# IMPROVED STABILITY FOR THE SIZE AND STRUCTURE OF SUMSETS 

ANDREW GRANVILLE, JACK SMITH, AND ALED WALKER

#### Abstract

Let $A \subset \mathbb{Z}^{d}$ be a finite set. It is known that the sumset $N A$ has predictable size $\left(|N A|=P_{A}(N)\right.$ for some $\left.P_{A}(X) \in \mathbb{Q}[X]\right)$ and structure (all of the lattice points in some finite cone other than all of the lattice points in a finite collection of exceptional subcones), once $N$ is larger than some threshold. In previous work, joint with Shakan, the first and third named authors established the first effective bounds for both of these thresholds for an arbitrary set $A$. In this article we substantially improve each of these bounds, coming much closer to the corresponding lower bounds known.

## 1. Introduction

Let $A \subset \mathbb{Z}^{d}$ be a finite set, and for each positive integer $N$ consider the sumset

$$
N A:=\left\{a_{1}+\cdots+a_{N}: a_{i} \in A \text { for all } i\right\} .
$$

When $N$ is sufficiently large, $N A$ becomes rigidly structured. In this article we study two indicators of such structure, establishing that the values of $N$ which are "sufficiently large" are not too large (and indeed are near to what we would guess are the smallest such $N$ ).

The first notion involves the size $|N A|$. Start with the convex hull of $A$, denoted

$$
H(A):=\left\{\sum_{a \in A} c_{a} a: \text { Each } c_{a} \in \mathbb{R}_{\geqslant 0}, \sum_{a \in A} c_{a}=1\right\} .
$$

Certainly $N A \subset N H(A) \cap \mathbb{Z}^{d}$, and therefore $|N A| \leqslant\left|N H(A) \cap \mathbb{Z}^{d}\right|$. Ehrhart showed ([5] [1, Theorem 3.8]) that there is a polynomial $R_{A} \in \mathbb{Q}[X]$ of degree at most $d$ for which

$$
\left|N H(A) \cap \mathbb{Z}^{d}\right|=R_{A}(N)
$$

for all positive integers $N$. Therefore $|N A| \leq R_{A}(N)$ for all $N$ but one can readily find examples for which $|N A|<R_{A}(N)$ for all $N$ : for instance, if $d=1$ and $A=\{0,3,5\}$ then $H(A)=[0,5]$ and $|N A|=5 N-5<R_{A}(N)=5 N+1$ for all $N \geqslant 3$.

Even though $|N A|$ is not equal to the Ehrhart polynomial in this example, it is still equal to a polynomial in $N$ once $N$ is sufficiently large. This was established when $A \subset \mathbb{Z}$ by Nathanson [13], using an explicit combinatorial argument and, remarkably, this holds in arbitrary dimension:

Theorem 1.1 (Khovanskii [10]). Let $A \subset \mathbb{Z}^{d}$ be finite. There is a polynomial $P_{A} \in \mathbb{Q}[X]$ of degree at most d, and a threshold $N_{\mathrm{Kh}}(A)$, such that $|N A|=P_{A}(N)$ provided $N \geqslant N_{\mathrm{Kh}}(A)$.

Khovanskii's proof related the sequence $N \mapsto|N A|$ to the Hilbert function of a certain graded module over the polynomial ring $\mathbb{C}\left[X_{1}, \ldots, X_{\ell}\right]$ (where $\ell=|A|$ ), and so agrees with the Hilbert polynomial of the graded module once $N \geq N_{\mathrm{Kh}}(A)$. But Hilbert's proof [6, Theorem 1.11] does not yield an explicit bound on $N_{\mathrm{Kh}}(A)$. Nathanson and Ruzsa [14] later gave a combinatorial proof of Theorem [1.1, but this did not provide an effective bound on $N_{\mathrm{Kh}}(A)$ either, relying on the following well-known principle (proved in [7, Lemma 5], say).

Lemma 1.2 (The Mann-Dickson Lemma). For any $S \subset \mathbb{Z}_{\geqslant 0}^{d}$ there exists a finite subset $S_{\min } \subset S$ such that for all $s \in S$ there exists $x \in S_{\min }$ with $s-x \in \mathbb{Z}_{\geqslant 0}^{d}$.

Prior to 2021, explicit bounds were known when $d=1$ ([13, 18, 7, 9], with the strongest results in [11]); when $H(A)$ is a $d$-simplex ([4], with a refinement in [8]); or when $H(A)$ is $d$-dimensional and $|A|=d+1$ or $d+2$ (4], with a refinement in [8]).

The first and third named authors, with Shakan in [8, proved the first effective bounds for arbitrary $d$ and arbitrary $A \subset \mathbb{Z}^{d}$ showing in [8, Theorem 1.1] that

$$
\begin{equation*}
N_{\mathrm{Kh}}(A) \leqslant(2|A| \cdot \operatorname{width}(A))^{(d+4)|A|} \tag{1.1}
\end{equation*}
$$

where $\operatorname{width}(A):=\max _{a_{1}, a_{2} \in A}\left\|a_{1}-a_{2}\right\|_{\infty}$ is the 'width' of $A$. The proof used a complicated explicit linear algebra argument to bound $\left|S_{\text {min }}\right|$ in the cases that the Nathanson-Ruszsa argument required.

By returning to Khovanskii's original approach, and adapting techniques in Gröbner bases from [16, Chapter 4] as applied to toric ideals, we have been able to greatly improve (1.1). To state the new bound, we define two quantities that will occur frequently throughout.
Definition 1.3. If $A=\left\{a_{1}, \ldots, a_{\ell}\right\} \subset \mathbb{Z}^{d}$, we define

$$
\begin{aligned}
& \operatorname{Vol}^{\dagger, \text { max }}(H(A)):=\max _{\left\{i_{0}, i_{1}, \ldots, i_{d}\right\} \subset\{1, \ldots, \ell\}}\left|\operatorname{det}\left(a_{i_{1}}-a_{i_{0}}, \cdots, a_{i_{d}}-a_{i_{0}}\right)\right| \\
& \operatorname{Vol}^{\dagger, \min }(H(A)):=\min _{\substack{\left\{i_{0}, i_{1}, \ldots, i_{d}\right\} \subset\{1, \ldots, \ell\} \\
\operatorname{det}\left(a_{\left.i_{1}-a_{i_{0}}, \cdots, a_{i_{d}}-a_{i_{0}}\right)}\right) \neq 0}}\left|\operatorname{det}\left(a_{i_{1}}-a_{i_{0}}, \cdots, a_{i_{d}}-a_{i_{0}}\right)\right| .
\end{aligned}
$$

Remark 1.4. Note that $\frac{1}{d!} \operatorname{Vol}^{\dagger, \text { max }}(H(A))$ is equal to the volume of the largest $d$-simplex subtended by elements of $A$. In particular $\operatorname{Vol}^{\dagger, \text { max }}(H(A)) \leqslant d!\operatorname{Vol}(H(A))$. By Hadamard's inequality we also have $\operatorname{Vol}^{\dagger, \text { max }}(H(A)) \leqslant d^{d / 2} \operatorname{width}(A)^{d}$.

Letting $\Lambda_{A-A} \subset \mathbb{Z}^{d}$ denote the lattice generated by $A-A$, our first result is as follows.
Theorem 1.5 (Improved Khovanskii threshold). Suppose that $A \subset \mathbb{Z}^{d}$ is finite and that $\Lambda_{A-A}$ is d-dimensional. Then

$$
\begin{equation*}
N_{\mathrm{Kh}}(A) \leqslant|A|^{2} \operatorname{Vol}^{\dagger, m a x}(H(A))-|A|+1 \tag{1.2}
\end{equation*}
$$

Our proof is motivated by notions in algebraic geometry (as in [16, Chapter 4]), but we present a simpler, more-or-less equivalent, formulation using only linear algebra. This will be useful when considering the second notion of structure for $N A$, discussed below.

Theorem 1.5 implies the upper bounds

$$
N_{\mathrm{Kh}}(A) \leqslant d!|A|^{2} \operatorname{Vol}(H(A))-|A|+1
$$

and

$$
N_{\mathrm{Kh}}(A) \leqslant|A|^{2} d^{d / 2} \operatorname{width}(A)^{d}-|A|+1,
$$

indicating the scale of improvement over (1.1). These may be compared with lower bounds. For example, when $|A|=d+2$ and $\Lambda_{A-A}=\mathbb{Z}^{d}$ it was shown in [4, Theorem 1.2] that $N_{\mathrm{Kh}}(A)=d!\operatorname{Vol}(H(A))-d-1$. This means that Theorem 1.5 is optimal up to the $|A|^{2}$ term (and the $|A|^{2}$ term in (1.2) cannot be replaced by 1 , as $\operatorname{Vol}^{\dagger}{ }^{\dagger, m a x}(H(A))<d!\operatorname{Vol}(H(A))$ for some sets with $|A|=d+2$ ).

The bound on $N_{\mathrm{Kh}}(A)$ is related to an influential conjecture in algebraic geometry called the Eisenbud-Goto regularity conjecture [12]. Though now known to be false in full generality, the conjecture may still be true for projective toric varieties, which is the relevant case for bounding $N_{\mathrm{Kh}}(A)$. A proof of this case of the conjecture would imply $N_{\mathrm{Kh}}(A) \leqslant d!\operatorname{Vol}(H(A))-|A|+O_{d}(1)$ which, given the above comments on the bounds when $|A|=d+2$, would be essentially optimal. We direct the interested reader to [17, Conjectures 4.1 and 4.2], also available at [15], and to [16, Chapter 4].

For the second notion of structure, we consider the inclusion $N A \subset N H(A) \cap \mathbb{Z}^{d}$ in more detail, an inclusion introduced in [7], with antecedents in Khovanskii's original paper [10].

Let $\operatorname{ex}(H(A)) \subset A$ denote the set of extremal points of the polytope $H(A)$, and translate $A$ so that $0 \in \operatorname{ex}(H(A))$ and $\Lambda_{A}=\mathbb{Z}^{d}$, without loss of generality. Then $N H(A) \subset C_{A}$ where

$$
C_{A}:=\left\{\sum_{a \in A} c_{a} a: c_{a} \in \mathbb{R}_{\geqslant 0} \text { for all } a\right\}
$$

is the cone generated by $A$, and the semigroup generated by $A$ is the nested union (as $0 \in A$ )

$$
\mathcal{P}(A):=\bigcup_{N=1}^{\infty} N A \subset C_{A} \cap \mathbb{Z}^{d}
$$

The set of exceptional elements are those lattice points in $C_{A}$ which do not belong to $\mathcal{P}(A)$,

$$
\mathcal{E}(A):=\left(C_{A} \cap \mathbb{Z}^{d}\right) \backslash \mathcal{P}(A)
$$

and so

$$
N A \subset\left(N H(A) \cap \mathbb{Z}^{d}\right) \backslash \mathcal{E}(A)
$$

Similarly, for all $a \in \operatorname{ex}(H(A))$ we have $0 \in a-\operatorname{ex}(H(A))=\operatorname{ex}(H(a-A))$. Since $\Lambda_{a-A}=\mathbb{Z}^{d}$ too, we have

$$
N(a-A) \subset\left(N H(a-A) \cap \mathbb{Z}^{d}\right) \backslash \mathcal{E}(a-A)
$$

Rearranging and taking the intersection over all $a \in \operatorname{ex}(H(A))$, we get

$$
\begin{equation*}
N A \subset\left(N H(A) \cap \mathbb{Z}^{d}\right) \backslash\left(\bigcup_{a \in \operatorname{ex}(H(A))}(a N-\mathcal{E}(a-A))\right) \tag{1.3}
\end{equation*}
$$

It was shown in [7] that there is equality in (1.3) once $N \geqslant N_{\mathrm{Str}}(A)$; that is

$$
\begin{equation*}
N A=\left(N H(A) \cap \mathbb{Z}^{d}\right) \backslash\left(\bigcup_{a \in \operatorname{ex}(H(A))}(a N-\mathcal{E}(a-A))\right) \tag{1.4}
\end{equation*}
$$

filling out to its maximal possible size. This was proved by Nathanson [13] when $d=1$ and for $d \geqslant 2$ in [7]; however the proof in [7] did not produce a value for $N_{\text {Str }}(A)$ as it relied on the ineffective Lemma 1.2, The article [8, Theorem 1.3] then gave the first effective bound on $N_{\text {Str }}(A)$ for all $A$ :

$$
\begin{equation*}
N_{\text {Str }} \leqslant(d|A| \cdot \operatorname{width}(A))^{13 d^{6}} . \tag{1.5}
\end{equation*}
$$

Previous bounds were known when $d=1$ [13, 18, 7, 9, 11] and when $H(A)$ is a $d$-simplex ([4], with refined bounds in [8]).

The proof of (1.5) in [8] was intricate involving an "induction on dimension" strategy. This required repeated use of Siegel's Lemma from quantitative linear algebra (in the version proved by Bombieri-Vaaler [2]) together with delicate geometric considerations, such as the size and shape of the intersection between neighbourhoods of two cones $C_{A}$ and $C_{B}$.

Our second main result gives a strengthening of (1.5), with a much simpler proof. This is based in part on ideas from the proof of Theorem 1.5, developed out of the ideas in [16, Chapter 4]. Before stating the result, we introduce one final quantity associated to $A$.
Definition 1.6. Let $A \subset \mathbb{R}^{d}$ be finite with $\operatorname{span}(A-A)=\mathbb{R}^{d}$. Given a facet (i.e. $(d-1)$ dimensional face) $F$ of $H(A)$, and a point $a \in A \backslash F$, let $\operatorname{Vol}(F, a)$ denote the volume of the polytope given by the convex hull of $F$ and $a$. Then set

$$
\kappa(A)=\max _{F} \frac{\max _{a} \operatorname{Vol}(F, a)}{\min _{a} \operatorname{Vol}(F, a)} .
$$

Remark 1.7. There are several equivalent ways to define $\kappa(A)$. Indeed, for each $F$ we could equivalently replace $\operatorname{Vol}(F, a)$ by $g_{F}(a)$ for any affine-linear function $g_{F}: \mathbb{R}^{d} \rightarrow \mathbb{R}$ which vanishes on $F$ and is strictly positive on $H(A) \backslash F$. For example, we could take $g_{F}(a)$ to be the (signed) orthogonal distance from $F$ to $a$. Or we could pick linearly independent points $b^{(1)}, \ldots, b^{(d)}$ in $F \cap A$ and let $g_{F}(a)=\operatorname{det}\left(b^{(1)}-a, \ldots, b^{(d)}-a\right)$, where the $b^{(j)}$ are
ordered to make this determinant positive for $a \in H(A) \backslash F$. Using the latter choice of $g_{F}$ we see that

$$
\begin{equation*}
\kappa(A) \leqslant \frac{\operatorname{Vol}^{\dagger, \max }(H(A))}{\operatorname{Vol}^{\dagger, \min }(H(A))} . \tag{1.6}
\end{equation*}
$$

Our main result is the first general effective bound for $N_{\text {Str }}(A)$ that captures the geometry of $A$ by involving the quantities $\kappa(A), \operatorname{Vol}(H(A))$, and $\operatorname{Vol}^{\dagger}{ }^{\dagger}$ max $(H(A))$ :
Theorem 1.8 (Improved structural threshold). Let $A \subset \mathbb{Z}^{d}$ be a finite set, with $0 \in \operatorname{ex}(H(A))$ and $\Lambda_{A}=\mathbb{Z}^{d}$. Then we have the following two upper bounds:

$$
\begin{equation*}
N_{\mathrm{Str}}(A) \leqslant(d+1) \kappa(A)\left(d!\operatorname{Vol}(H(A))+(|\operatorname{ex}(H(A))|-d-1) \operatorname{Vol}^{\dagger, \max }(H(A))\right) \tag{1.7}
\end{equation*}
$$

and

$$
\begin{equation*}
N_{\mathrm{Str}}(A) \leqslant(d+1) \kappa(A)(|A|-d-1) \operatorname{Vol}^{\dagger, \max }(H(A)) \tag{1.8}
\end{equation*}
$$

The bound (1.7) is better when $|A|$ is substantially larger than $\operatorname{ex}(H(A))$; and (1.8) when $d!\operatorname{Vol}(H(A))$ is substantially larger than $\operatorname{Vol}^{\dagger}{ }^{\dagger \text { max }}(H(A))$. Using (1.6) and bounding $\operatorname{Vol}^{\dagger, m i n}(H(A)) \geqslant 1$ and $\operatorname{Vol}^{\dagger, m a x}(H(A)) \leqslant d!\operatorname{Vol}(H(A))$, (1.7) implies the cleaner but slightly weaker bound

$$
\begin{equation*}
N_{\mathrm{Str}}(A) \leqslant(d+1)(d!)^{2}(|\operatorname{ex}(H(A))|-d) \operatorname{Vol}(H(A))^{2} \tag{1.9}
\end{equation*}
$$

but still much stronger than (1.5).
Similar to the Khovanskii threshold, we guess that a bound like $N_{\text {Str }}(A) \leqslant d!\operatorname{Vol}(H(A))$ holds in general. Our (1.9) is roughly the square of this bound, so still far from optimal.

If $H(A)$ is a simplex then $\kappa(A)=1$ and $|\operatorname{ex}(H(A))|=d+1$, so (1.7) implies that $N_{\text {Str }}(A) \leqslant(d+1)!\operatorname{Vol}(H(A))$, which essentially recovers the best known bound in this case [8, Theorem 1.5].

The paper is structured as follows. In Section 2 we prove Theorem 1.5, while developing general lemmas on equations $\sum_{a \in A} a=\sum_{b \in B} b$ (with $B \subset A$ ) that will be useful throughout. In Section 3 we use these lemmas, with some convex geometry, to deduce Theorem 1.8.

Acknowledgements. This material is partly based upon work supported by the Swedish Research Council under grant no. 2021-06594 while the third author was in residence at Institut Mittag-Leffler in Djursholm, Sweden, during the winter semester of 2024. Our proof of Theorem [1.5 is pretty much that presented in [16, Chapter 4], albeit written in a different mathematical language and context; it also helped inspire the proof of 1.8 .

## 2. Proof of Theorem 1.5

Let $A=\left\{a_{1}, \ldots, a_{\ell}\right\}$. To keep track of various quantities throughout the proof, we define the weight of a vector $m \in \mathbb{Z}^{\ell}$ by $\operatorname{wt}(m):=m \cdot 1=\sum_{i=1}^{\ell} m_{i}$. We also let $A_{\text {mat }}:=\left(a_{1}, \ldots, a_{\ell}\right)$ be the $d$-by- $\ell$ matrix formed with the $a_{i}$ as column vectors, so that $A_{\text {mat }} m=\sum_{i} m_{i} a_{i}$.

We begin with a result and proof due to Nathanson and Ruzsa.
Proposition 2.1. There exists a finite set of lattice points $\mathcal{M} \subset \mathbb{Z}_{\geqslant 0}^{\ell}$, as described in the proof, such that for all positive integers $h$ we have

$$
|h A|=\sum_{T \subset \mathcal{M}}(-1)^{|T|}\binom{h-\mathrm{wt}\left(m_{T}\right)+\ell-1}{\ell-1}
$$

where $m_{T}$ is the vector with $\left(m_{T}\right)_{i}:=\max _{m \in T}(m)_{i}$, and $\binom{N}{\ell-1}=0$ if $N<\ell-1$.

Proof. If $x \in h A$ then let

$$
\operatorname{rep}_{h}(x):=\left\{m \in \mathbb{Z}_{\geqslant 0}^{\ell}: \mathrm{wt}(m)=h \text { and } A_{\mathrm{mat}} m=x\right\},
$$

denote the coefficient set of non-negative combinations of $h$ elements of $A$ that represent $x$. Let $m_{h}(x)$ be the minimum element in $\operatorname{rep}_{h}(x)$ with respect to the lexicographic ordering, and let

$$
\mathcal{U}:=\bigcup_{h \geqslant 0} \bigcup_{x \in h A}\left\{m \in \operatorname{rep}_{h}(x): m \neq m_{h}(x)\right\} .
$$

Evidently $|h A|=\left|\left\{m_{h}(x): x \in h A\right\}\right|$. We will calculate this size using the relationship

$$
\left\{m_{h}(x): x \in h A\right\}=\left\{n \in \mathbb{Z}_{\geqslant 0}^{\ell}: \operatorname{wt}(n)=h \text { and } n \notin \mathcal{U}\right\} .
$$

To this end, note that $\mathcal{U}+\mathbb{Z}_{\geqslant 0}^{\ell}=\mathcal{U}$. Indeed, if $y \in \mathbb{Z}_{\geqslant 0}^{\ell}$ then writing $v=A_{\text {mat }} y$ and $k=\mathrm{wt}(y)$ we have $\operatorname{rep}_{h}(x)+y \subset \operatorname{rep}_{h+k}(x+v)$. So if $m \in \operatorname{rep}_{h}(x) \cap \mathcal{U}$ then

$$
m+y>_{\operatorname{lex}} m_{h}(x)+y \geq_{\operatorname{lex}} m_{h+k}(x+v)
$$

So $m+y \in \mathcal{U}$ as needed.
We now apply Lemma 1.2 (the Mann-Dickson Lemma) to $\mathcal{U}$. Writing $x \leq_{\text {coord }} y$ if $x_{i} \leqslant y_{i}$ for all $i$, this implies the set

$$
\mathcal{M}=\mathcal{M}(\mathcal{U}):=\left\{m \in \mathcal{U}: \text { for all } u \in \mathcal{U}, u \leq_{\text {coord }} m \Longrightarrow u=m\right\}
$$

of minimal elements is finite, and for every $u \in \mathcal{U}$ there exists some $m \in \mathcal{M}$ with $m \leq_{\text {coord }} u$. Therefore we can use inclusion-exclusion to obtain

$$
\begin{aligned}
\{n \in & \left.\mathbb{Z}_{\geqslant 0}^{\ell}: \operatorname{wt}(n)=h \text { and } n \notin \mathcal{U}\right\} \\
& =\sum_{T \subset \mathcal{M}}(-1)^{|T|}\left\{n \in \mathbb{Z}_{\geqslant 0}^{\ell}: \operatorname{wt}(n)=h \text { and } m \leq_{\text {coord }} n \forall m \in T\right\} \\
& =\sum_{T \subset \mathcal{M}}(-1)^{|T|}\left\{n \in \mathbb{Z}_{\geqslant 0}^{\ell}: \mathrm{wt}(n)=h \text { and } m_{T} \leq_{\text {coord }} n\right\} .
\end{aligned}
$$

We have written this in terms of sets, and one should think of $+S$ as including the elements of $S$ with multiplicity, and $-S$ as removing one copy of each element of $S$.

Note that if $n \in \mathbb{Z}_{\geqslant 0}^{\ell}$ with $\operatorname{wt}(n)=h$ and $m_{T} \leq_{\text {coord }} n$, then $\operatorname{wt}\left(m_{T}\right) \leqslant h$. In that case, writing $n=m_{T}+r$ we obtain

$$
\left\{n \in \mathbb{Z}_{\geqslant 0}^{\ell}: \operatorname{wt}(n)=h \text { and } m_{T} \leq_{\text {coord }} n\right\}=\left\{r \in \mathbb{Z}_{\geqslant 0}^{\ell}: \operatorname{wt}(r)=h-\operatorname{wt}\left(m_{T}\right)\right\}
$$

and the result follows from the usual 'stars and bars' bound.
The remainder of the proof of Theorem 1.5 concerns bounding $\mathrm{wt}\left(m_{T}\right)$ above. To describe this argument we introduce some more notation, which will be of use throughout the paper. Given $u \in \mathbb{Z}^{\ell}$ define vectors $u^{+}, u^{-} \in \mathbb{Z}_{\geqslant 0}^{\ell}$ where $\left(u^{+}\right)_{i}=\max \left\{0, u_{i}\right\}$ and $\left(u^{-}\right)_{i}=\max \left\{0,-u_{i}\right\}$, so that $u=u^{+}-u^{-}$. If $u \in \mathbb{Z}^{\ell}$, we let $\operatorname{supp}(u)=\left\{i: u_{i} \neq 0\right\}$. Next let

$$
\begin{equation*}
\mathcal{Z}=\mathcal{Z}(A):=\left\{z \in \mathbb{Z}^{\ell}: \mathrm{wt}(z)=0 \text { and } A_{\mathrm{mat}} z=0\right\} \tag{2.1}
\end{equation*}
$$

which is a lattice. By taking $m=z^{+}, m^{\prime}=z^{-}$with $x=A_{\text {mat }} m$ and $h=\mathrm{wt}(m)$ we obtain

$$
\mathcal{Z}=\bigcup_{h \geqslant 0} \bigcup_{x \in h A}\left\{m-m^{\prime}: m, m^{\prime} \in \operatorname{rep}_{h}(x)\right\} .
$$

We continue with a lemma relating $\mathcal{M}$ and $\mathcal{Z}$.
Lemma 2.2. Given $m \in \mathcal{M}$ let $x=A_{\text {mat }} m$ and $h=\mathrm{wt}(m)$. Then $\operatorname{supp}(m) \cap \operatorname{supp}\left(m_{h}(x)\right)=$ $\emptyset$. Moreover if there exists $v \in \mathcal{Z} \backslash\{0\}$ with $v^{+} \leq_{\text {coord }} m$ and $v^{-} \leq_{\text {coord }} m_{h}(x)$ then $v^{+}=m$, $v^{-}=m_{h}(x)$, and $v=m-m_{h}(x)$.

Proof. Write $n=m_{h}(x)$ so that $A_{\text {mat }}(m-n)=x-x=0$. If $\operatorname{supp}(m) \cap \operatorname{supp}(n) \neq \emptyset$, say that $m_{i}, n_{i} \geqslant 1$. Then $m-e_{i}>_{\text {lex }} n-e_{i}$ with $m-e_{i}, n-e_{i} \in \mathbb{Z}_{\geqslant 0}^{\ell}$ so $m-e_{i} \in \mathcal{U}$, and $m-e_{i}<_{\text {coord }} m$, contradicting that $m \in \mathcal{M}(\mathcal{U})$. So $\operatorname{supp}(m) \cap \operatorname{supp}(n)=\emptyset$ as claimed.

Now if $v \in \mathcal{Z} \backslash\{0\}$ with $v^{+} \leq_{\text {coord }} m$ and $v^{-} \leq_{\text {coord }} n$ then $v^{+}>_{\text {lex }} v^{-}$. Indeed, if not then $w:=v^{+}+n-v^{-}<_{\text {lex }} n$ and $w \in \mathbb{Z}_{\geqslant 0}^{\ell}$. Moreover $m-w=(m-n)-\left(v^{+}-v^{-}\right) \in \mathcal{Z}$, so that $w \in \operatorname{rep}_{h}(x)$ with $w<_{\text {lex }} n$. However $n=m_{h}(x) \leq_{\text {lex }} w$ by definition, which gives a contradiction. So $v^{+}>_{\text {lex }} v^{-}$.

Finally, let $y=A_{\text {mat }} v^{+}$and $k=\operatorname{wt}\left(v^{+}\right)$, so that $v^{+}, v^{-} \in \operatorname{rep}_{k}(y)$ and $v^{+} \in \mathcal{U}$ (as $v^{+}>_{\text {lex }} v^{-}$). Then $v^{+} \leq_{\text {coord }} m$ and $m \in \mathcal{M}$, so $v^{+}=m$. Therefore $y=x, k=h$ and so $v^{-} \in \operatorname{rep}_{h}(x)$ which implies that $n \leq_{\text {lex }} v^{-}$. Moreover $v^{-} \leq_{\text {coord }} n$ which implies $v^{-} \leq_{\text {lex }} n$, and so $v^{-}=n$. So $v=v^{+}-v^{-}=m-n$ as claimed.

We define $\mathcal{Z}^{\dagger}=\mathcal{Z}^{\dagger}(A)$ by
$\mathcal{Z}^{\dagger}:=\{u \in \mathcal{Z} \backslash\{0\}:$ If $v \in \mathcal{Z} \backslash\{0\}$ with $\operatorname{supp}(v) \subset \operatorname{supp}(u)$ then $v=\lambda u$ for some $\lambda \in \mathbb{Z}\}$. Note that if $v \in \mathcal{Z} \backslash\{0\}$ then there must exist some $u \in \mathcal{Z}^{\dagger}$ with $\operatorname{supp}(u) \subset \operatorname{supp}(v)$. It transpires that elements in $\mathcal{Z}^{\dagger}$ may be strongly controlled, and this in turn will help control $\mathcal{Z}$ and finally $\mathcal{M}$.
Lemma 2.3. If $u \in \mathcal{Z}^{\dagger}$ then $\|u\|_{\infty}:=\max _{i}\left|u_{i}\right| \leqslant \operatorname{Vol}^{\dagger, m a x}(H(A))$.
Proof. For each $a_{i} \in A$ let $b_{i}=\binom{a_{i}}{1} \in \mathbb{Z}^{d+1}$ If $\operatorname{supp}(u)=\left\{i_{1}, \ldots, i_{r}\right\}$ then the only linear dependence (up to scalars) amongst the the vectors $\left\{b_{i_{1}}, \cdots, b_{i_{r}}\right\}$ is $\sum_{j} u_{i_{j}} b_{i_{j}}=0$, so that the $(d+1)$-by- $r$ matrix $M=\left(b_{i_{1}}, \cdots, b_{i_{r}}\right)$ has rank $r-1$. Since $\operatorname{span}\left(\left\{b_{1}, \ldots, b_{\ell}\right\}\right)=\mathbb{R}^{d+1}$ (as $\Lambda_{A-A}$ is $d$-dimensional), we can find column vectors $b_{i_{r+1}}, \ldots b_{i_{d+2}}$ such that the $(d+1)$ -by- $(d+2)$ matrix $M^{\prime}=\left(b_{i_{1}}, \cdots, b_{i_{d+2}}\right)$ has rank $d+1$ and so has a 1-dimensional null space. Cramer's rule gives a non-zero null vector

$$
\begin{equation*}
w:=\sum_{j=1}^{d+2}(-1)^{j} \operatorname{det}\left(b_{i_{1}} \cdots, b_{i_{j-1}}, b_{i_{j+1}}, \cdots b_{i_{d+2}}\right) \cdot e_{i_{j}} \tag{2.2}
\end{equation*}
$$

(non-zero as the subdeterminants cannot all be zero since $M^{\prime}$ has rank $d+1$ ). We already have the null vector $u$, so $w$ and $u$ must be scalar multiples of one another. In particular $\operatorname{supp}(w) \subset \operatorname{supp}(u)$, and hence $w=\lambda u$ for some $\lambda \in \mathbb{Z}$. This implies that $\left|u_{i_{j}}\right| \leqslant\left|w_{i_{j}}\right| \leqslant$ $\left|\operatorname{det}\left(b_{i_{1}} \cdots, b_{i_{j-1}}, b_{i_{j+1}}, \cdots b_{i_{d+2}}\right)\right|$ for all $j$, and hence

$$
\|u\|_{\infty} \leqslant \max _{\left\{k_{0}, k_{1}, \ldots, k_{d}\right\} \subset\{1, \ldots, \ell\}}\left|\operatorname{det}\left(\binom{a_{k_{0}}}{1}, \cdots,\binom{a_{k_{d}}}{1}\right)\right|=\operatorname{Vol}^{\dagger, m a x}(H(A)) .
$$

For the final equality, we have relabelled $\left\{b_{i_{1}}, \cdots, b_{i_{j-1}}, b_{i_{j+1}}, \cdots b_{i_{d+2}}\right\}$ as $\left\{a_{k_{0}}, \ldots, a_{k_{d}}\right\}$ and then subtracted the first column from the others, expanding the determinant about the bottom row.

We continue by relating $\mathcal{Z}^{\dagger}$ and $\mathcal{Z}$. To this end we write $\operatorname{supp}\left(u^{ \pm}\right) \subset \operatorname{supp}\left(v^{ \pm}\right)$as shorthand for the two conditions $\operatorname{supp}\left(u^{+}\right) \subset \operatorname{supp}\left(v^{+}\right)$and $\operatorname{supp}\left(u^{-}\right) \subset \operatorname{supp}\left(v^{-}\right)$
Lemma 2.4. If $v \in \mathcal{Z} \backslash\{0\}$ then there exists $u \in \mathcal{Z}^{\dagger}$ such that $\operatorname{supp}\left(u^{ \pm}\right) \subset \operatorname{supp}\left(v^{ \pm}\right)$.
Proof. Let $w=v / \operatorname{gcd}_{i} v_{i}$. If $w \in \mathcal{Z}^{\dagger}$ let $u=w$ and we are done, so we may assume that $w \in$ $\mathcal{Z} \backslash \mathcal{Z}^{\dagger}$. If $|\operatorname{supp}(v)|=1$ then $w \in \mathcal{Z}^{\dagger}$ automatically, so we assume that $|\operatorname{supp}(v)| \geqslant 2$ and proceed by induction on $|\operatorname{supp}(v)|$. Since $w \in \mathcal{Z} \backslash \mathcal{Z}^{\dagger}$ is non-zero there exists $u \in \mathcal{Z} \backslash\{0\}$ with $\operatorname{supp}(u) \subset \operatorname{supp}(w)$ but which is not an integer multiple of $w$. Select $\lambda:=\min _{i: u_{i} \neq 0}\left|w_{i} / u_{i}\right|$, which is $>0$ as $\operatorname{supp}(u) \subset \operatorname{supp}(w)$. Pick $i$ so that $w_{i}= \pm \lambda u_{i}$ with $u_{i} \neq 0$, and then adjust the sign of $u$ so that $u_{i}>0$. Now let $y:=u_{i} w-w_{i} u$, so that $y_{i}=0$ and for all $j$ either $y_{j}$ equals 0 or has the same sign as $w_{j}$, since $\left|w_{i} u_{j}\right|=\lambda\left|u_{i} u_{j}\right|=\left|u_{i}\right| \cdot \lambda\left|u_{j}\right| \leqslant\left|u_{i} w_{j}\right|$. Therefore $\operatorname{supp}(y) \subset \operatorname{supp}(w) \backslash\{i\}$ with $\operatorname{supp}\left(y^{ \pm}\right) \subset \operatorname{supp}\left(w^{ \pm}\right)$. Note further that $y \neq 0$, since if
$0=y=u_{i} w-w_{i} u$ then $w_{i} \neq 1$, since $u$ is not an integer multiple of $w$, but this in turn contradicts the coprimality of the coordinates of $w$.

Since $y \in \mathcal{Z} \backslash\{0\}$, by the induction hypothesis there exists $u \in \mathcal{Z}^{\dagger}$ for which

$$
\operatorname{supp}\left(u^{ \pm}\right) \subset \operatorname{supp}\left(y^{ \pm}\right) \subset \operatorname{supp}\left(w^{ \pm}\right)=\operatorname{supp}\left(v^{ \pm}\right)
$$

We may iterate this argument to entirely decompose elements $v \in \mathcal{Z}$ in terms of a combination of elements $u \in \mathcal{Z}^{\dagger}$.
Lemma 2.5 (Decomposing using $\mathcal{Z}^{\dagger}$ ). Any $v \in \mathcal{Z} \backslash\{0\}$ can be written as $\sum_{j=1}^{I} \lambda_{j} u_{j}$ with each $u_{j} \in \mathcal{Z}^{\dagger}, \lambda_{j} \in \mathbb{Q}_{>0}$ and $I \leqslant|\operatorname{supp}(v)|$. Furthermore each $\operatorname{supp}\left(u_{j}^{ \pm}\right) \subset \operatorname{supp}\left(v^{ \pm}\right)$, so that $v^{+}=\sum_{j=1}^{I} \lambda_{j} u_{j}^{+}$and $v^{-}=\sum_{j=1}^{I} \lambda_{j} u_{j}^{-}$.
Proof. By induction on $m:=|\operatorname{supp}(v)|$. Select $u \in \mathcal{Z}^{\dagger}$ by Lemma [2.4, let $\lambda:=\min _{i: u_{i} \neq 0} v_{i} / u_{i}$ (noting $v_{i}$ and $u_{i}$ have the same $\operatorname{sign}$ as $\operatorname{supp}\left(u^{ \pm}\right) \subset \operatorname{supp}\left(v^{ \pm}\right)$), choose $i$ so that $v_{i}=\lambda u_{i}$, and let $y:=v-\lambda u$. Now $\operatorname{supp}(y) \subset \operatorname{supp}(w)-\{i\}$ so that $|\operatorname{supp}(y)| \leqslant m-1$. If $y=0$ (for example if $m=1$ ) then $v=\lambda u$. Otherwise the result follows by the induction hypothesis.

The preceding lemmas may be combined to control the size of elements in $\mathcal{M}$.
Lemma 2.6. If $m \in \mathcal{M}$ then $\|m\|_{\infty} \leqslant \ell \operatorname{Vol}^{\dagger, \text { max }}(H(A))$.
Proof. Let $x=A_{\text {mat }} m$ and $h=\operatorname{wt}(m)$. By Lemma 2.2, letting $u:=m-m_{h}(x) \in \mathcal{Z}$ we have $u \neq 0$, and if $v \in \mathcal{Z} \backslash\{0\}$ with $v^{+} \leq_{\text {coord }} u^{+}$and $v^{-} \leq_{\text {coord }} u^{-}$then $v=u$. Now by Lemma 2.5 we can write $u=\sum_{j=1}^{I} \lambda_{j} u_{j}$ with each $u_{j} \in \mathcal{Z}^{\dagger}, \lambda_{j} \in \mathbb{Q}_{>0}$ and $I \leqslant|\operatorname{supp}(u)|$, where each $\operatorname{supp}\left(u_{j}^{ \pm}\right) \subset \operatorname{supp}\left(u^{ \pm}\right)$, so that $u^{+}=\sum_{j=1}^{I} \lambda_{j} u_{j}^{+}$and $u^{-}=\sum_{j=1}^{I} \lambda_{j} u_{j}^{-}$.

We claim each $\lambda_{j} \leqslant 1$, else $u_{j}^{+}<_{\text {coord }} \lambda_{j} u_{j}^{+} \leq_{\text {coord }} u^{+}$and $u_{j}^{-}<_{\text {coord }} \lambda_{j} u_{j}^{-} \leq_{\text {coord }} u^{-}$. Then applying Lemma 2.2 as above with $v=u_{j}$ we conclude $u_{j}=u$, but this contradicts the strict inequality $u_{j}^{+}<_{\text {coord }} u^{+}$.

Therefore, by the triangle inequality,

$$
\|m\|_{\infty} \leqslant\|u\|_{\infty} \leqslant \sum_{j=1}^{I} \lambda_{j}\left\|u_{j}\right\|_{\infty} \leqslant I \cdot \max _{j}\left\|u_{j}\right\|_{\infty} \leqslant \ell \cdot \max _{u \in \mathcal{Z}^{\dagger}}\|u\|_{\infty}
$$

and the result then follows from Lemma 2.3.
Substituting this control on $\mathcal{M}$ into the Proposition 2.1 will quickly resolve Theorem 1.5.
Proof of Theorem 1.5. Define

$$
P_{A}(x):=\frac{1}{(\ell-1)!} \sum_{T \subset \mathcal{M}}(-1)^{|T|}\left(x-\mathrm{wt}\left(m_{T}\right)+\ell-1\right) \cdots\left(x-\mathrm{wt}\left(m_{T}\right)+1\right) .
$$

We observe that

$$
\frac{\left(h-\mathrm{wt}\left(m_{T}\right)+\ell-1\right) \cdots\left(x-\mathrm{wt}\left(m_{T}\right)+1\right)}{(\ell-1)!}=\binom{h-\mathrm{wt}\left(m_{T}\right)+\ell-1}{\ell-1}
$$

for all integers $h \geqslant \operatorname{wt}\left(m_{T}\right)-\ell+1$. Therefore, by Proposition 2.1,

$$
h \mathcal{A}=P_{A}(h) \text { for all } h \geqslant \operatorname{wt}\left(m_{\mathcal{M}(\mathcal{U})}\right)-\ell+1
$$

since $\max _{T \subset \mathcal{M}(\mathcal{U})} w_{T}=\operatorname{wt}\left(m_{\mathcal{M}(\mathcal{U})}\right)$, by definition. Hence

$$
N_{\mathrm{Kh}}(A)+\ell-1 \leqslant \mathrm{wt}\left(m_{\mathcal{M}(\mathcal{U})}\right)=\sum_{i=1}^{\ell} \max _{m \in \mathcal{M}(\mathcal{U})}|m|_{i} \leqslant \ell \max _{m \in \mathcal{M}(\mathcal{U})}\|m\|_{\infty} \leqslant \ell^{2} \operatorname{Vol}^{\dagger, \max }(H(A))
$$

by Lemma 2.6. This is the claimed bound on $N_{\mathrm{Kh}}(A)$.

## 3. Proof of Theorem 1.8

Let us first describe the general strategy. Let $A \subset \mathbb{Z}^{d}$ be finite with $0 \in \operatorname{ex}(H(A))$ and $\Lambda_{A}=\mathbb{Z}^{d}$. If $v \in \mathcal{P}(A)$, we aim to find $u$ and $w$ such that $v=u+w$, where:

- $u \in M A$, for a bounded $M$;
- $w \in \mathcal{P}(B \cup\{0\})$, where $B \subset A$ is contained within a single facet of $H(A)$. One may also assume that this facet does not contain the origin.
In some ways, this strategy is similar to [8, Lemma 7.1]. However, in [8, Lemma 7.1] the set $B$ was pre-determined at the outset, with the further assumptions that $v \in \mathcal{P}(A) \cap C_{B}$ and the further requirement that $u \in C_{B}$. It turns out to be much easier to prove the weaker version outlined above, where $B$ is found as a consequence of the decomposition $v=u+w$ rather than being fixed in the hypotheses.

To find the decomposition $v=u+w$, one may consider a representation $v=\sum_{i=1}^{\ell} \eta_{i} a_{i}$ in which $\eta \in \mathbb{Z}_{\geqslant 0}^{\ell}$ and the weight $\mathrm{wt}(\eta)$ is minimal. Recall that $A=\left\{a_{1}, \ldots, a_{\ell}\right\}$ and $\mathrm{wt}(\eta)$ denotes $\sum_{i} \eta_{i}$. In this section it will actually be more convenient to index $\eta$ directly by $A$ itself, so $v=\sum_{a \in A} \eta_{a} a$ and $\operatorname{wt}(\eta)=\sum_{a \in A} \eta_{a}$. The basic idea is then to let

$$
u=\sum_{\substack{a \in A \\ \eta_{a} \text { is small }}} \eta_{a} a \text { and } w=\sum_{\substack{a \in A \\ \eta_{a} \text { is large }}} \eta_{a} a .
$$

If the set $\left\{a \in A: \eta_{a}\right.$ is large $\}$ is not contained within a single facet of $H(A)$, one can use properties of the sets $\mathcal{Z}(A)$ and $\mathcal{Z}^{\dagger}(A)$ established previously (Lemmas 2.3 and 2.5) to reduce $\mathrm{wt}(\eta)$, contradicting minimality.

Having proved this decomposition, suppose $v \in N H(A)$ as well, with $N$ at least the right-hand side of (1.8). If the facet on which $B$ lies is defined by $\beta=1$ for a linear map $\beta: \mathbb{R}^{d} \rightarrow \mathbb{R}$, then one can apply $\beta$ to both sides of the equation $v=u+w$. Writing $w=\sum_{b \in B} \lambda_{b} b$, we have $\beta(w)=\operatorname{wt}(\lambda)$, and this enables us to bound $\mathrm{wt}(\lambda)$ above in terms of $N$ and $M$. Putting everything together, we can place $v \in N A$ as required. (We extend the definition of wt to mean simply the sum of the entries of a vector. We will also implicitly allow ourselves to enlarge the indexing set of a vector, by setting all previously undefined entries to zero.)

This method gives (1.8). In order to prove (1.7), which involves $|\operatorname{ex}(H(A))|$ instead of $|A|$, one first excises the contribution from non-extremal elements (Lemma 3.7 below). This is a simple additive-combinatorial argument, adapted from similar results in 4] and [8]. This done, one proceeds as above but with $A$ replaced by $\operatorname{ex}(H(A))$.

To begin the proof proper, we state some standard results on convex polytopes. Let $A \subset \mathbb{Z}^{d}$ be finite, and assume $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Then from the structure theorem for convex polytopes [3, Theorem 9.2], we know that there are linear maps $\beta_{1}, \ldots, \beta_{K}, \gamma_{1}, \ldots, \gamma_{L},: \mathbb{R}^{d} \rightarrow \mathbb{R}$ for which

$$
H(A)=\bigcap_{i=1}^{K}\left\{x \in \mathbb{R}^{d}: \beta_{i}(x) \leqslant 1\right\} \cap \bigcap_{j=1}^{L}\left\{x \in \mathbb{R}^{d}: \gamma_{j}(x) \geqslant 0\right\}
$$

and the sets $\left\{x \in H(A): \beta_{i}(x)=1\right\}$ and $\left\{x \in H(A): \gamma_{j}(x)=0\right\}$ form the facets of $H(A)$. For each $i$ and $j$ we call $\left\{x \in H(A): \beta_{i}(x)=1\right\}$ an outer facet of $H(A)$ and $\left\{x \in H(A): \gamma_{j}(x)=1\right\}$ an inner facet of $H(A)$.

We continue with a technical lemma which we will use to reduce wt $(n)$ as discussed above.
Lemma 3.1 (Preparation for reduction step). Let $A \subset \mathbb{Z}^{d}$ be finite, and assume $0 \in$ $\operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Let $S \subset A$, and suppose that $S$ does not lie in an outer facet of $H(A)$. Then for any linear map $\alpha: \mathbb{R}^{d} \rightarrow \mathbb{R}$ satisfying $\alpha(s)=1$ for all $s \in S$ there exists $p \in H(A) \cap \operatorname{span}(S) \cap \mathbb{Q}^{d}$ for which $\alpha(p)>1$.

Proof. Each outer facet of $H(A)$ is defined by $\left\{x \in H(A): \beta_{i}(x)=1\right\}$ for some linear map $\beta_{i}$. Now $\beta_{i}(s) \leqslant 1$ for all $s \in S$ as $S \subset A \subset H(A)$, and we cannot have equality for all $s \in S$ as $S$ is not contained in any outer facet by the hypothesis, and so the barycentre

$$
q:=\frac{1}{|S|} \sum_{s \in S} s
$$

of $S$ satisfies $\beta_{i}(q)<1$. Letting $\hat{\beta}=\max _{i} \beta_{i}(q) \in[0,1)$, we see that $q$ lies inside $\hat{\beta} H(A)$, and so for any $\varepsilon \in\left(0, \hat{\beta}^{-1}-1\right) \cap \mathbb{Q}$ the point $p=(1+\varepsilon) q$ lies in $H(A)$. This $p$ is clearly also in $\operatorname{span}(S)$ and $\mathbb{Q}^{d}$, and satisfies $\alpha(p)=(1+\varepsilon) \alpha(q)=1+\varepsilon>1$.

We now use this observation to prove the existence of certain relations between sums of elements in $A$.

Lemma 3.2 (Reduction step). Let $A \subset \mathbb{Z}^{d}$ be finite, and assume $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Suppose the elements of $S \subset A$ are linearly independent, and that $S$ is not a subset of any outer facet of $H(A)$. Then there exist non-negative integers $\left\{\lambda_{s}\right\}_{s \in S}$ and $\left\{\rho_{a}\right\}_{a \in A \backslash\{0\}}$ such that

$$
\sum_{s \in S} \lambda_{s} s=\sum_{a \in A \backslash\{0\}} \rho_{a} a \quad \text { and } \quad \operatorname{wt}(\lambda)>\operatorname{wt}(\rho),
$$

where $\lambda_{s}, \rho_{a} \leqslant \operatorname{Vol}^{\dagger, \text { max }}(H(A))$ for all $s \in S$ and $a \in A \backslash\{0\}$.
Proof. As $S$ is linearly independent, we know that $0 \notin S$ and there exists a linear map $\alpha: \mathbb{R}^{d} \rightarrow \mathbb{R}$ with $\alpha(s)=1$ for all $s \in S$. From Lemma 3.1, choose $p \in H(A) \cap \operatorname{span}(S) \cap \mathbb{Q}^{d}$ with $\alpha(p)>1$. Therefore $p=\sum_{s \in S} \gamma_{s} s$ for some coefficients $\gamma_{s} \in \mathbb{Q}$, and $p=\sum_{a \in A} \delta_{a} a$ where $\operatorname{wt}(\delta)=1$ and $\delta_{a} \in[0,1] \cap \mathbb{Q}$ for all $a \in A$. Then

$$
\sum_{s \in S} \gamma_{s} s=p=\sum_{a \in A} \delta_{a} a \quad \text { and } \quad \operatorname{wt}(\gamma)=\alpha(p)>1=\operatorname{wt}(\delta) .
$$

Let $L$ be the least common denominator of all the $\gamma_{s}$ and $\delta_{a}$. Define $z_{a}=L\left(\delta_{a}-\gamma_{a}\right)$ for $a \in A \backslash\{0\}$, and

$$
z_{0}=L\left(\mathrm{wt}(\gamma)-\mathrm{wt}(\delta)+\delta_{0}\right)>0
$$

so that

$$
\operatorname{wt}(z)=z_{0}+\sum_{a \in A \backslash\{0\}} L\left(\delta_{a}-\gamma_{a}\right)=0 .
$$

We then have $z \in \mathcal{Z}$ (as defined in (2.1), where we identify $\mathbb{Z}^{A}$ with $\mathbb{Z}^{\ell}$ ) and $\operatorname{supp}\left(z^{-}\right) \subset S$.
By Lemma 2.5, we write $z=\sum_{j} \eta_{j} u_{j}$ with each $u_{j} \in \mathcal{Z}^{\dagger}, \eta_{j} \in \mathbb{Q}_{>0}$, and $\operatorname{supp}\left(u_{j}^{ \pm}\right) \subset$ $\operatorname{supp}\left(z^{ \pm}\right)$. Now $0 \in \operatorname{supp}\left(z^{+}\right)$as $z_{0}>0$, so $0 \in \operatorname{supp}\left(u^{+}\right) \subset \operatorname{supp}\left(z^{+}\right)$for some $u=u_{j} \in \mathcal{Z}^{\dagger}$ and $\operatorname{supp}\left(u^{-}\right) \subset \operatorname{supp}\left(z^{-}\right) \subset S$. Define

$$
\lambda_{s}=\left\{\begin{array}{ll}
\left(-u_{s}\right) & \text { if } s \in \operatorname{supp}\left(u^{-}\right) \\
0 & \text { if } s \in S \backslash \operatorname{supp}\left(u^{-}\right),
\end{array} \text {and } \rho_{a}= \begin{cases}u_{a} & \text { if } a \in \operatorname{supp}\left(u^{+}\right) \backslash\{0\} \\
0 & \text { otherwise }\end{cases}\right.
$$

Then, since $u \in \mathcal{Z}$, we have

$$
\begin{aligned}
& \sum_{s \in S} \lambda_{s} s=\sum_{a \in \operatorname{supp}\left(u^{-}\right)}\left(-u_{a}\right) a=\sum_{a \in \operatorname{supp}\left(u^{+}\right)} u_{a} a=\sum_{a \in A \backslash\{0\}} \rho_{a} a \\
& \text { and } \operatorname{wt}(\lambda)=\sum_{a \in \operatorname{supp}\left(u^{-}\right)}\left(-u_{a}\right)=\sum_{a \in \operatorname{supp}\left(u^{+}\right)} u_{a}>\operatorname{wt}(\rho) .
\end{aligned}
$$

The final inequality uses the fact that $u_{0}>0$. The condition $\max _{s \in S, a \in A} \lambda_{s}, \rho_{a}=\|u\|_{\infty} \leqslant$ $\operatorname{Vol}^{\dagger}{ }^{\dagger}$ max $(H(A))$ then follows from Lemma 2.3,

Using the relation from the previous lemma, we can derive the decomposition $v=u+w$ as discussed at the start of the section.

Lemma 3.3 (Regular representation). Let $A \subset \mathbb{Z}^{d}$ be finite, and assume $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Let $v \in \mathcal{P}(A)$. Then there is a decomposition $v=u+w$ and an outer facet $F$ of $H(A)$ for which

- $w \in \mathcal{P}(B \cup\{0\})$, where $B=A \cap F$;
- $u \in M A$ where $M=(|A|-1-|B|)\left(\operatorname{Vol}^{\dagger, m a x}(H(A))-1\right)$.

Proof. By definition we can write $v \in \mathcal{P}(A)$ as a $\mathbb{Z}_{\geqslant 0}$-linear combination of the $a \in A$, so we select the representation

$$
v=\sum_{a \in A \backslash\{0\}} \eta_{a} a \text { where each } \eta_{a} \in \mathbb{Z}_{\geqslant 0}
$$

for which $\mathrm{wt}(\eta)$ is minimal, and then for which

$$
T=T\left(\left(\eta_{a}\right)_{a}\right):=\left\{a \in A \backslash\{0\}: \eta_{a} \geqslant \operatorname{Vol}^{\dagger, m a x}(H(A))\right\}
$$

is also minimal. If $T$ is contained in an outer facet $F$ of $H(A)$ then we obtain the desired decomposition $v=u+w$, where

$$
u:=\sum_{a \in A \backslash(B \cup\{0\})} \eta_{a} a \in M A \quad \text { and } \quad w:=\sum_{b \in B:=A \cap F} \eta_{b} b,
$$

since $\eta_{a} \leqslant \operatorname{Vol}^{\dagger, m a x}(H(A))-1$ for all $a \in A \backslash(B \cup\{0\})$, and $|A \backslash(B \cup\{0\})|=|A|-1-|B|$.
Henceforth we may assume that no such facet $F$ exists, so that $T \neq \emptyset$. We obtain a contradiction as follows.

Case I: If the elements of $T$ are linearly independent then we apply Lemma 3.2 with $S:=T$ to obtain another representation of $v$,

$$
v=\sum_{a \in A \backslash\{0\}} \eta_{a}^{\prime} a, \quad \text { where } \quad \eta_{a}^{\prime}:= \begin{cases}\eta_{a}-\lambda_{a}+\rho_{a} & \text { if } a \in T \\ \eta_{a}+\rho_{a} & \text { otherwise }\end{cases}
$$

The coefficients $\eta_{a}^{\prime}$ are all non-negative since each $\eta_{a}, \rho_{a} \geqslant 0$ and

$$
\lambda_{t} \leqslant \operatorname{Vol}^{\dagger, \max }(H(A)) \leqslant \eta_{t} \text { for all } t \in T
$$

However

$$
\mathrm{wt}\left(\eta^{\prime}\right)=\mathrm{wt}(\eta)+\mathrm{wt}(\rho)-\mathrm{wt}(\lambda)<\mathrm{wt}(\eta),
$$

contradicting the minimality of $\mathrm{wt}(\eta)$.
Case II: Otherwise the elements of $T$ are linearly dependent and so there exist $z_{t} \in \mathbb{Z}$, not all zero, for which

$$
\sum_{t \in T} z_{t} t=0
$$

Define $z_{0}:=-\sum_{t \in T} z_{t}$, and multiply through all the $z_{v}$-values by -1 if necessary to ensure that $z_{0} \geqslant 0$. As usual, we define $z_{a}=0$ for all $a \in A$ on which it is not yet defined, so we can consider $z$ as a non-zero element of $\mathbb{Z}^{A}$ with $z \in \mathcal{Z}$. By Lemma 2.4 there then exists $\mu \in \mathcal{Z}^{\dagger}$ with $\operatorname{supp}\left(\mu^{ \pm}\right) \subset \operatorname{supp}\left(z^{ \pm}\right)$, and by Lemma 2.3 we have $\|\mu\|_{\infty} \leqslant \operatorname{Vol}^{\dagger, m a x}(H(A))$.

Case IIa: If $\mu_{0} \neq 0$ then we must have $\mu_{0}>0$ since $\operatorname{supp}\left(\mu^{ \pm}\right) \subset \operatorname{supp}\left(z^{ \pm}\right)$and $z_{0}>0$. Now write $v=\sum_{a \in A} \eta_{a}^{\prime} a$, where $\eta_{a}^{\prime}=\eta_{a}+\mu_{a}$ for $a \neq 0$ and $\eta_{0}^{\prime}=0$. We have $\eta_{a}^{\prime} \geqslant 0$ for all $a$, since $\eta_{a}^{\prime}$ agrees with $\eta_{a} \geqslant 0$ unless $a \in T$, in which case $\eta_{a} \geqslant \operatorname{Vol}^{\dagger, m a x}(H(A))$ and $\mu_{a} \geqslant-\|\mu\|_{\infty} \geqslant-\operatorname{Vol}^{\dagger, m a x}(H(A))$. But we also have

$$
\operatorname{wt}\left(\eta^{\prime}\right)=\operatorname{wt}(\eta)+\operatorname{wt}(\mu)-\mu_{0}=\operatorname{wt}(\eta)-\mu_{0}<\operatorname{wt}(\eta),
$$

contradicting the minimality of $\mathrm{wt}(\eta)$.

Case IIb: Otherwise $\mu_{0}=0$. Then pick $n \in \mathbb{N}$ maximal such that $\eta^{\prime}:=\eta-n \mu$ has all components non-negative. We obtain $v=\sum_{a \in A} \eta_{a}^{\prime} a$ and $\mathrm{wt}\left(\eta^{\prime}\right)=\mathrm{wt}(\eta)$. But we must have $\eta_{t}^{\prime}<\operatorname{Vol}^{\dagger}{ }^{\dagger}$ max $(H(A))$ for some $t \in T$, otherwise we can increase $n$, so $T\left(\eta^{\prime}\right)$ must be a proper subset of $T$, contradicting minimality of $T$.

In order to leverage the decomposition $v=u+w$ to show that $v \in N A$, we need to control how negative the evaluation $\beta(u)$ can get, when $\beta$ defines an outer facet of $H(A)$. This is the purpose of the next lemma. Recall from Definition 1.6 and Remark 1.7 that

$$
\kappa(A)=\max _{F} \frac{\max _{a} g_{F}(a)}{\min _{a} g_{F}(a)},
$$

where $F$ ranges over facets of $H(A), a$ ranges over points of $A \backslash F$, and $g_{F}$ is any affine-linear function $\mathbb{R}^{d} \rightarrow \mathbb{R}$ which vanishes on $F$ and is strictly positive on $H(A) \backslash F$.
Lemma 3.4 (Negative coefficients). Let $A \subset \mathbb{R}^{d}$ be finite with $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=$ $\mathbb{R}^{d}$. Let $\beta: \mathbb{R}^{d} \rightarrow \mathbb{R}$ be a linear map for which $F=\{x \in H(A): \beta(x)=1\}$ is an outer facet of $H(A)$. Then, for all $a \in A$,

$$
\beta(a) \geqslant 1-\kappa(A) .
$$

Proof. The facet $F$ of the $d$-dimensional convex polytope $H(A)$ is the convex hull of at least $d$ points of $A$ (see [8, Lemma A. 2 (4)] for a discussion). In particular there are $d$ linearly independent $b^{(1)}, \ldots, b^{(d)} \in A$ for which $\beta\left(b^{(j)}\right)=1$ (and these uniquely determine $\beta$ ). Let $b_{i}^{(j)}$ denote the $i^{\text {th }}$ coordinate of $b^{(j)}$ with respect to the standard basis, and for $a \in A$ let $a_{i}$ denote the $i^{t h}$ coordinate with respect to the standard basis. Expressing $\beta$ in coordinates and computing the necessary matrix inverses, we derive

$$
\beta(a)=\frac{1}{\operatorname{det} B_{\mathrm{mat}}} \sum_{i, j \leqslant d}(-1)^{i+j} a_{i} M_{i j}
$$

where $B_{\text {mat }}$ is the $d$-by- $d$ matrix with $\left(B_{\text {mat }}\right)_{i j}=b_{i}^{(j)}$, and $M_{i j}$ is the minor formed by deleting the $i^{\text {th }}$ row and $j^{\text {th }}$ column of $B_{\text {mat }}$ and taking the determinant. Yet

$$
\operatorname{det} B_{\mathrm{mat}}-\sum_{i, j \leqslant d}(-1)^{i+j} a_{i} M_{i j}=\operatorname{det}\left(\begin{array}{cccc}
1 & 1 & \cdots & 1 \\
a_{1} & b_{1}^{(1)} & \cdots & b_{1}^{(d)} \\
\vdots & \vdots & & \vdots \\
a_{d} & b_{d}^{(1)} & \cdots & b_{d}^{(d)}
\end{array}\right) \text {, }
$$

as can be seen from expanding the determinant along the top row, and from column operations we have

$$
\operatorname{det}\left(\begin{array}{cccc}
1 & 1 & \cdots & 1 \\
a_{1} & b_{1}^{(1)} & \cdots & b_{1}^{(d)} \\
\vdots & \vdots & & \vdots \\
a_{d} & b_{d}^{(1)} & \cdots & b_{d}^{(d)}
\end{array}\right)=\operatorname{det}\left(b^{(1)}-a, \cdots, b^{(d)}-a\right)
$$

Letting $g_{F}(a)=\operatorname{det}\left(b^{(1)}-a, \cdots, b^{(d)}-a\right)$, and assuming that the $b^{(j)}$ are ordered so that $\operatorname{det} B_{\text {mat }}=g_{F}(0)$ is positive, we obtain

$$
\beta(a)=1-\frac{\operatorname{det}\left(b^{(1)}-a, \cdots, b^{(d)}-a\right)}{\operatorname{det} B_{\mathrm{mat}}}=1-\frac{g_{F}(a)}{g_{F}(0)} \geqslant 1-\kappa(A),
$$

as required.
Remark 3.5. Less explicitly, one can argue that $1-\beta$ and $\frac{g_{F}}{g_{F}(0)}$ are the unique affine-linear functions $\mathbb{R}^{d} \rightarrow \mathbb{R}$ which vanish on $F$ and map 0 to 1 , so they must agree.

We can now deduce part of Theorem 1.8:

Proof of bound (1.8). Let

$$
v \in\left(N H(A) \cap \mathbb{Z}^{d}\right) \backslash\left(\bigcup_{b \in \operatorname{ex}(H(A))}(b N-\mathcal{E}(b-A))\right)
$$

where $N \geqslant(d+1) N_{0}$ with $N_{0}:=\kappa(A)(|A|-d-1) \operatorname{Vol}^{\dagger}{ }^{\dagger, m a x}(H(A))$.
Since $v \in N H(A)$ there is some subset $S=\left\{s_{0}, \ldots, s_{d}\right\} \subset \operatorname{ex}(H(A))$ with $v \in N H(S)$, by Caratheodory's theorem [3, Corollary 2.5]. Writing $v=\sum_{s \in S} c_{s} s$, with $c_{s} \geqslant 0$ for all $s$ and $\operatorname{wt}(c)=N$, there must be some $c_{s} \geqslant N_{0}$ as $N \geqslant(d+1) N_{0}$. By re-labelling the vectors in $S$ we may assume that $c_{s_{0}} \geqslant N_{0}$, and then

$$
v^{\prime}:=s_{0} N-v=\sum_{s \in S \backslash\left\{s_{0}\right\}} c_{s}\left(s_{0}-s\right) \in\left(N-c_{s_{0}}\right) H\left(s_{0}-S\right) \subset\left(N-N_{0}\right) H\left(s_{0}-S\right) .
$$

Letting $A^{\prime}=s_{0}-A$, we have $s_{0}-S \subset A^{\prime}$, so by the preceding equation $v^{\prime}$ is contained in $\left(N-N_{0}\right) H\left(A^{\prime}\right)$. We also have, by assumption, that $v \notin s_{0} N-\mathcal{E}\left(s_{0}-A\right)$, so $v^{\prime} \notin \mathcal{E}\left(s_{0}-A\right)=$ $\mathcal{E}\left(A^{\prime}\right)$. We conclude that $v^{\prime} \in \mathcal{P}\left(A^{\prime}\right)$. Note also that $\left|A^{\prime}\right|=|A|,\left|\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right|=|\operatorname{ex}(H(A))|$, $\operatorname{Vol}\left(H\left(A^{\prime}\right)\right)=\operatorname{Vol}(H(A)), \operatorname{Vol}^{\dagger, m a x}\left(A^{\prime}\right)=\operatorname{Vol}^{\dagger, \text { max }}(A)$, and the same for min.

Now apply Lemma 3.3 to $v^{\prime}$, with $A^{\prime}$ in place of $A$. We see that there exists an outer facet $F$ of $H\left(A^{\prime}\right)$ such that we can write $v^{\prime}=u+w$, where

$$
w=\sum_{b \in B} \lambda_{b} b \quad \text { and } \quad u=\sum_{a \in A^{\prime}} \eta_{a} a
$$

with $B:=A^{\prime} \cap F$, all $\eta_{a}, \lambda_{b} \in \mathbb{Z}_{\geqslant 0}$, and

$$
\begin{equation*}
\mathrm{wt}(\eta) \leqslant\left(\left|A^{\prime}\right|-|B|-1\right)\left(\operatorname{Vol}^{\dagger, \max }\left(H\left(A^{\prime}\right)\right)-1\right) \leqslant(|A|-d-1) \operatorname{Vol}^{\dagger, \max }(H(A)) . \tag{3.1}
\end{equation*}
$$

The second inequality here uses that $|B| \geqslant d$, which follows from the fact that every facet of the $d$-dimensional convex polytope $H\left(A^{\prime}\right)$ is the convex hull of at least $d$ points of $A^{\prime}$.

We know that $F=\left\{x \in H\left(A^{\prime}\right): \beta(x)=1\right\}$ for some linear map $\beta: \mathbb{R}^{d} \rightarrow \mathbb{R}$. As $v^{\prime} \in\left(N-N_{0}\right) H\left(A^{\prime}\right)$ we have

$$
N-N_{0} \geqslant \beta(v)=\beta(u)+\beta(w)=\sum_{a \in A^{\prime}} \eta_{a} \beta(a)+\mathrm{wt}(\lambda)
$$

as $\beta(b)=1$ for each $b \in B$. Moreover, combining (3.1) with Lemma 3.4 applied to $A^{\prime}$ gives

$$
\operatorname{wt}(\eta)-\sum_{a \in A^{\prime}} \eta_{a} \beta(a)=\sum_{a \in A^{\prime}} \eta_{a}(1-\beta(a)) \leqslant \kappa(A) \operatorname{wt}(\eta) \leqslant N_{0} .
$$

Summing the last two inequalities we then obtain

$$
\mathrm{wt}(\eta)+\mathrm{wt}(\lambda) \leqslant N
$$

and so $v^{\prime} \in N A^{\prime}$. Therefore $v=s_{0} N-v^{\prime} \in s_{0} N-N A^{\prime}=N\left(s_{0}-A^{\prime}\right)=N A$ as required.
It remains to prove the bound (1.7), which separates the contribution from $\operatorname{ex}(H(A))$. To effect this separation, we begin with an argument about triangulating polytopes.

Lemma 3.6 (Splitting $A$ into simplices centred at the origin). Let $A \subset \mathbb{Z}^{d}$ be finite with $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Then $H(A)$ may be partitioned as a finite union of simplices $\cup_{j} H\left(B^{(j)} \cup\{0\}\right)$, where each $B^{(j)} \subset \operatorname{ex}(H(A))$ is a basis of $\mathbb{R}^{d}$, and for each $i \neq j$ the set $H\left(B^{(i)} \cup\{0\}\right) \cap H\left(B^{(j)} \cup\{0\}\right)$ is contained in a subspace of dimension at most $d-1$. In particular, $H\left(B^{(i)} \cup\{0\}\right) \cap H\left(B^{(j)} \cup\{0\}\right)$ has zero measure.

When $d=2$, this is the obvious statement that any polygon with a vertex at the origin may be decomposed into disjoint triangles, all of which have a common vertex at the origin.

Proof. The $d=1$ case is trivial, so assume that $d \geqslant 2$. We will induct on dimension. Let $F_{1}, \ldots, F_{K}$ denote the list of outer facets of $H(A)$. Each $F_{i}$ is a convex polytope of dimension $d-1$, generated by points in $\operatorname{ex}(H(A))$. Therefore, by the induction hypotheses, one may decompose $F_{i}$ as a union of $(d-1)$-dimensional simplices of the form $H\left(\left\{a_{1}, \ldots, a_{d}\right\}\right)$, where $\left\{a_{1}, \ldots, a_{d}\right\} \subset \operatorname{ex}(H(A))$ is linearly independent and the intersection of any two of these simplices is contained in an affine subspace of dimension at most $d-2$. (In fact one may further assume that there is a common vertex $a_{1}$ to all these simplices, but that will not be necessary for the induction step.)

Choose $B^{(j)}$ to be the list of such sets $\left\{a_{1}, \ldots, a_{d}\right\}$, taken over all the facets $F_{1}, \ldots, F_{K}$. We claim that these $B^{(j)}$ satisfy the requirements of the lemma. By construction, each $B^{(j)} \subset \operatorname{ex}(H(A))$ is a basis of $\mathbb{R}^{d}$. To show that the union of the $H\left(B^{(j)} \cup\{0\}\right)$ is $H(A)$, fix $x \in H(A) \backslash\{0\}$ and pick (the unique) $\lambda_{x} \geqslant 1$ such that $\lambda_{x} x \in \cup_{K} F_{K}$. Then $\lambda_{x} x \in H\left(B^{(j)}\right)$ for some $B^{(j)}$. Thus there exist coefficients $c_{b}$ for $b \in B^{(j)}$ such that $c_{b} \geqslant 0, \operatorname{wt}(c)=1$, and

$$
\lambda_{x} x=\sum_{b \in B^{(j)}} c_{b} b .
$$

We therefore have

$$
x=\left(1-\frac{1}{\lambda_{x}}\right) 0+\sum_{b \in B^{(j)}} \frac{c_{b}}{\lambda_{x}} b \in H\left(B^{(j)} \cup\{0\}\right),
$$

as wanted.
It remains to show that each intersection $H\left(B^{(i)} \cup\{0\}\right) \cap H\left(B^{(j)} \cup\{0\}\right)$ is contained in a subspace of dimension at most $d-1$. So fix an arbitrary non-zero $x \in H\left(B^{(1)} \cup\{0\}\right) \cap$ $H\left(B^{(2)} \cup\{0\}\right)$. There are coefficients $c_{i}^{(1)}, c_{i}^{(2)} \geqslant 0$ with

$$
x=\sum_{i \leqslant d} c_{i}^{(1)} b_{i}^{(1)}=\sum_{i \leqslant d} c_{i}^{(2)} b_{i}^{(2)}
$$

and $0<\operatorname{wt}\left(c^{(1)}\right), \operatorname{wt}\left(c^{(2)}\right) \leqslant 1$. Letting $\mathrm{wt}_{j}$ denote $\operatorname{wt}\left(c^{(j)}\right)$, and assuming WLOG that $\mathrm{wt}_{2} \geqslant \mathrm{wt}_{1}$, we can re-scale to obtain

$$
y:=\frac{x}{\mathrm{wt}_{2}}=\sum_{i \leqslant d} \frac{c_{i}^{(1)}}{\mathrm{wt}_{2}} b_{i}^{(1)}=\sum_{i \leqslant d} \frac{c_{i}^{(2)}}{\mathrm{wt}_{2}} b_{i}^{(2)},
$$

which lies in $H\left(B^{(1)} \cup\{0\}\right) \cap H\left(B^{(2)}\right)$ since $\operatorname{wt}\left(\frac{c^{(1)}}{\mathrm{wt}_{2}}\right) \leqslant 1$ and $\operatorname{wt}\left(\frac{c^{(2)}}{\mathrm{wt}_{2}}\right)=1$.
Suppose for contradiction that $\operatorname{wt}\left(\frac{c^{(1)}}{\mathrm{wt}_{2}}\right)<1$, so $(1+\varepsilon) y \in H\left(B^{(1)} \cup\{0\}\right) \subset H(A)$ for all sufficiently small $\varepsilon>0$. Let $B^{(2)}$ be a subset of the outer facet defined by the linear map $\beta^{(2)}: \mathbb{R}^{d} \rightarrow \mathbb{R}$, so that $B^{(2)} \subset\left\{u \in \mathbb{R}^{d}: \beta^{(2)}(u)=1\right\}$ and $H(A) \subset\left\{u \in \mathbb{R}^{d}: \beta^{(2)}(u) \leqslant 1\right\}$. Then for all sufficiently small $\varepsilon>0$ we have

$$
1 \geqslant \beta^{(2)}((1+\varepsilon) y)=(1+\varepsilon) \beta^{(2)}(y)=1+\varepsilon>1 .
$$

This gives the desired contradiction, and we deduce that $\mathrm{wt}\left(\frac{c^{(1)}}{\mathrm{wt}_{2}}\right)=1$. So

$$
y \in H\left(B^{(1)}\right) \cap H\left(B^{(2)}\right),
$$

and because $x=\mathrm{wt}_{2} y$ for some $\mathrm{wt}_{2} \in[0,1]$ we conclude that

$$
H\left(B^{(1)} \cup\{0\}\right) \cap H\left(B^{(2)} \cup\{0\}\right)=H\left(\left(H\left(B^{(1)}\right) \cap H\left(B^{(2)}\right)\right) \cup\{0\}\right)
$$

Hence $H\left(B^{(1)} \cup\{0\}\right) \cap H\left(B^{(2)} \cup\{0\}\right)$ is contained in a subspace of dimension at most $d-1$ by the induction hypothesis.

Using this decomposition, we can generalise an additive combinatorial argument from [8] and [4] (which was applied when $H(A)$ was a $d$-simplex).

Lemma 3.7 (Restricting the influence of non-extremal elements). Let $A \subset \mathbb{Z}^{d}$ be a finite set with $0 \in \operatorname{ex}(H(A))$ and $\operatorname{span}(A)=\mathbb{R}^{d}$. Then there exists a finite set $S=d!\operatorname{Vol}(H(A)) A$ for which

$$
\mathcal{P}(A)=S+\mathcal{P}(\operatorname{ex}(H(A)))
$$

The proof is similar to (but simpler than) [8, Lemma 3.2] with the set $B:=\operatorname{ex}(H(A))$.
Proof. Let $v \in N A$. We will show that $v \in S+\mathcal{P}(\operatorname{ex}(H(A)))$ by induction on $N$. For $N \leqslant d!\operatorname{Vol}(H(A))$ we have $v \in N A \subset S \subset S+\mathcal{P}(\operatorname{ex}(H(A)))$.

Suppose that $N>d!\operatorname{Vol}(H(A))$. We can write $v=a_{1}+a_{2}+\cdots+a_{N}$ with each $a_{i} \in A$. By Lemma 3.6, there is a partition $H(A)=\cup_{j} H\left(B^{(j)} \cup\{0\}\right)$ where each $B^{(j)} \subset \operatorname{ex}(H(A))$. Therefore we can partition $\{1, \ldots, N\}=\cup_{j} T_{j}$ to obtain

$$
v=\sum_{j} \sum_{i \in T_{j}} a_{i}
$$

where $i \in T_{j}$ implies that $a_{i} \in H\left(B^{(j)} \cup\{0\}\right)$.
Since $\operatorname{Vol}(H(A))=\sum_{j} \operatorname{Vol}\left(H\left(B^{(j)} \cup\{0\}\right)\right)$ by Lemma 3.6 there is some $j$ for which

$$
\left|T_{j}\right|>d!\operatorname{Vol}\left(H\left(B^{(j)} \cup\{0\}\right)\right)=\left|\mathbb{Z}^{d} / \Lambda_{B^{(j)} \cup\{0\}}\right|,
$$

by the pigeonhole principle. Reordering the indices on the $a_{i}$ we write $T_{j}=\left\{1, \ldots,\left|T_{j}\right|\right\}$. Two of the $\left|T_{j}\right|$ partial sums

$$
a_{1}, a_{1}+a_{2}, \ldots, a_{1}+a_{2}+\cdots+a_{\left|T_{j}\right|} \bmod \Lambda_{B^{(j)} \cup\{0\}}
$$

must be congruent to each other $\bmod \Lambda_{B^{(j)} \cup\{0\}}$ by the pigeonhole principle. Their difference yields a non-trivial partial sum $\sum_{i \in I} a_{i} \equiv 0 \bmod \Lambda_{B^{(j)} \cup\{0\}}$ (where $I \subset T_{j}$ is a non-empty interval) and so this partial sum can be replaced by a sum of elements from $B^{(j)} \cup\{0\}$. Therefore

$$
\sum_{i \in I} a_{i} \in \mathcal{P}\left(B^{(j)} \cup\{0\}\right) \subset \mathcal{P}(\operatorname{ex}(H(A)))
$$

By the induction hypothesis, we have $v-\sum_{i \in I} a_{i} \in S+\mathcal{P}(\operatorname{ex}(H(A)))$, and so

$$
v \in S+\mathcal{P}(\operatorname{ex}(H(A)))+\mathcal{P}(\operatorname{ex}(H(A))) \subset S+\mathcal{P}(\operatorname{ex}(H(A)))
$$

as required.
We are now ready to finish the argument by modifying the proof of (1.8).
Proof of bound (1.7). Let

$$
v \in\left(N H(A) \cap \mathbb{Z}^{d}\right) \backslash\left(\bigcup_{b \in \operatorname{ex}(H(A))}(b N-\mathcal{E}(b-A))\right)
$$

where $N \geqslant(d+1) N_{0}$ with

$$
N_{0}:=\kappa(A)\left(d!\operatorname{Vol}(H(A))+(|\operatorname{ex}(H(A))|-d-1) \operatorname{Vol}^{\dagger, \max }(H(A))\right)
$$

As in the proof of (1.8) we use Caratheodory's theorem to determine some $s_{0} \in \operatorname{ex}(H(A))$ for which

$$
v^{\prime}:=s_{0} N-v \in\left(N-N_{0}\right) H\left(A^{\prime}\right) \cap \mathcal{P}\left(A^{\prime}\right),
$$

where $A^{\prime}:=s_{0}-A$. By Lemma 3.7 applied to $A^{\prime}$, we may write $v^{\prime}=y+x$ where $y \in$ $d!\operatorname{Vol}\left(H\left(A^{\prime}\right)\right) A^{\prime}$ and $x \in \mathcal{P}\left(\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right)$. Applying Lemma 3.3 to $x \in \mathcal{P}\left(\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right.$ ) (in place of $v \in \mathcal{P}(A))$ we write $x=u+w$, where $w \in \mathcal{P}(B \cup\{0\})$ and $u \in M \operatorname{ex}\left(H\left(A^{\prime}\right)\right)$, with $B=\operatorname{ex}\left(H\left(A^{\prime}\right)\right) \cap F$ for some outer facet $F$ of $H\left(A^{\prime}\right)$, and $M=\left(\left|\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right|-1-\right.$ $|B|)\left(\operatorname{Vol}^{\dagger}{ }^{\dagger, \max }\left(H\left(A^{\prime}\right)\right)-1\right)$.

Now let

$$
z=y+u=\sum_{a \in A^{\prime}} \rho_{a} a \quad \text { and } \quad w=\sum_{b \in B} \lambda_{b} b,
$$

and note that $\rho_{a}, \lambda_{b} \in \mathbb{Z}_{\geqslant 0}$ for all $a$ and $b$. We obtain $v=z+w$ and

$$
\begin{equation*}
\operatorname{wt}(\rho) \leqslant d!\operatorname{Vol}(H(A))+(|\operatorname{ex}(H(A))|-1-d) \operatorname{Vol}^{\dagger, \max }(H(A)), \tag{3.2}
\end{equation*}
$$

using $\left|\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right|=|\operatorname{ex}(H(A))|, \operatorname{Vol}^{\dagger, m a x}\left(H\left(A^{\prime}\right)\right)=\operatorname{Vol}^{\dagger, \max }(H(A))$, and $|B| \geqslant d$, as in the proof of (1.8). The outer facet $F$ is given by $\left\{x \in H\left(\operatorname{ex}\left(H\left(A^{\prime}\right)\right)\right): \beta(x)=1\right\}$ for some linear $\beta: \mathbb{R}^{d} \rightarrow \mathbb{R}$ so we again obtain

$$
N-N_{0} \geqslant \beta(v)=\beta(z)+\beta(w)=\sum_{a \in A^{\prime}} \rho_{a} \beta(a)+\operatorname{wt}(\lambda) .
$$

By again applying Lemma 3.4 to $A^{\prime}$, this time using the bound (3.2) in place of (3.1), we obtain $\operatorname{wt}(\rho)+\operatorname{wt}(\lambda) \leqslant N$ with the modified value for $N_{0}$, and so $v^{\prime} \in N A^{\prime}$. Therefore $v=s_{0} N-v^{\prime} \in s_{0} N-N A^{\prime}=N\left(s_{0}-A^{\prime}\right)=N A$ as required.
