-1}$, and that

$$\mathbb{E} [\phi_{t_j}^2] \leq \frac{1}{\alpha}, \quad \forall j = 0, \dots, n-1.$$

Further, assume $f = F(v^0, Y)$ is a measurable function satisfying

$$\mathbb{E} [F(v^0, Y)^2] = \frac{q}{\alpha}, \quad \mathbb{E} [\partial_{v^0} F(v^0, Y)^2] \leq \frac{1}{\alpha}.$$

Then, $\text{Law}(Y, U_s) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$, where

$$U_s = v^0 + F(v^0, Y) + \sum_{j=0}^{n-1} q(t_j)(1 + \phi_{t_j})(B_{t_{j+1}} - B_{t_j}).$$

Next we move from simple adapted stochastic processes to general progressively measurable stochastic processes, thus completing the discussion of the stochastic integral representation for computationally feasible distributions in $\mathcal{F}_{1,\alpha}^{\text{alg}}$. As anticipated, we prove Theorem 3.1 for the case $m = 1$, as the proof general $m > 1$ is nearly identical.

Proof of Theorem 3.1 for the case $m = 1$. We prove this theorem via standard approximation arguments in stochastic analysis. We will use several times the fact that $\mathcal{F}_{1,\alpha}^{\text{alg}}$ is, by construction, closed under weak convergence. First, note that if we define

$$\tilde{U} = v^0 + F(v^0, Y) + \int_0^1 \tilde{q}(t)(1 + \phi_t) dB_t$$

for another $\tilde{q} \in L^2[0, 1]$ satisfying $\|\tilde{q}\|_{L^2}^2 = \|q\|_{L^2}^2 = 1 - q$, then Itô's isometry implies

$$\begin{aligned} \mathbb{E} \left[(U - \tilde{U})^2 \right] &= \int_0^1 \mathbb{E} \left[(q(t) - \tilde{q}(t))^2 (1 + \phi_t)^2 \right] dt \\ &= \int_0^1 (q(t) - \tilde{q}(t))^2 \mathbb{E} \left[(1 + \phi_t)^2 \right] dt \leq \left(1 + \frac{1}{\sqrt{\alpha}} \right)^2 \|q - \tilde{q}\|_{L^2}^2, \end{aligned}$$

where the last inequality follows from direct calculation:

$$\mathbb{E} \left[(1 + \phi_t)^2 \right] = 1 + 2\mathbb{E}[\phi_t] + \mathbb{E}[\phi_t^2] \leq 1 + 2\sqrt{\mathbb{E}[\phi_t^2]} + \mathbb{E}[\phi_t^2] = \left(1 + \sqrt{\mathbb{E}[\phi_t^2]} \right)^2 \leq \left(1 + \frac{1}{\sqrt{\alpha}} \right)^2.$$

Since $C[0, 1]$ is dense in $L^2[0, 1]$, we know that $\{\tilde{U} : \tilde{q} \in C[0, 1]\}$ is a dense subset of $\{U : q \in L^2[0, 1]\}$ in the space of L^2 -integrable random variables, which further implies that $\{\text{Law}(Y, \tilde{U}) : \tilde{q} \in C[0, 1]\}$ is dense in $\{\text{Law}(Y, U) : q \in L^2[0, 1]\}$ under weak limit. Since $\mathcal{F}_{1,\alpha}^{\text{alg}}$ is closed, we can assume without loss of generality that $q(t) \in C[0, 1]$. Now for any $M > 0$, we define the truncated process

$$\phi_t^M = \phi_t \mathbf{1}_{|\phi_t| \leq M}, \text{ and } U^M = v^0 + F(v^0, Y) + \int_0^1 q(t)(1 + \phi_t^M) dB_t,$$

then we obtain that

$$\mathbb{E} \left[(U - U^M)^2 \right] = \mathbb{E} \left[\left(\int_0^1 q(t) \phi_t \mathbf{1}_{|\phi_t| > M} dB_t \right)^2 \right] = \int_0^1 q(t)^2 \mathbb{E} \left[\phi_t^2 \mathbf{1}_{|\phi_t| > M} \right] dt \rightarrow 0$$

as $M \rightarrow \infty$ by bounded convergence theorem, since $\forall t \in [0, 1]$:

$$\sup_{M > 0} \mathbb{E} \left[\phi_t^2 \mathbf{1}_{|\phi_t| > M} \right] \leq \left(1 + \frac{1}{\sqrt{\alpha}} \right)^2, \quad \lim_{M \rightarrow \infty} \mathbb{E} \left[\phi_t^2 \mathbf{1}_{|\phi_t| > M} \right] = 0.$$

Therefore, $\text{Law}(Y, U^M) \xrightarrow{w} \text{Law}(Y, U)$.

Now it suffices to consider U^M , namely assuming $q(t)$ is continuous and ϕ_t is bounded without loss of generality. Note that by our assumption, the stochastic process $X_t^M = q(t)(1 + \phi_t^M)$ is

bounded and progressively measurable. According to Lemma 2.4 and the discussion of Problem 2.5 in [KS12], X_t^M can be arbitrarily approximated in $L^2([0, 1] \times \Omega)$ by a sequence of simple adapted processes as described in the statement of Lemma 4.9. As a consequence, there exists a sequence $\{U_s^n\}_{n \in \mathbb{N}}$ such that for all $n \in \mathbb{N}$, $\text{Law}(Y, U_s^n) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$, and that $U_s^n \xrightarrow{L^2} U^M$. Since $\mathcal{F}_{1,\alpha}^{\text{alg}}$ is closed, we know that $\text{Law}(Y, U^M)$ is $(\alpha, 1)$ -feasible, $\forall M > 0$. Letting $M \rightarrow \infty$ and using again the fact that $\mathcal{F}_{1,\alpha}^{\text{alg}}$ is closed, it finally follows that $\text{Law}(Y, U) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$. This completes the proof. \square

Note that in the statement of Theorem 3.1 and future sections, we have changed the vectors and matrices appeared in the current section to their transposes to align with usual notations.

5 Dual value $\mathcal{V}_{1,\alpha}^{\text{alg}}(h)$ and Parisi formula: Proof of Theorem 3.3

This section will be devoted to the proof of Theorem 3.3, thus yielding a dual characterization of $\mathcal{V}_{1,\alpha}^{\text{alg}}(h)$. While our final result is limited to the case $m = 1$, we will prove several intermediate results for general m . Throughout, we will work under the unsupervised setting in which the pure noise label Y in our general AMP achievability result (Theorem 3.1) is ignored.

We begin by defining a subset of $\mathcal{F}_{m,\alpha}^{\text{AMP}}$ corresponding to a fixed pair $(Q, \{Q(t)\}_{0 \leq t \leq 1})$ satisfying

$$\int_0^1 Q(t)Q(t)^\top dt = I_m - Q.$$

With an abuse of notation, we denote such a pair still by Q , and define the following set of probability distributions on \mathbb{R}^m :

$$\begin{aligned} \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q) := \text{cl} \left\{ \text{Law} \left(V^0 + F(V^0) + \int_0^1 Q(t) (I_m + \Phi_t) dB_t \right) : \right. \\ \left. \{\Phi_t\} \text{ is adapted to } \{\mathcal{F}_t\}, \text{ and } \mathbb{E} [\Phi_t \Phi_t^\top] \preceq \frac{I_m}{\alpha}, \forall t \in [0, 1] \right\}, \end{aligned} \quad (84)$$

where the closure is taken with respect to the weak topology. Throughout this section, $(B_t)_{0 \leq t \leq 1}$ always represents a standard Brownian motion, either m -dimensional or one-dimensional depending on the context.

When $m = 1$, the above definition reduces to

$$\begin{aligned} \mathcal{F}_{1,\alpha}^{\text{AMP}}(q) = \text{cl} \left\{ \text{Law} \left(v^0 + F(v^0) + \int_0^1 q(t) (1 + \phi_t) dB_t \right) : \right. \\ \left. \{\phi_t\} \text{ is adapted to } \{\mathcal{F}_t\}, \text{ and } \mathbb{E} [\phi_t^2] \leq \frac{1}{\alpha}, \forall t \in [0, 1] \right\}, \end{aligned} \quad (85)$$

where $\int_0^1 q(t)^2 dt = 1 - q$.

Here and in sequel, we will (implicitly) assume that F is fixed and will not attempt to optimize over its possible choices. Most technical details from this section are deferred to Appendix D.

5.1 A duality principle

By Theorem 3.1 and the closedness of $\mathcal{F}_{m,\alpha}^{\text{alg}}$, we know that for all $0 \preceq Q \preceq I_m$, $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q) \subset \mathcal{F}_{m,\alpha}^{\text{alg}}$. The proposition below establishes a dual characterization for $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$, whose proof is deferred to Appendix D.1.

Proposition 5.1. $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$ is convex and closed under weak limit. As a consequence, for any $\mu \in \mathcal{P}(\mathbb{R}^m)$, $\mu \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$ if and only if $\forall h \in C_b(\mathbb{R}^m)$,

$$\int_{\mathbb{R}^m} h d\mu \leq \sup_{\nu \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)} \left\{ \int_{\mathbb{R}^m} h d\nu \right\}.$$

As briefly discussed in Section 3, Proposition 5.1 implies that, in order to characterize $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$, it suffices to determine the following quantity for each $h \in C_b(\mathbb{R}^m)$:

$$\mathcal{V}_{m,\alpha}^{\text{AMP}}(Q, F; h) := \sup_{\nu \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)} \left\{ \int_{\mathbb{R}^m} h d\nu \right\} \quad (86)$$

$$= \sup_{\Phi \in D[0,1]} \mathbb{E} \left[h \left(V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t) dB_t \right) \right], \quad (87)$$

$$\text{subject to } \mathbb{E}[\Phi_t \Phi_t^\top] \preceq \frac{I_m}{\alpha}, \quad \forall t \in [0, 1]. \quad (88)$$

Here, the equality follows from continuity and the definition of $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$. Further, for $s \leq t$, $D[s, t]$ denotes the space of all admissible controls on the interval $[s, t]$, i.e., the collection of all progressively measurable processes $\{\Phi_r\}_{s \leq r \leq t}$ satisfying

$$\sigma(\Phi_r) \subset \mathcal{F}_r, \quad \forall r \in [s, t], \quad \text{and } \mathbb{E} \left[\int_s^t \Phi_r \Phi_r^\top dr \right] < \infty.$$

We can then transform the above constrained optimization problem into an unconstrained one using the method of Lagrange multipliers, based on the following theorem:

Theorem 5.1 (Theorem 2.9.2 in [Zal02]). *Let \mathcal{X} and \mathcal{Y} be two topological linear vector spaces, where \mathcal{Y} is ordered by a closed convex cone $\mathcal{C} \subset \mathcal{Y}$ (namely $y_1 \geq_{\mathcal{C}} y_2$ if and only if $y_1 - y_2 \in \mathcal{C}$). Assume that f is a proper convex function on \mathcal{X} , $\bar{x} \in \text{dom } f$, and $H : \mathcal{X} \rightarrow (\mathcal{Y}^\bullet, \mathcal{C})$ is a \mathcal{C} -convex map, i.e., $H((1-\lambda)x_1 + \lambda x_2) \leq_{\mathcal{C}} (1-\lambda)H(x_1) + \lambda H(x_2)$. Define the following primal optimization problem, whose value we denote by $v(P_0)$:*

$$\text{minimize } f(x), \quad \text{subject to } H(x) \leq_{\mathcal{C}} 0, \quad (P_0)$$

and the Lagrange function

$$L : \mathcal{X} \times \mathcal{C}^+ \rightarrow \overline{\mathbb{R}}, \quad L(x, y^*) := \begin{cases} f(x) + \langle H(x), y^* \rangle & \text{if } x \in \text{dom } H, \\ \infty & \text{if } x \notin \text{dom } H, \end{cases} \quad (89)$$

where \mathcal{C}^+ is the dual cone of \mathcal{C} . Moreover, we define the dual problem of (P_0) (whose value we denote by $v(D_0)$) as

$$\text{maximize } \inf_{x \in \mathcal{X}} L(x, y^*), \quad \text{subject to } y^* \in \mathcal{C}^+. \quad (D_0)$$

Suppose that the following Slater's condition holds:

$$\exists x_0 \in \text{dom } f : -H(x_0) \in \text{int } \mathcal{C}. \quad (90)$$

Then the problem (D_0) has optimal solutions and $v(P_0) = v(D_0)$, i.e., there exists $\bar{y}^* \in \mathcal{C}^+$ such that

$$\inf \{ f(x) \mid H(x) \leq_{\mathcal{C}} 0 \} = \inf \{ L(x, \bar{y}^*) \mid x \in \mathcal{X} \}. \quad (91)$$

Furthermore, the following statements are equivalent:

(i) \bar{x} is a solution of (P_0) ;

(ii) $H(\bar{x}) \leq_{\mathcal{C}} 0$ and there exists $\bar{y}^* \in \mathcal{C}^+$ such that

$$0 \in \partial(f + \bar{y}^* \circ H)(\bar{x}) \quad \text{and} \quad \langle H(\bar{x}), \bar{y}^* \rangle = 0;$$

(iii) There exists $\bar{y}^* \in \mathcal{C}^+$ such that (\bar{x}, \bar{y}^*) is a saddle point for L , i.e.,

$$\forall x \in \mathcal{X}, \forall y^* \in \mathcal{C}^+ : L(\bar{x}, y^*) \leq L(\bar{x}, \bar{y}^*) \leq L(x, \bar{y}^*).$$

Remark 7. If f is proper concave and the primal problem is

$$\text{maximize } f(x), \quad \text{subject to } H(x) \leq_{\mathcal{C}} 0, \quad (92)$$

then we can obviously apply the last theorem to $-f(x)$. We define $L(x, y^*) = f(x) - \langle H(x), y^* \rangle$ and conclude from the theorem that

$$\exists \bar{y}^* \in \mathcal{C}^+, \sup \{f(x) \mid H(x) \leq_{\mathcal{C}} 0\} = \sup \{L(x, \bar{y}^*) \mid x \in \mathcal{X}\}.$$

Now let us define \mathcal{X} to be $\{\text{Law}(V^0, \{\Phi_t\}_{0 \leq t \leq 1}) : \{\Phi_t\} \in D[0, 1]\}$ equipped with the topology of weak convergence. We further define $\mathcal{Y} = L^1([0, 1], \mathbb{R}^{m \times m})$ and $\mathcal{C} = \{\Gamma \in \mathcal{Y} : \Gamma(t) \succeq 0, \text{ for a.e. } t \in [0, 1]\}$. Finally, we define for $x \in \mathcal{X}$:

$$f(x) = \mathbb{E} \left[h \left(V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t) dB_t \right) \right], \quad (93)$$

$$H(x) = \mathbb{E} \left[\Phi_t \Phi_t^\top \right] - \frac{I_m}{\alpha} \in \mathcal{Y}. \quad (94)$$

Then the original stochastic optimal control problem can be written as Eq. (92), where f is a linear functional and H is a \mathcal{C} -convex operator. By definition, Slater's condition (90) obviously holds. According to Theorem 5.1, and noting that

$$\mathcal{C}^+ = \{\Gamma \in L^\infty([0, 1], \mathbb{R}^{m \times m}) : \Gamma(t) \succeq 0 \text{ for a.e. } t \in [0, 1]\},$$

we obtain

$$\begin{aligned} \mathcal{V}_{m, \alpha}^{\text{AMP}}(Q, F; h) &= \sup_{\nu \in \mathcal{P}_{m, \alpha}^{\text{AMP}}(Q)} \left\{ \int_{\mathbb{R}^m} h d\nu \right\} = \sup \{f(x) \mid H(x) \leq_{\mathcal{C}} 0\} = \inf_{y^* \in \mathcal{C}^+} \sup_{x \in \mathcal{X}} L(x, y^*) \\ &= \inf_{\Gamma \in \mathcal{C}^+} \sup_{\Phi \in D[0, 1]} \mathbb{E} \left[h \left(V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \left\langle \Gamma(t), \Phi_t \Phi_t^\top - \frac{I_m}{\alpha} \right\rangle dt \right] \\ &= \sup_{\Phi \in D[0, 1]} \mathbb{E} \left[h \left(V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \left\langle \bar{\Gamma}(t), \Phi_t \Phi_t^\top - \frac{I_m}{\alpha} \right\rangle dt \right] \end{aligned} \quad (95)$$

for some $\bar{\Gamma} \in L^\infty([0, 1], \mathbb{R}^{m \times m})$ satisfying $\bar{\Gamma}(t) \succeq 0, \forall t \in [0, 1]$, where the existence of $\bar{\Gamma}$ is guaranteed by the conclusion of Theorem 5.1.

In the following sections, we will study the above stochastic optimal control problem in more details for the case $m = 1$.

5.2 Reduction for the case $m = 1$

When $m = 1$, the structure of feasible sets can be significantly simplified by the next lemma, whose proof will be presented in Appendix D.2. We note that the reduction made here is similar to that in Corollary 3.1.

Lemma 5.2. *For any $q \in [0, 1]$ and $q(t) \in L^2[0, 1]$ satisfying $q + \int_0^1 q(t)^2 dt = 1$, we have*

$$\mathcal{F}_{1,\alpha}^{\text{AMP}}(q) = \text{cl} \left\{ \text{Law} \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) : \{\phi_t\} \text{ adapted to } \{\mathcal{F}_t\}, \sup_{t \in [q, 1]} \mathbb{E} [\phi_t^2] \leq \frac{1}{\alpha} \right\}, \quad (96)$$

In other words, we can eliminate the dependence on $q(t)$.

Based on the above lemma, we know that $\mathcal{F}_{1,\alpha}^{\text{AMP}}(q)$ only depends on $q \in [0, 1]$. Using the dual characterization in Eq. (95), we obtain that

$$\begin{aligned} \mathcal{V}_{1,\alpha}^{\text{AMP}}(q, F; h) &= \sup_{\nu \in \mathcal{F}_{1,\alpha}^{\text{AMP}}(q)} \left\{ \int_{\mathbb{R}} h d\nu \right\} \\ &= \inf_{\gamma \in \mathcal{C}^+} \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right] \\ &= \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \bar{\gamma}(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right] \end{aligned} \quad (97)$$

for some $\bar{\gamma} \in L^\infty[q, 1]$ such that $\bar{\gamma}(t) \geq 0, \forall t \in [q, 1]$. Now we define for any

$$\gamma \in \mathcal{C}^+ = L_+^\infty[q, 1] := \{ \gamma \in L^\infty[q, 1] : \gamma(t) \geq 0, \forall t \in [q, 1] \}, \quad (98)$$

the optimal value of the above stochastic control problem as

$$V_\gamma(q) := \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right]. \quad (99)$$

Note that we have dropped the argument h , which will be assumed to be fixed from now on. The following lemma (and the remark below it) shows that, in order to compute $V_\gamma(q)$, it suffices to consider the same quantity with $v^0 + F(v^0)$ replaced by a deterministic value, and the general problem can be reduced to this setting. We refer to Appendix D.3 for a proof of this lemma.

Lemma 5.3. *Define for any $z \in \mathbb{R}$, the following value function:*

$$V_\gamma(q, z) = \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(z + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right], \quad (100)$$

then $V_\gamma(q) = \mathbb{E}_{v^0 \sim \mathcal{N}(0, q)} [V_\gamma(q, v^0 + F(v^0))]$.

Remark 8. Because of Lemma 5.3, in order to compute $V_\gamma(q)$, it suffices to compute $V_\gamma(q, z)$ for all $z \in \mathbb{R}$, $\gamma \in \mathcal{C}^+$ and $h \in C_b(\mathbb{R})$. To this end, we will resort to tools from stochastic optimal control, namely the Hamilton-Jacobi-Bellmann (HJB) equation and verification argument. See Section 5.3 and Appendix E for details.

5.3 Proof of Theorem 3.3

In this section we present the proof of Theorem 3.3. This proof is based on some key propositions, whose proofs are deferred to Appendix E, where we will also establish the existence of solution to the Parisi PDE (39) under the assumptions of Theorem 3.3.

For the proof of parts (a) and (b), we need the following proposition regarding the dual relationship between V_γ and f_μ , the solution to the Parisi PDE.

Proposition 5.4. *Recall V_γ from Eq. (100) and f_μ from Eq. (39). Under the conditions of Theorem 3.3, we have for all $t \in [0, 1]$ and $x, z \in \mathbb{R}$:*

$$\begin{aligned} V_\gamma(t, z) &= \inf_{x \in \mathbb{R}} \left\{ f_\mu(t, x) + \frac{\gamma(t)}{2} (x - z)^2 \right\} + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds, \\ f_\mu(t, x) &= \sup_{z \in \mathbb{R}} \left\{ V_\gamma(t, z) - \frac{\gamma(t)}{2} (z - x)^2 \right\} - \frac{1}{2\alpha} \int_t^1 \gamma(s) ds. \end{aligned} \quad (101)$$

Further, the supremum in the definition of $V_\gamma(t, z)$ is achieved at $(\phi_s^z)_{s \in [t, 1]}$ satisfying

$$\phi_s^z = \frac{1}{\gamma(s)} \partial_x^2 f_\mu(s, X_s^z), \quad (102)$$

where $\{X_s^z\}_{s \in [t, 1]}$ solves the SDE

$$\frac{1}{\gamma(t)} \partial_x f_\mu(t, X_t^z) + X_t^z = z, \quad dX_s^z = \mu(s) \partial_x f_\mu(s, X_s^z) ds + dB_s, \quad s \in [t, 1]. \quad (103)$$

Proof of (a): Variational formula. For any fixed $F : \mathbb{R} \rightarrow \mathbb{R}$ and $v \in \mathbb{R}$, by definition of V_γ in Eq. (100), we have

$$V_\gamma(q, v + F(v)) = \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right]. \quad (104)$$

According to Proposition 5.4, we know that

$$V_\gamma(q, v + u) = \inf_{x \in \mathbb{R}} \left\{ f_\mu(q, x) + \frac{\gamma(q)}{2} (x - v - u)^2 \right\} + \frac{1}{2\alpha} \int_q^1 \gamma(s) ds, \quad (105)$$

$$f_\mu(q, v) = \sup_{z \in \mathbb{R}} \left\{ V_\gamma(q, z) - \frac{\gamma(q)}{2} (z - v)^2 \right\} - \frac{1}{2\alpha} \int_q^1 \gamma(s) ds. \quad (106)$$

Now since $\mu = 0$ on $[0, q]$, the Parisi PDE degenerates to a standard heat equation:

$$\partial_t f_\mu(t, x) + \frac{1}{2} \partial_x^2 f_\mu(t, x) = 0, \quad (t, x) \in [0, q] \times \mathbb{R}. \quad (107)$$

As a consequence, we deduce that

$$f_\mu(0, 0) = \mathbb{E}_{v \sim \mathcal{N}(0, q)} [f_\mu(q, v)] = \mathbb{E}_{v \sim \mathcal{N}(0, q)} \left[\sup_{z \in \mathbb{R}} \left\{ V_\gamma(q, z) - \frac{\gamma(q)}{2} (z - v)^2 \right\} \right] - \frac{1}{2\alpha} \int_q^1 \gamma(s) ds, \quad (108)$$

which further implies that

$$F(\mu, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \left(q\gamma(q) + \int_q^1 \gamma(s) ds \right) \quad (109)$$

$$= \mathbb{E}_{v \sim \mathcal{N}(0, q)} \left[\sup_{z \in \mathbb{R}} \left\{ V_\gamma(q, z) - \frac{\gamma(q)}{2} \left((z - v)^2 - \frac{q}{\alpha} \right) \right\} \right] \quad (110)$$

$$= \mathbb{E}_{v \sim \mathcal{N}(0, q)} \left[\sup_{u \in \mathbb{R}} \left\{ V_\gamma(q, v + u) - \frac{\gamma(q)}{2} \left(u^2 - \frac{q}{\alpha} \right) \right\} \right] \quad (111)$$

$$= \sup_{F: \mathbb{R} \rightarrow \mathbb{R}} \mathbb{E}_{v \sim \mathcal{N}(0, q)} \left[V_\gamma(q, v + F(v)) - \frac{\gamma(q)}{2} \left(F(v)^2 - \frac{q}{\alpha} \right) \right]. \quad (112)$$

By Lemma 5.3, we know that for any fixed F :

$$\mathbb{E}_{v \sim \mathcal{N}(0, q)} [V_\gamma(q, v + F(v))] = \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right], \quad (113)$$

which concludes the proof of part (a).

Proof of (b): Weak duality. The first inequality follows directly from the definition of $\mathcal{V}_{1, \alpha}^{\text{AMP}}(q; h)$ and $\overline{\mathcal{V}}_{1, \alpha}^{\text{AMP}}(q; h)$. To show the second one, note that by direct calculation:

$$\begin{aligned} \overline{\mathcal{V}}_{1, \alpha}^{\text{AMP}}(q; h) &= \sup_{\substack{\alpha \mathbb{E}[F(v)^2] \leq q \\ \mathbb{E}[\phi_t^2] \leq 1/\alpha}} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) \right] \\ &\leq \sup_{F, \phi} \inf_{\gamma \in \mathcal{L}_\#(q)} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt - \frac{\gamma(q)}{2} \left(F(v)^2 - \frac{q}{\alpha} \right) \right] \\ &\stackrel{(i)}{\leq} \inf_{\gamma \in \mathcal{L}_\#(q)} \sup_{F, \phi} \mathbb{E} \left[h \left(v + F(v) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt - \frac{\gamma(q)}{2} \left(F(v)^2 - \frac{q}{\alpha} \right) \right] \\ &\stackrel{(ii)}{=} \inf_{(\mu, c) \in \mathcal{L}(q)} F(\mu, c), \end{aligned}$$

where (i) follows from minimax inequality, (ii) follows from the variational formula of part (a). This proves part (b).

Proof of (c): Strong duality. For the sake of simplicity, in this section we only consider the case $1/c_* > \sup_{z \in \mathbb{R}} h''(z)$. The proof for $1/c_* \leq \sup_{z \in \mathbb{R}} h''(z)$ is technically more complicated but not substantially different, and we defer it to Appendix E.2. We will need the following proposition regarding the first-order variation of the Parisi functional $F(\mu, c)$.

Proposition 5.5. *For any $(\mu, c) \in \mathcal{L}(q)$ such that $1/c > \sup_{z \in \mathbb{R}} h''(z)$, let $(X_t)_{t \in [0, 1]}$ solve the SDE (existence and uniqueness of solution will be proved in Appendix E.1):*

$$X_0 = 0, \quad dX_t = \mu(t) \partial_x f_\mu(t, X_t) dt + dB_t, \quad t \in [0, 1]. \quad (114)$$

Let $\gamma \in \mathcal{L}_\#(q)$ be such that $\gamma'/\gamma^2 = \mu$, $\gamma(1) = 1/c$, and define

$$F(x) = \frac{1}{\gamma(q)} \partial_x f_\mu(q, x), \quad \phi_t = \frac{1}{\gamma(t)} \partial_x^2 f_\mu(t, X_t), \quad \forall t \in [0, 1]. \quad (115)$$

Then, we have

(i) $X_q = B_q \sim \mathbf{N}(0, q)$, and

$$F(\mu, c) = \mathbb{E} \left[h \left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right]. \quad (116)$$

(ii) $\forall 0 \leq s < t \leq 1$, $\mathbb{E}[(\partial_x f_\mu(t, X_t))^2] - \mathbb{E}[(\partial_x f_\mu(s, X_s))^2] = \int_s^t \gamma(u)^2 \mathbb{E}[\phi_u^2] du$.

(iii) Assume that $\delta : [0, 1] \rightarrow \mathbb{R}$ is in $L^1[0, 1]$ and $L^\infty[0, t]$ for any $t \in [0, 1]$, further $\delta \equiv 0$ on $[0, q]$. Then, $(\mu + s\delta, c) \in \mathcal{L}(q)$ for sufficiently small $s \in \mathbb{R}$, and

$$\frac{d}{ds} F(\mu + s\delta, c) \Big|_{s=0} = \frac{1}{2} \int_q^1 \delta(t) \left(\mathbb{E}[(\partial_x f_\mu(t, X_t))^2] - \frac{1}{\alpha} \int_0^t \gamma(s)^2 ds \right) dt. \quad (117)$$

We are now in position to complete the proof of part (c). Since the infimum of F is achieved at (μ_*, c_*) , the first-order variation of F at μ_* must be equal to 0 for any $\delta \in L^1[0, 1]$ that belongs to $L^\infty[0, t]$ for any $t \in [0, 1]$, and equals 0 on $[0, q]$. According to Proposition 5.5 (iii), we must have

$$\frac{1}{2} \int_q^1 \delta(t) \left(\mathbb{E}[(\partial_x f_{\mu_*}(t, X_t))^2] - \frac{1}{\alpha} \int_0^t \gamma_*(s)^2 ds \right) dt = 0 \quad (118)$$

for all such δ . Note that Proposition 5.5 (ii) implies that $\mathbb{E}[(\partial_x f_{\mu_*}(t, X_t))^2]$ is continuous in t , we therefore deduce that

$$\mathbb{E}[(\partial_x f_{\mu_*}(t, X_t))^2] = \frac{1}{\alpha} \int_0^t \gamma_*(s)^2 ds, \quad \forall t \in [q, 1]. \quad (119)$$

Now we define $(\phi_t^*)_{t \in [q, 1]}$ and F^* according to Eq. (115). Then from Proposition 5.5 (ii), we immediately know that

$$\mathbb{E}[(\phi_t^*)^2] = \frac{1}{\alpha}, \quad \forall t \in [q, 1], \quad (120)$$

namely, $(\phi_t^*)_{t \in [q, 1]}$ is feasible. It suffices to show that F^* is feasible, and

$$F(\mu_*, c_*) = \mathbb{E} \left[h \left(X_q + F^*(X_q) + \int_q^1 (1 + \phi_t^*) dB_t \right) \right], \quad (121)$$

since $X_q = B_q \sim \mathbf{N}(0, q)$.

We first establish the feasibility of F^* , i.e.,

$$\alpha \mathbb{E}[F^*(v)^2] = q, \quad \alpha \mathbb{E}[(F^*)'(v)^2] \leq 1, \quad v \sim \mathbf{N}(0, q). \quad (122)$$

Note that since $X_q \sim \mathbf{N}(0, q)$, we have

$$\alpha \mathbb{E}[F^*(v)^2] = \frac{\alpha}{\gamma_*(q)^2} \mathbb{E}[(\partial_x f_{\mu_*}(q, X_q))^2] = \frac{1}{\gamma_*(q)^2} \int_0^q \gamma_*(s)^2 ds = q, \quad (123)$$

which follows from Eq. (119) and the fact that γ_* is constant on $[0, q]$. Further,

$$\alpha \mathbb{E}[(F^*)'(v)^2] = \frac{\alpha}{\gamma_*(q)^2} \mathbb{E}[(\partial_x^2 f_{\mu_*}(q, X_q))^2] = \alpha \mathbb{E}[(\phi_q^*)^2] = 1. \quad (124)$$

This proves that F^* is feasible. Eq. (121) then automatically follows from Proposition 5.5 (i). This completes the proof of part (c).

A Duality between $\mathcal{F}_{m,\alpha}$ and $\mathcal{V}_{m,\alpha}(\cdot)$: Proof of Theorem 1.1

To facilitate our proof, we first introduce some preliminary results on the convergence of probability measures on Euclidean spaces. Denote by $C_b(\mathbb{R}^m)$ the space of bounded continuous functions on \mathbb{R}^m equipped with the sup-norm, and by $rba(\mathbb{R}^m)$ the space of regular, bounded and finitely additive measures on the same space, respectively (see Section IV.6 of [DS88] for their detailed definitions). Note that $C_b(\mathbb{R}^m)$ and $rba(\mathbb{R}^m)$ are all topological vector spaces. The following theorem reveals their relationship:

Theorem A.1 (Theorem IV.6 from [DS88]). *$rba(\mathbb{R}^m)$ is the topological dual space of $C_b(\mathbb{R}^m)$, i.e.,*

$$C_b(\mathbb{R}^m)^* = rba(\mathbb{R}^m).$$

It is noteworthy that the validity of the above theorem does not depend on the topological structure of $rba(\mathbb{R}^m)$, so here and in sequel we may equip $rba(\mathbb{R}^m)$ with the weak* topology. Namely, for $\{\mu_n\}_{n \geq 0}$ and $\mu \in rba(\mathbb{R}^m)$, μ_n converges to μ if and only if

$$\forall f \in C_b(\mathbb{R}^m), \lim_{n \rightarrow \infty} \int_{\mathbb{R}^m} f d\mu_n = \int_{\mathbb{R}^m} f d\mu. \quad (125)$$

If μ_n 's and μ are probability measures, then this convergence is equivalent to convergence in distribution. That is to say,

$$\mu_n \xrightarrow{w_*} \mu \iff \mu_n \xrightarrow{w} \mu,$$

where $\xrightarrow{w_*}$ denotes weak* convergence as defined in Eq. (125). We can then regard $E \subset \mathcal{P}(\mathbb{R}^m)$ as a subspace of $rba(\mathbb{R}^m)$, since all probability measures on \mathbb{R}^m are regular, bounded by 1 and countably additive.

We are now in position to prove Theorem 1.1. The “only if” part is obvious. As for the “if” part, we assume that $\mu \notin E$, and aim to prove the contrapositive statement. Since $C_b(\mathbb{R}^m)$ is a normed space, it's locally convex. The dual space $rba(\mathbb{R}^m)$ is equipped with the weak* topology, hence by Lemma F.1,

$$(rba(\mathbb{R}^m), \text{weak}^*)^* = C_b(\mathbb{R}^m).$$

Moreover, similar to the proof of [Bre10, Prop. 3.4], one can show that the weak* topology is locally convex, thus implying the local convexity of $rba(\mathbb{R}^m)$. Now since E is closed and convex in $rba(\mathbb{R}^m)$, the singleton $\{\mu\}$ is compact and convex. According to the Hahn-Banach theorem (Theorem 1.7 in [Bre10]), there exists an $h \in C_b(\mathbb{R}^m)$ that strictly separates E and $\{\mu\}$. Without loss of generality we can choose h such that

$$\int_{\mathbb{R}^m} h d\mu > \sup_{\nu \in E} \left\{ \int_{\mathbb{R}^m} h d\nu \right\},$$

a contradiction. Therefore, $\mu \in E$, as desired. This completes the proof.

B Conjectures from statistical physics

In this section we carry out calculations using the non-rigorous replica method from statistical physics, to support Conjecture 2.1. We will focus on the case $m = 1$, since the case of general $m > 1$ is almost identical, but less transparent. We refer to [MS24] for a friendly introduction to these techniques. The derivation presented here is quite straightforward (from a physics perspective) and generalizes the replica calculation in [GR00].

Recall the definition of the Hamiltonian

$$H_{n,d}(\mathbf{w}) = \frac{1}{n} \sum_{i=1}^n h(\langle \mathbf{x}_i, \mathbf{w} \rangle), \quad \mathbf{w} \in \mathbb{S}^{d-1}. \quad (126)$$

Define for $\beta > 0$,

$$Z_\beta = \int_{\mathbb{S}^{d-1}} e^{n\beta H_{n,d}(\mathbf{w})} \nu_0(d\mathbf{w}), \quad (127)$$

where ν_0 is the uniform measure on \mathbb{S}^{d-1} . Assume that

$$\lim_{n,d \rightarrow \infty, n/d \rightarrow \alpha} \max_{\mathbf{w} \in \mathbb{S}^{d-1}} H_{n,d}(\mathbf{w})$$

exists almost surely, and concentrates around its expectation (this is true if h is Lipschitz), then we would like to compute

$$\lim_{n \rightarrow \infty} \mathbb{E} \left[\max_{\mathbf{w} \in \mathbb{S}^{d-1}} H_{n,d}(\mathbf{w}) \right] = \lim_{n \rightarrow \infty} \mathbb{E} \left[\lim_{\beta \rightarrow \infty} \frac{1}{n\beta} \log Z_\beta \right]. \quad (128)$$

Here, the limit $n \rightarrow \infty$ should be understood as $n, d \rightarrow \infty$ simultaneously with $n/d \rightarrow \alpha$. Within the replica method, we interchange expectation and limit arbitrarily. It then suffices to compute the quantity

$$\lim_{\beta \rightarrow \infty} \lim_{n \rightarrow \infty} \frac{1}{n\beta} \mathbb{E} [\log Z_\beta] = \lim_{\beta \rightarrow \infty} \lim_{n \rightarrow \infty} \lim_{k \rightarrow 0^+} \frac{1}{n\beta k} \log \mathbb{E} [Z_\beta^k], \quad (129)$$

where we use the identity

$$\mathbb{E} [\log Z] = \lim_{k \rightarrow 0^+} \frac{1}{k} \log \mathbb{E} [Z^k]. \quad (130)$$

While the above interchange of limits is not justified in the present derivation, it is not the most problematic step in the replica calculation. Indeed, the critical step is to first consider k as an integer, and then extrapolate to non-integer values of k . For $k \in \mathbb{N}$, we have

$$\mathbb{E} [Z_\beta^k] = \mathbb{E} \left[\int_{(\mathbb{S}^{d-1})^k} \exp \left(\beta \cdot \sum_{j=1}^k \sum_{i=1}^n h(\langle \mathbf{w}_j, \mathbf{x}_i \rangle) \right) \cdot \prod_{j=1}^k \nu_0(d\mathbf{w}_j) \right] \quad (131)$$

$$= \int_{(\mathbb{S}^{d-1})^k} \mathbb{E} \left[\exp \left(\beta \cdot \sum_{j=1}^k \sum_{i=1}^n h(\langle \mathbf{w}_j, \mathbf{x}_i \rangle) \right) \right] \cdot \prod_{j=1}^k \nu_0(d\mathbf{w}_j) \quad (132)$$

$$= \int_{(\mathbb{S}^{d-1})^k} \mathbb{E} \left[\exp \left(\beta \cdot \sum_{j=1}^k h(\langle \mathbf{w}_j, \mathbf{x} \rangle) \right) \right]^n \cdot \prod_{j=1}^k \nu_0(d\mathbf{w}_j). \quad (133)$$

Denoting by Q the overlap matrix of the \mathbf{w}_j 's, namely $Q_{ij} = \langle \mathbf{w}_i, \mathbf{w}_j \rangle$ for $1 \leq i, j \leq k$, then we have for $\mathbf{x} \sim \mathbf{N}(\mathbf{0}, \mathbf{I}_d)$,

$$\mathbb{E} \left[\exp \left(\beta \cdot \sum_{j=1}^k h(\langle \mathbf{w}_j, \mathbf{x} \rangle) \right) \right] = \mathbb{E}_{G \sim \mathbf{N}(0, Q)} \left[\exp \left(\beta \cdot \sum_{j=1}^k h(G_j) \right) \right]. \quad (134)$$

For future convenience, we denote the above quantity as $f_{\beta,h}(Q)$, i.e.,

$$f_{\beta,h}(Q) = \mathbb{E}_{G \sim \mathbf{N}(0, Q)} \left[\exp \left(\beta \cdot \sum_{j=1}^k h(G_j) \right) \right], \quad (135)$$

it then follows that

$$\mathbb{E} \left[Z_\beta^k \right] = \int_{(\mathbb{S}^{d-1})^k} f_{\beta,h}(Q)^n \cdot \prod_{j=1}^k \nu_0(d\mathbf{w}_j) \quad (136)$$

$$= \int_{S_+^k(1)} f_{\beta,h}(Q)^n \exp(dI_d(Q)) dQ, \quad (137)$$

where $S_+^k(1)$ denotes the space of all $k \times k$ positive semidefinite matrices with all ones on the diagonal, and $dQ = \prod_{1 \leq i < j \leq k} dQ_{ij}$ represents the uniform probability measure on this space. Moreover, we have for fixed k ,

$$\lim_{d \rightarrow \infty} I_d(Q) = \frac{1}{2} \log \det Q, \quad (138)$$

thus leading to

$$\lim_{n \rightarrow \infty} \frac{1}{n} \log \mathbb{E} \left[Z_\beta^k \right] = \max_{Q \in S_+^k(1)} \left\{ \log f_{\beta,h}(Q) + \frac{1}{2\alpha} \log \det Q \right\} \quad (139)$$

$$= \max_{Q \in S_+^k(1)} \left\{ \log \mathbb{E}_{G \sim \mathcal{N}(0,Q)} \left[\exp \left(\beta \cdot \sum_{j=1}^k h(G_j) \right) \right] + \frac{1}{2\alpha} \log \det Q \right\} \quad (140)$$

$$:= S_{\beta,h}(\alpha, k). \quad (141)$$

Assume again that we can interchange the limits arbitrarily, then we get that

$$\lim_{\beta \rightarrow \infty} \lim_{n \rightarrow \infty} \frac{1}{n\beta} \mathbb{E} [\log Z_\beta] = \lim_{\beta \rightarrow \infty} \lim_{n \rightarrow \infty} \lim_{k \rightarrow 0^+} \frac{1}{n\beta k} \log \mathbb{E} \left[Z_\beta^k \right] \quad (142)$$

$$= \lim_{\beta \rightarrow \infty} \frac{1}{\beta} \lim_{k \rightarrow 0^+} \frac{1}{k} \lim_{n \rightarrow \infty} \frac{1}{n} \log \mathbb{E} \left[Z_\beta^k \right] \quad (143)$$

$$= \lim_{\beta \rightarrow \infty} \frac{1}{\beta} \lim_{k \rightarrow 0^+} \frac{1}{k} S_{\beta,h}(\alpha, k). \quad (144)$$

To compute this limit, we resort to the full RSB (full replica symmetry breaking) ansatz described in Section 3 of [GR00]. Following their calculation, the limiting free energy can be expressed as the extreme value of a variational problem. To be specific, we have

$$\frac{1}{\beta} \lim_{k \rightarrow 0^+} \frac{1}{k} S_{\beta,h}(\alpha, k) = \inf_{y \in \mathcal{U}[0,1]} \mathbf{A}(y; \beta), \quad (145)$$

$$\mathbf{A}(y; \beta) := f_y(0, 0) + \frac{1}{2\alpha\beta} \int_0^1 \left(\frac{1}{D_y(t)} - \frac{1}{1-t} \right) dt, \quad (146)$$

where $\mathcal{U}[0, 1]$ is the space of all non-decreasing function $y : [0, 1] \rightarrow [0, 1]$,

$$D_y(t) = \int_t^1 y(s) ds, \quad (147)$$

and $f_y(t, x)$ satisfies the PDE:

$$\partial_t f_y(t, x) + \frac{1}{2} \beta y(t) (\partial_x f_y(t, x))^2 + \frac{1}{2} \partial_x^2 f_y(t, x) = 0, \quad (148)$$

$$f_y(1, x) = h(x). \quad (149)$$

The lemma below gives the zero-temperature limit ($\beta \rightarrow \infty$) of the variational functional $\mathbf{A}(y; \beta)$, along specific sequences of y_β .

Lemma B.1. Let $c > 0$, and $\mu(t) : [0, 1] \rightarrow \mathbb{R}_{\geq 0}$ be a non-decreasing function with $\int_0^1 \mu(t) dt < \infty$. Further, assume that $y(t)$ has the following form:

$$y_\beta(t) = \frac{\mu(t)}{\beta} \mathbf{1}_{t < 1 - \frac{c}{\beta}} + \mathbf{1}_{t \geq 1 - \frac{c}{\beta}}. \quad (150)$$

Then, we have

$$\lim_{\beta \rightarrow \infty} A(y_\beta; \beta) = F_1(\mu, c), \quad (151)$$

$$F_1(\mu, c) := f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds}, \quad (152)$$

where f_μ solves the terminal-value problem:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) (\partial_x f_\mu(t, x))^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \quad (153)$$

Proof. Defining $t_\beta = 1 - c/\beta$, Eq. (148) reduces to

$$\partial_t f_y(t, x) + \frac{1}{2} \mu(t) (\partial_x f_y(t, x))^2 + \frac{1}{2} \partial_x^2 f_y(t, x) = 0, \quad t \in [0, t_\beta], \quad (154)$$

$$\partial_t f_y(t, x) + \frac{1}{2} \beta (\partial_x f_y(t, x))^2 + \frac{1}{2} \partial_x^2 f_y(t, x) = 0, \quad t \in [t_\beta, 1], \quad (155)$$

$$f_y(1, x) = h(x). \quad (156)$$

Using Cole-Hopf transform, we know that

$$f_y(t_\beta, x) = \frac{1}{\beta} \log \mathbb{E}_{G \sim \mathcal{N}(0, 1)} \left[\exp \left(\beta \cdot h \left(x + \sqrt{\frac{c}{\beta}} G \right) \right) \right] \quad (157)$$

$$= \frac{1}{\beta} \log \left(\frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} \exp \left(\beta \cdot h \left(x + \sqrt{\frac{c}{\beta}} z \right) - \frac{z^2}{2} \right) dz \right) \quad (158)$$

$$= \frac{1}{\beta} \log \left(\frac{\sqrt{\beta}}{\sqrt{2\pi c}} \int_{\mathbb{R}} \exp \left(\beta \cdot h(x + u) - \frac{\beta u^2}{2c} \right) du \right), \quad (159)$$

which converges to $\sup_{u \in \mathbb{R}} \{h(x + u) - u^2/(2c)\}$ as $\beta \rightarrow \infty$, uniformly over compact sets. Moreover, since $t_\beta \rightarrow 1$, we deduce that f_y converges to f_μ where f_μ solves Eq. (15). As a consequence, $f_y(0, 0) \rightarrow f_\mu(0, 0)$. To compute the limit of the second term, we note that $D(t) = 1 - t$ if $t \geq t_\beta$. Therefore,

$$\frac{1}{2\alpha\beta} \int_0^1 \left(\frac{1}{D(t)} - \frac{1}{1-t} \right) dt = \frac{1}{2\alpha\beta} \int_0^{t_\beta} \left(\frac{1}{D(t)} - \frac{1}{1-t} \right) dt \quad (160)$$

$$= \frac{1}{2\alpha} \int_0^{t_\beta} \frac{dt}{c + \int_t^{t_\beta} \mu(s) ds} + \frac{1}{2\alpha\beta} \log(1 - t_\beta) \quad (161)$$

$$= \frac{1}{2\alpha} \int_0^{t_\beta} \frac{dt}{c + \int_t^{t_\beta} \mu(s) ds} + \frac{1}{2\alpha\beta} \log \left(\frac{c}{\beta} \right) \quad (162)$$

$$\rightarrow \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds} \text{ as } \beta \rightarrow \infty. \quad (163)$$

This completes the proof. \square

Defining

$$\mathcal{U} = \left\{ \mu : [0, 1) \rightarrow \mathbb{R}_{\geq 0} : \mu \text{ non-decreasing, } \int_0^1 \mu(t) dt < \infty \right\}, \quad (164)$$

we note that the function $F_1 : \mathcal{U} \times \mathbb{R}_{>0} \rightarrow \mathbb{R}$ defined in the last lemma coincides with the one of Conjecture 2.1 and Remark 1. This establishes the replica prediction.

C Proofs for Section 4

C.1 Proof of Proposition 4.6

Proof. Without loss of generality we may assume that $F(\overline{Z}; Y) = F(\overline{Z}; \varphi(\varepsilon))$ is only a function of \overline{Z} , namely $F(\overline{Z}; \varphi(\varepsilon)) = F(\overline{Z})$. Hence, $\psi(C)$ admits the following representation:

$$\begin{aligned} \psi(C) &= \frac{1}{\alpha} \mathbb{E}_{(C, Q)} \left[F(\overline{Z})^\top F(\overline{Z}') \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[F \left(C^{1/2} V + (Q - C)^{1/2} V' \right)^\top F \left(C^{1/2} V + (Q - C)^{1/2} V'' \right) \right], \end{aligned}$$

where the expectation is taken over $V, V', V'' \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$. Next, we will show that

- (a) ψ is increasing, i.e., for $0 \leq A \leq B \leq Q$, we have $\psi(A) \leq \psi(B)$.
- (b) For any $0 \leq C \leq Q$, $\psi(C) = C$ if and only if $C = Q$, namely Q is the only fixed point of ψ .

Proof of (a). Denote $H = B - A \geq 0$, and define for $\beta \in \mathbb{R}^m$ and $t \in [0, 1]$:

$$\psi_{\beta, H}(t) = \beta^\top \psi(A + tH) \beta.$$

Then, it suffices to show that $\psi_{\beta, H}(1) \geq \psi_{\beta, H}(0)$ for all $\beta \in \mathbb{R}^m$. To this end, we show that $\psi'_{\beta, H}(t) \geq 0$ for all t . Note that

$$\begin{aligned} \psi_{\beta, H}(t) &= \frac{1}{\alpha} \mathbb{E} \left[\beta^\top F \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V' \right)^\top F \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V'' \right) \beta \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[F_\beta \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V' \right) F_\beta \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V'' \right) \right], \end{aligned}$$

where we denote $F_\beta = F\beta$. By direct calculation, we obtain that

$$\psi'_{\beta, H}(t) = \frac{1}{\alpha} \mathbb{E} \left[\nabla F_\beta \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V' \right)^\top H \nabla F_\beta \left((A + tH)^{1/2} V + (Q - A - tH)^{1/2} V'' \right) \right],$$

which is of course non-negative. This proves that $\psi_{\beta, H}(1) \geq \psi_{\beta, H}(0)$ for all $\beta \in \mathbb{R}^m$, namely

$$\beta^\top \psi(B) \beta \geq \beta^\top \psi(A) \beta, \quad \forall \beta \in \mathbb{R}^m \implies \psi(B) \succeq \psi(A). \quad (165)$$

This completes the proof of part (a).

Proof of (b). Assume by contradiction that $\psi(C) = C$, and set $H = Q - C$. Similarly, define for $\beta \in \mathbb{R}^m \setminus \{0\}$ and $t \in [0, 1]$:

$$\psi_{\beta,H}(t) = \beta^\top \psi(C + tH)\beta.$$

Then, we know that $\psi'_{\beta,H}(t) \geq 0$, and similar calculation as in part (a) implies that $\psi''_{\beta,H}(t) \geq 0$. Further, these quantities are positive since F is non-linear. Hence,

$$\begin{aligned} \beta^\top (Q - C)\beta &= \beta^\top (\psi(Q) - \psi(C))\beta = \psi_{\beta,H}(1) - \psi_{\beta,H}(0) = \int_0^1 \psi'_{\beta,H}(t) dt \\ &< \psi'_{\beta,H}(1) = \frac{1}{\alpha} \mathbb{E} \left[\nabla F_\beta \left(Q^{1/2} V \right)^\top H \nabla F_\beta \left(Q^{1/2} V \right) \right] \\ &= \frac{1}{\alpha} \beta^\top \mathbb{E} \left[\left(Q^{1/2} V \right)^\top H J_F \left(Q^{1/2} V \right) \right] \beta, \end{aligned}$$

which implies that for all $\beta \in \mathbb{R}^m \setminus \{0\}$,

$$\beta^\top H \beta = \beta^\top (Q - C)\beta < \frac{1}{\alpha} \beta^\top \mathbb{E} \left[J_F \left(Q^{1/2} V \right)^\top H J_F \left(Q^{1/2} V \right) \right] \beta \quad (166)$$

$$\iff \langle H, \beta \beta^\top \rangle < \left\langle \frac{1}{\alpha} \mathbb{E} \left[J_F \left(Q^{1/2} V \right)^\top H J_F \left(Q^{1/2} V \right) \right], \beta \beta^\top \right\rangle, \quad (167)$$

thus leading to $\forall S \in \mathbb{S}_+^m$,

$$\begin{aligned} \langle H, S \rangle &< \left\langle \frac{1}{\alpha} \mathbb{E} \left[J_F \left(Q^{1/2} V \right)^\top H J_F \left(Q^{1/2} V \right) \right], S \right\rangle \\ &\iff \langle H, S \rangle < \left\langle H, \frac{1}{\alpha} \mathbb{E} \left[J_F \left(Q^{1/2} V \right) S J_F \left(Q^{1/2} V \right)^\top \right] \right\rangle, \end{aligned}$$

which contradicts our assumption that F is a Q -contraction. This proves part (b).

Proof of $\lim_{t \rightarrow \infty} C_t = Q$. Now we show that $C_t \rightarrow Q$ as $t \rightarrow \infty$. Since ψ is increasing and $C_1 = 0 \preceq C_2$, we know that the sequence $\{C_t\}$ is increasing. Further since $C_t \preceq Q$ is bounded, we know that $C_t \rightarrow C$ for some $0 \preceq C \preceq Q$, and C is a fixed point of ψ . By part (b), we know that $C = Q$. This completes the proof. \square

C.2 Proof of Proposition 4.7

Proof. According to Proposition 4.2, we already know that $(Z_t)_{t \geq T_1+1}$ and $(\bar{Z}_t)_{t \geq T_1+1}$ are centered multivariate Gaussians, hence it suffices to show that for any $k \geq 1$,

$$\begin{aligned} (Z_t)_{T_1+1 \leq t \leq T_1+k} &\sim \text{i.i.d. } \mathbf{N}(0, I_m), \quad (Z_t)_{T_1+1 \leq t \leq T_1+k} \perp ((Z_t)_{1 \leq t \leq T_1}, V), \\ (\bar{Z}_t)_{T_1+1 \leq t \leq T_1+k} &\sim \text{i.i.d. } \mathbf{N}(0, I_m), \quad (\bar{Z}_t)_{T_1+1 \leq t \leq T_1+k} \perp ((\bar{Z}_t)_{1 \leq t \leq T_1}, Y). \end{aligned} \quad (168)$$

We prove the above claim, and additionally that $\mu_{T_1+k+1} = 0$ via induction on k . For $k = 1$, using Eq. (49) and Assumption 4.2, we obtain that

$$\mathbb{E} \left[Z_{T_1+1}^\top Z_{T_1+1} \right] = \mathbb{E} \left[F_{T_1}(Y)^\top F_{T_1}(Y) \right] = I_m.$$

Further, for any $1 \leq t \leq T_1$, we have

$$\begin{aligned}\mathbb{E} \left[Z_{T_1+1}^\top Z_t \right] &= \mathbb{E} \left[F_{T_1} (\varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}_{t-1}; \varphi(\bar{Z}_0; \varepsilon)) \right] \\ &= \mathbb{E}_{(\mu, Q)} \left[F_{T_1} (\varphi(\bar{Z}_0; \varepsilon))^\top F(\bar{Z}; \varphi(\bar{Z}_0; \varepsilon)) \right] = 0.\end{aligned}$$

Therefore, $Z_{T_1+1} \sim \mathbf{N}(0, I_m)$, and is independent of $((Z_t)_{1 \leq t \leq T_1}, V)$. Similarly, by Eq. (49) and Assumption 4.2 we know that

$$\begin{aligned}\mathbb{E} \left[\bar{Z}_{T_1+1}^\top \bar{Z}_{T_1+1} \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1}) \right] = I_m, \\ \mathbb{E} \left[\bar{Z}_{T_1+1}^\top \bar{Z}_0 \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top V \right] = 0, \\ \mathbb{E} \left[\bar{Z}_{T_1+1}^\top \bar{Z}_t \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top (V\mu + W^t) \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+1} (V\mu_{T_1+1} + W^{T_1+1})^\top W^t \right] = 0,\end{aligned}$$

where the last line follows from the fact that $W^t \perp (V, W^{T_1+1})$. As a consequence, we deduce that $\bar{Z}_{T_1+1} \sim \mathbf{N}(0, I_m)$ and is independent of $((\bar{Z}_t)_{1 \leq t \leq T_1}, Y)$. Moreover,

$$\begin{aligned}\mu_{T_1+2} &= \mathbb{E} \left[\frac{\partial F_{T_1+1}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1+1}; \varphi(\bar{Z}_0; \varepsilon)) \right] = \mathbb{E} \left[\bar{Z}_{T_1+1} \frac{\partial \Phi_{T_1}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1}; \varphi(\bar{Z}_0; \varepsilon)) \right] \\ &= \mathbb{E} [\bar{Z}_{T_1+1}] \mathbb{E} \left[\frac{\partial \Phi_{T_1}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1}; \varphi(\bar{Z}_0; \varepsilon)) \right] = 0.\end{aligned}$$

This completes the base case of our induction. Now assume that our claim (168) holds for $k \in \mathbb{N}$. For $k+1$, we have

$$\begin{aligned}\mathbb{E} \left[Z_{T_1+k+1}^\top Z_{T_1+k+1} \right] &= \mathbb{E} \left[F_{T_1+k}(\bar{Z}_{\leq T_1+k}, Y)^\top F_{T_1+k}(\bar{Z}_{\leq T_1+k}, Y) \right] \\ &= \mathbb{E} \left[\Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y)^\top \bar{Z}_{T_1+k}^\top \bar{Z}_{T_1+k} \Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y) \right] \\ &= \mathbb{E} \left[\Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y)^\top \mathbb{E} \left[\bar{Z}_{T_1+k}^\top \bar{Z}_{T_1+k} \right] \Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y) \right] \\ &= \mathbb{E} \left[\Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y)^\top \Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y) \right] = I_m,\end{aligned}$$

and for all $t \leq T_1 + k$,

$$\begin{aligned}\mathbb{E} \left[Z_{T_1+k+1}^\top Z_t \right] &= \mathbb{E} \left[F_{T_1+k}(\bar{Z}_{\leq T_1+k}, Y)^\top F_{t-1}(\bar{Z}_{\leq t-1}, Y) \right] \\ &= \mathbb{E} \left[\Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y)^\top \bar{Z}_{T_1+k}^\top F_{t-1}(\bar{Z}_{\leq t-1}, Y) \right] \\ &= \mathbb{E} \left[\Phi_{T_1+k-1}(\bar{Z}_{\leq T_1+k-1}, Y)^\top \mathbb{E} [\bar{Z}_{T_1+k}^\top] F_{t-1}(\bar{Z}_{\leq t-1}, Y) \right] = 0.\end{aligned}$$

This proves $(Z_t)_{T_1+1 \leq t \leq T_1+k+1} \sim \text{i.i.d. } \mathbf{N}(0, I_m)$, and are independent of $((Z_t)_{1 \leq t \leq T_1}, V)$. Proceeding similarly, we get that

$$\begin{aligned}\mathbb{E} \left[\bar{Z}_{T_1+k+1}^\top \bar{Z}_{T_1+k+1} \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+k+1} (V\mu_{\leq T_1+k+1} + Z_{\leq T_1+k+1})^\top G_{T_1+k+1} (V\mu_{\leq T_1+k+1} + Z_{\leq T_1+k+1}) \right] \\ &\stackrel{(i)}{=} \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+k+1} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k+1})^\top G_{T_1+k+1} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k+1}) \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top \bar{Z}_{T_1+k+1}^\top \bar{Z}_{T_1+k+1} \Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k}) \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top \mathbb{E} [\bar{Z}_{T_1+k+1}^\top \bar{Z}_{T_1+k+1}] \Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k}) \right] \\ &= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top \Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k}) \right] = I_m,\end{aligned}$$

where (i) is because of $\mu_t = 0$ for $T_1 + 2 \leq t \leq T_1 + k + 1$. For any $1 \leq s \leq T_1 + k$, we deduce that

$$\begin{aligned}
\mathbb{E} \left[\bar{Z}_{T_1+k+1}^\top \bar{Z}_s \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+k+1} (V\mu_{\leq T_1+k+1} + Z_{\leq T_1+k+1})^\top G_s (V\mu_{\leq s} + Z_{\leq s}) \right] \\
&= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+k+1} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k+1})^\top G_s (V\mu_{\leq s} + Z_{\leq s}) \right] \\
&= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top Z_{T_1+k+1}^\top G_s (V\mu_{\leq s} + Z_{\leq s}) \right] \\
&= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top \mathbb{E} [Z_{T_1+k+1}]^\top G_s (V\mu_{\leq s} + Z_{\leq s}) \right] = 0.
\end{aligned}$$

Furthermore,

$$\begin{aligned}
\mathbb{E} \left[\bar{Z}_{T_1+k+1}^\top \bar{Z}_0 \right] &= \frac{1}{\alpha} \mathbb{E} \left[G_{T_1+k+1} (V\mu_{\leq T_1+k+1} + Z_{\leq T_1+k+1})^\top V \right] \\
&= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top Z_{T_1+k+1}^\top V \right] \\
&= \frac{1}{\alpha} \mathbb{E} \left[\Psi_{T_1+k} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+k})^\top \mathbb{E} [Z_{T_1+k+1}]^\top V \right] = 0.
\end{aligned}$$

This proves that $(\bar{Z}_t)_{T_1+1 \leq t \leq T_1+k+1} \sim_{\text{i.i.d.}} \mathbf{N}(0, I_m)$, and are independent of $((\bar{Z}_t)_{1 \leq t \leq T_1}, Y)$. Finally, we need to show that $\mu_{T_1+k+2} = 0$. Using Eq. (49), it follows that

$$\begin{aligned}
\mu_{T_1+k+2} &= \mathbb{E} \left[\frac{\partial F_{T_1+k+1}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1+k+1}; \varphi(\bar{Z}_0; \varepsilon)) \right] = \mathbb{E} \left[\bar{Z}_{T_1+k+1} \frac{\partial \Phi_{T_1+k}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1+k}; \varphi(\bar{Z}_0; \varepsilon)) \right] \\
&= \mathbb{E} [\bar{Z}_{T_1+k+1}] \mathbb{E} \left[\frac{\partial \Phi_{T_1+k}}{\partial \bar{z}_0} (\bar{Z}_{\leq T_1+k}; \varphi(\bar{Z}_0; \varepsilon)) \right] = 0.
\end{aligned}$$

This completes the induction step and the proof of the proposition. \square

C.3 Proof of Theorem 4.1

Proof. By our assumption, we know that for all $1 \leq s, t \leq T$, $G_t G_s$ is pseudo-Lipschitz of order 2, hence we have almost surely,

$$\begin{aligned}
\mathbf{W}_I^\top \mathbf{W}_I &= \frac{1}{n} \sum_{t=1}^{T_2} \sum_{s=1}^{T_2} Q_t^\top G_{T_1+t+1} (\mathbf{W}^{\leq T_1+t+1})^\top G_{T_1+s+1} (\mathbf{W}^{\leq T_1+s+1}) Q_s \\
&= \sum_{t=1}^{T_2} \sum_{s=1}^{T_2} Q_t^\top \left(\frac{1}{n} \sum_{i=1}^d G_{T_1+t+1} (\mathbf{w}_i^{\leq T_1+t+1})^\top G_{T_1+s+1} (\mathbf{w}_i^{\leq T_1+s+1}) \right) Q_s \\
&\rightarrow \frac{1}{\alpha} \sum_{t=1}^{T_2} \sum_{s=1}^{T_2} Q_t^\top \mathbb{E} \left[G_{T_1+t+1} (V\mu_{\leq T_1+t+1} + Z_{\leq T_1+t+1})^\top G_{T_1+s+1} (V\mu_{\leq T_1+s+1} + Z_{\leq T_1+s+1}) \right] Q_s \\
&= \sum_{t=1}^{T_2} \sum_{s=1}^{T_2} Q_t^\top \mathbb{E} \left[\bar{Z}_{T_1+t+1}^\top \bar{Z}_{T_1+s+1} \right] Q_s = \sum_{t=1}^{T_2} Q_t^\top Q_t = I_m - Q.
\end{aligned}$$

Similarly, we can show that $\mathbf{W}_F^\top \mathbf{W}_F \rightarrow Q$ and $\mathbf{W}_F^\top \mathbf{W}_I \rightarrow 0$. Therefore, $\mathbf{W}_Q^\top \mathbf{W}_Q \rightarrow I_m$ almost surely as $n \rightarrow \infty$. Using Slutsky's theorem, it now suffices to consider \mathbf{W}_Q and the empirical joint

distribution of $(\mathbf{y}, \mathbf{X}\mathbf{W}_Q)$. By direct calculation, we obtain that

$$\begin{aligned}\mathbf{X}\mathbf{W}_Q &= \mathbf{X}\mathbf{W}_F + \mathbf{X}\mathbf{W}_I = \mathbf{V}^{T_1} + \frac{d}{n}F(\mathbf{V}^{T_1-1}; \mathbf{y}) + \frac{1}{\sqrt{n}} \sum_{t=1}^{T_2} \mathbf{X}G_{T_1+t+1}(\mathbf{W}^{\leq T_1+t+1}) Q_t \\ &= \mathbf{V}^{T_1} + \frac{d}{n}F(\mathbf{V}^{T_1-1}; \mathbf{y}) + \sum_{t=1}^{T_2} \left(\mathbf{V}^{T_1+t+1} + \sum_{s=1}^{T_1+t+1} F_{s-1}(\mathbf{V}^{\leq s-1}; \mathbf{y}) D_{T_1+t+1,s}^\top \right) Q_t,\end{aligned}$$

where by state evolution,

$$\begin{aligned}D_{T_1+t+1,s} &= \frac{1}{n} \sum_{i=1}^d \frac{\partial G_{T_1+t+1}}{\partial \mathbf{w}^s}(\mathbf{w}_i^1, \dots, \mathbf{w}_i^{T_1+t+1}) \\ &\xrightarrow{a.s.} \frac{1}{\alpha} \mathbb{E} \left[\frac{\partial G_{T_1+t+1}}{\partial w^s} (V\mu_{\leq T_1+t+1} + Z_{\leq T_1+t+1}) \right] \\ &= \frac{\mathbf{1}_{s=T_1+t+1}}{\alpha} \mathbb{E} [\Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})]^\top.\end{aligned}$$

For future convenience, we define

$$A_t = \text{p-lim}_{n \rightarrow \infty} D_{T_1+t+1, T_1+t+1}^\top = \frac{1}{\alpha} \mathbb{E} [\Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})]. \quad (169)$$

Therefore, it suffices to consider the empirical joint distribution of \mathbf{y} and

$$\mathbf{V}^{T_1} + \frac{1}{\alpha} F(\mathbf{V}^{T_1-1}; \mathbf{y}) + \sum_{t=1}^{T_2} (\mathbf{V}^{T_1+t+1} + F_{T_1+t}(\mathbf{V}^{\leq T_1+t}; \mathbf{y}) A_t) Q_t.$$

Now, since F_{T_1+t} and F are continuous, applying continuous mapping theorem implies that the joint empirical distribution of the rows of

$$\left(\mathbf{y}, \mathbf{V}^{T_1} + \frac{1}{\alpha} F(\mathbf{V}^{T_1-1}; \mathbf{y}) + \sum_{t=1}^{T_2} (\mathbf{V}^{T_1+t+1} + F_{T_1+t}(\mathbf{V}^{\leq T_1+t}; \mathbf{y}) A_t) Q_t \right)$$

almost surely weakly converges to the law of

$$\left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right),$$

and we conclude that $(1/n) \sum_{i=1}^n \delta_{(y_i, (\mathbf{X}\mathbf{W})_i)}$ almost surely weakly converges to the same limiting distribution as $n \rightarrow \infty$. As a consequence,

$$\text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right)$$

is (α, m) -feasible, where we recall that

$$A_t = \frac{1}{\alpha} \mathbb{E} [\Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})]. \quad (170)$$

Finally, note that for the IAMP stage, the only requirement for the function Ψ_{T_1+t} is that

$$\mathbb{E} \left[\Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})^\top \Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t}) \right] = \alpha I_m.$$

Hence, for any $t \geq 1$ and $A_t \in \mathbb{R}^{m \times m}$ such that $A_t^\top A_t \preceq I_m/\alpha$, there exists a function Ψ_{T_1+t} that satisfies the condition of this theorem and that

$$\mathbb{E} [\Psi_{T_1+t} (V\mu_{\leq T_1+1} + Z_{\leq T_1+1}, (Z_t)_{T_1+2 \leq t \leq T_1+t})] = \alpha A_t.$$

This proves that if F and F_{T_1+t} are continuous, then

$$\text{Law} \left(Y, \bar{Z}_{T_1} + \frac{1}{\alpha} F(\bar{Z}_{T_1-1}; Y) + \sum_{t=1}^{T_2} (\bar{Z}_{T_1+t+1} + F_{T_1+t}(\bar{Z}_{\leq T_1+t}; Y) A_t) Q_t \right)$$

is (α, m) -feasible and can be achieved by our two-stage AMP algorithm, where the only constraint on $\{A_t\}_{1 \leq t \leq T_2}$ is that $A_t^\top A_t \preceq I_m/\alpha$. The second part of Theorem 4.1 follows immediately by combining this result and the fact that $\mathcal{F}_{m,\alpha}^{\text{alg}}$ is closed under weak limits, since we can approximate general L^2 functions by continuous functions to arbitrary accuracy. \square

C.4 Proof of Lemma 4.9

Proof. First, note that we can assume without loss of generality that each t_j is a rational number, otherwise one can reparametrize the time argument. Moreover, by adding more points to $\{t_j\}_{0 \leq j \leq n}$ to make this discretization finer, it suffices to consider the setting $t_j = j/n$. It then follows that

$$U_s = v^0 + F(v^0, Y) + \sum_{j=0}^{n-1} q(j/n)(1 + \phi_{j/n})(B_{(j+1)/n} - B_{j/n}).$$

Now for any $m \geq 0$, we write

$$\begin{aligned} & \sum_{j=0}^{n-1} q(j/n)(1 + \phi_{j/n})(B_{(j+1)/n} - B_{j/n}) \\ &= \sum_{j=0}^{n-1} q(j/n)(1 + \phi_{j/n}) \sum_{i=1}^{2^m} (B_{(j2^m+i)/2^m n} - B_{(j2^m+i-1)/2^m n}) \\ &= \sum_{j=0}^{n-1} \sum_{i=1}^{2^m} q(j/n)(1 + \phi_{j/n})(B_{(j2^m+i)/2^m n} - B_{(j2^m+i-1)/2^m n}) \\ &= \sum_{l=0}^{2^m n-1} q(l/2^m n, m)(1 + \phi_{l/2^m n, m})(B_{(l+1)/2^m n} - B_{l/2^m n}), \end{aligned}$$

where $q(l/2^m n, m) = q(j/n)$, $\phi_{l/2^m n, m} = \phi_{j/n}$ if $l = j2^m + i - 1$. We further notice that the sequences $\{q(l/2^m n, m)\}_{0 \leq l \leq 2^m n-1}$ and $\{\phi_{l/2^m n, m}\}_{0 \leq l \leq 2^m n-1}$ satisfy the conditions in the statement of Lemma 4.9, since $\{l/2^m n\}_{0 \leq l \leq 2^m n}$ is just a more refined discretization of $[0, 1]$. Now for each $1 \leq l \leq 2^m n$, define the σ -algebra

$$\mathcal{F}_{l/2^m n, m} = \sigma(v^0, Y, (B_{r/2^m n})_{1 \leq r \leq l}) = \sigma(v^0, Y, (B_{r/2^m n} - B_{(r-1)/2^m n})_{1 \leq r \leq l}),$$

it then follows that

$$\mathbb{E} [\phi_{l/2^m n, m} | \mathcal{F}_{l/2^m n, m}] = \mathbb{E} [\phi_{j/n} | \mathcal{F}_{l/2^m n, m}] = \mathbb{E} [\phi_{j/n} | \mathcal{F}_{j/n, m}].$$

According to Paul Lévy's construction of Brownian motion (cf. Chapter 1 of [MP10]), we know that $\mathcal{F}_{j/n, m} \uparrow \mathcal{F}_{j/n}$ as $m \rightarrow \infty$. Since $\mathbb{E}[\phi_{j/n}^2] \leq 1/\alpha$, we know that $\phi_{j/n}$ is integrable. Applying Lévy's upwards theorem yields

$$\lim_{m \rightarrow \infty} \mathbb{E} [\phi_{j/n} | \mathcal{F}_{j/n, m}] = \mathbb{E} [\phi_{j/n} | \mathcal{F}_{j/n}] = \phi_{j/n}, \text{ almost surely and in } L^2.$$

As a consequence, we deduce that

$$U_{s, m} = v^0 + F(v^0, Y) + \sum_{l=0}^{2^m n - 1} q(l/2^m n, m) (1 + \mathbb{E} [\phi_{l/2^m n, m} | \mathcal{F}_{l/2^m n, m}]) (B_{(l+1)/2^m n} - B_{l/2^m n})$$

converges to U_s almost surely and in L^2 as $m \rightarrow \infty$.

Now, it suffices to consider the feasibility of $\text{Law}(Y, U_{s, m})$. For future convenience, let us simplify the notation here. For fixed n , denote $T_m = 2^m n$. For $1 \leq t \leq T_m$, set

$$v^t = \sqrt{T_m} (B_{t/2^m n} - B_{(t-1)/2^m n}), \quad q_t = \frac{q((t-1)/2^m n, m)}{\sqrt{T_m}},$$

$$\phi_{t-1} (v^{\leq t-1}, v^0, Y) = \mathbb{E} [\phi_{(t-1)/2^m n, m} | \mathcal{F}_{(t-1)/2^m n, m}],$$

since by definition, $\mathcal{F}_{(t-1)/2^m n, m} = \sigma(v^0, Y, v^{\leq t-1})$, which further implies that $\mathbb{E}[\phi_{(t-1)/2^m n, m} | \mathcal{F}_{(t-1)/2^m n, m}]$ is an L^2 -integrable function of $(v^{\leq t-1}, v^0, Y)$. Note that the above quantities depend on m , but we suppress the subscript “ m ” here and in sequel to avoid heavy notation. We can then write

$$U_{s, m} = v^0 + F(v^0, Y) + \sum_{t=1}^{T_m} \sqrt{T_m} q_t (1 + \phi_{t-1} (v^{\leq t-1}, v^0, Y)) \frac{v^t}{\sqrt{T_m}}$$

$$= v^0 + F(v^0, Y) + \sum_{t=1}^{T_m} q_t (1 + \phi_{t-1} (v^{\leq t-1}, v^0, Y)) v^t,$$

where by Jensen's inequality,

$$\mathbb{E} [\phi_{t-1} (v^{\leq t-1}, v^0, Y)^2] \leq \mathbb{E} [\phi_{(t-1)/2^m n, m}^2] \leq \frac{1}{\alpha}.$$

We are now in position to complete the proof. Define

$$U_{s, m}^{(1)} = v^0 + F(v^0, Y) + \sum_{t=1}^{T_m} q_t (v^{t+1} + \phi_{t-1} (v^{\leq t-1}, v^0, Y) v^t),$$

then we have the following estimates:

$$\begin{aligned}
\mathbb{E} \left[\left(U_{s,m} - U_{s,m}^{(1)} \right)^2 \right] &= \mathbb{E} \left[\left(\sum_{t=1}^{T_m-1} (q_t - q_{t+1}) v^{t+1} + q_{T_m} v^{T_m+1} - q_1 v^1 \right)^2 \right] \\
&= \sum_{t=1}^{T_m-1} (q_t - q_{t+1})^2 + q_1^2 + q_{T_m}^2 \\
&= \frac{1}{T_m} \left(\sum_{t=1}^{T_m-1} (q((t-1)/2^m n, m) - q(t/2^m n, m))^2 + q(0, m)^2 + q((T_m-1)/2^m n, m)^2 \right) \\
&\leq \frac{1}{2^m n} \left(\sum_{j=0}^{n-1} (q(j/n) - q((j+1)/n))^2 + q(0)^2 + q(1)^2 \right) \rightarrow 0, \text{ as } m \rightarrow \infty.
\end{aligned}$$

Hence, $U_{s,m}^{(1)} - U_{s,m} \xrightarrow{p} 0$. As we've shown $U_{s,m} \xrightarrow{a.s.} U_s$, it follows that $U_{s,m}^{(1)} \xrightarrow{p} U_s$, which implies

$$\text{Law}(Y, U_{s,m}^{(1)}) \xrightarrow{w} \text{Law}(Y, U_s) \text{ as } m \rightarrow \infty.$$

Now since $\mathbb{E} \left[\phi_{t-1} (v^{\leq t-1}, v^0, Y)^2 \right] \leq 1/\alpha$, and

$$\sum_{t=1}^{T_m} q_t^2 = \frac{1}{T_m} \sum_{l=0}^{T_m-1} q(l/2^m n, m)^2 = \frac{1}{n} \sum_{j=0}^{n-1} q(j/n)^2 = 1 - q$$

by our assumption, we conclude that $\text{Law}(Y, U_{s,m}^{(1)}) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$. Using again the fact that $\mathcal{F}_{1,\alpha}^{\text{alg}}$ is closed under weak limits, we know that $\text{Law}(Y, U_s) \in \mathcal{F}_{1,\alpha}^{\text{alg}}$. This completes the proof. \square

D Proofs for Section 5

D.1 Proof of Proposition 5.1

By definition, $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$ is automatically closed, next we show its convexity. Assume $P_1, P_2 \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$, then there exist two sequences of probability measures $\{P_{1,n}\}$ and $\{P_{2,n}\}$ with corresponding stochastic integral representations, such that $P_{1,n} \xrightarrow{w} P_1$, $P_{2,n} \xrightarrow{w} P_2$ as $n \rightarrow \infty$. For each $\alpha \in [0, 1]$, we aim to prove

$$\alpha P_1 + (1 - \alpha) P_2 \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q).$$

Since $\alpha P_{1,n} + (1 - \alpha) P_{2,n} \xrightarrow{w} \alpha P_1 + (1 - \alpha) P_2$, it suffices to show

$$\alpha P_{1,n} + (1 - \alpha) P_{2,n} \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q), \quad \forall n. \quad (171)$$

Fix n , by definition of $\mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$, we can write

$$P_{1,n} = \text{Law}(U_1), \quad P_{2,n} = \text{Law}(U_2),$$

where

$$\begin{aligned}
U_1 &= V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t^{(1)}) dB_t, \\
U_2 &= V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t^{(2)}) dB_t.
\end{aligned}$$

Let $0 < \varepsilon < 1$, define a new standard Brownian motion $(W_t)_{0 \leq t \leq 1}$ by requiring that $(W_t)_{0 \leq t \leq \varepsilon}$ is independent of $\mathcal{F}_1 = \sigma(V^0, (B_t)_{0 \leq t \leq 1})$, and for $\varepsilon \leq t \leq 1$,

$$W_t = W_\varepsilon + \sqrt{1 - \varepsilon} B_{\frac{t - \varepsilon}{1 - \varepsilon}}.$$

We further define

$$\tilde{Q}(t) = \frac{1}{\sqrt{1 - \varepsilon}} Q\left(\frac{t - \varepsilon}{1 - \varepsilon}\right), \quad \tilde{\Phi}_t^{(i)} = \Phi_{\frac{t - \varepsilon}{1 - \varepsilon}}^{(i)}, \quad i = 1, 2.$$

Then, it follows that for $i = 1, 2$,

$$\begin{aligned} U_i &= V^0 + F(V^0) + \int_0^1 Q(t)(I_m + \Phi_t^{(i)}) dB_t \\ &= V^0 + F(V^0) + \int_\varepsilon^1 Q\left(\frac{t - \varepsilon}{1 - \varepsilon}\right) \left(I_m + \Phi_{\frac{t - \varepsilon}{1 - \varepsilon}}^{(i)}\right) dB_{\frac{t - \varepsilon}{1 - \varepsilon}} \\ &= V^0 + F(V^0) + \int_\varepsilon^1 \frac{1}{\sqrt{1 - \varepsilon}} Q\left(\frac{t - \varepsilon}{1 - \varepsilon}\right) \left(I_m + \Phi_{\frac{t - \varepsilon}{1 - \varepsilon}}^{(i)}\right) \sqrt{1 - \varepsilon} dB_{\frac{t - \varepsilon}{1 - \varepsilon}} \\ &= V^0 + F(V^0) + \int_\varepsilon^1 \tilde{Q}(t)(I_m + \tilde{\Phi}_t^{(i)}) dW_t. \end{aligned}$$

It's not hard to see that there exists a Bernoulli random variable T such that $T \in \mathcal{F}_\varepsilon^W$, and that

$$\mathbb{P}(T = 1) = \alpha = 1 - \mathbb{P}(T = 0),$$

for example, we can take $T = \mathbf{1}_{\|W_\varepsilon\|_2 > C_\alpha}$ where $\mathbb{P}(\|W_\varepsilon\|_2 > C_\alpha) = \alpha$. Therefore, T is independent of (U_1, U_2) . Set $U = TU_1 + (1 - T)U_2$, then we have

$$\text{Law}(U) = \alpha \text{Law}(U_1) + (1 - \alpha) \text{Law}(U_2) = \alpha P_{1,n} + (1 - \alpha) P_{2,n},$$

and

$$\begin{aligned} U &= V^0 + F(V^0) + \int_\varepsilon^1 \tilde{Q}(t) \left(I_m + T\tilde{\Phi}_t^{(1)} + (1 - T)\tilde{\Phi}_t^{(2)}\right) dW_t \\ &= V^0 + F(V^0) + \int_0^1 \tilde{Q}(t) \left(I_m + T\tilde{\Phi}_t^{(1)} + (1 - T)\tilde{\Phi}_t^{(2)}\right) dW_t, \end{aligned}$$

where the last line is due to the fact that $\tilde{Q}(t) = 0$ when $0 \leq t \leq \varepsilon$. By definition of \tilde{Q} , $\tilde{\Phi}$ and T , we know that $\text{Law}(U) \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(\tilde{Q})$. Moreover, if we denote

$$V = V^0 + F(V^0) + \int_0^1 Q(t) \left(I_m + T\tilde{\Phi}_t^{(1)} + (1 - T)\tilde{\Phi}_t^{(2)}\right) dW_t,$$

then $V \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q)$ and $\mathbb{E}[(V - U)^2] \rightarrow 0$ as $\varepsilon \rightarrow 0$ according to Itô's isometry. This implies that

$$\text{Law}(U) \in \mathcal{F}_{m,\alpha}^{\text{AMP}}(Q),$$

thus proving Eq. (171), and the desired result follows immediately.

D.2 Proof of Lemma 5.2

This can be proven via a reparametrization of the time argument of $\{B_t\}$. For notational simplicity, let us ignore the closure operation and assume $q = 0$, as this proof can be easily adapted to the case of general $q \in [0, 1]$. Under this assumption, one can write

$$\mathcal{F}_{1,\alpha}^{\text{AMP}}(q) = \left\{ \text{Law} \left(\int_0^1 q(t) (1 + \phi_t) dB_t \right) : \{\phi_t\} \text{ adapted to } \{\mathcal{F}_t\}, \sup_{t \in [0,1]} \mathbb{E} [\phi_t^2] \leq \frac{1}{\alpha} \right\}$$

where $\|q\|_{L^2} = 1$, and we will show that

$$\mathcal{F}_{1,\alpha}^{\text{AMP}}(q) = \left\{ \text{Law} \left(\int_0^1 (1 + \phi_t) dB_t \right) : \{\phi_t\} \text{ adapted to } \{\mathcal{F}_t\}, \sup_{t \in [0,1]} \mathbb{E} [\phi_t^2] \leq \frac{1}{\alpha} \right\}.$$

Since $q \in L^2[0, 1]$, the function

$$t \mapsto s(t) := \int_0^t q(u)^2 du$$

is increasing and satisfies $s(0) = 0$, $s(1) = 1$. Therefore, $s(t)$ admits a unique inverse $s^{-1}(t)$ with $s^{-1}(0) = 0$, $s^{-1}(1) = 1$. Now let us define a new Gaussian process

$$W_t := \int_0^t q(u) dB_u \iff W_0 = 0, dW_t = q(t) dB_t,$$

then it follows that for any $0 \leq t, v \leq 1$,

$$\mathbb{E} [W_{s^{-1}(t)} W_{s^{-1}(v)}] = \int_0^{s^{-1}(t) \wedge s^{-1}(v)} q(u)^2 du = s(s^{-1}(t) \wedge s^{-1}(v)) = t \wedge v.$$

Moreover, $W_{s^{-1}(t)}$ has a continuous modification, thus can be regarded as a continuous martingale, and we conclude that $\{W_{s^{-1}(t)}\}_{0 \leq t \leq 1}$ is a standard Brownian motion.

Now, according to the time-change formula for stochastic integrals (cf. Proposition 3.4.8 in [KS12]), we obtain that

$$\int_0^1 q(t) (1 + \phi_t) dB_t = \int_0^1 (1 + \phi_t) dW_t = \int_0^1 (1 + \phi_{s^{-1}(t)}) dW_{s^{-1}(t)},$$

where $\phi_{s^{-1}(t)} \in \mathcal{F}_{s^{-1}(t)}^B = \mathcal{F}_{s^{-1}(t)}^W$ is progressively measurable and satisfies $\mathbb{E}[\phi_{s^{-1}(t)}^2] \leq 1/\alpha$. Hence,

$$\text{Law} \left(\int_0^1 q(t) (1 + \phi_t) dB_t \right) = \text{Law} \left(\int_0^1 (1 + \phi_{s^{-1}(t)}) dW_{s^{-1}(t)} \right),$$

which completes the proof of this lemma.

D.3 Proof of Lemma 5.3

First, using the law of total expectation, we obtain that

$$\begin{aligned} & \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right] \\ &= \mathbb{E} \left[\mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \mid \sigma(v^0) \right] \right]. \end{aligned}$$

Denote by $D^B[q, 1]$ the space of all square integrable processes $\{\phi_t^B\}_{t \in [q, 1]}$ that is progressively measurable with respect to $\{\mathcal{F}_t^B\}$, the canonical filtration of the standard Brownian motion $\{B_t\}$. For any $\phi \in D[q, 1]$, we know that the R.C.P.D. of $\{\phi_t\}$ given $\sigma(v^0)$ is equivalent to the law of some $\{\phi_t^B\} \in D^B[q, 1]$ almost surely (which may depend on the value of v^0). Therefore,

$$\begin{aligned} & \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \mid \sigma(v^0) \right] \\ & \leq \sup_{\phi^B \in D^B[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B)^2 - \frac{1}{\alpha} \right) dt \right], \end{aligned}$$

which leads to the inequality

$$\begin{aligned} V_\gamma(q) &= \sup_{\phi \in D[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right] \\ &\leq \mathbb{E}_{v^0 \sim \mathbf{N}(0, q)} \left[\sup_{\phi^B \in D^B[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B)^2 - \frac{1}{\alpha} \right) dt \right] \right] \\ &= \mathbb{E}_{v^0 \sim \mathbf{N}(0, q)} [V_\gamma(q, v^0 + F(v^0))]. \end{aligned}$$

Next, we prove the inverse bound. Fix $\varepsilon > 0$, for any realization of v^0 , let $\phi^B(v^0) \in D^B[q, 1]$ be such that

$$\begin{aligned} & \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B(v^0)) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B(v^0))^2 - \frac{1}{\alpha} \right) dt \right] \\ & \geq \sup_{\phi^B \in D^B[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B)^2 - \frac{1}{\alpha} \right) dt \right] - \varepsilon. \end{aligned}$$

Now, setting $\phi = \phi^B(v^0)$ for $v^0 \sim \mathbf{N}(0, q)$, we know that $\phi \in D[q, 1]$, and that

$$\begin{aligned} & \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt \right] \\ &= \mathbb{E}_{v^0 \sim \mathbf{N}(0, q)} \left[\mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B(v^0)) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B(v^0))^2 - \frac{1}{\alpha} \right) dt \right] \right] \\ &\geq \mathbb{E}_{v^0 \sim \mathbf{N}(0, q)} \left[\sup_{\phi^B \in D^B[q, 1]} \mathbb{E} \left[h \left(v^0 + F(v^0) + \int_q^1 (1 + \phi_t^B) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left((\phi_t^B)^2 - \frac{1}{\alpha} \right) dt \right] \right] - \varepsilon \\ &= \mathbb{E}_{v^0 \sim \mathbf{N}(0, q)} [V_\gamma(q, v^0 + F(v^0))] - \varepsilon. \end{aligned}$$

Taking supremum over all $\phi \in D[q, 1]$ and sending $\varepsilon \rightarrow 0$ yields the desired result. This completes the proof of the lemma.

E Deferred proofs for Theorem 3.3

This section will be devoted to the presentation of technical details required in Section 5.3: the proofs of intermediate results used in the proof of Theorem 3.3. In Appendix E.1, we deal with the case $\gamma(1) > \sup_{z \in \mathbb{R}} h''(z)$, for which we will construct a solution to the Parisi PDE and prove Proposition 5.4 and Proposition 5.5. In Appendix E.2, we consider the case $\gamma(1) \leq \sup_{z \in \mathbb{R}} h''(z)$,

for which we will construct a solution to the Parisi PDE and prove Proposition 5.4 and part (c) of Theorem 3.3.

Recall the function spaces \mathcal{L} and $\mathcal{L}_\#$ in Definition 2. In what follows, we define the convergence of sequences in these two spaces.

Definition 3 (Convergence in \mathcal{L} and $\mathcal{L}_\#$). *Let $\{(\mu_n, c_n)\}_{n=1}^\infty$ be a sequence in \mathcal{L} , or equivalently, the corresponding $\{\gamma_n\}_{n=1}^\infty \subset \mathcal{L}_\#$. For any $(\mu, c) \in \mathcal{L}$, we say that $(\mu_n, c_n) \xrightarrow{\mathcal{L}} (\mu, c)$ if $c_n \rightarrow c$, $\mu_n \rightarrow \mu$ in $L^1[0, 1]$, and*

$$\left\| \mu_n|_{[0,t]} \right\|_{L^\infty[0,t]} \longrightarrow \left\| \mu|_{[0,t]} \right\|_{L^\infty[0,t]} \text{ for all } t \in [0, 1]. \quad (172)$$

For $\gamma \in \mathcal{L}_\#$ associated with (μ, c) , we say $\gamma_n \xrightarrow{\mathcal{L}_\#} \gamma$ if $(\mu_n, c_n) \xrightarrow{\mathcal{L}} (\mu, c)$.

For the reader's convenience, we collect below a few important definitions from the main text.

Parisi functional. For $(\mu, c) \in \mathcal{L}$, define

$$F(\mu, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds}, \quad (173)$$

where f_μ solves the Parisi PDE:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) (\partial_x f_\mu(t, x))^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \quad (174)$$

Value function. For $\gamma \in \mathcal{L}_\#$, $(t, z) \in [0, 1] \times \mathbb{R}$, define

$$V_\gamma(t, z) = \sup_{\phi \in D[t, 1]} \mathbb{E} \left[h \left(z + \int_t^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) \left(\phi_s^2 - \frac{1}{\alpha} \right) ds \right]. \quad (175)$$

E.1 The case $\gamma(1) > \sup_{z \in \mathbb{R}} h''(z)$

The aim of this section is to construct a solution to the Parisi PDE and complete the proof of Theorem 3.3 in the case $\gamma(1) > \sup_{z \in \mathbb{R}} h''(z)$. To this end, we will first work under the stronger assumption that $h \in C^4(\mathbb{R})$ (instead of $h \in C^2(\mathbb{R})$ assumed by Theorem 3.3) in Sections E.1.1 to E.1.3, and then remove this assumption via an approximation argument in Section E.1.4. In particular, we require h to satisfy the following assumption throughout Sections E.1.1 to E.1.3:

Assumption E.1. *The test function $h : \mathbb{R} \rightarrow \mathbb{R}$ satisfies:*

(a) *h is bounded from above, i.e., $\sup_{x \in \mathbb{R}} h(x) < +\infty$.*

(b) *$h \in C^4(\mathbb{R})$. Further, for $1 \leq k \leq 4$,*

$$\left\| h^{(k)} \right\|_{L^\infty(\mathbb{R})} = \sup_{x \in \mathbb{R}} \left| h^{(k)}(x) \right| < \infty. \quad (176)$$

E.1.1 Solving the Parisi PDE

We start with constructing a solution to the Parisi PDE (174) for $(\mu, c) \in \mathcal{L}$ with $\sup_{z \in \mathbb{R}} h''(z) < \gamma(1) = 1/c$. To this end, we first show that the terminal value $f_\mu(1, \cdot)$ has sufficient regularity.

Lemma E.1. *Assume $\sup_{z \in \mathbb{R}} h''(z) < \gamma(1) = 1/c$. Recall that*

$$f_\mu(1, x) = \sup_{u \in \mathbb{R}} \left\{ h(x+u) - \frac{u^2}{2c} \right\}. \quad (177)$$

Then, we have $\|\partial_x f_\mu(1, x)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}$ and

$$-\gamma(1) < \partial_x^2 f_\mu(1, x) \leq \frac{\gamma(1) \cdot \sup_{z \in \mathbb{R}} h''(z)}{\gamma(1) - \sup_{z \in \mathbb{R}} h''(z)}, \quad \forall x \in \mathbb{R}. \quad (178)$$

Further, for $k = 3, 4$, there exists constants $C = C(c, k) > 0$ such that

$$\left\| \partial_x^k f_\mu(1, x) \right\|_{L^\infty(\mathbb{R})} \leq C(c, k). \quad (179)$$

Proof. The claim on $\partial_x f_\mu(1, x)$ follows from the simple observation

$$|f_\mu(1, x) - f_\mu(1, y)| \leq \sup_{u \in \mathbb{R}} |h(x+u) - h(y+u)| \leq \|h'\|_{L^\infty(\mathbb{R})} |x - y|.$$

To prove the estimates for higher-order derivatives, note that $f_\mu(1, \cdot)$ can be rewritten as

$$\begin{aligned} f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x+u) - \frac{u^2}{2c} \right\} = \sup_{z \in \mathbb{R}} \left\{ h(z) - \frac{(z-x)^2}{2c} \right\} \\ &= -\frac{x^2}{2c} + \sup_{z \in \mathbb{R}} \left\{ xz - \frac{cz^2}{2} + h(cz) \right\}. \end{aligned}$$

Define $g(z) = cz^2/2 - h(cz)$, then we know that g is c_h -strongly convex, where

$$c_h = c - c^2 \sup_{z \in \mathbb{R}} h''(z) > 0.$$

Since $f_\mu(1, x) = -x^2/2c + g^*(x)$, the bounds on $\partial_x^2 f_\mu(1, x)$ follows immediately. Further, we have

$$\max \left\{ \|g^{(3)}\|_{L^\infty(\mathbb{R})}, \|g^{(4)}\|_{L^\infty(\mathbb{R})} \right\} < \infty.$$

It then suffices to show that

$$\max \left\{ \|(g^*)^{(3)}\|_{L^\infty(\mathbb{R})}, \|(g^*)^{(4)}\|_{L^\infty(\mathbb{R})} \right\} < \infty.$$

By Legendre-Fenchel duality, we have

$$(g^*)''(x) = \frac{1}{g''(u(x))}, \quad u = (g')^{-1} \implies u'(x) = \frac{1}{g''(u(x))}.$$

Since g is c_h -strongly convex, we always have $g'' \geq c_h$. Therefore,

$$\begin{aligned} (g^*)^{(3)}(x) &= -\frac{g^{(3)}(u(x))u'(x)}{g''(u(x))^2} = -\frac{g^{(3)}(u(x))}{g''(u(x))^3} \in L^\infty(\mathbb{R}), \\ (g^*)^{(4)}(x) &= \frac{3g^{(3)}(u(x))^2 g''(u(x))^2 u'(x) - g^{(4)}(u(x))g''(u(x))^3 u'(x)}{g''(u(x))^6} \\ &= \frac{3g^{(3)}(u(x))^2}{g''(u(x))^5} - \frac{g^{(4)}(u(x))}{g''(u(x))^4} \in L^\infty(\mathbb{R}), \end{aligned}$$

which completes the proof. \square

The next proposition establishes regularity of f_μ on $[0, 1] \times \mathbb{R}$ for $\mu \in \mathbf{SF}[0, 1]$, the space of all simple functions on $[0, 1]$:

$$\mathbf{SF}[0, 1] = \left\{ \mu(t) = \sum_{i=1}^m \mu_i \mathbf{1}_{[t_{i-1}, t_i)}(t) : 0 = t_0 < t_1 < \dots < t_m = 1 \right\}. \quad (180)$$

Proposition E.2. Assume $\mu \in \mathbf{SF}[0, 1]$ is such that $(\mu, c) \in \mathcal{L}$, i.e., $c + \int_t^1 \mu(s) ds > 0$ for all $t \in [0, 1]$, and that $\exists \theta \in [0, 1)$ such that $\inf_{t \in [\theta, 1]} \gamma(t) > \sup_{z \in \mathbb{R}} h''(z)$. Then, we have

$$\partial_x^2 f_\mu(t, x) > -\gamma(t), \quad \forall (t, x) \in [0, 1] \times \mathbb{R}. \quad (181)$$

Further, if there exists $\theta \in [0, 1)$ such that $\inf_{t \in [\theta, 1]} \gamma(t) > \sup_{z \in \mathbb{R}} h''(z)$, then

$$\partial_x^2 f_\mu(t, x) \leq \frac{\gamma(t) \cdot \sup_{z \in \mathbb{R}} h''(z)}{\gamma(t) - \sup_{z \in \mathbb{R}} h''(z)}, \quad \forall (t, x) \in [\theta, 1] \times \mathbb{R}. \quad (182)$$

Proof. For future convenience we denote $h_2 = \sup_{z \in \mathbb{R}} h''(z)$. In what follows we will consider the following non-linear parabolic equation instead of the Parisi PDE:

$$\begin{aligned} \partial_t \Phi(t, x) + \frac{\gamma'(t)}{2} (\partial_x \Phi(t, x))^2 + \frac{\gamma(t)^2}{2} \partial_x^2 \Phi(t, x) &= 0, \\ \Phi(1, x) &= \left(\frac{\gamma(1)}{2} x^2 - h(x) \right)^*. \end{aligned} \quad (183)$$

Note that the relation between Φ and f_μ is given by the following transform, which can be verified by direct calculation:

$$\begin{aligned} f_\mu(t, x) &= -\frac{\gamma(t)}{2} x^2 + \Phi(t, \gamma(t)x) - \frac{1}{2} \int_t^1 \gamma(s) ds, \\ \Phi(t, x) &= f_\mu\left(t, \frac{x}{\gamma(t)}\right) + \frac{x^2}{2\gamma(t)} + \frac{1}{2} \int_t^1 \gamma(s) ds. \end{aligned} \quad (184)$$

Further, Eqs. (181), (182) are equivalent to

$$\begin{aligned} \partial_x^2 \Phi(t, x) &> 0, \quad \forall (t, x) \in [0, 1] \times \mathbb{R}, \\ \partial_x^2 \Phi(t, x) &\leq \frac{1}{\gamma(t) - h_2}, \quad \forall (t, x) \in [\theta, 1] \times \mathbb{R}. \end{aligned} \quad (185)$$

It remains to prove the curvature bound on $\Phi(t, x)$, i.e., Eq. (185). Since $\gamma'(t)/\gamma(t)^2$ is piecewise constant, we may assume that

$$-\left(\frac{1}{\gamma(t)}\right)' = \frac{\gamma'(t)}{\gamma(t)^2} = c_i \text{ for } t \in [t_{i-1}, t_i), \quad i = 1, \dots, m,$$

where $0 = t_0 < t_1 < \dots < t_m = 1$ is a discretization of $[0, 1]$. According to Lemma E.1, we have

$$0 < \partial_x^2 \Phi(1, x) \leq \frac{1}{\gamma(1) - h_2}.$$

For $t \in [t_{m-1}, 1)$, the Parisi PDE reads

$$\partial_t \Phi(t, x) + \frac{\gamma(t)^2}{2} \left(\partial_x^2 \Phi(t, x) + c_m (\partial_x \Phi(t, x))^2 \right) = 0,$$

whose solution can be explicitly expressed using Cole-Hopf transform:

$$\Phi(t, x) = \frac{1}{c_m} \log \mathbb{E} \left[\exp \left(c_m \Phi \left(1, x + \sqrt{\int_t^1 \gamma(s)^2 ds} \cdot G \right) \right) \right], \quad G \sim \mathcal{N}(0, 1).$$

If $c_m = 0$, it is understood that

$$\Phi(t, x) = \mathbb{E} \left[\Phi \left(1, x + \sqrt{\int_t^1 \gamma(s)^2 ds} \cdot G \right) \right].$$

For simplicity, we denote $f(x) = \Phi(1, x)$, $\kappa = c_m$ and $C(t, \gamma) = \sqrt{\int_t^1 \gamma(s)^2 ds}$, then exploiting the above expression yields that

$$\begin{aligned} \partial_x^2 \Phi(t, x) &= \frac{\kappa \mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f'(x + C(t, \gamma)G)^2 \right] + \mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f''(x + C(t, \gamma)G) \right]}{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right]} \\ &\quad - \frac{\kappa \mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f'(x + C(t, \gamma)G) \right]^2}{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right]^2}. \end{aligned}$$

Note that applying Cauchy-Schwarz inequality gives

$$\begin{aligned} &\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f'(x + C(t, \gamma)G)^2 \right] \cdot \mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right] \\ &\geq \mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f'(x + C(t, \gamma)G) \right]^2. \end{aligned}$$

Hence, if $\kappa \geq 0$, we obtain that

$$\partial_x^2 \Phi(t, x) \geq \frac{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) f''(x + C(t, \gamma)G) \right]}{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right]} > 0,$$

where the last inequality follows from the fact that f is strictly convex.

Next we assume that $\kappa < 0$, for any integrable test function ϕ , we have

$$\begin{aligned} &\frac{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \phi(x + C(t, \gamma)G) \right]}{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right]} \\ &= \frac{1}{\mathbb{E} \left[\exp(\kappa f(x + C(t, \gamma)G)) \right]} \int_{\mathbb{R}} \frac{1}{\sqrt{2\pi}C(t, \gamma)} \exp \left(\kappa f(z) - \frac{(z - x)^2}{2C(t, \gamma)^2} \right) \phi(z) dz \\ &= \int_{\mathbb{R}} p_{t,x}(z) \phi(z) dz := \mathbb{E}_{t,x} [\phi(Z)], \end{aligned}$$

where we denote

$$p_{t,x}(z) \propto \exp \left(\kappa f(z) - \frac{(z - x)^2}{2C(t, \gamma)^2} \right) = \exp \left(-\frac{(z - x)^2}{2C(t, \gamma)^2} - |\kappa| f(z) \right).$$

We further denote $\mathbb{E}_{t,x}$ and $\text{Var}_{t,x}$ as the expectation and variance operator with respect to the density $p_{t,x}$, then it follows that

$$\begin{aligned} \partial_x^2 \Phi(t, x) &= \mathbb{E}_{t,x} [f''(Z)] + \kappa \cdot \left(\mathbb{E}_{t,x} [f'(Z)^2] - \mathbb{E}_{t,x} [f'(Z)]^2 \right) \\ &= \mathbb{E}_{t,x} [f''(Z)] - |\kappa| \cdot \text{Var}_{t,x} (f'(Z)). \end{aligned}$$

Before proceeding with the proof, we recall a celebrated inequality by Brascamp and Lieb [BL02].

Theorem E.1 (Theorem 4.1 in [BL02]: Poincaré inequality for log-concave densities). *Let $p(z) = \exp(-u(z))$, where u is twice continuously differentiable and strictly convex. Assume that u has a minimum, so that p decreases exponentially in all directions, then $\int_{\mathbb{R}} p(z) dz < \infty$. Let $\phi \in C^1(\mathbb{R})$ and $\text{Var}(\phi(Z)) < \infty$. Then*

$$\text{Var}(\phi(Z)) \leq \mathbb{E} \left[\frac{\phi'(Z)^2}{u''(Z)} \right].$$

Now we turn to the proof of strict convexity of $\Phi(t, x)$ when $\kappa < 0$. Note that since $u(z) = |\kappa|f(z) + (z - x)^2/2C(t, \gamma)^2$ is strongly convex, $p_{t,x}(z) \propto \exp(-u(z))$ is a log-concave density. According to Theorem E.1, we have

$$\text{Var}_{t,x}(f'(Z)) \leq \mathbb{E}_{t,x} \left[\frac{f''(Z)^2}{u''(Z)} \right] = \mathbb{E}_{t,x} \left[\frac{f''(Z)^2}{|\kappa|f''(Z) + 1/C(t, \gamma)^2} \right] < \frac{1}{|\kappa|} \mathbb{E}_{t,x}[f''(Z)],$$

which leads to

$$\partial_x^2 \Phi(t, x) = \mathbb{E}_{t,x}[f''(Z)] - |\kappa| \cdot \text{Var}_{t,x}(f'(Z)) > 0.$$

Repeating the same argument for $t \in [t_{m-2}, t_{m-1})$ and so on yields that $\partial_x^2 \Phi(t, x) > 0$ for all $(t, x) \in [0, 1] \times \mathbb{R}$. This proves the first part of Eq. (185),

To prove the second part of Eq. (185), it suffices to show that

$$\gamma(t) > h_2 \implies \partial_x^2 \Phi(t, x) \leq \frac{1}{\gamma(t) - h_2}, \quad \forall x \in \mathbb{R}, \quad t \in [t_{m-1}, 1). \quad (186)$$

Consider the situation $\kappa \geq 0$, in this case we have $p_{t,x}(z) \propto \exp(-u(z))$, where $u(z) = (z - x)^2/2C(t, \gamma)^2 - \kappa f(z)$. Note that for all $z \in \mathbb{R}$,

$$\begin{aligned} u''(z) &= \frac{1}{C(t, \gamma)^2} - \kappa f''(z) \geq \frac{1}{C(t, \gamma)^2} - \frac{\kappa}{\gamma(1) - h_2} = \frac{1}{\int_t^1 \gamma(s)^2 ds} - \frac{\kappa}{\gamma(1) - h_2} \\ &= \frac{\kappa}{\int_t^1 \gamma'(s) ds} - \frac{\kappa}{\gamma(1) - h_2} = \frac{\kappa}{\gamma(1) - \gamma(t)} - \frac{\kappa}{\gamma(1) - h_2} > 0, \end{aligned}$$

which implies that u is strongly convex. Therefore, applying the Brascamp-Lieb inequality (Theorem E.1) again yields

$$\begin{aligned} \partial_x^2 \Phi(t, x) &= \mathbb{E}_{t,x}[f''(Z)] + \kappa \cdot \text{Var}_{t,x}(f'(Z)) \leq \mathbb{E}_{t,x}[f''(Z)] + \kappa \cdot \mathbb{E}_{t,x} \left[\frac{f''(Z)^2}{u''(Z)} \right] \\ &= \mathbb{E}_{t,x} \left[\frac{f''(Z)(u''(Z) + \kappa f''(Z))}{u''(Z)} \right] = \mathbb{E}_{t,x} \left[\frac{f''(Z)}{C(t, \gamma)^2 u''(Z)} \right] \\ &= \mathbb{E}_{t,x} \left[\frac{f''(Z)}{1 - \kappa C(t, \gamma)^2 f''(Z)} \right] \stackrel{(i)}{=} \mathbb{E}_{t,x} \left[\frac{f''(Z)}{1 - (\gamma(1) - \gamma(t)) f''(Z)} \right] \\ &\stackrel{(ii)}{\leq} \mathbb{E}_{t,x} \left[\frac{1/(\gamma(1) - h_2)}{1 - (\gamma(1) - \gamma(t))/(\gamma(1) - h_2)} \right] = \frac{1}{\gamma(t) - h_2}, \end{aligned}$$

where (i) holds because $\kappa \gamma^2(t) = \gamma'(t)$ for $t \in [t_{m-1}, 1)$, whence $\kappa C(t, \gamma)^2 = \int_t^1 \gamma'(s) ds = \gamma(1) - \gamma(t)$, and (ii) is due to the fact that $\sup_{z \in \mathbb{R}} \{f''(z)\} \leq 1/(\gamma(1) - h_2)$.

Finally, we deal with the case $\kappa < 0$ in Eq. (185). Note that without loss of generality we may assume that $\gamma(t) - h_2 \leq (1 + 1/\sqrt{2})(\gamma(1) - h_2)$, otherwise it is always possible to find interpolating points $t = s_0 < s_1 < \dots < s_{k-1} < s_k = 1$ such that

$$\gamma(s_{i-1}) - h_2 \leq (1 + 1/\sqrt{2})(\gamma(s_i) - h_2), \quad \text{for all } i = 1, \dots, k.$$

Given $\partial_x^2 \Phi(1, x) \leq 1/(\gamma(1) - h_2)$, if we can show that $\partial_x^2 \Phi(s_{k-1}, x) \leq 1/(\gamma(s_{k-1}) - h_2)$, then proceeding with the same argument we obtain that $\partial_x^2 \Phi(s_{k-2}, x) \leq 1/(\gamma(s_{k-2}) - h_2)$, and eventually $\partial_x^2 \Phi(t, x) \leq 1/(\gamma(t) - h_2)$. Hence, it suffices to prove that under the additional assumption $\gamma(t) - h_2 \leq (1 + 1/\sqrt{2})(\gamma(1) - h_2)$, we have $\partial_x^2 \Phi(t, x) \leq 1/(\gamma(t) - h_2)$.

For future convenience, let us denote

$$b = \frac{1}{\gamma(t) - \gamma(1)}, \quad d = \frac{1}{\gamma(1) - h_2},$$

then it follows that $0 \leq f''(z) \leq d$, and

$$u(z) = |\kappa|f(z) + \frac{(z-x)^2}{2C(t, \gamma)^2} = |\kappa|f(z) + \frac{|\kappa|(z-x)^2}{2(\gamma(t) - \gamma(1))} = |\kappa| \left(f(z) + \frac{b}{2}(z-x)^2 \right).$$

To simplify the notation, we drop the subscripts from $p_{t,x}$, $\mathbb{E}_{t,x}$ and $\text{Var}_{t,x}$ whenever no confusion arises. Since $p(z) \propto \exp(-u(z))$, by integration by parts we obtain that

$$\mathbb{E}[u'(Z)] = 0, \quad \text{Var}(u'(Z)) = \mathbb{E}[u''(Z)],$$

which leads to

$$\begin{aligned} \mathbb{E}[f''(Z)] + b &= \frac{1}{|\kappa|} \mathbb{E}[u''(Z)] \\ &= \frac{1}{|\kappa|} \text{Var}(u'(Z)) = |\kappa| \cdot \text{Var}(f'(Z) + g(Z)), \end{aligned}$$

where we denote $g(z) = b(z-x)$. Using Cauchy-Schwarz inequality and Theorem E.1, we obtain the following estimate:

$$\begin{aligned} \mathbb{E}[f''(Z)] + b - |\kappa| \cdot \text{Var}(f'(Z)) &= |\kappa| \cdot \text{Var}(g(Z)) + 2|\kappa| \cdot \text{Cov}(f'(Z), g(Z)) \\ &= |\kappa| \cdot \text{Cov}(g(Z), g(Z) + 2f'(Z)) \leq |\kappa| \cdot \sqrt{\text{Var}(g(Z)) \text{Var}(g(Z) + 2f'(Z))} \\ &\leq |\kappa| \cdot \sqrt{\mathbb{E}\left[\frac{g'(Z)^2}{u''(Z)}\right] \mathbb{E}\left[\frac{(g'(Z) + 2f''(Z))^2}{u''(Z)}\right]} = \sqrt{\mathbb{E}\left[\frac{b^2}{f''(Z) + b}\right] \mathbb{E}\left[\frac{(b + 2f''(Z))^2}{f''(Z) + b}\right]}. \end{aligned}$$

Denote $A = f''(Z)$, then A is a bounded random variable such that $0 \leq A \leq d$. Our previous assumption $\gamma(t) - h_2 \leq (1 + 1/\sqrt{2})(\gamma(1) - h_2)$ is equivalent to $b \geq \sqrt{2}d$. We claim that

$$\sqrt{\mathbb{E}\left[\frac{b^2}{A+b}\right] \mathbb{E}\left[\frac{(b+2A)^2}{A+b}\right]} \leq \frac{b(2d+b)}{d+b}, \quad (187)$$

which further implies

$$\partial_x^2 \Phi(t, x) \leq \mathbb{E}[f''(Z)] - |\kappa| \cdot \text{Var}(f'(Z)) \leq \frac{b(2d+b)}{d+b} - b = \frac{bd}{d+b} = \frac{1}{\gamma(t) - h_2},$$

the desired curvature upper bound.

Now it suffices to prove the claimed inequality (187). First, note that

$$\mathbb{E}\left[\frac{(b+2A)^2}{A+b}\right] = 4\mathbb{E}[A+b] + \mathbb{E}\left[\frac{b^2}{A+b}\right] - 4b.$$

Hence, when $\mathbb{E}[b^2/(A+b)]$ is fixed, $\mathbb{E}[A+b]$ is maximized if and only if A only takes its extreme values, i.e., $A \in \{0, d\}$. In particular, there exists $p \in [0, 1]$ such that

$$\mathbb{P}(A = d) = p, \quad \mathbb{P}(A = 0) = 1 - p.$$

With this choice of A , we define

$$\psi(p) = \mathbb{E} \left[\frac{b^2}{A+b} \right] \mathbb{E} \left[\frac{(b+2A)^2}{A+b} \right] = \left(p \cdot \frac{b^2}{d+b} + (1-p) \cdot b \right) \cdot \left(p \cdot \frac{(2d+b)^2}{d+b} + (1-p) \cdot b \right).$$

Direct calculation reveals that

$$\psi'(p) = \frac{2bd(2d+b)}{d+b} - \frac{2bd^2(4d+3b)}{(b+d)^2} \cdot p,$$

which is decreasing in p , and (recall that $b \geq \sqrt{2}d$)

$$\psi'(1) = \frac{2bd(b^2 - 2d^2)}{(d+b)^2} \geq 0.$$

Therefore, $\psi'(p) \geq 0$ for all $p \in [0, 1]$, meaning that

$$\mathbb{E} \left[\frac{b^2}{A+b} \right] \mathbb{E} \left[\frac{(b+2A)^2}{A+b} \right] \leq \psi(1) = \frac{b^2(b+2d)^2}{(d+b)^2},$$

which finally leads to our claim (187).

Now we have proved that for all $t \in [t_{m-1}, 1]$, $\gamma(t) > h_2$ implies that $\sup_{x \in \mathbb{R}} \partial_x^2 \Phi(t, x) \leq 1/(\gamma(t) - h_2)$. Repeating this argument for smaller t until $\gamma(t) \leq h_2$ gives us the second part of Eq. (185). This completes the proof. \square

Proposition E.3. Assume $\mu \in \text{SF}[0, 1]$ is such that $(\mu, c) \in \mathcal{L}$, i.e., $c + \int_t^1 \mu(s) ds > 0$ for all $t \in [0, 1]$. Then, $f_\mu(t, \cdot) \in C^\infty(\mathbb{R})$ for any $t \in [0, 1]$, and $f_\mu \in C^{\infty, \infty}$ at all continuity points of μ . Further, the following estimates hold:

$$\|\partial_x f_\mu(t, x)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}, \quad (188)$$

$$-\gamma(t) < \partial_x^2 f_\mu(t, x) \leq C(\mu, 2), \quad (189)$$

$$\left\| \partial_x^k f_\mu(t, x) \right\|_{L^\infty(\mathbb{R})} \leq C(\mu, k), \quad k = 3, 4. \quad (190)$$

Here, for all $2 \leq k \leq 4$, $C(\mu, k)$ has the following property: for any sequence $\{\mu_n\}$ such that $(\mu_n, c) \xrightarrow{\mathcal{L}} (\mu, c)$, $C(\mu_n, k) \rightarrow C(\mu, k)$ as $n \rightarrow \infty$.

Proof. Throughout the proof we denote $h_2 = \sup_{z \in \mathbb{R}} h''(z)$. The estimate (188) follows directly from Cole-Hopf transform and Lemma E.1. As for (189), we already know $\partial_x^2 f_\mu(t, x) > -\gamma(t)$ from Proposition E.2, it suffices to prove the upper bound. Since $\gamma(1) = 1/c > h_2$ and $\mu = \gamma'/\gamma^2 \in L^1[0, 1]$, there exists $\theta = \theta(\mu) \in [0, 1]$ such that

$$\inf_{t \in [\theta, 1]} \gamma(t) - h_2 \geq \frac{1}{2} (\gamma(1) - h_2).$$

According to Proposition E.2, on $[\theta, 1]$ we always have

$$\partial_x^2 f_\mu(t, x) \leq \frac{\gamma(t)h_2}{\gamma(t) - h_2} \leq \frac{(\gamma(1) + h_2)h_2}{\gamma(1) - h_2}. \quad (191)$$

On $[0, \theta]$, we can apply Duhamel's principle to the Parisi PDE (defined on $[0, \theta]$, with $f_\mu(\theta, \cdot)$ being the new terminal condition) to obtain that

$$f_\mu(t, x) = \int_{\mathbb{R}} K(\theta - t, x - y) f_\mu(\theta, y) dy + \frac{1}{2} \int_t^\theta \mu(s) ds \int_{\mathbb{R}} K(s - t, x - y) (\partial_x f_\mu(s, y))^2 dy, \quad (192)$$

where

$$K(t, x) = \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{x^2}{4t}\right)$$

is the heat kernel. Note that Eq. (192) implies

$$\partial_x^2 f_\mu(t, x) = \int_{\mathbb{R}} K(\theta - t, x - y) \partial_x^2 f_\mu(\theta, y) dy + \int_t^\theta \mu(s) ds \int_{\mathbb{R}} \partial_x K(s - t, x - y) \partial_x f_\mu(s, y) \partial_x^2 f_\mu(s, y) dy, \quad (193)$$

which leads to the estimate

$$\|\partial_x^2 f_\mu(t, \cdot)\|_{L^\infty(\mathbb{R})} \stackrel{(i)}{\leq} \|\partial_x^2 f_\mu(\theta, \cdot)\|_{L^\infty(\mathbb{R})} + C \int_t^\theta \frac{\mu(s)}{\sqrt{s-t}} \|\partial_x f_\mu(s, \cdot)\|_{L^\infty(\mathbb{R})} \|\partial_x^2 f_\mu(s, \cdot)\|_{L^\infty(\mathbb{R})} ds \quad (194)$$

$$\stackrel{(ii)}{\leq} C + C \|\mu\|_{L^\infty[0, \theta]} \int_t^\theta \frac{1}{\sqrt{s-t}} \|\partial_x^2 f_\mu(s, \cdot)\|_{L^\infty(\mathbb{R})} ds, \quad (195)$$

where (i) follows from Young's inequality, (ii) follows from the estimate (188). Note that the constant C does not depend on μ . Denote $g(t) = \|\partial_x^2 f_\mu(t, \cdot)\|_{L^\infty(\mathbb{R})}$, then we have

$$g(t) \leq C + C \|\mu\|_{L^\infty[0, \theta]} \int_t^\theta \frac{1}{\sqrt{s-t}} g(s) ds \quad (196)$$

$$\stackrel{(i)}{\leq} C + C \|\mu\|_{L^\infty[0, \theta]} \left(\int_t^\theta (s-t)^{-3/4} ds \right)^{2/3} \left(\int_t^\theta g(s)^3 ds \right)^{1/3} \quad (197)$$

$$\leq C + C \|\mu\|_{L^\infty[0, \theta]} \left(\int_t^\theta g(s)^3 ds \right)^{1/3}, \quad (198)$$

where (i) is due to Hölder's inequality. We thus obtain that

$$g(t)^3 \leq C + C \|\mu\|_{L^\infty[0, \theta]}^3 \int_t^\theta g(s)^3 ds. \quad (199)$$

Using Grönwall's inequality, it follows that

$$g(t)^3 \leq C \exp\left(C(\theta - t) \|\mu\|_{L^\infty[0, \theta]}^3\right) \leq C \exp\left(C \|\mu\|_{L^\infty[0, \theta]}^3\right), \quad (200)$$

which further implies $g(t) \leq C \exp(C \|\mu\|_{L^\infty[0, \theta]}^3)$. We can then define

$$C(\mu, 2) = \max \left\{ C \exp\left(C \|\mu\|_{L^\infty[0, \theta]}^3\right), \frac{(\gamma(1) + h_2)h_2}{\gamma(1) - h_2} \right\}. \quad (201)$$

For any sequence $\{\mu_n\}$ that converges to μ in the sense of Definition 3, we know that the corresponding θ_n must converge to θ . Therefore, $C(\mu_n, 2) \rightarrow C(\mu, 2)$ as $n \rightarrow \infty$.

In order to prove the estimate (190) on $\partial_x^k f_\mu$ for $k = 3, 4$, we can use a similar stochastic calculus argument as the proof of Proposition 6 in [EAS22]. The resulting constants $C(\mu, k)$ depends continuously on $C(\mu, 2)$ and $\|\mu\|_{L^1[0, 1]}$, thus naturally satisfying the desired property. This completes the proof. \square

The lemma below is crucial to constructing the weak solution to the Parisi PDE:

Lemma E.4. *Let $\{\varphi_n\}_{n \geq 1}$ be a sequence of twice-differentiable real-valued functions satisfying:*

- (a) *For any compact set $K \subset \mathbb{R}$, $\sup_{x \in K} |\varphi_n(x) - \varphi(x)| \rightarrow 0$ as $n \rightarrow \infty$.*
- (b) *$\sup_{n \in \mathbb{N}} \sup_{x \in K} |\varphi_n''(x)| < +\infty$ for any compact K .*

Then, φ is differentiable and $\varphi'_n \rightarrow \varphi'$ uniformly on any compact set as $n \rightarrow \infty$.

Proof. Fix a compact set K and denote $C_{2,K} = \sup_{n \in \mathbb{N}} \sup_{x \in K} |\varphi_n''(x)|$. We first show that $\{\varphi'_n\}_{n \geq 1}$ is a Cauchy sequence in $L^\infty(K)$. To this end, note that for any $x, y \in K$ and $m, n \in \mathbb{N}$,

$$\begin{aligned} |\varphi'_n(x) - \varphi'_m(x)| &\leq \left| \varphi'_n(x) - \frac{\varphi_n(y) - \varphi_n(x)}{y - x} \right| + \left| \varphi'_m(x) - \frac{\varphi_m(y) - \varphi_m(x)}{y - x} \right| \\ &\quad + \left| \frac{\varphi_m(y) - \varphi_m(x)}{y - x} - \frac{\varphi_n(y) - \varphi_n(x)}{y - x} \right| \\ &\leq 2C_{2,K}|x - y| + \frac{2}{|x - y|} \sup_{x \in K} |\varphi_n(x) - \varphi_m(x)|, \end{aligned}$$

which implies that for any $\varepsilon > 0$,

$$\begin{aligned} \sup_{x \in K} |\varphi'_n(x) - \varphi'_m(x)| &\leq 2C_{2,K}\varepsilon + \frac{2}{\varepsilon} \sup_{x \in K} |\varphi_n(x) - \varphi_m(x)| \\ \implies \limsup_{m, n \rightarrow \infty} \sup_{x \in K} |\varphi'_n(x) - \varphi'_m(x)| &\leq 2C_{2,K}\varepsilon. \end{aligned}$$

Since ε is arbitrary, this proves $\|\varphi'_n - \varphi'_m\|_{L^\infty(K)} \rightarrow 0$ as $m, n \rightarrow \infty$. As a consequence, φ'_n uniformly converges to some f in $C(K)$. It remains to show that $f = \varphi'$. For any $x, y \in K$, we have

$$\varphi(x) - \varphi(y) = \lim_{n \rightarrow \infty} \{\varphi_n(x) - \varphi_n(y)\} = \lim_{n \rightarrow \infty} \int_x^y \varphi'_n(z) dz = \int_x^y f(z) dz,$$

where the last inequality follows by dominated convergence. Since f is continuous, we know that $\varphi' = f$. This completes the proof. \square

Now, we are in position to establish the following:

Theorem E.2 (Solution to the Parisi PDE). *For any $(\mu, c) \in \mathcal{L}$ satisfying $\sup_{z \in \mathbb{R}} h''(z) < 1/c$, the Parisi PDE (174) admits a weak solution f_μ such that $f_\mu(t, \cdot) \in C^4(\mathbb{R})$, and*

$$\|\partial_x f_\mu(t, x)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}, \quad (202)$$

$$-\gamma(t) < \partial_x^2 f_\mu(t, x) \leq C(\mu, 2), \quad (203)$$

$$\left\| \partial_x^k f_\mu(t, x) \right\|_{L^\infty(\mathbb{R})} \leq C(\mu, k), \quad k = 3, 4. \quad (204)$$

Further, for any $\theta < 1$ and $0 \leq k \leq 2$, one has $\partial_t \partial_x^k f_\mu \in L^\infty([0, \theta] \times \mathbb{R})$.

Proof. We will establish the existence of a weak solution to the Parisi PDE (174) for general μ (not necessarily in $\text{SF}[0, 1]$) via an approximation procedure. Let $(\mu, c) \in \mathcal{L}$ be such that $\sup_{z \in \mathbb{R}} h''(z) < 1/c$. Then, there exists a sequence $\{\mu_n\}_{n=1}^\infty \subset \text{SF}[0, 1]$ such that $(\mu_n, c) \xrightarrow{\mathcal{L}} (\mu, c)$.

Let f_{μ_n} be the solution to the Parisi PDE associated with μ_n , we can follow the proof of Lemma 14 in [JT16] to show that

$$\|f_{\mu_n} - f_{\mu_m}\|_{L^\infty([0,1] \times \mathbb{R})} \leq \frac{\|h'\|_{L^\infty(\mathbb{R})}^2}{2} \|\mu_n - \mu_m\|_{L^1[0,1]} \rightarrow 0 \text{ as } n, m \rightarrow \infty. \quad (205)$$

Therefore, we know that as $n \rightarrow \infty$, f_{μ_n} converges pointwise to some function $f_\mu : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}$, and this convergence is uniform on $[0, 1] \times K$ for any compact set $K \subset \mathbb{R}$. Now since $\{\partial_x^2 f_{\mu_n}\}_{n \geq 1}$ is uniformly bounded on compact sets (Proposition E.3), we deduce from Lemma E.4 that $\partial_x f_\mu$ exists and $\partial_x f_{\mu_n} \rightarrow \partial_x f_\mu$ uniformly on any compact set. Exploiting the bounds (190) and repeating the same argument, we know that $\partial_x^k f_\mu$ exists and $\partial_x^k f_{\mu_n} \rightarrow \partial_x^k f_\mu$ uniformly on compact sets for $k = 2, 3$. Further, since $\partial_x^3 f_{\mu_n}(t, \cdot)$ is $C(\mu_n, 4)$ -Lipschitz and $C(\mu_n, 4) \rightarrow C(\mu, 4)$, it follows that $\partial_x^3 f_\mu(t, \cdot)$ is $C(\mu, 4)$ -Lipschitz. Therefore, $\partial_x^4 f_\mu$ exists and is upper bounded by $C(\mu, 4)$ almost everywhere. As a consequence, the estimates (188) to (190) hold for f_μ up to $k = 4$ as well. This proves Eqs. (202), (203), and (204).

Finally, similar to the proof of Lemma 6.2 in [EAMS21], we can show that f_μ is a weak solution to the Parisi PDE (174). Further, as $\mu \in L^\infty[0, \theta]$ for any $\theta \in [0, 1]$, we know that $\partial_t \partial_x^k f_\mu \in L^\infty([0, \theta] \times \mathbb{R})$ for $k = 0, 1, 2$. This establishes the desired regularity of f_μ . \square

E.1.2 Verification argument: Proof of Proposition 5.4

This section is devoted to the proof of Proposition 5.4, i.e., the duality between V_γ and f_μ , and the characterization of the corresponding optimal control process. This is achieved by first establishing a connection between the Hamilton-Jacobi-Bellman (HJB) equation and the Parisi PDE, then constructing a control process and proving its optimality via the so-called “verification argument”. To begin with, we recall the definition of V_γ from Eq. (175):

$$V_\gamma(t, z) = \sup_{\phi \in D[t, 1]} \mathbb{E} \left[h \left(z + \int_t^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) \left(\phi_s^2 - \frac{1}{\alpha} \right) ds \right], \quad (206)$$

and define the HJB equation:

$$\partial_t V_\gamma(t, z) + \frac{1}{2} \frac{\gamma(t) \partial_z^2 V_\gamma(t, z)}{\gamma(t) - \partial_z^2 V_\gamma(t, z)} + \frac{\gamma(t)}{2\alpha} = 0, \quad (207)$$

$$V_\gamma(1, z) = h(z). \quad (208)$$

We first proceed with the verification argument for simple functions:

Proposition E.5. *Assume $\mu \in \text{SF}[0, 1]$ and $c > 0$ are such that $(\mu, c) \in \mathcal{L}$, and let γ be the associated Lagrange multiplier. Denote f_μ as the solution to the Parisi PDE. Then, we have*

$$\begin{aligned} V_\gamma(t, z) &= \inf_{x \in \mathbb{R}} \left\{ f_\mu(t, x) + \frac{\gamma(t)}{2} (x - z)^2 \right\} + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds, \\ f_\mu(t, x) &= \sup_{z \in \mathbb{R}} \left\{ V_\gamma(t, z) - \frac{\gamma(t)}{2} (z - x)^2 \right\} - \frac{1}{2\alpha} \int_t^1 \gamma(s) ds, \end{aligned} \quad (209)$$

for all $t \in [0, 1)$ and $x, z \in \mathbb{R}$. Further, V_γ solves Eq. (207), and the supremum in the definition of $V_\gamma(t, z)$ is achieved at $(\phi_s^z)_{s \in [t, 1]}$ satisfying

$$\phi_s^z = \frac{1}{\gamma(s)} \partial_x^2 f_\mu(s, X_s^z), \quad (210)$$

where $\{X_s^z\}_{s \in [t, 1]}$ solves the SDE

$$\frac{1}{\gamma(t)} \partial_x f_\mu(t, X_t^z) + X_t^z = z, \quad dX_s^z = \mu(s) \partial_x f_\mu(s, X_s^z) ds + dB_s, \quad s \in [t, 1]. \quad (211)$$

Proof. In virtue of Eqs. (183) and (184), we will prove the following statements instead:

(a) Defining for $(t, z) \in [0, 1] \times \mathbb{R}$:

$$V(t, z) = \frac{\gamma(t)}{2} z^2 - \Phi^*(t, z) - \frac{1}{2} \left(1 - \frac{1}{\alpha}\right) \int_t^1 \gamma(s) ds, \quad (212)$$

then V solves the HJB equation (207).

(b) The verification argument implies $V_\gamma = V$, and characterizes the optimal control process.

Proof of (a). Since $\Phi(t, \cdot)$ is strictly convex, we have $\partial_z^2 V(t, z) < \gamma(t)$. By direct calculation,

$$\begin{aligned} \partial_t V(t, z) &= \frac{\gamma'(t)}{2} z^2 - \partial_t \Phi^*(t, z) + \frac{1}{2} \left(1 - \frac{1}{\alpha}\right) \gamma(t) \\ &= \frac{\gamma'(t)}{2} z^2 + \partial_t \Phi(t, x_t^*(z)) + \frac{1}{2} \left(1 - \frac{1}{\alpha}\right) \gamma(t), \end{aligned}$$

and

$$\partial_z^2 V(t, z) = \gamma(t) - \partial_z^2 \Phi^*(t, z) = \gamma(t) - \frac{1}{\partial_x^2 \Phi(t, x_t^*(z))},$$

where $x_t^*(z)$ is the unique solution to the equation $z = \partial_x \Phi(t, x)$. We thus obtain that

$$\partial_t V(t, z) + \frac{1}{2} \frac{\gamma(t) \partial_z^2 V(t, z)}{\gamma(t) - \partial_z^2 V(t, z)} + \frac{\gamma(t)}{2\alpha} \quad (213)$$

$$= \frac{\gamma'(t)}{2} z^2 + \partial_t \Phi(t, x_t^*(z)) + \frac{1}{2} \left(1 - \frac{1}{\alpha}\right) \gamma(t) + \frac{\gamma(t)^2}{2} \partial_x^2 \Phi(t, x_t^*(z)) - \frac{\gamma(t)}{2} + \frac{\gamma(t)}{2\alpha} \quad (214)$$

$$= \partial_t \Phi(t, x_t^*(z)) + \frac{\gamma(t)^2}{2} \partial_x^2 \Phi(t, x_t^*(z)) + \frac{\gamma'(t)}{2} (\partial_x \Phi(t, x_t^*(z)))^2 = 0, \quad (215)$$

where the last line follows from the Parisi PDE observed by Φ . The terminal condition $V(1, z) = h(z)$ is quite straightforward to verify:

$$V(1, z) = \frac{\gamma(1)}{2} z^2 - \Phi^*(1, z) = \frac{\gamma(1)}{2} z^2 - \left(\frac{\gamma(1)}{2} z^2 - h(z) \right)^{**} = h(z). \quad (216)$$

This proves that V solves the HJB equation.

Proof of (b). We next show that $V_\gamma = V$ via the verification argument. Fix any $(t, z) \in [0, 1] \times \mathbb{R}$, we will prove that $V(t, z) = V_\gamma(t, z)$. To this end, we need to define the candidate process $(\phi_s^\gamma)_{s \in [t, 1]}$ as follows (note that this process depends on (t, z)):

1. Let $(X_s^\gamma)_{s \in [t, 1]}$ be the solution to the SDE:

$$dX_s^\gamma = \gamma(s) dB_s + \gamma'(s) \partial_x \Phi(s, X_s^\gamma) ds \quad (217)$$

with initial condition $\partial_x \Phi(t, X_t^\gamma) = z$. The existence and uniqueness of (X_s^γ) is guaranteed by Lipschitzness of $\partial_x \Phi(t, x)$ with respect to x .

2. We then define for $s \in [t, 1]$:

$$\phi_s^\gamma = \gamma(s) \cdot \partial_x^2 \Phi(s, X_s^\gamma) - 1. \quad (218)$$

From the curvature bound on Φ (cf. Proposition E.3), we know that ϕ_s^γ is almost surely bounded, uniformly for all $s \in [t, 1]$.

First, we show that $V_\gamma(t, z) \leq V(t, z)$. Let $\phi \in D[t, 1]$ be an arbitrary control process, and define for $\theta \in [t, 1]$ the continuous martingale:

$$M_\theta^\phi = z + \int_t^\theta (1 + \phi_s) dB_s. \quad (219)$$

Then, using Itô's formula, we obtain that

$$\begin{aligned} \mathbb{E} \left[V \left(\theta, M_\theta^\phi \right) \right] - V(t, z) &= \mathbb{E} \left[\int_t^\theta \partial_s V \left(s, M_s^\phi \right) ds + \partial_x V \left(s, M_s^\phi \right) dM_s^\phi + \frac{1}{2} \partial_x^2 V \left(s, M_s^\phi \right) d\langle M^\phi \rangle_s \right] \\ &= \mathbb{E} \left[\int_t^\theta \left(\partial_s V \left(s, M_s^\phi \right) + \frac{1}{2} \partial_x^2 V \left(s, M_s^\phi \right) (1 + \phi_s)^2 \right) ds \right] \\ &\stackrel{(i)}{\leq} \mathbb{E} \left[\int_t^\theta \frac{\gamma(s)}{2} \left(\phi_s^2 - \frac{1}{\alpha} \right) ds \right], \end{aligned}$$

where (i) follows from the HJB equation. Sending $\theta \rightarrow 1^-$ and using the terminal condition $V(1, z) = h(z)$, we further deduce that

$$\begin{aligned} \mathbb{E} \left[h \left(z + \int_t^1 (1 + \phi_s) dB_s \right) \right] - V(t, z) &\leq \mathbb{E} \left[\int_t^1 \frac{\gamma(s)}{2} \left(\phi_s^2 - \frac{1}{\alpha} \right) ds \right] \\ \implies \mathbb{E} \left[h \left(z + \int_t^1 (1 + \phi_s) dB_s \right) \right] - \frac{1}{2} \int_t^1 \gamma(s) \left(\phi_s^2 - \frac{1}{\alpha} \right) ds &\leq V(t, z). \end{aligned}$$

Taking supremum over all $\phi \in D[t, 1]$ gives $V_\gamma(t, z) \leq V(t, z)$.

To show the reverse bound, it suffices to find an optimal control which achieves equality in (i), namely

$$\phi_s = \operatorname{argmax}_{\phi \in \mathbb{R}} \left\{ \partial_z^2 V \left(s, M_s^\phi \right) (1 + \phi)^2 - \gamma(s) \phi^2 \right\} = \frac{\partial_z^2 V(s, M_s^\phi)}{\gamma(s) - \partial_z^2 V(s, M_s^\phi)}. \quad (220)$$

(By definition of V we know that $\partial_z^2 V(s, M_s^\phi) < \gamma(s)$, so the above argmax exists.) Next, we verify that the candidate process defined as per Eq. (218) satisfies the above condition. We claim that

$$M_\theta^{\phi^\gamma} = z + \int_t^\theta (1 + \phi_s^\gamma) dB_s = \partial_x \Phi(\theta, X_\theta^\gamma), \quad \forall \theta \in [t, 1]. \quad (221)$$

Note that our claim holds trivially for $\theta = t$ from the definition of X_t^γ . For $\theta > t$, applying Itô's formula yields

$$\begin{aligned} d\partial_x \Phi(\theta, X_\theta^\gamma) &= \partial_{tx} \Phi(\theta, X_\theta^\gamma) d\theta + \partial_x^2 \Phi(\theta, X_\theta^\gamma) dX_\theta^\gamma + \frac{1}{2} \partial_x^3 \Phi(\theta, X_\theta^\gamma) d\langle X^\gamma \rangle_\theta \\ &= \partial_{tx} \Phi(\theta, X_\theta^\gamma) d\theta + \gamma(\theta) \partial_x^2 \Phi(\theta, X_\theta^\gamma) dB_\theta + \gamma'(\theta) \partial_x \Phi(\theta, X_\theta^\gamma) \partial_x^2 \Phi(\theta, X_\theta^\gamma) d\theta \\ &\quad + \frac{1}{2} \gamma(\theta)^2 \partial_x^3 \Phi(\theta, X_\theta^\gamma) d\theta \\ &= \partial_x \left(\partial_t \Phi(\theta, X_\theta^\gamma) + \frac{1}{2} \gamma'(\theta) (\partial_x \Phi(\theta, X_\theta^\gamma))^2 + \frac{1}{2} \gamma(\theta)^2 \partial_x^2 \Phi(\theta, X_\theta^\gamma) \right) d\theta \\ &\quad + \gamma(\theta) \partial_x^2 \Phi(\theta, X_\theta^\gamma) dB_\theta \\ &\stackrel{(i)}{=} \gamma(\theta) \partial_x^2 \Phi(\theta, X_\theta^\gamma) dB_\theta = (1 + \phi_\theta^\gamma) dB_\theta = dM_\theta^{\phi^\gamma}, \end{aligned}$$

where (i) follows from Eq. (183). This proves the claim. It then follows that for any $s \in [t, 1]$:

$$\phi_s^\gamma = \gamma(s) \cdot \partial_x^2 \Phi(s, X_s^\gamma) - 1 = \frac{\gamma(s)}{\gamma(s) - \partial_z^2 V(s, M_s^{\phi^\gamma})} - 1 = \frac{\partial_z^2 V(s, M_s^{\phi^\gamma})}{\gamma(s) - \partial_z^2 V(s, M_s^{\phi^\gamma})}.$$

This justifies Eq. (220) and proves that $(\phi_s^\gamma)_{s \in [t, 1]}$ is indeed an optimal control process, which implies that $V(t, z) = V_\gamma(t, z)$. Further, using Eq. (184), one can easily verify that $\phi^\gamma = \phi^z$, thus establishing the optimality of ϕ^z . This completes the proof of Proposition E.5. \square

We are now ready to prove Proposition 5.4 for general function order parameters, which follows from a standard approximation procedure. Similar to the proof of Proposition E.5, it suffices to show that for all t, z :

$$V_\gamma(t, z) = \inf_{x \in \mathbb{R}} \left\{ f_\mu(t, x) + \frac{\gamma(t)}{2} (x - z)^2 \right\} + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds, \quad (222)$$

and that the supremum in the definition of $V_\gamma(t, z)$ is achieved at $(\phi_s^z)_{s \in [t, 1]}$ defined in Eqs. (102) and (103).

Note that because of Theorem E.2, Eq. (222) implies Proposition 5.4, and the above equation uniquely specifies X^z and ϕ^z . Without loss of generality, we can assume that $(t, z) = (0, 0)$, otherwise one can just shift z and reparametrize t . For notational simplicity we also suppress the superscript “ z ” in the definition of the SDE above. To prove Eq. (222) for general μ , we choose a sequence of $\mu_n \in \mathbf{SF}[0, 1]$ such that $(\mu_n, c) \xrightarrow{\mathcal{L}} (\mu, c)$. Then, by definition we know that the corresponding $\gamma_n \rightarrow \gamma$ in $L^\infty[0, 1]$. Since γ is strictly positive, applying Proposition F.2 yields that $V_{\gamma_n}(0, 0) \rightarrow V_\gamma(0, 0)$. Further, since $f_{\mu_n} \rightarrow f_\mu$ and they are uniformly Lipschitz (by Theorem E.2), we know that as $n \rightarrow \infty$,

$$\inf_{x \in \mathbb{R}} \left\{ f_{\mu_n}(0, x) + \frac{\gamma_n(0)}{2} x^2 \right\} + \frac{1}{2\alpha} \int_0^1 \gamma_n(s) ds \rightarrow \inf_{x \in \mathbb{R}} \left\{ f_\mu(0, x) + \frac{\gamma(0)}{2} x^2 \right\} + \frac{1}{2\alpha} \int_0^1 \gamma(s) ds.$$

Applying Proposition E.5 then yields Eq. (222). It remains to show that

$$\inf_{x \in \mathbb{R}} \left\{ f_\mu(0, x) + \frac{\gamma(0)}{2} x^2 \right\} = \mathbb{E} \left[h \left(\int_0^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_0^1 \gamma(s) \phi_s^2 ds \right]. \quad (223)$$

Note that $\{X_t\}$ uniquely exists and $\{\phi_t\}$ is well-defined, since $\partial_x f_\mu$ is bounded and Lipschitz in x (see, e.g., Proposition 1.10 in [Che05]). In what follows, we recast f_μ as f to avoid heavy notation. Define $M_t^\phi = \int_0^t (1 + \phi_s) dB_s$ for all $t \in [0, 1]$. Since $h''(z) < \gamma(1)$ for all $z \in \mathbb{R}$, Legendre-Fenchel duality implies that the terminal condition of Parisi PDE is equivalent to

$$h(z) = \inf_{x \in \mathbb{R}} \left\{ f(1, x) + \frac{\gamma(1)}{2} (x - z)^2 \right\}.$$

The optimization problem on the right hand side is convex, thus having a unique minimizer $x = x(z)$ characterized by the first-order condition

$$z = \frac{1}{\gamma(1)} \partial_x f(1, x) + x.$$

In other words, the following equivalence holds:

$$z = \frac{1}{\gamma(1)} \partial_x f(1, x) + x \iff h(z) = f(1, x) + \frac{\gamma(1)}{2} (x - z)^2.$$

Combining this identity with Proposition E.6, we obtain that

$$h\left(M_1^\phi\right) = f(1, X_1) + \frac{\gamma(1)}{2} \left(X_1 - M_1^\phi\right)^2 = f(1, X_1) + \frac{1}{2\gamma(1)} (\partial_x f(1, X_1))^2. \quad (224)$$

Further, by definition of X_0 , we have

$$\inf_{x \in \mathbb{R}} \left\{ f(0, x) + \frac{\gamma(0)}{2} x^2 \right\} = f(0, X_0) + \frac{\gamma(0)}{2} X_0^2 = f(0, X_0) + \frac{1}{2\gamma(0)} (\partial_x f(0, X_0))^2.$$

Therefore, one only needs to show that

$$f(0, X_0) + \frac{1}{2\gamma(0)} (\partial_x f(0, X_0))^2 = \mathbb{E} \left[f(1, X_1) + \frac{1}{2\gamma(1)} (\partial_x f(1, X_1))^2 - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right], \quad (225)$$

which reduces to proving

$$\frac{d}{dt} \mathbb{E} \left[f(t, X_t) + \frac{1}{2\gamma(t)} (\partial_x f(t, X_t))^2 - \frac{1}{2} \int_0^t \gamma(s) \phi_s^2 ds \right] = 0. \quad (226)$$

Using Itô's lemma (Proposition 22 of [JT16]), we compute

$$\begin{aligned} & d \left(f(t, X_t) + \frac{1}{2\gamma(t)} (\partial_x f(t, X_t))^2 - \frac{1}{2} \int_0^t \gamma(s) \phi_s^2 ds \right) \\ &= \partial_t f(t, X_t) dt + \partial_x f(t, X_t) dX_t + \frac{1}{2} \partial_x^2 f(t, X_t) dt \\ &\quad - \frac{\mu(t)}{2} (\partial_x f(t, X_t))^2 dt + \frac{1}{\gamma(t)} \partial_x f(t, X_t) \cdot d\partial_x f(t, X_t) \\ &\quad + \frac{1}{2\gamma(t)} (d\partial_x f(t, X_t))^2 - \frac{1}{2} \gamma(t) \phi_t^2 dt \\ &= \left(\partial_t f(t, X_t) + \frac{\mu(t)}{2} (\partial_x f(t, X_t))^2 + \frac{1}{2} \partial_x^2 f(t, X_t) \right) dt \\ &\quad + \partial_x f(t, X_t) dB_t + \frac{1}{\gamma(t)} \partial_x f(t, X_t) \partial_x^2 f(t, X_t) dB_t \\ &\quad + \frac{1}{2\gamma(t)} (\partial_x^2 f(t, X_t))^2 dt - \frac{1}{2} \gamma(t) \phi_t^2 dt \\ &= \partial_x f(t, X_t) \left(1 + \frac{1}{\gamma(t)} \partial_x^2 f(t, X_t) \right) dB_t, \end{aligned}$$

which immediately implies Eq. (226). This completes the proof of our claims.

Proposition E.6. *Let $\{X_s^z\}_{s \in [t, 1]}$ and $\{\phi_s^z\}_{s \in [t, 1]}$ be as defined in Eq. (102) and Eq. (103), respectively. For any $t \leq s \leq \theta \leq 1$, we have*

$$\int_s^\theta (1 + \phi_u^z) dB_u = \frac{1}{\gamma(\theta)} \partial_x f_\mu(\theta, X_\theta^z) + X_\theta^z - \left(\frac{1}{\gamma(s)} \partial_x f_\mu(s, X_s^z) + X_s^z \right). \quad (227)$$

Proof. In this proof we recast f_μ as f , and drop the superscript “ z ” for simplicity. Since $\partial_x f \in C^{1,2}$, and satisfies the regularity conditions of [JT16, Proposition 22], we can apply Itô's lemma to

compute for $u \in [t, 1]$:

$$\begin{aligned}
d\left(\frac{1}{\gamma(u)}\partial_x f(u, X_u) + X_u\right) &= -\mu(u)\partial_x f(u, X_u)du + \frac{1}{\gamma(u)}d\partial_x f(u, X_u) + dX_u \\
&= \frac{1}{\gamma(u)}d\partial_x f(u, X_u) + dB_u \\
&= \frac{1}{\gamma(u)}\left(\partial_{tx}f(u, X_u)du + \partial_x^2 f(u, X_u)dX_u + \frac{1}{2}\partial_x^3 f(u, X_u)du\right) + dB_u \\
&= \left(\frac{1}{\gamma(u)}\partial_x^2 f(u, X_u) + 1\right)dB_u \\
&\quad + \frac{1}{\gamma(u)}\left(\partial_{tx}f(u, X_u) + \mu(u)\partial_x f(u, X_u)\partial_x^2 f(u, X_u) + \frac{1}{2}\partial_x^3 f(u, X_u)\right)du \\
&\stackrel{(i)}{=} \left(\frac{1}{\gamma(u)}\partial_x^2 f(u, X_u) + 1\right)dB_u = (1 + \phi_u)dB_u,
\end{aligned}$$

where (i) follows from the PDE satisfied by $\partial_x f$. This immediately completes the proof. \square

E.1.3 First-order variation: Proof of Proposition 5.5

We begin by stating a useful lemma.

Lemma E.7. *For any $s, t \in [0, 1]$, we have*

$$\mathbb{E}\left[(\partial_x f_\mu(t, X_t))^2\right] - \mathbb{E}\left[(\partial_x f_\mu(s, X_s))^2\right] = \int_s^t \mathbb{E}\left[(\partial_x^2 f_\mu(u, X_u))^2\right] du. \quad (228)$$

Proof. This follows from a straightforward application of Itô's formula. \square

In the rest of this section, we present the proof of Proposition 5.5.

Proof of (i). Note that $X_q = B_q \sim \mathcal{N}(0, q)$ follows directly from definition. To prove Eq. (116), we note that by Proposition 5.4, ϕ_t defined there achieves the value V_γ , whence

$$\mathbb{E}\left[h\left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t\right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha}\right) dt\right] = \mathbb{E}[V_\gamma(q, X_q + F(X_q))]. \quad (229)$$

Hence, the right hand side of Eq. (116) equals

$$\mathbb{E}\left[V_\gamma(q, X_q + F(X_q)) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha}\right)\right]. \quad (230)$$

Note that by our choice of F and Proposition 5.4, it follows that

$$f_\mu(x) + \frac{1}{2\alpha} \int_q^1 \gamma(s) ds = V_\gamma(q, x + F(x)) - \frac{\gamma(q)}{2} F(x)^2, \quad \forall x \in \mathbb{R}, \quad (231)$$

thus leading to

$$\begin{aligned}
&\mathbb{E}\left[V_\gamma(q, X_q + F(X_q)) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha}\right)\right] \\
&= \mathbb{E}[f_\mu(X_q)] + \frac{1}{2\alpha} \left(q\gamma(q) + \int_q^1 \gamma(s) ds\right) \\
&\stackrel{(i)}{=} f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \gamma(s) ds = F(\mu, c),
\end{aligned}$$

where (i) follows from the fact that $\mu \equiv 0$ on $[0, q]$, so the Parisi PDE degenerates to a Heat equation. This completes the proof of part (i).

Proof of (ii). This is a direct consequence of Lemma E.7 and the definition of $\{\phi_t\}$.

Proof of (iii). We are now ready to compute the first-order variation of $F(\mu, c)$ with respect to μ . The proof is similar to Proposition 6.8 in [EAMS21]. Recall that

$$F(\mu, c) = f_\mu(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds} =: f_\mu(0, 0) + S(\mu). \quad (232)$$

Then, it is easy to see that the first-order variation of the entropy term $S(\mu)$ equals

$$\left. \frac{d}{ds} S(\mu + s\delta) \right|_{s=0} = -\frac{1}{2\alpha} \int_0^1 \delta(t) \int_0^t \gamma(s)^2 ds dt, \quad (233)$$

so we only need to show that

$$\left. \frac{d}{ds} f_{\mu+s\delta}(0, 0) \right|_{s=0} = \frac{1}{2} \int_0^1 \delta(t) \mathbb{E} \left[(\partial_x f_\mu(t, X_t))^2 \right] dt. \quad (234)$$

To this end, we rewrite $f_{\mu+s\delta}$ as f_s . Similar to the proof of Lemma 14 in [JT16], we obtain that

$$f_s(0, x) - f_0(0, x) = \frac{s}{2} \int_0^1 \delta(t) \mathbb{E}_{X_0^s=x} \left[(\partial_x f_0(t, X_t^s))^2 \right] dt, \quad (235)$$

where $\{X_t^s\}_{t \in [0,1]}$ is the unique solution to the SDE:

$$dX_t^s = \mu(t) \frac{\partial_x f_s + \partial_x f_0}{2}(t, X_t^s) dt + dB_t, \quad X_0^s = x. \quad (236)$$

Now since $\partial_x f_s \rightarrow \partial_x f$ as $s \rightarrow 0$ (via a similar argument as in the proof of [JT16, Lemma 14]), further they are continuous and uniformly bounded and $\mu \in L^1[0, 1]$, we deduce from Proposition F.6 that $\text{Law}(X^s) \xrightarrow{w} \text{Law}(X)$ as $s \rightarrow 0$. By bounded convergence theorem,

$$\int_0^1 \delta(t) \mathbb{E}_{X_0^s=x} \left[(\partial_x f_0(t, X_t^s))^2 \right] dt = \int_0^1 \delta(t) \mathbb{E}_{X_0=x} \left[(\partial_x f_0(t, X_t))^2 \right] dt + o_s(1), \quad s \rightarrow 0,$$

which further implies that

$$\left. \frac{d}{ds} f_s(0, x) \right|_{s=0} = \frac{1}{2} \int_0^1 \delta(t) \mathbb{E}_{X_0=x} \left[(\partial_x f_0(t, X_t))^2 \right] dt. \quad (237)$$

The desired result Eq. (234) follows by taking $x = 0$.

E.1.4 Extention to general C^2 test function

In previous sections we have constructed solutions to the Parisi PDE with C^4 terminal conditions (Assumption E.1) and proved Proposition 5.4 and 5.5. In this section, we will show that these conclusions still hold under the assumptions of Theorem 3.3 via an approximation argument. Consider the following Parisi PDE:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) (\partial_x f_\mu(t, x))^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h(x + u) - \frac{u^2}{2c} \right\}, \end{aligned} \quad (238)$$

where we only assume h is upper bounded and in $C^2(\mathbb{R})$ (we do not assume $h \in C^4(\mathbb{R})$ any longer). Further, we require $\|h'\|_{L^\infty(\mathbb{R})} < \infty$ and $\sup_{z \in \mathbb{R}} h''(z) < 1/c$, so that the terminal condition is C^2 as well and satisfies $\|\partial_x f_\mu(1, \cdot)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}$ and $\partial_x^2 f_\mu(1, \cdot) \in C_b(\mathbb{R})$, which follows from Proposition E.3. We will show that the above PDE admits a weak solution on $[0, 1] \times \mathbb{R}$ via an approximation argument.

For any $\varepsilon > 0$, define $f_\mu^\varepsilon(1, \cdot)$ to be the ε -mollifier of $f_\mu(1, \cdot)$ via the heat kernel, namely

$$f_\mu^\varepsilon(1, x) = \int_{\mathbb{R}} \frac{1}{\varepsilon} \phi\left(\frac{x-y}{\varepsilon}\right) f_\mu(1, y) dy = \mathbb{E}_{G \sim N(0,1)} [f_\mu(1, x + \varepsilon G)]$$

where ϕ is the Gaussian PDF. Of course, $f_\mu^\varepsilon(1, \cdot) \in C^\infty(\mathbb{R})$, and we have the following L^∞ -norm bounds regarding its partial derivatives:

Proposition E.8. *For any $\varepsilon > 0$, we have*

$$(a) \quad \|f_\mu^\varepsilon(1, \cdot) - f_\mu(1, \cdot)\|_{L^\infty(\mathbb{R})} \leq \varepsilon^2 \|\partial_x^2 f_\mu(1, \cdot)\|_{L^\infty(\mathbb{R})}.$$

(b) *For any compact set $K \subset \mathbb{R}$, we have*

$$\begin{aligned} \|\partial_x f_\mu^\varepsilon(1, \cdot) - \partial_x f_\mu(1, \cdot)\|_{L^\infty(K)} &\leq \varepsilon \sup_{x \in K} \sup_{t \in [0, \varepsilon]} |\mathbb{E}_G [G \cdot \partial_x^2 f_\mu(1, x + tG)]|, \\ \|\partial_x^2 f_\mu^\varepsilon(1, \cdot) - \partial_x^2 f_\mu(1, \cdot)\|_{L^\infty(K)} &\rightarrow 0 \text{ as } \varepsilon \rightarrow 0, \\ \|\partial_x^3 f_\mu^\varepsilon(1, \cdot)\|_{L^\infty(K)} &\leq \frac{1}{\varepsilon} \sup_{x \in K} \sup_{t \in [0, \varepsilon]} |\mathbb{E}_G [G \cdot \partial_x^3 f_\mu(1, x + tG)]|. \end{aligned}$$

Further, we have

$$\sup_{x \in K} \sup_{t \in [0, \varepsilon]} |\mathbb{E}_G [G \cdot \partial_x^2 f_\mu(1, x + tG)]| \rightarrow 0 \text{ as } \varepsilon \rightarrow 0.$$

Proof. We first prove (a). By definition, we have

$$\begin{aligned} \|f_\mu^\varepsilon(1, \cdot) - f_\mu(1, \cdot)\|_{L^\infty(\mathbb{R})} &= \sup_{x \in \mathbb{R}} |f_\mu^\varepsilon(1, x) - f_\mu(1, x)| \\ &= \sup_{x \in \mathbb{R}} |\mathbb{E}_G [f_\mu(1, x + \varepsilon G) - f_\mu(1, x)]| = \sup_{x \in \mathbb{R}} \left| \mathbb{E}_G \left[\partial_x f_\mu(1, x) \cdot \varepsilon G + \frac{1}{2} \partial_x^2 f_\mu(1, x^*) \cdot \varepsilon^2 G^2 \right] \right| \\ &\leq \frac{\varepsilon^2}{2} \sup_{x \in \mathbb{R}} |\partial_x^2 f_\mu(1, x)| \cdot \mathbb{E}_G [G^2] \leq \varepsilon^2 \|\partial_x^2 f_\mu(1, \cdot)\|_{L^\infty(\mathbb{R})}. \end{aligned}$$

Similarly, we can show that

$$\begin{aligned}
& \left\| \partial_x f_\mu^\varepsilon(1, \cdot) - \partial_x f_\mu(1, \cdot) \right\|_{L^\infty(K)} = \sup_{x \in K} \left| \partial_x f_\mu^\varepsilon(1, x) - \partial_x f_\mu(1, x) \right| \\
&= \sup_{x \in K} \left| \mathbb{E}_G [\partial_x f_\mu(1, x + \varepsilon G) - \partial_x f_\mu(1, x)] \right| \leq \sup_{x \in K} \left\{ \varepsilon \cdot \sup_{t \in [0, \varepsilon]} \left| \mathbb{E}_G [G \cdot \partial_x^2 f_\mu(1, x + tG)] \right| \right\} \\
&= \varepsilon \sup_{x \in K} \sup_{t \in [0, \varepsilon]} \left| \mathbb{E}_G [G \cdot \partial_x^2 f_\mu(1, x + tG)] \right|,
\end{aligned}$$

where we have

$$\sup_{x \in K} \sup_{t \in [0, \varepsilon]} \left| \mathbb{E}_G [G \cdot \partial_x^2 f_\mu(1, x + tG)] \right| \rightarrow 0$$

since $\partial_x^2 f_\mu(1, \cdot)$ is uniformly continuous on K . The other estimates in (b) follows similarly. \square

Remark 9. These estimates are still valid if we replace f_μ by f_μ^η for some $\eta \leq \varepsilon$, since f_μ^ε can be viewed as a mollifier of f_μ^η as well.

Now, let $f_\mu^\varepsilon : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}$ be the solution to the Parisi PDE (238) with terminal value $f_\mu^\varepsilon(1, \cdot)$. We will show that for any sequence $\varepsilon_n \rightarrow 0$, $\{f_\mu^{\varepsilon_n}\}_{n \geq 1}$ is a Cauchy sequence in the following sense:

Theorem E.3. *The following holds for the sequence $\{f_\mu^{\varepsilon_n}\}_{n \geq 1}$ as $\varepsilon_n \rightarrow 0$:*

$$(a) \lim_{m, n \rightarrow \infty} \|f_\mu^{\varepsilon_m} - f_\mu^{\varepsilon_n}\|_{L^\infty([0, 1] \times \mathbb{R})} = 0.$$

$$(b) \lim_{m, n \rightarrow \infty} \|\partial_x f_\mu^{\varepsilon_m} - \partial_x f_\mu^{\varepsilon_n}\|_{L^\infty([0, 1] \times \mathbb{R})} = 0.$$

(c) For any compact set $K \subset \mathbb{R}$, we have

$$\lim_{m, n \rightarrow \infty} \|\partial_x^2 f_\mu^{\varepsilon_m} - \partial_x^2 f_\mu^{\varepsilon_n}\|_{L^\infty([0, 1] \times K)} = 0. \quad (239)$$

Proof. Throughout the proof we denote $\varepsilon = \varepsilon_n$, $\eta = \varepsilon_m$, and $w = f_\mu^{\varepsilon_m} - f_\mu^{\varepsilon_n}$.

Proof of (a). Note that w satisfies the following PDE:

$$\partial_t w + \frac{1}{2} \mu(t) (\partial_x f_\mu^\varepsilon + \partial_x f_\mu^\eta) \partial_x w + \frac{1}{2} \partial_x^2 w = 0.$$

Fix $(t, x) \in [0, 1] \times \mathbb{R}$, and let $\{X_s\}_{s \in [t, 1]}$ be the solution to the SDE:

$$X_t = x, \quad dX_s = \frac{1}{2} \mu(s) (\partial_x f_\mu^\varepsilon(s, X_s) + \partial_x f_\mu^\eta(s, X_s)) ds + dB_s.$$

Note that the solution uniquely exists since $\partial_x f_\mu^\varepsilon$ and $\partial_x f_\mu^\eta$ are Lipschitz. Using Itô's formula, we obtain that

$$dw(s, X_s) = \partial_x w(s, X_s) dB_s \implies w(t, x) = \mathbb{E}_{X_t=x} [w(1, X_1)].$$

The conclusion then follows from Proposition E.8 (a).

Proof of (b). Define $w_1 = \partial_x w$, then we know that w_1 satisfies

$$\partial_t w_1 + \mu(t) \partial_x f_\mu^\varepsilon \cdot \partial_x w_1 + \frac{1}{2} \partial_x^2 w_1 + \mu(t) \partial_x^2 f_\mu^\eta \cdot w_1 = 0.$$

Fix $(t, x) \in [0, 1] \times \mathbb{R}$, and let $\{Y_s\}_{s \in [t, 1]}$ solve the SDE:

$$Y_t = x, \quad dY_s = \mu(s) \partial_x f_\mu^\varepsilon(s, Y_s) ds + dB_s.$$

Similarly, we know that the solution exists uniquely. Using Feynman-Kac formula, it follows that

$$w_1(t, x) = \mathbb{E}_{Y_t=x} \left[\exp \left(\int_t^1 \mu(s) \partial_x^2 f_\mu^\eta(s, Y_s) ds \right) w_1(1, X_1) \right].$$

Since $\partial_x^2 f_\mu^\eta$ is uniformly bounded, and from the proof of Proposition E.8 we know that

$$\|w_1(1, \cdot)\|_{L^\infty(\mathbb{R})} = \sup_{x \in \mathbb{R}} |\partial_x f_\mu^\varepsilon(1, x) - \partial_x f_\mu^\eta(1, x)| \rightarrow 0 \text{ as } \varepsilon, \eta \rightarrow 0,$$

we deduce that $\|w_1\|_{L^\infty([0, 1] \times \mathbb{R})} \rightarrow 0$ as $\varepsilon, \eta \rightarrow 0$. This proves part (b).

Proof of (c). Define $w_2 = \partial_x^2 w$. Then, we know that w_2 satisfies the following PDE:

$$\partial_t w_2 + \mu(t) \partial_x f_\mu^\eta \cdot \partial_x w_2 + \frac{1}{2} \partial_x^2 w_2 + \mu(t) (\partial_x^2 f_\mu^\varepsilon + \partial_x^2 f_\mu^\eta) \cdot w_2 + \mu(t) w_1 \cdot \partial_x^3 f_\mu^\varepsilon = 0.$$

Fix $(t, x) \in [0, 1] \times \mathbb{R}$, and let $\{Z_s\}_{s \in [t, 1]}$ be the unique solution to the SDE:

$$Z_t = x, \quad dZ_s = \mu(s) \partial_x f_\mu^\eta(s, Z_s) ds + dB_s.$$

Using again Feynman-Kac formula, we obtain that

$$\begin{aligned} w_2(t, x) = & \mathbb{E}_{Z_t=x} \left[\int_t^1 \exp \left(\int_t^\tau \mu(s) (\partial_x^2 f_\mu^\varepsilon(s, Z_s) + \partial_x^2 f_\mu^\eta(s, Z_s)) ds \right) \mu(\tau) w_1(\tau, Z_\tau) \partial_x^3 f_\mu^\varepsilon(\tau, Z_\tau) d\tau \right] \\ & + \mathbb{E}_{Z_t=x} \left[\exp \left(\int_t^1 \mu(s) (\partial_x^2 f_\mu^\varepsilon(s, Z_s) + \partial_x^2 f_\mu^\eta(s, Z_s)) ds \right) w_2(1, Z_1) \right]. \end{aligned}$$

The second term converges to 0 uniformly on $[0, 1] \times K$, since $\{\text{Law}(Z_1 | Z_t = x) : (t, x) \in [0, 1] \times K\}$ is a tight family of probability distributions (see, e.g., the proof of Proposition F.6), and we recall from Proposition E.8 (b) that $w_2(1, x) \rightarrow 0$ uniformly on K . To prove that the first term converges to 0 uniformly on $[0, 1] \times K$, we can use Feynman-Kac formula to estimate $\partial_x^3 f_\mu^\varepsilon$ and combine this with the estimate of w_1 in part (b). Finally, one can show that their product uniformly converges to 0 on $[0, 1] \times K$ using the estimates in Proposition E.8 (b). \square

Theorem E.3 (a) immediately implies that as $\varepsilon \rightarrow 0$, f_μ^ε converges to some f_μ uniformly on $[0, 1] \times \mathbb{R}$ (hence of course on any compact set). Further, Theorem E.3 (b) tells us that $\partial_x f_\mu^\varepsilon$ uniformly converges to some g_μ . Applying Dominated Convergence Theorem, we know that $\partial_x f_\mu$ exists and equals g_μ , namely $\partial_x f_\mu^\varepsilon$ uniformly converges to $\partial_x f_\mu$. Repeating the same argument and using Theorem E.3 (c), we know that $\partial_x^2 f_\mu$ exists and $\partial_x^2 f_\mu^\varepsilon$ converges to $\partial_x^2 f_\mu$ uniformly on any compact set as $\varepsilon \rightarrow 0$.

According to the Parisi PDEs observed by f_μ^ε , we know that $\partial_t f_\mu^\varepsilon$ converges to some h_μ uniformly on compact sets as $\varepsilon \rightarrow 0$. Using again the Dominated Convergence Theorem, we know that $h_\mu = \partial_t f_\mu$, i.e., $\partial_t f_\mu^\varepsilon$ converges to $\partial_t f_\mu$ uniformly on any compact set as $\varepsilon \rightarrow 0$. Similar to the proof of [EAMS21, Lemma 6.2], we obtain that f_μ is a weak solution of Eq. (238), and the Parisi SDE (114) admits a unique solution $\{X_t\}$. Further, the control process $\phi_t = (1/\gamma(t)) \partial_x^2 f_\mu(t, X_t)$ is well defined. In what follows we will extend the proof of Proposition 5.4 and Proposition 5.5 to any C^2 test function h as described in the beginning of this section.

Proof of Proposition 5.4 for $h \in C^2$. We now extend the proof of Proposition 5.4. As before, it is sufficient to prove the first identity of Eq. (101) for the case $(t, z) = (0, 0)$, and that the optimal control process is given by Eqs. (102) and (103). For $\varepsilon > 0$, let $f_\mu^\varepsilon(1, \cdot)$ be the ε -mollification of $f_\mu(1, \cdot)$ and define

$$h^\varepsilon(z) = \inf_{x \in \mathbb{R}} \left\{ f_\mu^\varepsilon(1, x) + \frac{\gamma(1)}{2}(x - z)^2 \right\}, \quad (240)$$

$$V_\gamma^\varepsilon(0, 0) = \sup_{\phi \in D[0, 1]} \mathbb{E} \left[h^\varepsilon \left(\int_0^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma(t) dt. \quad (241)$$

Since h_ε satisfies Assumption E.1 by construction, we know that

$$V_\gamma^\varepsilon(0, 0) = \inf_{x \in \mathbb{R}} \left\{ f_\mu^\varepsilon(0, x) + \frac{x^2}{2(c + \int_0^1 \mu(t) dt)} \right\} + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds} \quad (242)$$

$$= \mathbb{E} \left[h^\varepsilon \left(\int_0^1 (1 + \phi_t^\varepsilon) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) (\phi_t^\varepsilon)^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma(t) dt, \quad (243)$$

where $\phi_t^\varepsilon = \partial_x^2 f_\mu^\varepsilon(t, X_t^\varepsilon) / \gamma(t)$, and $\{X_t^\varepsilon\}_{t \in [0, 1]}$ solves the Parisi SDE

$$dX_t^\varepsilon = \mu(t) \partial_x f_\mu^\varepsilon(t, X_t^\varepsilon) dt + dB_t, \quad \partial_x f_\mu^\varepsilon(0, X_0^\varepsilon) + \gamma(0) X_0^\varepsilon = 0. \quad (244)$$

Since $f_\mu^\varepsilon \rightarrow f_\mu$ uniformly, we know $h^\varepsilon \rightarrow h$ uniformly. This further implies that

$$V_\gamma(0, 0) = \inf_{x \in \mathbb{R}} \left\{ f_\mu(0, x) + \frac{x^2}{2(c + \int_0^1 \mu(t) dt)} \right\} + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds}. \quad (245)$$

It remains to show that

$$\lim_{\varepsilon \rightarrow 0^+} \mathbb{E} \left[h^\varepsilon \left(\int_0^1 (1 + \phi_t^\varepsilon) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) (\phi_t^\varepsilon)^2 dt \right] = \mathbb{E} \left[h \left(\int_0^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right]. \quad (246)$$

Using Proposition F.6, we know that X^ε converges in law to X . Theorem E.3 (c) then implies that ϕ^ε converges in law to ϕ . Further, since ϕ^ε is uniformly bounded and $h^\varepsilon \rightarrow h$ uniformly, the above equation immediately follows from Bounded Convergence Theorem. This completes the proof of Proposition 5.4 for $h \in C^2$.

Proof of Proposition 5.5 for $h \in C^2$. The proof of part (i) follows from a similar approximation argument as in the proof of Proposition 5.4 for $h \in C^2$. For any $\varepsilon > 0$, denote by $F^\varepsilon(\mu, c)$ the Parisi functional associated with f_μ^ε and h^ε . We can then define F^ε and ϕ^ε accordingly. Further, we know that Eq. (116) holds for $F^\varepsilon(\mu, c)$, h^ε , F^ε and ϕ^ε . From the proof of Proposition 5.4 for $h \in C^2$, we know that $f_\mu^\varepsilon \rightarrow f_\mu$ uniformly, $h^\varepsilon \rightarrow h$ uniformly, $\phi^\varepsilon \rightarrow \phi$ in law, and $\partial_x f_\mu^\varepsilon \rightarrow \partial_x f_\mu$ uniformly, which further implies that $F^\varepsilon(\mu, c) \rightarrow F(\mu, c)$ and $F^\varepsilon \rightarrow F$ uniformly. Similar to the proof of Proposition 5.4, sending $\varepsilon \rightarrow 0$ and applying Dominated Convergence Theorem yields Eq. (116), completing the proof of part (i).

To prove part (ii), we need to extend Lemma E.7, which again follows from Proposition F.6, Theorem E.3, and the same approximation argument. Indeed, as $X^\varepsilon \rightarrow X$ in law, $\partial_x f_\mu^\varepsilon, \partial_x^2 f_\mu^\varepsilon \rightarrow \partial_x f_\mu, \partial_x^2 f_\mu$ uniformly and the limiting functions are bounded, we deduce from Bounded Convergence

Theorem that $\forall t \in [0, 1]$:

$$\lim_{\varepsilon \rightarrow 0} \mathbb{E} \left[(\partial_x f_\mu^\varepsilon(t, X_t^\varepsilon))^2 \right] = \mathbb{E} \left[(\partial_x f_\mu(t, X_t))^2 \right], \quad (247)$$

$$\lim_{\varepsilon \rightarrow 0} \mathbb{E} \left[(\partial_x^2 f_\mu^\varepsilon(t, X_t^\varepsilon))^2 \right] = \mathbb{E} \left[(\partial_x^2 f_\mu(t, X_t))^2 \right]. \quad (248)$$

Part (ii) then follows from the conclusion of Lemma E.7 for f_μ^ε and taking the limit $\varepsilon \rightarrow 0$.

It now remains to show part (iii). To this end, note that Eq. (235) still holds since its proof does not involve third or higher-order partial derivatives with respect to x . It then suffices to show that $\partial_x f_s \rightarrow \partial_x f$ as $s \rightarrow 0$. Re-examining the proof of Theorem E.3 (b), we know that $\partial_x f_s^\varepsilon \rightarrow \partial_x f_s$ uniformly for s in a neighborhood of 0 as $\varepsilon \rightarrow 0$, since the error bound depends continuously on μ . Further, for any fixed $\varepsilon > 0$, we have $\lim_{s \rightarrow 0} \partial_x f_s^\varepsilon = \partial_x f^\varepsilon$, which follows in a similarly way as the proof of Theorem E.2. We thus conclude that $\lim_{s \rightarrow 0} \partial_x f_s = \partial_x f$, and the same approximation argument as in the proof of part (iii) for the C^4 case follows. This concludes the proof of Proposition 5.5 (iii) for $h \in C^2$.

E.2 The case $\gamma(1) \leq \sup_{z \in \mathbb{R}} h''(z)$

This section is devoted to the construction of solutions to the Parisi PDE, the proof of Proposition 5.4, and the proof of Theorem 3.3 (c) (strong duality) under the situation $\gamma(1) \leq \sup_{z \in \mathbb{R}} h''(z)$.

Reduce to the case $\gamma(1) \geq \sup_{z \in \mathbb{R}} h''(z)$. We let $\text{conc}(g(x))$ denote the upper concave envelope of function g . For $c = 1/\gamma(1)$, we define

$$h_c(x) = \text{conc} \left(h(x) - \frac{x^2}{2c} \right) + \frac{x^2}{2c} = \text{conc} \left(h(x) - \frac{\gamma(1)x^2}{2} \right) + \frac{\gamma(1)x^2}{2}. \quad (249)$$

Then, we know that $h_c \in C^2(\mathbb{R})$ is also Lipschitz continuous, and bounded from above. Further, we have $\gamma(1) \geq \sup_{z \in \mathbb{R}} h_c''(z)$. The proposition below shows that h_c and h define the same value function $V_\gamma(t, z)$ and Parisi functional $F(\mu, c)$:

Proposition E.9 (Equivalence of h_c and h). *Recall $V_\gamma(t, z)$ from Eq. (175), we have*

$$V_\gamma(t, z) = \sup_{\phi \in D[t, 1]} \mathbb{E} \left[h_c \left(z + \int_t^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) \phi_s^2 ds \right] + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds.$$

Further, the terminal condition of the Parisi PDE (174) can be re-written as

$$f_\mu(1, x) = \sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c} \right\},$$

which means that one can use h_c instead of h when defining $F(\mu, c)$.

Proof. Again for simplicity, we assume $(t, z) = (0, 0)$, and use shorthand $V(\gamma)$ for $V_\gamma(0, 0)$. First, we prove that $V(\gamma) = V_c(\gamma)$, where we denote

$$V_c(\gamma) = \sup_{\phi \in D[0, 1]} \mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma(t) dt. \quad (250)$$

Without loss of generality, we can assume $\gamma(t) = \gamma(1)$ on $[\theta, 1]$ for some $\theta < 1$. Otherwise, one can find a sequence of γ_n , each satisfying $\gamma_n(t) = \gamma_n(1)$ on $[\theta_n, 1]$ for some $\theta_n < 1$, and $\gamma_n \xrightarrow{L^\infty} \gamma$. If we can show that $V_c(\gamma_n) = V(\gamma_n)$ for each n , then applying Proposition F.2 yields

$$V_c(\gamma) = \lim_{n \rightarrow \infty} V_c(\gamma_n) = \lim_{n \rightarrow \infty} V(\gamma_n) = V(\gamma).$$

Based on this consideration, we will assume that $\gamma(t) = \gamma(1)$ on $[\theta, 1]$ for some $\theta < 1$. Since $h_c \geq h$, we always have $V_c(\gamma) \geq V(\gamma)$. To prove the reverse bound, note that for any $\varepsilon > 0$, there exists $\phi \in D[0, 1]$ such that

$$\mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma(t) dt \geq V_c(\gamma) - \varepsilon. \quad (251)$$

Further, by continuity, there exists $\theta_\varepsilon \geq \theta$, such that

$$\mathbb{E} \left[h_c \left(\int_0^{\theta_\varepsilon} (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^{\theta_\varepsilon} \gamma(t) \phi_t^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma(t) dt \geq V_c(\gamma) - 2\varepsilon.$$

According to Lemma F.3, we have

$$h_c(x) = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=0} \mathbb{E} \left[h(x + U) - \frac{\gamma(1)}{2} U^2 \right]. \quad (252)$$

Using martingale representation theorem, we get that

$$\mathbb{E} \left[h_c \left(\int_0^{\theta_\varepsilon} (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^{\theta_\varepsilon} \gamma(t) \phi_t^2 dt \right] \quad (253)$$

$$\stackrel{(i)}{=} \sup_{\psi \in D[\theta_\varepsilon, 1]} \mathbb{E} \left[h \left(\int_0^{\theta_\varepsilon} (1 + \phi_t) dB_t + \int_{\theta_\varepsilon}^1 \psi_t dB_t \right) - \frac{1}{2} \int_0^{\theta_\varepsilon} \gamma(t) \phi_t^2 dt - \frac{1}{2} \int_{\theta_\varepsilon}^1 \gamma(t) \psi_t^2 dt \right] \quad (254)$$

$$\stackrel{(ii)}{\leq} \sup_{\psi \in D[\theta_\varepsilon, 1]} \mathbb{E} \left[h \left(\int_0^{\theta_\varepsilon} (1 + \phi_t) dB_t + \int_{\theta_\varepsilon}^1 (1 + \psi_t) dB_t \right) - \frac{1}{2} \int_0^{\theta_\varepsilon} \gamma(t) \phi_t^2 dt - \frac{1}{2} \int_{\theta_\varepsilon}^1 \gamma(t) \psi_t^2 dt \right] + \varepsilon \quad (255)$$

$$\leq V(\gamma) - \frac{1}{2\alpha} \int_0^1 \gamma(t) dt + \varepsilon \quad (256)$$

for θ_ε sufficiently close to 1, where (i) is due to $\gamma(t) = \gamma(1)$ on $[\theta_\varepsilon, 1]$, (ii) is because of the Lipschitzness of h . We thus deduce that

$$V_c(\gamma) - 2\varepsilon \leq V(\gamma) + \varepsilon.$$

Sending $\varepsilon \rightarrow 0$ yields that $V_c(\gamma) \leq V(\gamma)$. This concludes the proof of $V_c(\gamma) = V(\gamma)$. The equivalent form of $f_\mu(1, x)$ can be verified by direct calculation. \square

From now on, we use $V_\gamma^c(\cdot, \cdot)$ and $F_c(\mu, c)$ to denote the value function and Parisi functional with h replaced by h_c , which satisfies $\gamma(1) \geq \sup_{z \in \mathbb{R}} h_c''(z)$. The above proposition implies that $V_\gamma^c = V_\gamma$ and $F_c(\mu, c) = F(\mu, c)$.

We next proceed to constructing solutions to the Parisi PDE for general h .

Proposition E.10. Assume $h \in C^2(\mathbb{R})$ is Lipschitz continuous and bounded above and $(\mu, c) \in \mathcal{L}$. Then a weak solution to the PDE below exists and is unique:

$$\begin{aligned} \partial_t f_\mu(t, x) + \frac{1}{2} \mu(t) (\partial_x f_\mu(t, x))^2 + \frac{1}{2} \partial_x^2 f_\mu(t, x) &= 0, \\ f_\mu(1, x) &= \sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c} \right\}. \end{aligned} \quad (257)$$

Further, for a sequence $c_n < c$, let $f_\mu^n(t, x)$ denote the solution to the Parisi PDE with terminal condition

$$f_\mu^n(1, x) = \sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c_n} \right\}.$$

Then, we have $f_\mu^n \rightarrow f_\mu$ uniformly as $c_n \uparrow c$. Finally:

$$\|\partial_x f_\mu(t, x)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}, \quad \forall t \in [0, 1], \quad (258)$$

$$\partial_x^2 f_\mu(t, x) > -\gamma(t), \quad \forall (t, x) \in [0, 1] \times \mathbb{R}. \quad (259)$$

Proof. Let $c_n \in \mathbb{R}_+$ be a sequence such that $c_n < c$ for each n and $c_n \rightarrow c$. As in the theorem statement, denote the (weak) solution to Eq. (257) with c replaced by c_n as f_μ^n , i.e., $f_\mu^n(t, x)$ satisfies Eq. (257) with terminal condition

$$f_\mu^n(1, x) = \sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c_n} \right\}.$$

Then, from the conclusions of Appendix E.1 (cf. Proposition E.3 and Theorem E.3) we know that

$$\|\partial_x f_\mu^n(t, x)\|_{L^\infty(\mathbb{R})} \leq \|h'\|_{L^\infty(\mathbb{R})}, \quad \forall t \in [0, 1], \quad (260)$$

$$-\gamma_n(t) < \partial_x^2 f_\mu^n(t, x) \leq C_n(\mu, 2), \quad \forall (t, x) \in [0, 1] \times \mathbb{R}. \quad (261)$$

By direct calculation, we know that $f_\mu^n(1, \cdot)$ converges uniformly to $f_\mu(1, \cdot)$. According to the maximum principle (or similar to the proof of Theorem E.3 (a)), it follows that $f_\mu^n(t, \cdot)$ converges uniformly to some $f_\mu(t, \cdot)$ for all $t \in [0, 1]$. Further, since $\partial_x^2 f_\mu^n(t, x) > -\gamma_n(t)$ and the sequence $\{\partial_x f_\mu^n(t, \cdot)\}_{n \geq 1}$ is uniformly bounded in L^∞ , we know that $\partial_x f_\mu^n(t, \cdot)$ is of bounded variation on any finite interval. Using an argument similar to that in the proof of [EAMS21, Lemma 6.2], we deduce that $\partial_x f_\mu$ exists and $\partial_x f_\mu^n \rightarrow \partial_x f_\mu$ almost everywhere. As a consequence, $\partial_x f_\mu(t, \cdot)$ is of bounded variation on any finite interval as well, which implies that $\partial_x^2 f_\mu$ exists almost everywhere. Via a similar argument to the proof of [EAMS21, Lemma 6.2], we know that f_μ weakly solves the Parisi PDE (257), thus establishing existence. Uniqueness follows from the uniqueness theorem for weak solutions of the heat equation with at most linear growth (since $\partial_x f_\mu$ is bounded we know that f_μ has at most linear growth).

Further, applying Duhamel's principle implies that $\partial_x^2 f_\mu$ is continuous in x . Hence, it follows that $\forall t \in [0, 1]$, $\partial_x f_\mu(t, \cdot) \in C^1(\mathbb{R})$, and consequently $\partial_x f_\mu^n(t, \cdot)$ uniformly converges to $\partial_x f_\mu(t, \cdot)$ on any compact set (Dini's theorem). This in turns implies the estimates (258), (259), completing the proof of Proposition E.10. \square

Remark 10. Note that in the case of general h , we do not have an upper bound on $\partial_x^2 f_\mu(t, x)$ because $C_n(\mu, 2) \rightarrow \infty$ as $n \rightarrow \infty$. Since $\partial_x f_\mu(t, x)$ is bounded, the Parisi SDE has a unique solution (cf. [Che05, Proposition 1.10]), which can be approximated by the Parisi SDEs associated with f_μ^n due to Proposition F.6.

Proof of Proposition 5.4. We now prove Proposition 5.4 under the more general assumption $h \in C^2(\mathbb{R})$, Lipschitz, and bounded from above. Equation (101) follows immediately from Proposition E.9 and Proposition E.10. To see this, take a sequence $c_n < c$, with $c_n \uparrow c$, and let V_γ^n, f_μ^n be defined as in the theorem statement with h replaced by h_{c_n} , and (μ, c) replaced by (μ, c_n) . Then we have $f_\mu^n \rightarrow f_\mu$ uniformly by Proposition E.9 and Proposition E.10, and $V_\gamma^n \rightarrow V_\gamma$ uniformly by Proposition E.9 and Proposition F.2.

Next, we will construct the corresponding optimal control process $\{\phi_s^z\}_{s \in [t, 1]}$ and show that it achieves

$$V_\gamma^c(t, z) = \sup_{\phi \in D[t, 1]} \mathbb{E} \left[h_c \left(z + \int_t^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) \phi_s^2 ds \right] + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds. \quad (262)$$

One natural idea would be to use the same definition as before: $\phi_s^z = \partial_x^2 f_\mu(s, X_s^z) / \gamma(s)$, where $(X_s^z)_{s \in [t, 1]}$ solves the SDE

$$\frac{1}{\gamma(t)} \partial_x f_\mu(t, X_t^z) + X_t^z = z, \quad dX_s^z = \mu(s) \partial_x f_\mu(s, X_s^z) ds + dB_s, \quad s \in [t, 1]. \quad (263)$$

However, due to the lack of existence and a priori estimates for third or higher-order partial derivatives of f_μ with respect to x (they can not be established using Duhamel's principle or stochastic calculus techniques as before if we only assume $\mu \in L^1[0, 1]$), we are not able to show Proposition E.6 and Lemma E.7, which are crucial ingredients for carrying out the verification argument and computing the first-order variation of the Parisi functional. To circumvent this difficulty, we will construct $\{\phi_s^z\}$ via martingale representation theorem instead, and show that such defined $\{\phi_s^z\}$ has desired properties. Namely, defining

$$M_s^z = \frac{1}{\gamma(s)} \partial_x f_\mu(s, X_s^z) + X_s^z, \quad (264)$$

we then have the following:

Lemma E.11. $\{M_s^z\}_{s \in [t, 1]}$ is a square integrable martingale with respect to the standard filtration.

Proof. Without loss of generality, we assume $(t, z) = (0, 0)$, and drop the superscript “ z ” from now on. Using the definition of $\{X_s\}$, and the fact that $\partial_x f_\mu(t, \cdot)$ is bounded (by Proposition E.10) it is easy to see that $\{M_s\}$ is square integrable with $M_0 = 0$. It then remains to show that $\mathbb{E}[M_s - M_u | \mathcal{F}_u] = 0$ for any $u < s$. Since $\{X_s\}$ is a Markov process and M_s only depends on X_s , it suffices to prove that $\mathbb{E}[M_s - M_u | X_u = x] = 0$ for any $x \in \mathbb{R}$. For simplicity, we will show that $\mathbb{E}[M_s | X_0] = \mathbb{E}[M_s] = 0$, as the proof for general u and x is similar. To this end, let $\{X_s^n\}_{s \in [0, 1]}$ be the solution to the SDE:

$$\begin{aligned} dX_s^n &= \mu(s) \partial_x f_\mu^n(s, X_s^n) ds + dB_s, \\ \partial_x f_\mu^n(0, X_0^n) + \gamma(0) X_0^n &= 0, \end{aligned}$$

where f_μ^n is defined as in Proposition E.10.

According to Proposition E.6, we know that

$$M_s^n = \frac{1}{\gamma_n(s)} \partial_x f_\mu^n(s, X_s^n) + X_s^n$$

is a martingale. Hence, $\mathbb{E}[M_s^n] = 0$. Further, Proposition F.6 implies that M_s^n converges to M_s in distribution as $n \rightarrow \infty$. Now since $\{M_s^n\}_{n=1}^\infty$ is a family of uniformly integrable random variables (easily seen from its definition), we know that

$$\mathbb{E}[M_s] = \lim_{n \rightarrow \infty} \mathbb{E}[M_s^n] = 0. \quad (265)$$

This completes the proof. \square

According to martingale representation theorem, there exists $\{\phi_s^z\} \in D[t, 1]$ such that

$$M_s^z = M_t^z + \int_t^s (1 + \phi_u^z) dB_u, \quad \forall s \in [t, 1]. \quad (266)$$

The proposition below shows that $\{\phi_s^z\}_{s \in [t, 1]}$ achieves $V_\gamma^c(t, z)$:

Proposition E.12. *For $\{\phi_s^z\}_{s \in [t, 1]}$ defined as per Eq. (266), we have*

$$V_\gamma^c(t, z) = \mathbb{E} \left[h_c \left(z + \int_t^1 (1 + \phi_s^z) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) (\phi_s^z)^2 ds \right] + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds, \quad (267)$$

i.e., $\{\phi_s^z\}_{s \in [t, 1]}$ is indeed optimal.

Proof. Similar as before, we assume $(t, z) = (0, 0)$, drop the superscript “ z ”, and use $V_c(\gamma)$ as a shorthand for $V_\gamma^c(0, 0)$. Let $\phi^n \in D[0, 1]$ be the optimal control process associated with h_c and (μ, c_n) , where $c_n \rightarrow c$ from below. Then, from Section E.1.4 we know that

$$V_c(\gamma_n) = \mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t^n) dB_t \right) - \frac{1}{2} \int_0^1 \gamma_n(t) (\phi_t^n)^2 dt \right] + \frac{1}{2\alpha} \int_0^1 \gamma_n(t) dt. \quad (268)$$

Since $V_c(\gamma_n) \rightarrow V_c(\gamma)$, $\gamma_n(t) \rightarrow \gamma(t)$ in $L^\infty[0, 1]$, it suffices to show that

$$\mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t^n) dB_t \right) - \frac{1}{2} \int_0^1 \gamma_n(t) (\phi_t^n)^2 dt \right] \rightarrow \mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_0^1 \gamma(t) \phi_t^2 dt \right] \quad (269)$$

as $n \rightarrow \infty$. To this end, we will prove

$$\mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t^n) dB_t \right) \right] \rightarrow \mathbb{E} \left[h_c \left(\int_0^1 (1 + \phi_t) dB_t \right) \right] \quad (270)$$

and

$$\frac{1}{2} \int_0^1 \gamma_n(t) \mathbb{E} [(\phi_t^n)^2] dt \rightarrow \frac{1}{2} \int_0^1 \gamma(t) \mathbb{E} [\phi_t^2] dt, \quad (271)$$

respectively. First, note that

$$\int_0^1 (1 + \phi_t) dB_t = M_1, \quad \int_0^1 (1 + \phi_t^n) dB_t = M_1^n,$$

where $\{M_t^n\}_{t \in [0, 1]}$ is defined in the proof of Lemma E.11. Similarly as in that proof, we know that M_1^n is a sequence of uniformly integrable random variables that converges to M_1 in law. Since h_c is Lipschitz, we know that $\mathbb{E}[h_c(M_1^n)] \rightarrow \mathbb{E}[h_c(M_1)]$. This proves Eq. (270). To show Eq. (271), let us define

$$A(t) = \int_0^t \mathbb{E}[\phi_s^2] ds, \quad N_t = M_t - B_t, \quad \forall t \in [0, 1]. \quad (272)$$

Then, by definition, we know that $A(t) = \mathbb{E}[N_t^2]$. Further,

$$\frac{1}{2} \int_0^1 \gamma(t) \mathbb{E} [\phi_t^2] dt = \frac{1}{2} \int_0^1 \gamma(t) dA(t) = \frac{1}{2} \left(\gamma(1)A(1) - \int_0^1 \gamma'(t)A(t) dt \right). \quad (273)$$

Similarly,

$$\frac{1}{2} \int_0^1 \gamma_n(t) \mathbb{E} [(\phi_t^n)^2] dt = \frac{1}{2} \left(\gamma_n(1) A_n(1) - \int_0^1 \gamma_n'(t) A_n(t) dt \right). \quad (274)$$

Note that for all $n \in \mathbb{N}$ and $t \in [0, 1]$,

$$N_t^n = M_t^n - B_t = \frac{1}{\gamma_n(t)} \partial_x f_\mu^n(t, X_t^n) + X_t^n - B_t \quad (275)$$

$$= \frac{1}{\gamma_n(t)} \partial_x f_\mu^n(t, X_t^n) + \int_0^t \mu(s) \partial_x f_\mu^n(s, X_s^n) ds \quad (276)$$

is uniformly bounded. Applying Proposition F.6 and bounded convergence theorem, we deduce that $A_n(t) = \mathbb{E}[(N_t^n)^2] \rightarrow \mathbb{E}[N_t^2] = A(t)$ as $n \rightarrow \infty$. Further, $\gamma_n'(t) = \gamma_n(t)^2 \mu(t) \rightarrow \gamma(t)^2 \mu(t) = \gamma'(t)$, thus leading to (use dominated convergence theorem)

$$\frac{1}{2} \int_0^1 \gamma_n(t) \mathbb{E} [(\phi_t^n)^2] dt = \frac{1}{2} \left(\gamma_n(1) A_n(1) - \int_0^1 \gamma_n'(t) A_n(t) dt \right) \quad (277)$$

$$\rightarrow \frac{1}{2} \left(\gamma(1) A(1) - \int_0^1 \gamma'(t) A(t) dt \right) = \frac{1}{2} \int_0^1 \gamma(t) \mathbb{E} [\phi_t^2] dt. \quad (278)$$

This proves Eq. (271) and concludes Eq. (267). \square

Proof of Theorem 3.3 (c). Finally, we are in position to prove part (c) of Theorem 3.3: strong duality. We follow here the same approach as in Section 5.3 (and Appendix E.1.4) extending that proof to the case $\gamma(1) \leq \sup_{z \in \mathbb{R}} h''(z)$.

Fix any $(\mu, c) \in \mathcal{L}(q)$. Let $\{X_t\}_{t \in [0,1]}$ solve the Parisi SDE (114), and define $\{\phi_t\}_{t \in [0,1]}$ in the same way as the last paragraph, namely, via martingale representation. We also define

$$F(x) = \frac{1}{\gamma(q)} \partial_x f_\mu(q, x). \quad (279)$$

Then, similarly to the case $\gamma(1) > \sup_{z \in \mathbb{R}} h''(z)$, we can use Propositions 5.4, E.12, and E.12 to show that

$$F_c(\mu, c) = \mathbb{E} \left[h_c \left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{1}{2} \int_q^1 \gamma(t) \left(\phi_t^2 - \frac{1}{\alpha} \right) dt - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right], \quad (280)$$

which proves Proposition 5.5 (i).

Further, Proposition 5.5 (ii) is established by the following:

Proposition E.13. *For any $0 \leq s < t \leq 1$, we have*

$$\mathbb{E} \left[(\partial_x f_\mu(t, X_t))^2 \right] - \mathbb{E} \left[(\partial_x f_\mu(s, X_s))^2 \right] = \int_s^t \gamma(u)^2 \mathbb{E} [\phi_u^2] du. \quad (281)$$

Proof. Without loss of generality we assume $s = 0$. Recall the definition of $A_n(t)$ and $A(t)$ in the proof of Proposition E.12. Using integration by parts, we obtain that $\forall t \in [0, 1]$:

$$\begin{aligned} \int_0^t \gamma(s)^2 \mathbb{E} [\phi_s^2] ds &= \int_0^t \gamma(s)^2 dA(s) = \gamma(t)^2 A(t) - 2 \int_0^t \gamma(s) \gamma'(s) A(s) ds, \\ \int_0^t \gamma_n(s)^2 \mathbb{E} [(\phi_s^n)^2] ds &= \int_0^t \gamma_n(s)^2 dA_n(s) = \gamma_n(t)^2 A_n(t) - 2 \int_0^t \gamma_n(s) \gamma_n'(s) A_n(s) ds. \end{aligned}$$

Since $\gamma_n \rightarrow \gamma$, $\gamma'_n \rightarrow \gamma'$, $A_n \rightarrow A$, by dominated convergence theorem we know that

$$\lim_{n \rightarrow \infty} \int_0^t \gamma_n(s)^2 \mathbb{E}[(\phi_s^n)^2] ds = \int_0^t \gamma(s)^2 \mathbb{E}[\phi_s^2] ds.$$

According to Lemma E.7, we have

$$\mathbb{E}[(\partial_x f_\mu^n(t, X_t^n))^2] - \partial_x f_\mu^n(0, X_0^n)^2 = \int_0^t \gamma_n(s)^2 \mathbb{E}[(\phi_s^n)^2] ds.$$

Further, since $\partial_x f_\mu^n$ uniformly converges to $\partial_x f_\mu$ on any compact set, we know that $\partial_x f_\mu^n(t, X_t^n) \rightarrow \partial_x f_\mu(t, X_t)$ in distribution. By bounded convergence theorem,

$$\lim_{n \rightarrow \infty} \mathbb{E}[(\partial_x f_\mu^n(t, X_t^n))^2] = \mathbb{E}[(\partial_x f_\mu(t, X_t))^2].$$

This completes the proof. \square

We are now ready to establish Proposition 5.5 (iii), namely computing the first-order variation of F with respect to μ . As in the proof of Proposition 5.5 (iii) in the case $\gamma(1) > \sup_{z \in \mathbb{R}} h''(z)$ (cf. Eq. (235)), we still have

$$f_{\mu+s\delta}(0, x) - f_\mu(0, x) = \frac{s}{2} \int_0^1 \delta(t) \mathbb{E}_{X_0^s=x} [(\partial_x f_\mu(t, X_t^s))^2] dt, \quad (282)$$

where $\{X_t^s\}_{t \in [0,1]}$ solves the SDE:

$$dX_t^s = \mu(t) \frac{\partial_x f_{\mu+s\delta} + \partial_x f_\mu}{2}(t, X_t^s) dt + dB_t, \quad X_0^s = x, \quad (283)$$

since the proof of this identity does not involve third or higher-order partial derivatives of f_μ with respect to x . Then, we know that $\partial_x f_{\mu+s\delta} \rightarrow \partial_x f_\mu$ as $s \rightarrow 0$ almost everywhere, which follows from a similar argument as that in the proof of Proposition E.10, and the following facts: (a) $f_{\mu+s\delta} \rightarrow f_\mu$ uniformly as $s \rightarrow 0$, which can be established using Feynman-Kac formula, see also in the proof of Theorem E.2 and [JT16, Lemma 14]; (b) $\partial_x f_{\mu+s\delta}$ and $\partial_x f_\mu$ are continuous, uniformly bounded, and of bounded variation on any finite interval, which follows from Proposition E.10. As a consequence, we deduce similarly that

$$\left. \frac{d}{ds} f_{\mu+s\delta}(0, x) \right|_{s=0} = \frac{1}{2} \int_0^1 \delta(t) \mathbb{E}_{X_0=x} [(\partial_x f_\mu(t, X_t))^2] dt, \quad (284)$$

which concludes the calculation, as the first-order variation of the entropy term $S(\mu)$ is still the same, cf. Eqs. (232) and (233).

However, in this case, we need to compute the first derivative of $F(\mu, c) = F_c(\mu, c)$ with respect to c for fixed μ as well, which is summarized in the following lemma:

Lemma E.14 (First derivative with respect to c). *We have (note that the derivative is taken with respect to the “ c ” in both the subscript and the second argument of $F_c(\mu, c)$)*

$$\frac{d}{dc} F(\mu, c) = \frac{d}{dc} F_c(\mu, c) = \mathbb{E}[g_c(M_1)] + \frac{1}{2} \mathbb{E}[\partial_x f_\mu(1, X_1)^2] - \frac{1}{2\alpha} \int_0^1 \gamma(t)^2 dt, \quad (285)$$

where we recall that M_t is the martingale defined by Eq. (264) and $g_c(x) := (\partial/\partial c)h_c(x)$.

Proof. We denote by f_μ^c the solution to Parisi PDE (257) to emphasize its dependence on c . Recall

$$F_c(\mu, c) = f_\mu^c(0, 0) + \frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds}. \quad (286)$$

By dominated convergence theorem, we know that

$$\frac{d}{dc} \left(\frac{1}{2\alpha} \int_0^1 \frac{dt}{c + \int_t^1 \mu(s) ds} \right) = \frac{1}{2\alpha} \int_0^1 -\frac{dt}{(c + \int_t^1 \mu(s) ds)^2} = -\frac{1}{2\alpha} \int_0^1 \gamma(t)^2 dt. \quad (287)$$

It then suffices to compute $df_\mu^c(0, x)/dc$ for each $x \in \mathbb{R}$, then we can just take $x = 0$. Using stochastic calculus, we know that for $c, c' > 0$,

$$f_\mu^{c'}(0, x) - f_\mu^c(0, x) = \mathbb{E}_{X'_0=x} \left[\left(f_\mu^{c'} - f_\mu^c \right) (1, X'_1) \right], \quad (288)$$

where $\{X'_t\}_{t \in [0,1]}$ solves the SDE

$$dX'_t = \frac{1}{2} \mu(t) \left(\partial_x f_\mu^c + \partial_x f_\mu^{c'} \right) (t, X'_t) dt + dB_t, \quad X'_0 = x. \quad (289)$$

As $c' \rightarrow c$, we know that $f_\mu^{c'}$ converges uniformly to f_μ^c , which follows from a similar argument as in the proof of Proposition E.10. Further since $\partial_x f_\mu^{c'}$ and $\partial_x f_\mu^c$ are continuous and have bounded total variation on any finite interval, we deduce (similarly as before) that $\partial_x f_\mu^{c'} \rightarrow \partial_x f_\mu^c$. Applying Proposition F.6 implies that $\{X'_t\}$ converges in law to $\{X_t\}$, the solution to the Parisi SDE. As a special case, X'_1 converges in law to X_1 . According to Lemma F.4, we know that

$$\partial_c f_\mu^c(1, x) = g_c \left(x + c \partial_x f_\mu^c(1, x) \right) + \frac{(\partial_x f_\mu^c(1, x))^2}{2},$$

which is bounded and continuous. Further, one can show that the above convergence is uniform on any compact set in \mathbb{R} . As a consequence, applying continuous mapping theorem and bounded convergence theorem yields that

$$\begin{aligned} \frac{df_\mu^c(0, x)}{dc} &= \lim_{c' \rightarrow c} \frac{f_\mu^{c'}(0, x) - f_\mu^c(0, x)}{c' - c} \\ &= \lim_{c' \rightarrow c} \mathbb{E}_{X'_0=x} \left[\left(\frac{f_\mu^{c'} - f_\mu^c}{c' - c} \right) (1, X'_1) \right] \\ &= \mathbb{E}_{X_0=x} \left[g_c \left(X_1 + c \partial_x f_\mu^c(1, X_1) \right) \right] + \frac{1}{2} \mathbb{E}_{X_0=x} \left[\partial_x f_\mu^c(1, X_1)^2 \right]. \end{aligned}$$

Choosing $x = 0$, and noting that

$$M_1 = \frac{1}{\gamma(1)} \partial_x f_\mu^c(1, X_1) + X_1 = X_1 + c \partial_x f_\mu^c(1, X_1)$$

(since $c = 1/\gamma(1)$) completes the proof. \square

We are now ready to prove the part (c) of Theorem 3.3. Assume that $\inf_{(\mu, c) \in \mathcal{L}(q)} F_c(\mu, c)$ is achieved at some (μ_*, c_*) . For notational simplicity, we recast (μ_*, c_*) as (μ, c) , and denote

the associated (F^*, ϕ^*) by (F, ϕ) . Exploiting the expressions for the first-order variation of F_c (Proposition 5.5 (iii) and Lemma E.14), we obtain that

$$\mathbb{E} \left[(\partial_x f_\mu(t, X_t))^2 \right] - \frac{1}{\alpha} \int_0^t \gamma(s)^2 ds = 0, \quad \forall t \in [q, 1], \quad (290)$$

$$\mathbb{E} [g_c(M_1)] + \frac{1}{2} \mathbb{E} [\partial_x f_\mu(1, X_1)^2] - \frac{1}{2\alpha} \int_0^1 \gamma(t)^2 dt = 0, \quad (291)$$

which further implies $\mathbb{E}[g_c(M_1)] = 0$. Applying Proposition E.13, we get, using the fact that $\gamma(t) > 0$ for all $t \in [0, 1]$,

$$\mathbb{E}[\phi_t^2] = \frac{1}{\alpha}, \quad \text{a.e. } t \in [q, 1]. \quad (292)$$

Then, there exists a modification of $\{\phi_t\}$ (still denoted as $\{\phi_t\}$) such that $\mathbb{E}[\phi_t^2] = 1/\alpha$ for all $t \in [q, 1]$. Therefore, $\{\phi_t\}_{t \in [q, 1]}$ is feasible. As a consequence, using Eq. (280), we deduce that

$$F(\mu, c) = F_c(\mu, c) = \mathbb{E} \left[h_c \left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right] \quad (293)$$

$$= \mathbb{E} \left[h_c(M_1) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right]. \quad (294)$$

Next, we claim that $\mathbb{E}[h_c(M_1)] = \mathbb{E}[h(M_1)]$. To see this, note that since g_c is non-negative, $\mathbb{E}[g_c(M_1)] = 0$ implies that $g_c(M_1) = 0$ almost surely. Hence, $h_c(M_1) = h(M_1)$ almost surely (use Proposition F.5), and consequently $\mathbb{E}[h_c(M_1)] = \mathbb{E}[h(M_1)]$. We thus conclude that

$$F(\mu, c) = \mathbb{E} \left[h(M_1) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right] \quad (295)$$

$$= \mathbb{E} \left[h \left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t \right) - \frac{\gamma(q)}{2} \left(F(X_q)^2 - \frac{q}{\alpha} \right) \right]. \quad (296)$$

It now remains to show that F is feasible. By definition, we have

$$\mathbb{E} [F(v)^2] = \frac{1}{\gamma(q)^2} \mathbb{E} \left[(\partial_x f_\mu(q, X_q))^2 \right] = \frac{1}{\alpha \gamma(q)^2} \int_0^q \gamma(s)^2 ds = \frac{q}{\alpha}, \quad (297)$$

since γ is constant on $[0, q]$. This immediately implies that

$$F(\mu, c) = \mathbb{E} [h(M_1)] = \mathbb{E} \left[h \left(X_q + F(X_q) + \int_q^1 (1 + \phi_t) dB_t \right) \right]. \quad (298)$$

Namely, (μ, c) achieves the optimal value.

However, here we cannot directly conclude $\mathbb{E}[F'(v)^2] \leq 1/\alpha$ from the feasibility of ϕ , since ϕ is not defined in terms of F' . To circumvent this issue, we use the same standard approximation argument as before, i.e., approximating (μ, c) by a sequence $\{(\mu, c_n)\}_{n \geq 1}$ with $c_n \rightarrow c^-$. Denoting the corresponding solution to the Parisi PDE by f_μ^n , we define (note that ϕ^n is defined via $\partial_x^2 f_\mu^n$ since $c_n < c$)

$$F_n(x) = \frac{1}{\gamma_n(q)} \partial_x f_\mu^n(q, x), \quad \phi_t^n = \frac{1}{\gamma_n(t)} \partial_x^2 f_\mu^n(t, X_t^n), \quad \forall t \in [0, 1], \quad (299)$$

where X^n is the solution to the corresponding Parisi SDE. Then, we know that $\mathbb{E}[F'_n(v)^2] = \mathbb{E}[(\phi_q^n)^2]$, and $F_n \rightarrow F$ uniformly on any compact set. Further, Proposition E.13 and Itô's isometry together

imply that $\mathbb{E}[(\phi_t^n)^2] \rightarrow \mathbb{E}[\phi_t^2]$ as $n \rightarrow \infty$. To show that $\mathbb{E}[F'(v)^2] \leq 1/\alpha$, it suffices to establish that for any test function $\psi \in C_c^\infty(\mathbb{R})$:

$$|\mathbb{E}[F'(v)\psi(v)]| \leq \frac{1}{\sqrt{\alpha}} \mathbb{E}[\psi(v)^2]^{1/2}. \quad (300)$$

Using integration by parts, we know that $\mathbb{E}[F'_n(v)\psi(v)]$ converges to $\mathbb{E}[F'(v)\psi(v)]$ as $n \rightarrow \infty$. Further, Cauchy-Schwarz inequality implies that

$$|\mathbb{E}[F'_n(v)\psi(v)]| \leq \mathbb{E}[F'_n(v)^2]^{1/2} \mathbb{E}[\psi(v)^2]^{1/2} = \mathbb{E}[(\phi_q^n)^2]^{1/2} \mathbb{E}[\psi(v)^2]^{1/2}. \quad (301)$$

Taking the limit $n \rightarrow \infty$, we obtain that

$$|\mathbb{E}[F'(v)\psi(v)]| \leq \mathbb{E}[(\phi_q)^2]^{1/2} \mathbb{E}[\psi(v)^2]^{1/2}. \quad (302)$$

The feasibility of F' then follows from the feasibility of ϕ and Eq. (300). This completes the proof.

F Technical lemmas

We begin with a lemma that underpins the proof of Theorem 1.1.

Lemma F.1. *Let E be a locally convex topological vector space with topological dual E' , which is equipped with the weak* topology. Then, every continuous linear functional $\phi : E' \rightarrow \mathbb{R}$ or \mathbb{C} is of the form $f \mapsto f(e)$ for some $e \in E$. In other words,*

$$(E', \text{weak}^*)^* = E.$$

Proof. Since ϕ is continuous, the set $U = \{f \in E' : |\phi(f)| < 1\}$ is an open neighborhood of the origin. Recalling the definition of the weak* topology in E' , we conclude that there exists $e_1, \dots, e_n \in E$ and $\varepsilon > 0$ such that

$$V = \{f \in E' : |f(e_i)| < \varepsilon, i = 1, \dots, n\} \subset U.$$

Now we define $\phi_i(f) = f(e_i)$. Note that if $\phi_i(f) = 0, \forall i$, then $Mf \in V$ for all $M > 0$, hence $Mf \in U$ and $|\phi(f)| < 1/M$. Letting $M \rightarrow \infty$ gives $\phi(f) = 0$. This proves

$$\bigcap_{i=1}^n \ker(\phi_i) \subset \ker(\phi).$$

From linear algebra we deduce that $\phi = \sum_{i=1}^n \lambda_i \phi_i$ for some $\lambda_i \in \mathbb{R}$ or \mathbb{C} . Therefore,

$$\phi(f) = \sum_{i=1}^n \lambda_i \phi_i(f) = \sum_{i=1}^n \lambda_i f(e_i) = f\left(\sum_{i=1}^n \lambda_i e_i\right).$$

Taking $e = \sum_{i=1}^n \lambda_i e_i \in E$ closes the argument. \square

The proposition below presents some analytical properties of $V_\gamma(t, z)$ (defined in Eq. (175)) as a function of γ with fixed t, z .

Proposition F.2 (Properties of V_γ). *Fix t and z , then $\gamma \mapsto V_\gamma(t, z)$ is convex and lower semicontinuous with respect to the L^∞ -norm. Further, let $\gamma_0 \in L_\infty^+[0, 1]$ be such that $\inf_{t \in [0, 1]} \gamma_0(t) > 0$, then V_γ is continuous at γ_0 with respect to the L^∞ -norm.*

Proof. The convexity follows directly from the definition of V_γ , since it is the pointwise supremum of linear functionals. For lower semicontinuity, note that we the supremum is over adapted processes that are square-integrable, c.f. Eq. (8), and therefore the supremum is over linear functionals that are continuous in L^∞ -norm.

To prove the second part, let $\gamma_n \xrightarrow{L^\infty} \gamma_0$, then we know that $\inf_{t \in [0,1]} \gamma_n(t) \geq \inf_{t \in [0,1]} \gamma_0(t)/2 > 0$ for sufficiently large n . As a consequence, there exists a constant $C_0 > 0$ such that

$$V_\gamma(t, z) = \sup_{\int_t^1 \mathbb{E}[\phi_s^2] ds \leq C_0} \mathbb{E} \left[h \left(z + \int_t^1 (1 + \phi_s) dB_s \right) - \frac{1}{2} \int_t^1 \gamma(s) \phi_s^2 ds \right] + \frac{1}{2\alpha} \int_t^1 \gamma(s) ds$$

for $\gamma = \gamma_n$ or γ_0 . We thus obtain that

$$|V_{\gamma_n}(t, z) - V_{\gamma_0}(t, z)| \leq \frac{1}{2} \left(C_0 + \frac{1}{\alpha} \right) \|\gamma_n - \gamma_0\|_{L^\infty[0,1]}.$$

This completes the proof. In fact, we even proved a stronger statement: V_γ is locally Lipschitz at the interior of $L_\infty^+[0, 1]$. \square

We collect below a few useful properties of the functions h_c and $f_\mu^c(1, \cdot)$. Recall that

$$h_c(z) = \text{conc} \left(h(z) - \frac{z^2}{2c} \right) + \frac{z^2}{2c}, \quad f_\mu^c(1, x) = \sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c} \right\}.$$

The following lemma gives a variational representation for the concave envelope of a function.

Lemma F.3. *Let $h \in C(\mathbb{R})$ be upper bounded, denote by $\text{conc } h$ the concave envelope of h , then*

$$\text{conc } h(z) = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=0} \mathbb{E}[h(z + U)]. \quad (303)$$

As a consequence, we have

$$\text{conc} \left(h(z) - \frac{t}{2} z^2 \right) + \frac{t}{2} z^2 = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=0} \mathbb{E} \left[h(z + U) - \frac{t}{2} U^2 \right]. \quad (304)$$

Proof. Since h is upper bounded, we know that the right hand side of Eq. (303) is well-defined and upper bounded. Let us denote

$$g(z) = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=0} \mathbb{E}[h(z + U)] = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=z} \mathbb{E}[h(U)],$$

then obviously we have $g(z) \geq h(z)$. Next we show that g is concave. Fix $z_1, z_2 \in \mathbb{R}$ and $\alpha \in [0, 1]$, $\forall \varepsilon > 0$ there exists $U_1, U_2 \in L^2(\Omega)$ such that $\mathbb{E}[U_1] = z_1$, $\mathbb{E}[U_2] = z_2$, and

$$g(z_1) \leq \mathbb{E}[h(U_1)] + \varepsilon, \quad g(z_2) \leq \mathbb{E}[h(U_2)] + \varepsilon.$$

Now we define a new random variable $U \in L^2(\Omega)$ by requiring

$$\mathbb{P}(U = U_1) = \alpha, \quad \mathbb{P}(U = U_2) = 1 - \alpha,$$

it follows that $\mathbb{E}[U] = \alpha z_1 + (1 - \alpha) z_2$, thus leading to

$$g(\alpha z_1 + (1 - \alpha) z_2) \geq \mathbb{E}[h(U)] = \alpha \mathbb{E}[h(U_1)] + (1 - \alpha) \mathbb{E}[h(U_2)] \geq \alpha g(z_1) + (1 - \alpha) g(z_2) - \varepsilon.$$

Since $\varepsilon > 0$ can be arbitrary, we finally deduce that $g(\alpha z_1 + (1 - \alpha)z_2) \geq \alpha g(z_1) + (1 - \alpha)g(z_2)$. Therefore, g is concave. It finally remains to show that g is the smallest concave function that dominates h . To this end, assume $f \geq h$ is concave, then for any $U \in L^2(\Omega)$ with $\mathbb{E}[U] = z$, we deduce from Jensen's inequality:

$$\mathbb{E}[h(U)] \leq \mathbb{E}[f(U)] \leq f(\mathbb{E}[U]) = f(z).$$

Taking supremum over all such random variable U yields that $g(z) \leq f(z)$. We have thus established that $g = \text{conc } h$. The “as a consequence” part follows by direct calculation. \square

Lemma F.4. *For any $x \in \mathbb{R}$ and $c > 0$, define $g_c(x) = (\partial/\partial c)h_c(x)$ (existence is guaranteed by monotonicity and convexity with respect to $1/c$). Then, we have*

$$\frac{d}{dc}f_\mu^c(1, x) = g_c(x + c\partial_x f_\mu^c(1, x)) + \frac{(\partial_x f_\mu^c(1, x))^2}{2}. \quad (305)$$

Proof. By definition of $f_\mu^c(1, x)$ and the envelope theorem, we obtain

$$\frac{d}{dc}f_\mu^c(1, x) = \frac{d}{dc} \left(\sup_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c} \right\} \right) = g_c(x + u(c, x)) + \frac{u(c, x)^2}{2c^2}, \quad (306)$$

where

$$u(c, x) \in \operatorname{argmax}_{u \in \mathbb{R}} \left\{ h_c(x + u) - \frac{u^2}{2c} \right\}.$$

The above optimization problem is concave, and its first-order condition reads

$$h'_c(x + u(c, x)) = \frac{u(c, x)}{c}.$$

Further, by duality, we know that one can take $u(c, x) = c\partial_x f_\mu^c(1, x)$. Now since h'_c is uniformly bounded, it follows that as long as c is bounded away from 0, $\frac{d}{dc}f_\mu^c(1, x)$ is bounded. This completes the proof. \square

Proposition F.5. *Fix $x \in \mathbb{R}$, then $h_c(x) = h(x)$ if and only if $g_c(x) = 0$.*

Proof. By definition, we know that for any $c_1 \leq c_2$, $h_{c_1}(x) \leq h_{c_2}(x)$. Further, $h(x) = h_0(x) = \lim_{c \rightarrow 0^+} h_c(x)$. We first prove the “only if” part. Assume $h_c(x) = h(x)$, then by monotonicity, $h_{c'}(x) = h_c(x)$ for any $c' \leq c$, which implies $g_c(x) = 0$ since $h_c(x)$ is differentiable in c . To show the “if” part, define for $t > 0$:

$$\varphi(t) = h_{1/t}(x) = \text{conc} \left(h(x) - \frac{t}{2}x^2 \right) + \frac{t}{2}x^2. \quad (307)$$

Then, we know that $\varphi(1/c) = \varphi(+\infty)$. Further, Lemma F.3 implies that

$$\varphi(t) = \sup_{U \in L^2(\Omega), \mathbb{E}[U]=0} \mathbb{E} \left[h(x + U) - \frac{t}{2}U^2 \right] \quad (308)$$

is convex and continuous in t . Now since $\varphi'(1/c) = g_c(x) = 0$, we know that $\varphi'(t) \geq 0$ for all $t \geq 1/c$, which implies that φ is increasing on $[1/c, +\infty]$. However, we know that φ is non-increasing, by (308). Therefore, φ must be constant on $[1/c, +\infty]$, which implies $\varphi(1/c) = \varphi(+\infty)$, i.e., $h_c(x) = h(x)$. This concludes the proof. \square

Remark 11. Note that if $\varphi \in C(\mathbb{R})$ is lower bounded, then $\varphi^{**} = \text{conv } \varphi$ is the convex envelope of φ , i.e., the greatest convex function dominated by φ (see for example [Tou05, Thm. 10]). Here, $*$ denotes the Legendre-Fenchel transformation. Therefore, $\text{conc } h = -\text{conv}(-h) = -(-h)^{**}$.

The proposition below is crucial to a number of approximation arguments in Appendix E.

Proposition F.6. *Let $\{g_n\}_{n=1}^\infty$ and g be measurable functions defined on $[0, 1] \times \mathbb{R}$, satisfying*

- (a) $\forall t \in [0, 1]$, $g_n(t, \cdot)$ and $g(t, \cdot) : \mathbb{R} \rightarrow \mathbb{R}$ are continuous functions.
- (b) There exists a function $m \in L^1[0, 1]$, such that $|g_n(t, x)| \leq m(t)$ and $|g(t, x)| \leq m(t)$ for all $(t, x) \in [0, 1] \times \mathbb{R}$.
- (c) $g_n(t, x) \rightarrow g(t, x)$ for all $(t, x) \in [0, 1] \times \mathbb{R}$.

Assume $\{x_n\}_{n=1}^\infty$ is a sequence of real numbers converging to $x \in \mathbb{R}$, consider the SDEs (strong existence and pathwise uniqueness guaranteed by Proposition 1.10 of [Che05])

$$dX_t^n = g_n(t, X_t^n)dt + dB_t, \quad X_0^n = x_n, \quad (309)$$

$$dX_t = g(t, X_t)dt + dB_t, \quad X_0 = x. \quad (310)$$

Then, we have $\text{Law}((X_t^n)_{t \in [0, 1]})$ weakly converges to $\text{Law}((X_t)_{t \in [0, 1]})$ as $n \rightarrow \infty$, where $(X_t^n)_{t \in [0, 1]}$ and $(X_t)_{t \in [0, 1]}$ are viewed as random elements in $C[0, 1]$.

Proof. We first show that $\{X^n\}_{n=1}^\infty$ is a tight sequence of $C[0, 1]$ -valued random variables. First, it is obvious that $X_0^n = x_n$ is a tight sequence of random variables. Next, note that $\forall s \leq t \in [0, 1]$,

$$|X_t^n - X_s^n| = \left| \int_s^t g_n(u, X_u^n)du + B_t - B_s \right| \leq \int_s^t m(u)du + |B_t - B_s|, \quad (311)$$

which implies that for any $\epsilon > 0$ and $\eta > 0$, there is some $\delta > 0$ such that for all large enough n (depending on ϵ and η),

$$\mathbb{P}(\omega_{X^n}(\delta) > \eta) \leq \epsilon,$$

where

$$\omega_f(\delta) := \sup\{|f(s) - f(t)| : 0 \leq s, t \leq 1, |s - t| \leq \delta\}$$

defines the modulus of continuity for any $f \in C[0, 1]$. This proves that $\{X^n\}_{n=1}^\infty$ is tight (cf. [Mit83]). As a consequence, any subsequence of $\{X^{n_k}\}_{k=1}^\infty$ has a further subsequence that converges in distribution. It thus suffices to show that any such weak limit must be equal to $\text{Law}(\{X_t\}_{t \in [0, 1]})$. For simplicity, we still denote this subsequence by $\{X^n\}_{n=1}^\infty$. According to Skorokhod's representation theorem, we may assume without loss of generality that each X^n satisfies

$$dX_t^n = g_n(t, X_t^n)dt + dB_t^n, \quad X_0^n = x_n, \quad (312)$$

where B^n can possibly be different standard Brownian motions, and X^n converges to some $Y \in C[0, 1]$ almost surely. Exploiting the SDE observed by X^n , we get that

$$X_t^n = x_n + \int_0^t g_n(s, X_s^n)ds + B_t^n, \quad \forall t \in [0, 1]. \quad (313)$$

By our assumption, on the event $X^n \rightarrow Y$, we have $g_n(t, X_t^n) \rightarrow g(t, Y_t)$ for all $t \in [0, 1]$ as $n \rightarrow \infty$, since g_n converges to g and g is continuous. Using dominated convergence theorem (g_n and g are dominated by m), it follows that

$$x_n + \int_0^t g_n(s, X_s^n)ds \rightarrow x + \int_0^t g(s, Y_s)ds, \quad \forall t \in [0, 1].$$

As a consequence, $\{B^n\}_{n=1}^\infty$ converges to some $B \in C[0, 1]$ almost surely. Of course, B is a standard Brownian motion, which finally leads to the SDE

$$Y_t = x + \int_0^t g(s, Y_s) ds + B_t, \quad \forall t \in [0, 1]. \quad (314)$$

By uniqueness, we must have $\text{Law}(Y) = \text{Law}(X)$. This concludes the proof. \square

Remark 12. If we have stronger assumption, e.g., $\{g_n\}$ are uniformly Lipschitz in x and $g_n \rightarrow g$ uniformly on any compact set, then we can show that $X^n \rightarrow X$ in $C[0, 1]$ almost surely as $n \rightarrow \infty$. However, the weak convergence of Proposition [F.6](#) is adequate for our purpose.
