#### Abstract

Imbalanced data and spurious correlations are common challenges in machine learning and data science. Oversampling, which artificially increases the number of instances in the underrepresented classes, has been widely adopted to tackle these challenges. In this article, we introduce OPAL (OversamPling with Artificial LLMgenerated data), a systematic oversampling approach that leverages the capabilities of large language models (LLMs) to generate high-quality synthetic data for minority groups. Recent studies on synthetic data generation using deep generative models mostly target prediction tasks. Our proposal differs in that we focus on handling imbalanced data and spurious correlations. More importantly, we develop a novel theory that rigorously characterizes the benefits of using the synthetic data, and shows the capacity of transformers in generating high-quality synthetic data for both labels and covariates. We further conduct intensive numerical experiments to demonstrate the efficacy of our proposed approach compared to some representative alternative solutions.

# 1 Introduction

Imbalanced data and spurious correlations are common challenges in machine learning and data science [Haixiang et al.](#page-14-0) [\(2017\)](#page-14-0); [Ye et al.](#page-16-0) [\(2024\)](#page-16-0). Imbalanced data occurs when classes in a dataset are not equally represented, such as in fraud detection or rare disease diagnosis, where positive samples are much less frequent than negative ones. Spurious correlations arise from misleading statistical relationships between variables due to irrelevant features. Imbalanced data can lead to spurious correlations, e.g., when some features predominantly present in the majority class, giving the illusion that these features are more predictive than they actually are. In both situations, statistical analyses may suffer from biased models that favor the majority group, or overfitting to irrelevant spurious features, which eventually lead to poor model performance, misleading insights, and compromised model generalizability and fairness.

Oversampling, which artificially balances the data by increasing the number of instances in the underrepresented classes, is a widely adopted technique to address the challenges of imbalanced data and spurious correlations [Gosain and Sardana](#page-14-1) [\(2017\)](#page-14-1). This approach

provides a more comprehensive view of the data landscape, helps achieve fairness in predictions, and improves the model's generalization capability.

In the era of AI-driven innovations, large language models (LLMs) have risen to prominence as indispensable tools across a wide spectrum of applications. By leveraging the knowledge learned from training on vast amounts of data, LLMs generate coherent and contextually relevant text, often resembling human-generated content.

In this article, we introduce a systematic oversampling framework, which we term as OPAL (OversamPling with Artificial LLM-generated data), to generate high-quality synthetic data for underrepresented classes. Leveraging the capacity of large language models (LLMs), specifically the transformer-based GPT models, we apply in-context learning to tabular data. We develop a novel theoretical framework that elucidates the conditions under which adding synthetic data is beneficial for reducing the variance and improving the minority group performance in the presence of imbalanced data and spurious correlations. Our theory rigorously characterizes the benefits of using synthetic data, and provides an exact dependence of the convergence rate on the synthetic data bias. In addition, we theoretically demonstrate the capacity of transformers to generate high-quality synthetic data for both labels and covariates given in-context examples, which contrasts with existing theories that mostly focus on prediction or inference from in-context examples [Xie et al.](#page-16-1) [\(2021\)](#page-16-1); [Garg et al.](#page-14-2) [\(2022\)](#page-14-2); [Zhang et al.](#page-16-2) [\(2023a\)](#page-16-2); [Bai et al.](#page-13-0) [\(2023\)](#page-13-0). Our proposal thus differs from recent studies on synthetic data generation, which have primarily targeted prediction tasks [Huang et al.](#page-14-3) [\(2022\)](#page-14-3); [Jain et al.](#page-14-4) [\(2024\)](#page-14-4). In contrast, we focus specifically on the challenges of imbalanced data and spurious correlations, and we establish the corresponding theoretical guarantees. Finally, we validate our approach against conventional oversampling techniques such as random replication [Loyola-González et al.](#page-15-0) [\(2016\)](#page-15-0) and SMOTE [Chawla](#page-13-1) [et al.](#page-13-1) [\(2002\)](#page-13-1), demonstrating the empirical competitiveness of our method. In summary, by harnessing the sophisticated generative capabilities of LLMs, our proposed method addresses the limitations of traditional oversampling methods, and provides a scalable and effective solution to improve the performance on imbalanced data and mitigate spurious correlations.

Outline of the paper. Section [2](#page-2-0) introduces the problem set-up and a general framework for oversampling with synthetic samples generated by GPT. Section [3](#page-3-0) first presents how the synthetic data quality affects the performance of the proposed method theoretically, and then analyzes the data quality of the synthetic data generated by transformers. Section [4](#page-9-0) provides numerical evidence that our proposed method is better than conventional oversampling methods and other baseline methods.

### 1.1 Related works

LLM-based synthetic data generation. Current works primarily focus on pre-training and fine-tuning GPT on specific datasets. [Borisov et al.](#page-13-2) [\(2023\)](#page-13-2) proposed GReaT, a pipeline to fine-tune GPT-2 on tabular datasets to generate synthetic samples. [Solatorio and Dupriez](#page-15-1) [\(2023\)](#page-15-1) extended this and proposed REalTabFormer that synthesizes relational tabular data. [Zhang et al.](#page-16-3) [\(2023b\)](#page-16-3) developed TAPTAP that is pre-fine-tuned from GPT-2 using 450 public tables to incorporate more prior knowledge. [Zhao et al.](#page-16-4) [\(2023\)](#page-16-4) proposed Tabula that involves iterative fine-tuning to address the long training times of LLMs for tabular data. [Gulati and Roysdon](#page-14-5) [\(2023\)](#page-14-5) proposed TabMT that employs masking to enable different data types and imputation. [Seedat et al.](#page-15-2) [\(2024\)](#page-15-2) developed Curated LLM to monitor the confidence and uncertainty to screen out lower-quality synthetic data. More recently, [Huang](#page-14-3) [et al.](#page-14-3) [\(2022\)](#page-14-3) presented catalytic priors, which use synthetic data to improve Bayesian

analysis when data is scarce. This approach combines the observed and synthetic data from simpler models for stable and interpretable inferences. [Jain et al.](#page-14-4) [\(2024\)](#page-14-4) explored how to improve machine learning by using "surrogate" data to supplement limited original data, proposed a weighted empirical risk minimization method, and introduced a scaling law to optimize the use of surrogate data. They showed that integrating surrogate data can significantly reduce test error, both theoretically and empirically.

Oversampling techniques. Oversampling has been widely adapted for handling imbalanced data and spurious correlation [Viloria et al.](#page-15-3) [\(2020\)](#page-15-3); [An et al.](#page-13-3) [\(2020\)](#page-13-3); [Ye et al.](#page-16-0) [\(2024\)](#page-16-0). Synthetic Minority Oversampling Technique (SMOTE) [Chawla et al.](#page-13-1) [\(2002\)](#page-13-1) and its variants [Han et al.](#page-14-6) [\(2005\)](#page-14-6); [Bunkhumpornpat et al.](#page-13-4) [\(2009\)](#page-13-4); [Douzas et al.](#page-14-7) [\(2018\)](#page-14-7) are popular oversampling methods that demonstrate significant improvements in handling class imbalance by oversampling. [He et al.](#page-14-8) [\(2008\)](#page-14-8) further proposed ADASYN by adaptively generating more synthetic data for the minority class that is harder to learn. More recently, [Douzas and Bacao](#page-14-9) [\(2018\)](#page-14-9); [Oh et al.](#page-15-4) [\(2019\)](#page-15-4); [Jo and Kim](#page-14-10) [\(2022\)](#page-14-10) have started to employ Generative Adversarial Networks (GANs) [Goodfellow et al.](#page-14-11) [\(2014\)](#page-14-11) for oversampling [Douzas](#page-14-9) [and Bacao](#page-14-9) [\(2018\)](#page-14-9) leveraged GANs to create more realistic synthetic samples, enhancing the diversity and quality of the oversampled data. See also [Krawczyk](#page-15-5) [\(2016\)](#page-15-5) for a review on oversampling techniques. On the other hand, [Chawla et al.](#page-13-5) [\(2004\)](#page-13-5); [Fernández et al.](#page-14-12) [\(2018\)](#page-14-12); [Johnson and Khoshgoftaar](#page-14-13) [\(2019\)](#page-14-13) have shown that the oversampling minority group could lead to overfitting. [Chatterji et al.](#page-13-6) [\(2022\)](#page-13-6) theoretically proved that undersampling the majority group to balance out the groups is minimax optimal in handling the imbalanced data for non-parametric classification. These results highlight the room for improvement in oversampling methodology.

# <span id="page-2-0"></span>2 Oversampling with artificial LLM-generated data

### 2.1 Problem setup

In many real-world datasets, individual samples are naturally organized into groups. Machine learning models trained on such datasets often perform poorly on the under-represented minority groups. To enhance the performance, we introduce the synthetic data that mimic the raw data in these groups.

We first introduce the problem setup. Let  $\mathcal G$  denote the set of groups. For each group  $g \in \mathcal{G}$ , let  $n_q$  be the number of observed raw samples, while we further generate  $m_q$  synthetic samples for this group. Let  $n_{\text{total}} := \sum_{g \in \mathcal{G}} n_g$ , and  $m_{\text{total}} := \sum_{g \in \mathcal{G}} m_g$  be the total number of raw and synthetic data, respectively. We aim to investigate the effect of the synthetically balanced data on the risk of both majority and minority groups. Denote the observed raw data for group g as  $\{(\boldsymbol{x}_i^{(g)}\})$  $\binom{g}{i},y_i^{(g)}$  $\{S^{(g)}\}_{i\in[n_g]}$ , and the generated synthetic data for group g as  $\{(\tilde{\bm{x}}_i^{(g)}$  $_{i}^{\left( g\right) },\tilde{y}_{i}^{\left( g\right) }$  $\{S^{(g)}\}_{i\in[m_g]}$ . Given a loss function  $\ell(\theta; x, y)$  parameterized by  $\theta \in \Theta$ , we define the empirical risk with the raw and synthetic data as follows:

<span id="page-2-1"></span>
$$
\widehat{\mathcal{R}}_{syn}(\boldsymbol{\theta}) := \frac{1}{n_{\text{total}} + m_{\text{total}}} \left( \sum_{g \in \mathcal{G}} \sum_{i \in [n_g]} \ell(\boldsymbol{\theta}; \boldsymbol{x}_i^{(g)}, y_i^{(g)}) + \sum_{g \in \mathcal{G}} \sum_{i \in [m_g]} \ell(\boldsymbol{\theta}; \tilde{\boldsymbol{x}}_i^{(g)}, \tilde{y}_i^{(g)}) \right). \tag{1}
$$

We minimize the above empirical risk to obtain the parameter estimate  $\widehat{\theta}_{syn}$ . Our goal is to analyze the group specific risk  $\mathcal{R}_g(\widehat{\theta}_{syn})$ , where  $R_g(\theta) := \mathbb{E}[\ell(\theta; x_1^{(g)})]$  $\mathfrak{g}^{(g)}_1, \mathfrak{y}_1^{(g)}$  $[g<sup>(g)</sup>]$ , for  $g \in \mathcal{G}$ . We next consider two specific situations: imbalanced classification and spurious correlations.

<span id="page-3-1"></span>

**Imbalanced classification.** We observe the pairs of label and covariate  $(x_i, y_i)_{i \in [n_{\text{total}}]}$  $X \times Y$ , where X is the set of covariates, Y is the label set, and there is an unequal distribution among the group labels. For this task, the group structure is determined by the label, i.e.,  $\mathcal{G} = \mathcal{Y}$ . Our goal is to improve the minority group risk for predicting  $y_i$  given  $\boldsymbol{x}_i$ .

Spurious correlations. We observe the triples of the core feature, the spurious feature, and the label  $(z_i, a_i, y_i)_{i \in [n_{\text{total}}]} \subset \mathcal{X} \times \mathcal{A} \times \mathcal{Y}$ . Such a setting is commonly used in the spurious correlations literature [Sagawa et al.](#page-15-6) [\(2019,](#page-15-6) [2020\)](#page-15-7); [Chaudhuri et al.](#page-13-7) [\(2023\)](#page-13-7); [Ye et al.](#page-16-0) [\(2024\)](#page-16-0). For this task, the group structure is determined by the combination of the label and spurious feature, i.e.,  $\mathcal{G} = \mathcal{Y} \times \mathcal{A}$ . Our goal is to disentangle  $a_i$  and  $y_i$ , and improve the prediction performance of  $y_i$  for the minority groups.

### 2.2 A general algorithm

We propose OPAL, short for **O**versamPling with **A**rtificial LLM-generated data, a new oversampling approach that leverages the capability of large language models (LLMs) to generate high-quality synthetic data for minority groups. We illustrate our approach in Figure [1](#page-3-1) and Algorithm 1 with the setting of two groups, the minority group  $g_{\text{min}}$  and the majority group  $g_{\text{maj}}$ . More specifically, to prepare the tabular data to feed into the LLM, we follow [Borisov et al.](#page-13-2) [\(2023\)](#page-13-2) to convert the numeric values into the sentence serialized format  $[f_i$  "is"  $v_{ij}]$ , where  $f_j$  is the j-th feature name and  $v_{ij}$  is the value of the j-th feature of i-th data sample. To ensure that the LLM captures the characteristics of the minority group, we balance the input seed data by subsampling a balanced dataset from the original data (Algorithm [1,](#page-3-1) line 1). We then craft prompts that instruct the LLM to identify the underlying patterns, understand the data distributions, and generate synthetic samples that are distinct from the input data (line 2). The details of the prompts and the format of the serialized data are elaborated in Appendix [E.1.](#page-49-0) Finally, we choose the synthetic samples that correspond to the minority group, and augment them to the raw data (line 3), completing the oversampling process.

# <span id="page-3-0"></span>3 Theoretical Analysis

We establish the theoretical guarantees for effective oversampling with synthetic data when employing a high-quality synthetic data generator. Furthermore, we theoretically demonstrate that the transformers are indeed capable of producing such high-quality synthetic data.

### <span id="page-4-4"></span>3.1 Oversampling with synthetic data

We first investigate the performance of the general empirical risk minimizer of the risk  $\mathcal{R}_{\text{syn}}$  in equation [1.](#page-2-1) We then study the imbalanced classification and spurious correlations settings, respectively. We present the main results here, while giving a more rigorous characterization in Appendix [B.](#page-19-0)

We define the population-level balanced risk that puts equal weights on all groups as

<span id="page-4-5"></span>
$$
\mathcal{R}_{\text{bal}}(\boldsymbol{\theta}) := \frac{1}{|\mathcal{G}|} \sum_{g \in \mathcal{G}} \mathcal{R}_g(\boldsymbol{\theta}), \quad \text{where} \quad \mathcal{R}_g(\boldsymbol{\theta}) := \mathbb{E}[\ell(\boldsymbol{\theta}; \boldsymbol{x}_1^{(g)}, y_1^{(g)})]. \tag{2}
$$

Let the minimizer of  $\widehat{\mathcal{R}}_{syn}$  and  $\mathcal{R}_{bal}$  be  $\widehat{\theta}_{syn}$  and  $\theta_{bal}$ , respectively. Note that  $\theta_{bal}$  is the oracle solution, balancing out the parameters over all groups present in the dataset. We assume that  $\mathcal{B}_q$  and  $\mathcal{R}_q$  are twice differentiable around  $\theta_{\text{bal}}$  with bounded Lipschitz Hessians, and  $\sum_{g} \nabla^2 \mathcal{R}_g(\boldsymbol{\theta})$  is strictly positive definite around  $\boldsymbol{\theta}_{\text{bal}}$ .

Our goal is to investigate the effect of bias present in the synthetic data to the estimator  $\hat{\theta}_{syn}$ , by measuring the risk of group g:  $\mathcal{R}_g(\theta_{syn}) - \mathcal{R}_g(\theta_{bal})$ . To demonstrate the scaling behavior of this risk, we consider the regime where  $\min_{g \in \mathcal{G}} n_g$  grows. Define the bias of the risk for group g as  $\mathcal{B}_g(\boldsymbol{\theta}) := \mathbb{E}[\ell(\boldsymbol{\theta}; \tilde{\boldsymbol{x}}_1^{(g)})]$  $\widetilde{y}^{(g)}_1, \widetilde{y}^{(g)}_1$  $[\mathcal{E}^{(g)}_1)] - \mathbb{E}[\ell(\bm{\theta};\bm{x}^{(g)}_1)]$  $\binom{g}{1}, y_1^{(g)}$  $\binom{1}{1}$ . We introduce some regularity assumptions.

<span id="page-4-0"></span>**Assumption 3.1.** Assume that  $\sup_{\theta \in \Theta} |\mathcal{B}_q(\theta)| \vee ||\nabla \mathcal{B}_q(\theta)|| = o(1)$  for all  $g \in \mathcal{G}$ .

<span id="page-4-1"></span>**Assumption 3.2.** Assume that  $\sup_{\theta \in \Theta} |\widehat{\mathcal{R}}_{syn}(\theta) - \mathcal{R}_{syn}(\theta)| = o_p(1)$ , and that

$$
\inf_{\theta \in \Theta: \|\theta-\theta_{\mathrm{syn}}\| \geq \epsilon} \mathbb{E}[\widehat{\mathcal{R}}_{\mathrm{syn}}(\theta)] > \mathbb{E}[\widehat{\mathcal{R}}_{\mathrm{syn}}(\theta_{\mathrm{syn}})], \quad \text{and} \quad \inf_{\theta \in \Theta: \|\theta-\theta_{\mathrm{bal}}\| \geq \epsilon} \mathcal{R}_{\mathrm{bal}}(\theta) > \mathcal{R}_{\mathrm{bal}}(\theta_{\mathrm{bal}}).
$$

<span id="page-4-2"></span>**Assumption 3.3.** Assume that  $\ell(\theta; x, y)$  and  $\ell(\theta; \tilde{x}, \tilde{y})$  are differentiable around  $\theta_{bal}$  almost surely under the distributions for the raw data  $(x, y)$  and the synthetic data  $(\tilde{x}, \tilde{y})$ , with the second order moments of gradient Lipschitz around  $\theta_{\text{bal}}$ .

Assumption [3.1](#page-4-0) describes the regime where the bias for each group  $q \in \mathcal{G}$  decreases as the amount of seed data increases. It is satisfied when the synthetic data generator improves its output quality with more seed data. Assumptions [3.2](#page-4-1) and [3.3](#page-4-2) are standard assumptions in proving the consistency and asymptotic normality of the estimators in statistical learning [Van der Vaart](#page-15-8) [\(2000\)](#page-15-8); [Jain et al.](#page-14-4) [\(2024\)](#page-14-4).

<span id="page-4-3"></span>**Theorem [3.1](#page-4-0).** Under Assumptions 3.1[-3.3,](#page-4-2) for any  $g \in \mathcal{G}$ ,

$$
\mathcal{R}_{g}(\widehat{\theta}_{syn}) = \mathcal{R}_{g}(\theta_{bal}) - \{\nabla \mathcal{R}_{g}(\theta_{bal})\}^{\top} \{\nabla^{2} \mathcal{R}_{bal}(\theta_{bal})\}^{-1} \boldsymbol{b} + O_{p} \bigg(\frac{v_{g}}{\sqrt{n_{total} + m_{total}}} + \frac{1}{m_{total} \wedge n_{total}} + ||\boldsymbol{b}||^{2}\bigg),
$$
  
where  $\boldsymbol{b} := \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{total} + m_{total}} \nabla \mathcal{B}_{g'}(\theta_{bal}), and v_{g} > 0$  is given in equation 7.

Within the  $O_p$  term,  $v_g/\sqrt{n_{\text{total}} + m_{\text{total}}}$  accounts for the variance of the gradients, arising from the finite sample variation of  $\mathcal{R}_{syn}$ . We observe that the group-specific risk is influenced by the bias term  $\{\nabla \mathcal{R}_g(\theta_{\text{bal}})\}^{\top} \{\nabla^2 \mathcal{R}_{\text{bal}}(\theta_{\text{bal}})\}^{-1}$ *b*. The term *b* originates from two sources: the group-specific bias  $\|\mathcal{B}_{g'}(\theta_{bal})\|$  introduced by the synthetic data, and the ratio  $m_{g'}/(n_{\text{total}} + m_{\text{total}})$  of the group-specific synthetic data size to the total number of

raw and synthetic samples, which reflects the data imbalance. A direct consequence of Theorem [3.1](#page-4-3) is that choosing  $m_{g'} \asymp \frac{v_g^2}{|\mathcal{G}| ||\nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_{\text{bal}})||^2}$  for all  $g' \in \mathcal{G}$  gives

$$
|\mathcal{R}_g(\widehat{\theta}_\text{syn}) - \mathcal{R}_g(\boldsymbol{\theta}_\text{bal})| = O_p(\max_{g' \in \mathcal{G}} \|\nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_\text{bal})\| \vee n_\text{total}^{-1}).
$$

Therefore, having a high-quality synthetic data generator is beneficial for the convergence of the risk. We also briefly note that the notation  $O_p$  hides the constants in the assumptions and the constants depending on  $\mathcal{R}_g$ .

### 3.1.1 Imbalanced classification

We first apply the general result in Section [3.1](#page-4-4) to the binary imbalanced classification task with the label set  $\mathcal{G} = \mathcal{Y} = \{0, 1\}$ , where group 0 is treated as the minority group and group 1 as the majority group. For imbalanced data classification, we add the synthetic data only to the minority group  $q = 0$ , such that the total number of samples for each group becomes equal, i.e.,  $n_0 + m_0 = n_1$ . Let  $\mathcal{R}_{bal}$  be the balanced risk defined in equation [2](#page-4-5) with  $\mathcal{G} = \mathcal{Y}$ . We are interested in the performance of  $\hat{\theta}_{syn}$  against  $\theta_{bal}$  for the minority group. Recall that  $\mathcal{R}_0(\boldsymbol{\theta}) := \mathbb{E}[\ell(\boldsymbol{\theta}; \boldsymbol{x}_1, y_1)|y_1 = 0]$  in our setting.

<span id="page-5-0"></span>**Corollary [3.1](#page-4-0).** Under Assumptions 3.1[-3.3,](#page-4-2) if  $n_0 \le cn_1$  holds for some constant  $c \in (0,1)$ , then,

$$
\mathcal{R}_1(\widehat{\theta}_\text{syn}) = \mathcal{R}_0(\boldsymbol{\theta}_\text{bal}) - \frac{n_1 - n_0}{2n_1} b_{0,0} + O_p\bigg(\frac{1}{\sqrt{n_1}}v_0 + \|\nabla \mathcal{B}_0(\boldsymbol{\theta}_\text{bal})\|^2\bigg),
$$

where  $b_{0,0} = \{\nabla \mathcal{R}_0(\boldsymbol{\theta}_{bal})\}^{\top} \{\nabla^2 \mathcal{R}_{bal}(\boldsymbol{\theta}_{bal})\}^{-1} \nabla \mathcal{B}_0(\boldsymbol{\theta}_{bal})$  and  $v_0 > 0$  is given in equation [13.](#page-23-0)

The term  $\frac{n_1-n_0}{2n_1}$  b<sub>0,0</sub> represents the bias introduced by the addition of the synthetic data for group  $g = 1$ . The variance term is proportional to  $n_1^{-1/2}$  $\frac{-1}{2}$ . This corollary indicates that  $\widehat{\theta}_{syn}$  achieves similar minority-group performance as  $\theta_{bal}$  when the introduced bias is small.

#### 3.1.2 Spurious correlations

We next apply the general result in Section [3.1](#page-4-4) to the spurious correlations setting with a binary label and a discrete-value spurious feature, i.e.,  $\mathcal{Y} = \{-1, 1\}$  and  $\mathcal{A} = \{-\gamma, \gamma\}$ with some  $\gamma \in \mathbb{R}^q$ . A similar setting has been used in the learning theory under spurious correlations [Arjovsky et al.](#page-13-8) [\(2019\)](#page-13-8); [Ye et al.](#page-16-5) [\(2023\)](#page-16-5). We observe  $\mathbf{x}_i = (\mathbf{z}_i, \mathbf{a}_i)$  and  $y_i$ , where  $z_i \in \mathbb{R}^p$  is the core feature and  $a_i \in \mathcal{A}$  is the spurious feature. We assume the conditional independence of  $a_i$  and  $z_i$  given  $y_i$ . For simplicity, assume  $n_{(-1,\gamma)} = n_{(1,-\gamma)} = n_{\min}$  $n_{\text{maj}} = n_{(1,\gamma)} = n_{(-1,-\gamma)}$ , so that groups  $(-1,-\gamma)$  and  $(1,\gamma)$  are the majority groups. We choose the synthetic data size for group  $g = (y, a) \in \mathcal{G}$  by  $m_{(y, a)} = (n_{\text{maj}} - n_{\text{min}}) \mathbb{I} \{y = a\}$ to equal the raw and synthetic data size for each group. Define the reweighted risk and its minimizer by

$$
\mathcal{R}_{\text{rw}}(\boldsymbol{\theta}) := \frac{1}{2} \sum_y \mathbb{E}[\ell(\boldsymbol{\theta};\boldsymbol{x}_1',y_1)|y_1=y], \quad \text{and} \quad \boldsymbol{\theta}_{\text{rw}} := \operatorname*{arg\,min}_{\boldsymbol{\theta} \in \Theta} \mathcal{R}_{\text{rw}}(\boldsymbol{\theta}).
$$

<span id="page-5-1"></span>where  $x'_1 = (z_1, a'_1)$  with  $a'_1 \sim \text{Unif}(\{-\gamma, \gamma\})$  independent of  $y_1$ . Note that  $\mathcal{R}_{rw}$  is the so-called reweighted loss [Shimodaira](#page-15-9) [\(2000\)](#page-15-9); [Byrd and Lipton](#page-13-9) [\(2019\)](#page-13-9); [Sagawa et al.](#page-15-7) [\(2020\)](#page-15-7) beneficial in handling spurious correlations. It successfully decouples the correlation between  $y_i$  and  $a_i$ , mitigating the effect of spurious correlations. We are interested in the performance of  $\hat{\theta}_{syn}$  against  $\theta_{rw}$ , measured in the worst group risk max $_{g \in \mathcal{G}} \mathcal{R}_g(\theta) :=$  $\max_{y \in \mathcal{Y}, \boldsymbol{a} \in \mathcal{A}} \mathbb{E}[\ell(\boldsymbol{\theta}; (\boldsymbol{z}_1, \boldsymbol{a}_1), \boldsymbol{y}_1)|y_1 = y, \boldsymbol{a}_1 = \boldsymbol{a}].$ 

**Corollary 3.2.** Under Assumptions [3.1-](#page-4-0)[3.3,](#page-4-2) if  $n_{min} \leq cn_{maj}$  holds for some constant  $c \in (0,1)$ , then,

$$
\max_{g \in \mathcal{G}} \mathcal{R}_g(\widehat{\theta}_{syn}) = \max_{g \in \mathcal{G}} \mathcal{R}_g(\theta_{rw}) + O_p\bigg(\|\nabla \mathcal{B}_{(-1,\gamma)}(\theta_{rw})\| + \|\nabla \mathcal{B}_{(1,-\gamma)}(\theta_{rw})\| + \frac{\max_{g \in \mathcal{G}} v_g}{\sqrt{n_{maj}}}\bigg),
$$

where  $v_q > 0$  is given in equation [15.](#page-23-1)

Within the  $O_p$  term, there are bias terms for the minority groups, and a variance term of order  $n_{\text{maj}}^{-1/2}$ . The worst group risk of  $\hat{\theta}_{\text{syn}}$  becomes close to the worst group risk of  $\theta_{\text{rw}}$ when the bias of the minority group, coming from the synthetic data generation, decreases.

### <span id="page-6-1"></span>3.2 Transformers are high-quality synthetic data generators

We next provide theories to quantify the data quality generated by the transformers. Recall that Algorithm [1](#page-3-1) utilizes the balanced seed data selected from the raw dataset. For our theoretical analysis, we consider a dataset that is already balanced and omit the "seed" superscript for the raw data. Let  $\mathcal X$  be any space containing the covariates and labels. Suppose that we have *n* i.i.d. seed data  $\mathcal{D}_n := (X_i, Y_i)_{i \in [n]},$  where  $X_i, Y_i \in \mathcal{X}$ . Given  $\mathcal{D}_n$ in-context, we aim to show that the transformers can generate the high-quality synthetic data  $(\tilde{X}_1, \tilde{Y}_1),(\tilde{X}_2, \tilde{Y}_2),\ldots$  that mimic the distribution of  $(X_1, Y_1)$ . We also provide more technical details in Appendix [A](#page-17-0) and Appendix [C.](#page-24-0)

#### <span id="page-6-2"></span>3.2.1 Data generating process

We first introduce the data generating process for  $(X_i, Y_i)_{i \in [n]}$ . As assumed in the literature on word representations [Arora et al.](#page-13-10) [\(2015\)](#page-13-10); [Khalife et al.](#page-14-14) [\(2021\)](#page-14-14); [Li et al.](#page-15-10) [\(2022\)](#page-15-10), we consider a Bayesian setting for the token embeddings, where  $u_1, \ldots, u_d \in \mathbb{R}^r$  are modeled as i.i.d. realizations of  $N(0, I_r/r)$ . Let  $U = [\boldsymbol{u}_1, \dots, \boldsymbol{u}_d]^\top$ . We assume that  $X_i$  and  $Y_i$  take values in a finite set  $\mathcal{X} = [d]$ , reflecting the treatment of tabular data as a collection of finite tokens for language models. We define a "subject" as any background information providing context for each tabular data. For instance, the data on heart failure rates could be specified by the subject "heart failure".

We then introduce the data generating process for tabular data: generative models for covariates and discriminative models for labels given the covariates. Specifically,  $(X_i, Y_i) \in \mathcal{X}^2$  given subject  $T = t$  and discriminative function index  $M = m$  follows a multinomial distribution defined by,

<span id="page-6-0"></span>
$$
\mathbb{P}(X_i = x; T = t, U, \eta) \propto \exp(\eta^{-1} \langle \mathbf{z}^{(t)}, \mathbf{u}_x \rangle),
$$
  

$$
\mathbb{P}(Y_i = y | X_i = x; M = m, U, \eta) \propto \exp(\eta^{-1} \langle f^{(m)}(\mathbf{u}_x), \mathbf{u}_y \rangle),
$$
 (3)

where  $t \in \mathcal{T}$ ,  $m \in \mathcal{M}$  are possible indices of subjects and discriminative function indices,  $\eta > 0$  is a parameter,  $u_x \in \mathbb{R}^r$  is the embedding of the token  $x \in \mathcal{X}, z^{(t)} \in \mathbb{R}^r$  is the representation of subject t, and  $f^{(m)} : \mathbb{R}^r \to \mathbb{R}^r$  is a discriminative function with index m. We consider the case where  $|\mathcal{M}| \geq |\mathcal{T}|$  for simplicity. We allow  $\eta$  to vary on the interval  $[(1/\sqrt{r})\log d, \infty)$ , while assume  $||z^{(t)}|| = 1$  for any  $t \in \mathcal{T}$  and  $\sup_{\mathbf{u} \in \mathbb{B}_r(\log d)} ||f^{(m)}(\mathbf{u})|| \leq 1$ for identifiability. A similar model has been proposed and used in the language modeling literature [Mnih and Hinton](#page-15-11) [\(2007\)](#page-15-11); [Arora et al.](#page-13-10) [\(2015,](#page-13-10) [2017\)](#page-13-11); [Shi et al.](#page-15-12) [\(2017\)](#page-15-12); [Khalife et al.](#page-14-14) [\(2021\)](#page-14-14). Denote the joint distribution of  $X_1$  and  $Y_1$  by  $P_{X_1,Y_1;T=t,M=m,U,\eta}$  and (conditional) distributions of  $X_1$  and  $Y_1|X_1$  under model [3](#page-6-0) by  $P_{X_1;T=t,U,\eta}$  and  $P_{Y_1|X_1;M=m,U,\eta}$ , respectively. Based on the intuition that the transformers are pre-trained on vast amount of data, we further assume that the candidate of subject embeddings  $\{z^{(t)}\}_{t\in\mathcal{T}}$  and candidate of functions  $\{f^{(m)}\}_{m\in\mathcal{M}}$  are known to the transformers.

Finite known candidates of subject embeddings and functions Based on the intuition that transformers are pre-trained on vast amount of data, we further assume that the transformer knows the candidate of subject embeddings  $\{z^{(t)}\}_{t\in\mathcal{T}}$  and candidate of  $\text{functions } \{f^{(m)}\}_{m\in\mathcal{M}}\subset \mathcal{F}(L_0,r_0)\subset \{\text{FFN}_{\nu_{\text{pre},L_0}}\circ\text{FFN}_{\nu_{\text{pre},L_0-1}}\circ\cdots\circ\text{FFN}_{\nu_{\text{pre},1}}:\nu_{\text{pre},\ell}\in$  $\mathbb{R}^{r_0 \times r} \times \mathbb{R}^{r \times r_0}$  for  $\ell \in [L_0]$  with  $L_0, r_0 \in \mathbb{N}^+$ .

We remark that our modeling differs from those in in-context learning theory papers. For instance, [Xie et al.](#page-16-1) [\(2021\)](#page-16-1); [Garg et al.](#page-14-2) [\(2022\)](#page-14-2); [Zhang et al.](#page-16-2) [\(2023a\)](#page-16-2); [Bai et al.](#page-13-0) [\(2023\)](#page-13-0) consider settings where seed data is directly treated as tokens. In contrast, our approach is motivated by the use of proprietary text-based LLMs with serialised tabular data, rather than training tabular transformers from scratch. Therefore, it is more natural to consider tokens indirectly embed the seed data in our setting.

#### 3.2.2 Preliminaries of transformers

We follow the notations in [Akyürek et al.](#page-13-12) [\(2022\)](#page-13-12); [Von Oswald et al.](#page-16-6) [\(2023\)](#page-16-6); [Bai et al.](#page-13-0) [\(2023\)](#page-13-0) to introduce the transformers, which consist of two main types of layers: the self-attention, and the feed-forward transformation. Denote the input by  $H = [\mathbf{h}_1, \mathbf{h}_2, \dots, \mathbf{h}_N] \in \mathbb{R}^{D \times N}$ , where  $h_s \in \mathbb{R}^D$  is a column vector denoting the embedding of the s-th token. A transformer layer is defined as the composition of a self-attention layer and a feedforward layer. Specifically, given an attention layer Attn<sub>u</sub> and FFN<sub>v</sub> defined below, we define TF<sub>*w*</sub> with  $\psi = (\mu, \nu)$ as  $TF_{\psi} := FFN_{\nu} \circ \text{Attn}_{\mu}$ . With a slight abuse of notation, we write multiple transformer layers as  $\mathrm{TF}_{(\psi_1,...,\psi_L)} := \mathrm{TF}_{\psi_L} \circ \cdots \circ \mathrm{TF}_{\psi_1}$ .

**Self-attention layer.** Given a matrix  $H \in \mathbb{R}^{D \times N}$ , the self-attention layer with J heads and parameters  $\mu = \{ (Q_j, K_j, V_j) \}_{j=1}^J$  takes H as input and outputs

$$
\text{Attn}_{\mu}(H)_{s} := \boldsymbol{h}_{s} + \sum_{j \in [J]} \sum_{s' \in [N]} \sigma(\langle Q_{j} \boldsymbol{h}_{s}, K_{j} \boldsymbol{h}_{s'} \rangle) V_{j} \boldsymbol{h}_{s'}, \quad s \in [N],
$$

where  $\sigma$  is the ReLU activation function, and  $Q, K, V \in \mathbb{R}^{D \times D}$ .

**Feed-forward transformation layer.** Given a matrix  $H \in \mathbb{R}^{D \times N}$ , the feed-forward transformation layer with parameters  $\nu = (W_1, W_2) \in \mathbb{R}^{D' \times D} \times \mathbb{R}^{D \times D'}$  takes H as input and outputs

$$
FFN_{\nu}(H) := H + W_2 \sigma(W_1 H).
$$

 $\textbf{Input tokens for tabular data.} \quad \text{We assume that tokens } (\boldsymbol{h}^Y_i)_{i \in [n]} \text{ correspond to } (Y_i)_{i \in [n]},$ and  $(h_i^X)_{i \in [n]}$  correspond to  $(X_i)_{i \in [n]}$ . The input of the transformer is given by

$$
H_n=[\boldsymbol{h}_1^X;\boldsymbol{h}_1^Y;\boldsymbol{h}_2^X;\boldsymbol{h}_2^Y;\ldots;\boldsymbol{h}_n^X;\boldsymbol{h}_n^Y].
$$

We consider the composite type positional encoding, i.e., the forms of  $h_i^X$  and  $h_i^Y$  are given by  $\boldsymbol{h}_i^X = (\boldsymbol{u}_{X_i}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2i-1,n}^\top)^\top$  and  $\boldsymbol{h}_i^Y = (\boldsymbol{u}_{X_i}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2i,n}^\top)^\top$ , respectively. Note that this differs from the practical additive positional encoding. Specifically for  $i \in [n]$ , the positional encoding  $p_{s,n} \in \mathbb{R}^4$  is defined as

$$
\boldsymbol{p}_{s,n}=\Big(\Big\lceil \frac{s}{2}\Big\rceil, (s\,\text{mod}\, 2), 2n, 1\Big)^{\top},
$$

where s mod 2 is 0 for even s and 1 for odd s. The first coordinate specifies the index of the current token, and the second coordinate indicates whether the current token corresponds to  $X_i$  or  $Y_i$ . The third coordinate takes the length of the given tokens. The last coordinate is a constant added for technical convenience.

**Output distribution.** Given the initial input tokens  $H_n \in \mathbb{R}^{D \times 2n}$ , a transformer parameterized by  $\Psi$  sequentially outputs  $h_{2n+1}, h_{2n+2}, \ldots$  corresponding to the synthetic data from a categorical distribution given the last output from the transformer layers. At each step  $\ell \in \mathbb{N}^+$ , given all previous tokens  $H_n$  and  $h_{2n+1}, h_{2n+2}, \ldots, h_{2n+\ell-1}$ , the next token  $h_{2n+\ell}$  is given by  $h_{2n+\ell} = (\boldsymbol{v}_{2n+\ell}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2n+\ell,n}^\top)^\top$ , where  $\boldsymbol{v}_{2n+\ell} \in \mathbb{R}^r$  is drawn from a categorical distribution with softmax probability over all possible tokens  $u_1, \ldots, u_d \in \mathbb{R}^r$ :

$$
\mathbb{P}(\boldsymbol{v}_{2n+\ell}=\boldsymbol{u}_x)\propto \exp(\tau^{-1}\langle \boldsymbol{u}_x, (\tilde{\boldsymbol{h}}_{2n+\ell-1})_{1:r}\rangle),
$$

where

$$
\tilde{\bm h}_{2n+\ell-1} := (\mathrm{TF}_{\Psi}([H_n,\bm h_{2n+1},\bm h_{2n+2},\ldots,\bm h_{2n+\ell-1}]))_{2n+\ell-1},
$$

and  $\tau > 0$  is the temperature parameter. Since we expect the outputs  $h_{2n+1}, h_{2n+2}, h_{2n+3}, h_{2n+4}, \ldots$ from a transformer TF<sub>V</sub> correspond to  $\tilde{X}_1, \tilde{Y}_1, \tilde{X}_2, \tilde{Y}_2, \ldots$ , we write the joint distribution of  $v_{2n+2s-1}$  and  $v_{2n+2s}$  as

$$
Q_{\tilde{X}_s,\tilde{Y}_s;\Psi,\tau,\mathcal{D}_n}(x,y):=\mathbb{P}(\boldsymbol{v}_{2n+2s-1}=\boldsymbol{u}_x,\boldsymbol{v}_{2n+2s}=\boldsymbol{u}_y).
$$

We similarly denote the marginal and conditional distributions of  $\tilde{X}_s$  and  $\tilde{Y}_s | \tilde{X}_s$  by  $Q_{\tilde{X}_s, \Psi, \tau, \mathcal{D}_n}(x)$  and  $Q_{\tilde{Y}_s | \tilde{X}_s, \Psi, \tau, \mathcal{D}_n}(y)$ . For an overview of the input and output tokens, see Table [2](#page-19-1) in Appendix.

We introduce an assumption for the identifiability of functions as follows.

<span id="page-8-0"></span>**Assumption 3.4.** There exists a constant  $C > 0$  and  $\epsilon > 0$  such that for any  $\epsilon' \leq \epsilon$  and  $m, m' \in \mathcal{M}$ , if  $|\mathbb{E}[f^{(m')}(\boldsymbol{u}_{X_1})^{\top}f^{(m)}(\boldsymbol{u}_{X_1})] - \mathbb{E}[\|f^{(m)}(\boldsymbol{u}_{X_1})\|^2]| \leq \epsilon'$ , then  $|\mathbb{E}[\|f^{(m')}(\boldsymbol{u}_{X_1})$  $f^{(m)}(\boldsymbol{u}_{X_1})$ ||<sup>2</sup>||  $\leq C\epsilon'$  holds with high probability in U, where the expectation is taken with respect to  $P_{X_1;T=t,U,\eta}$ .

Assumption [3.4](#page-8-0) requires that for any  $f^{(m')}$  whose projection to  $f^{(m)}$  is approximately  $f^{(m)}$ , it must be close to  $f^{(m)}$  on average. At the high level, this assumption requires that  $\{f^{(m)}\}_{m\in\mathcal{M}}$  locally takes values on a sphere on average. Note that this assumption is trivially satisfied by considering functions that take values on a sphere in  $\mathbb{R}^r$  on average, and introducing layer-normalization in the transformers.

We consider the regime where d and r both grows with  $r = o(\log d)$ , and investigate the capacity of language models to recover the original distribution measured by the Kullback-Leibler divergence.

<span id="page-8-1"></span>**Theorem 3.2.** Suppose that Assumption [3.4](#page-8-0) holds. Fix any  $d, r, r_0, L_0 \in \mathbb{N}^+, (z^{(t)})_{t \in \mathcal{T}}$  and  $(f^{(m)})_{m\in\mathcal{M}}\subset\mathcal{F}(L_0,r_0).$  Then, there exists transformer layers TF $_{\Psi^*}$  with  $O(|\mathcal{M}|)$  attention heads such that for any  $t \in \mathcal{T}$ ,  $m \in \mathcal{M}$ , and  $\eta \geq r^{-1/2} \log d$ ,

$$
D_{\mathrm{KL}}(P_{X_1;T=t,U,\eta}||Q_{\tilde{X}_s;\Psi^*,\tau,\mathcal{D}_n}) \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}},
$$
  

$$
\mathbb{E}\Big[D_{\mathrm{KL}}(P_{Y_1|X_1;M=m,U,\eta}||Q_{\tilde{Y}_s|X_1;\Psi^*,\tau,\mathcal{D}_n})|M=m,T=t,U,\eta\Big] \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}},
$$

and

$$
\min_{\tau>0} D_{\text{KL}}(P_{X_1,Y_1;T=t,M=m,U,\eta} \| Q_{\tilde{X}_s,\tilde{Y}_s;\Psi^*,\tau,\mathcal{D}_n}) \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}}
$$

hold for all  $s \in \mathbb{N}^+$  with probability  $1 - \exp(-\Omega(\log^2 d))$  in U.

In Theorem [3.2,](#page-8-1) the upper bound consists of the bias and variance terms. In a typical in-context learning setting, the number of possible tokens is huge while the number of in-context examples are small. Thus the dominating term in the upper bound is  $\tilde{O}(n^{-1/2})$ . From the results in Section [3.1,](#page-4-4) the minority group risk for imbalanced data and the worst group risk for spurious correlations settings depend on the quality of synthetic data via  $\|\nabla \mathcal{B}_q(\theta_{\text{bal}})\|$ , which in turn can be controlled by the KL divergence stated in Theorem [3.2.](#page-8-1) Therefore, language models indeed produce high-quality data, supporting the use of LLMs for synthetic oversampling. We defer the details of the constructed transformer to Proposition [C.1](#page-30-0) and Theorem [C.1](#page-31-0) in Appendix [C.](#page-24-0)

# <span id="page-9-0"></span>4 Numerical Experiments

### 4.1 Experiment setup

We conduct intensive numerical experiments to demonstrate the efficacy of  $OPAL<sup>1</sup>$  $OPAL<sup>1</sup>$  $OPAL<sup>1</sup>$  We use the GPT-4 turbo gpt-4-1106-preview (https://platform.openai.com/docs/models/gpt-4 turbo-and-gpt-4) for synthetic data generation. We give more details on the prompt we use in Appendix [E.1.](#page-49-0) We consider three datasets, Diabetes, HeartFailure, and Gender, all with binary classification tasks [Sigillito](#page-15-13) [\(2014\)](#page-15-13); [hea](#page-13-13) [\(2020\)](#page-13-13); [Issadeen](#page-14-15) [\(2020\)](#page-14-15). We apply three classifiers, logistic regression, CatBoost [Prokhorenkova et al.](#page-15-14) [\(2018\)](#page-15-14), and random forest [Breiman](#page-13-14) [\(2001\)](#page-13-14), where the tuning parameters are selected by three-fold crossvalidation. Due to the token size limit, to ensure that all the data can be fed into GPT-4, we randomly sample a small size, i.e., 100, 50, and 50, of data points from each of the three datasets as the raw data. We then sample 20 data points from the raw data to serve as the seed data to feed into GPT-4. We further randomly sample another 200, 100, and 1000 data points as the test data. The dataset information is summarized in Table [1.](#page-9-2) Following [Buda](#page-13-15) [et al.](#page-13-15) [\(2018\)](#page-13-15), we create imbalanced data and introduce spurious correlation by deliberately constructing disparities in the raw data. These imbalances manifest as uneven distributions in labels for classification tasks, and in label-attribute pairs for spurious correlations. The imbalanced ratio, i.e., the ratio of the number of majority samples to that of the minority samples, is set as  $9:1, 4:1,$  and  $4:1$  for the three datasets. To assess the impact of synthetic data, we first train the model using all the raw data. Then, we gradually augment the training set with synthetic samples in subsequent steps. We follow a sequence of synthetic-to-raw data ratios:  $\{0\%, 20\%, 40\%, 60\%, 80\%, 100\%\}$ . For instance, if the raw data size is 50 and the syn/raw =  $80\%$ , we add 40 synthetic samples to the raw data.

We compare OPAL with two benchmark alternative solutions: the duplication method [Loyola-González et al.](#page-15-0) [\(2016\)](#page-15-0), and the synthetic-minority oversampling technique [\(Chawla](#page-13-1) [et al., 2002,](#page-13-1) SMOTE). The former randomly picks samples from the minority group to add to the raw data. The latter generates the synthetic samples through linear interpolation between a minority class sample and its nearest neighbors within the same class, and we

<span id="page-9-2"></span><span id="page-9-1"></span><sup>1</sup>The code is available at [github.](https://github.com/Xyc-arch/OPAL-OversamPling-with-Artificial-LLM-generated-data)

Table 1: Summary of datasets used in numerical experiments.

Dataset		Total Size $#$ Features	Target	Task	<b>Source</b>	Raw	Test	Remain
<b>Diabetes</b>	768		indicator of diabetes classification OpenML			100	200	468
HeartFailure	299	12	death event	classification UCI ML		50	100	149
Gender	5001		gender	classification	Kaggle	50	1000	3551

<span id="page-10-0"></span>

Figure 2: Imbalanced classification: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, Gender, and the random forest classifier. The red line represents the mean error of the classifier trained with the raw data.

use the default value of 5 neighbors as in the imblearn package [Lemaître et al.](#page-15-15) [\(2017\)](#page-15-15) in our implementation.

We next conduct the experiments for the imbalanced classification and spurious correlations. We also conduct ablation studies and report the results in Appendix [E.3.](#page-50-0)

#### <span id="page-10-1"></span>4.2 Imbalanced classification

For imbalanced classification, we designate the samples with label 1 as the majority group, and those with label 0 as the minority group. When generating the synthetic data, we select a balanced subset of the raw data to serve as the seed data to feed into GPT-4. For instance, for the Diabetes dataset, the seed data consists of 10 samples from the majority group and 10 from the minority group.

Figure [2](#page-10-0) reports the misclassification error rate in graphs based on 5 data replications with random forest. In Appendix [E.4,](#page-52-0) Figure [5](#page-52-1) and Figure [6](#page-52-2) report the results with logistic regression and CatBoost, which show similar qualitative patterns. In addition, Table [4](#page-54-0) reports the corresponding numeric results in tabular forms. We see that, our OPAL outperforms both duplication and SMOTE considerably across all datasets and classifiers, while the improvement increases as more synthetic data is added for the classifier training. For instance, OPAL outperforms SMOTE up to 18.4%, 17.5%, and 5.2% in Diabetes, HeartFailure, and Gender when  $syn/raw = 1$ . Meanwhile, our method also improves the standard error for HeartFailure and Gender data.

#### <span id="page-10-2"></span>4.3 Spurious correlations

For spurious correlations, it involves imbalanced data in the pair  $(y, a)$ , where y represents the class label and  $a$  is the spurious attribute. The attribute  $a$  is considered spurious because its correlation with y in the training set may compromise fairness and under-represent the minority group. In our experiment, we artificially induce spurious correlations in the Diabetes, Heart Failure, and Gender datasets. For Diabetes, we select 'Triceps skin fold thickness' (skin) as the spurious attribute, paired with the binary diabetes indicator (class); that is,  $(y, a) =$  (class, skin). Here skin is positive if the thickness is measured and zero otherwise. The majority group in the raw data comprises samples with positive correlations between y and a:  ${class = 1, skin > 0}$  and  ${class = 0, skin = 0}$ . The minority group includes samples with negative correlations between y and a:  $\{\text{class} = 1, \text{skin} = 0\}$  and  ${class = 0, skin > 0}.$  For Heart Failure, the spurious pair  $(y, a)$  is (death event, sex), where the majority group exhibits a positive correlation between death and sex. In the

<span id="page-11-0"></span>

Figure 3: Spurious correlations: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, Gender, and the random forest classifier. The red line represents the mean error of the classifier trained with the raw data.

Gender dataset, the spurious pair  $(y, a)$  is (gender, long hair), with long hair indicating whether an individual has long hair, again showing a positive correlation in the majority group. We choose these artificial correlations due to their implications in practice and their correlations in the datasets; see a more detailed discussion in Appendix [E.2.](#page-50-1)

Figure [3](#page-11-0) reports the misclassification error rate in graphs based on 5 data replications with random forest for four different groups: the minority group, the majority group, the overall group with all samples, and the worst group, respectively. More information about these four groups are given in Appendix [E.2.](#page-50-1) In Appendix [E.4,](#page-52-0) Figure [7](#page-53-0) and Figure [8](#page-53-1) report the results with logistic regression and CatBoost, which again show similar qualitative patterns. In addition, Table [5,](#page-55-0) Table [6](#page-56-0) and Table [7](#page-57-0) report the corresponding numeric results in tabular forms. We see that, our OPAL outperforms both duplication and SMOTE considerably in the minority, overall, and worst groups in all datasets. For instance, for the minority group of the HeartFailure data, OPAL reduces the misclassification error by 23.4% when syn/raw  $= 1$ , while duplication and SMOTE only decrease the error by 9.0% and 9.1%, respectively. For the majority group, we observe an increase in misclassification error across all oversampling methods. This trend arises because the oversampling approach downweighs the role of the majority group during the training. By doing so, it inadvertently filters out some features that are particularly beneficial for accurate classification in the majority group, leading to an elevated error rate.

To further show our method can enhance fairness as well, we report the maximum absolute difference among all groups in Table [8](#page-58-0) in Appendix [E.4.](#page-52-0) We see that OPAL reduces the group-wise difference in accuracy across all datasets more effectively compared to the duplication and SMOTE.

# 5 Conclusions, Limitations, and Future Directions

In this article, we introduced OPAL, a systematic oversampling approach to address data imbalance by leveraging the generative capacity of large language models. We have provided a new theoretical framework to explicitly quantify the bias introduced by oversampling with the LLM-generated synthetic data, and to demonstrate that pre-trained language models can indeed generate high-quality data. Our empirical results have shown that our method outperforms traditional oversampling solutions such as duplication and SMOTE.

Meanwhile, there are some potential limitations with our method that leave room for further improvement. Theoretically, our theory requires a large token dimension,  $O(r|\mathcal{M}|)$ , because we use zeros in the input tokens as temporal memory to store computed results. Operationally, our implementation now hinges on GPT-4, which has a token limit, resulting in a small data scale, even though GPT-4 still demonstrates the great potential of our method with a very limited sample size.

There are several promising future directions. First, while the focus of this article has been on tabular data, our methodologies can be adapted to other data types, for instance, images. Second, we can further explore the transfer learning scenarios. In many real-world applications, obtaining labeled data is expensive and challenging, whereas there is often an abundance of unlabeled data. By generating synthetic labeled data for these unlabeled samples using LLMs, we expect to enhance the model performance in the target domain.

# <span id="page-17-0"></span>A More Details for Theoretical Analysis

In this section, we provide more details regarding the theoretical analysis in Section [3.](#page-3-0)

#### A.1 Notations

For two sequences of positive numbers  $(a_k)_k$  and  $(b_k)_k$  indexed by  $k \in \mathcal{K}$ , we write  $a_k \leq b_k$  if and only if there exists a constant  $C > 0$  independent of the index k such that sup<sub>k∈K</sub>  $a_k/b_k < C$  holds. For any matrix A, let  $||A||$  and  $||A||_F$  denote the operator norm and Frobenius norm of A, respectively.  $\mathbb{O}_{d,r} \triangleq \{O \in \mathbb{R}^{r \times d} : O^{\top}O = I_r\}$  is a set of orthogonal matrices of order  $d \times r$ . For any positive integer I, let  $[I] = \{1, 2, \dots, I\}$ . We write  $a \vee b$  and  $a \wedge b$  to denote  $\max(a, b)$  and  $\min(a, b)$ , respectively. When the right singular vectors are not unique, we choose arbitrary singular vectors. For any matrix  $A$ , let  $\lambda_{\min}(A)$  be the minimum singular value of A. For a vector  $\boldsymbol{a} = (a_1, \ldots, a_D)^\top \in \mathbb{R}^D$ , we write  $(a)_i = a_i$ ,  $(a)_{n_1:n_2} = (a_{n+1}, a_{n+2}, \ldots, a_{n_2})^\top \in \mathbb{R}^{n_2 - n_1}$ . For a matrix  $A = [\boldsymbol{a}_1; \ldots; \boldsymbol{a}_D]$ , we write  $(A)_i = a_i$ . Denote a ball in  $\mathbb{R}^D$  with radius  $R > 0$  centered at  $\mathbf{0}_D$  by  $\mathbb{B}_D(R)$ . For a finite set A, let conv $(A)$  be the convex hull of A. Hereafter we call an event  $\mathcal E$  occurs with high probability when  $\mathbb{P}(\mathcal{E}) = 1 - \exp(-\Omega(\log^2 d)).$ 

### A.2 Data generating process

As assumed in the literature on word representations [Arora et al.](#page-13-10) [\(2015\)](#page-13-10), we consider a Bayesian setting for the token embeddings;  $u_1, \ldots, u_d \in \mathbb{R}^r$  are modeled as i.i.d. realizations of  $N(0, (1/r)I_r)$ . Let  $U = [\boldsymbol{u}_1, \dots, \boldsymbol{u}_d]^\top$ . We assume that  $X_i$  and  $Y_i$  take values in a finite set  $\mathcal{X} = [d]$ . This assumption reflects the fact that tabular data is treated as a collection of finite tokens for language models. We define a "subject" as any background information that provides context for each tabular data. For example, data on heart failure rates is specified by the subject "heart failure".

We then formally introduce data generating process for tabular data: generative models for covariates and discriminative models for labels. More specifically,  $(X_i, Y_i) \in \mathcal{X}^2$  given subject  $T = t$  and discriminative function index  $M = m$  follows multinomial distribution defined by:

<span id="page-17-1"></span>
$$
\mathbb{P}(X_i = x; T = t, U, \eta) \propto \exp\left(\eta^{-1} \langle \mathbf{z}^{(t)}, \mathbf{u}_x \rangle\right),
$$
  

$$
\mathbb{P}(Y_i = y | X_i = x; M = m, U, \eta) \propto \exp\left(\eta^{-1} \langle f^{(m)}(\mathbf{u}_x), \mathbf{u}_y \rangle\right),
$$
 (4)

where  $t \in \mathcal{T}$ ,  $m \in \mathcal{M}$  are possible indices of subjects and discriminative function indices,  $\eta > 0$  is a parameter,  $u_x \in \mathbb{R}^r$  is the embedding of the token  $x \in \mathcal{X}$ ,  $z^{(t)} \in \mathbb{R}^r$  is the representation of subject t, and  $f^{(m)} : \mathbb{R}^r \to \mathbb{R}^r$  is a discriminative function with index m. We consider the case where  $|\mathcal{M}| \geq |\mathcal{T}|$  for simplicity. A similar model has been proposed and used in language modeling literature [Mnih and Hinton](#page-15-11) [\(2007\)](#page-15-11); [Arora et al.](#page-13-10) [\(2015,](#page-13-10) [2017\)](#page-13-11); [Shi et al.](#page-15-12) [\(2017\)](#page-15-12); [Khalife et al.](#page-14-14) [\(2021\)](#page-14-14).

 $\alpha$  assume that  $\mathcal T$  and  $\mathcal M$  are finite. We allow  $\eta$  to vary on the interval  $[(1/\sqrt{r}) \log d, \infty)$ , while assume  $||\mathbf{z}^{(t)}|| = 1$  for any  $t \in \mathcal{T}$  and  $\sup_{\mathbf{u} \in \mathbb{B}_r(\log d)} ||f^{(m)}(\mathbf{u})|| \leq 1$  for identifiability. The lower bound  $(1/\sqrt{r})\log d$  of  $\eta$  is due to the limitation of our theory; when  $\eta$  is too small, we cannot derive the concentration for the normalizing constant of  $P(X_i = x; T = t, U, \eta)$ .

Denote the joint distribution of  $X_1$  and  $Y_1$  by  $P_{X_1,Y_1;T=t,M=m,U,\eta}$  and (conditional) distributions of  $X_1$  and  $Y_1|X_1$  under model [4](#page-17-1) by  $P_{X_1;T=t,U,\eta}$  and  $P_{Y_1|X_1;M=m,U,\eta}$ , respectively.

We remark that, the probability mass of  $X_i$  given Z has mode at  $\arg \max_{x \in \mathcal{X}} Z^{\top} u_x$ . This implies that tokens similar to the subject embedding are likely to be generated. If  $\eta$  is

sufficiently large, the distribution of  $X$  given  $Z$  becomes closer to uniform distribution on  $\mathcal X$  almost independent of Z. Henceforth, the parameter  $\eta$  is responsible for the observation error of  $X$  and  $Y$ .

Finite known candidates of subject embeddings and functions Based on the intuition that transformers are pre-trained on vast amount of data, we further assume that the transformer knows the candidate of subject embeddings  $\{z^{(t)}\}_{t\in\mathcal{T}}$  and candidate of  $\text{functions } \{f^{(m)}\}_{m\in\mathcal{M}}\subset \mathcal{F}(L_0,r_0)\subset \{\text{FFN}_{\nu_{\text{pre},L_0}}\circ\text{FFN}_{\nu_{\text{pre},L_0-1}}\circ\cdots\circ\text{FFN}_{\nu_{\text{pre},1}}:\nu_{\text{pre},\ell}\in$  $\mathbb{R}^{r_0 \times r} \times \mathbb{R}^{r \times r_0}$  for  $\ell \in [L_0]$  with  $L_0, r_0 \in \mathbb{N}^+$ .

### A.3 Details of transformers

 $\textbf{Input tokens for tabular data} \quad \text{We assume that tokens } (\bm{h}^Y_i)_{i \in [n]} \text{ corresponds to } (Y_i)_{i \in [n]}$ and  $(h_i^X)_{i \in [n]}$  corresponds to  $(X_i)_{i \in [n]}$ . The input of the transformer is given by

<span id="page-18-0"></span>
$$
H_n = [\boldsymbol{h}_1^X; \boldsymbol{h}_1^Y; \boldsymbol{h}_2^X; \boldsymbol{h}_2^Y; \dots; \boldsymbol{h}_n^X; \boldsymbol{h}_n^Y].
$$
\n(5)

We consider the composite type positional encoding, that is, the forms of  $h_i^X$  and  $h_i^Y$ are given by  $\boldsymbol{h}_i^X = (\boldsymbol{u}_{X_i}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2i-1,n}^\top)^\top$  and  $\boldsymbol{h}_i^Y = (\boldsymbol{u}_{X_i}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2i,n}^\top)^\top$ , respectively. Note that this differs from practical additive positional encoding. Specifically for  $i \in [n]$ , the positional encoding  $p_{s,n} \in \mathbb{R}^4$  is defined as

$$
\boldsymbol{p}_{s,n} = (\lceil s/2 \rceil, (s \operatorname{mod} 2), 2n, 1)^\top,
$$

where the first coordinate specifies the index of the current token, and the second coordinate indicates whether the current token corresponds to  $X_i$  or  $Y_i$ . The third coordinate takes the length of the given tokens. The last coordinate is a constant added for technical convenience.

**Output distribution** Given the initial input tokens  $H_n \in \mathbb{R}^{D \times 2n}$  in equation [5,](#page-18-0) a transformer parameterized by  $\Psi$  sequentially outputs  $h_{2n+1}, h_{2n+2}, \ldots$  corresponding to synthetic data from categorical distribution given last output from the transformer layers. At each step  $\ell \in \mathbb{N}^+$ , given all previous tokens  $H_n$  and  $h_{2n+1}, h_{2n+2}, \ldots, h_{2n+\ell-1}$ , the next token  $h_{2n+\ell}$  is given by  $h_{2n+\ell} = (\boldsymbol{v}_{2n+\ell}^\top, \boldsymbol{0}^\top, \boldsymbol{p}_{2n+\ell,n}^\top)^\top$ , where  $\boldsymbol{v}_{2n+\ell} \in \mathbb{R}^r$  is drawn from a categorical distribution with softmax probability over all possible tokens  $u_1, \ldots, u_d \in \mathbb{R}^r$ :

$$
\mathbb{P}(\boldsymbol{v}_{2n+\ell}=\boldsymbol{u}_x)\propto \exp\Bigl(\tau^{-1}\langle \boldsymbol{u}_x,(\tilde{\boldsymbol{h}}_{2n+\ell-1})_{1:r}\rangle\Bigr),\tag{6}
$$

where  $\tilde{\bm{h}}_{2n+\ell-1} := (\mathrm{TF}_{\Psi}([H_n,\bm{h}_{2n+1},\bm{h}_{2n+2},\ldots,\bm{h}_{2n+\ell-1}]))_{2n+\ell-1}$  and  $\tau > 0$  is the temperature parameter. Since we expect the outputs  $h_{2n+1}, h_{2n+2}, h_{2n+3}, h_{2n+4}, \ldots$  from a transformer TF<sub> $\Psi$ </sub> correspond to  $\tilde{X}_1, \tilde{Y}_1, \tilde{X}_2, \tilde{Y}_2, \ldots$ , we write the joint distribution of  $v_{2n+2s-1}$  and  $v_{2n+2s}$  as

$$
Q_{\tilde{X}_s,\tilde{Y}_s;\Psi,\tau,\mathcal{D}_n}(x,y):=\mathbb{P}(\boldsymbol{v}_{2n+2s-1}=\boldsymbol{u}_x,\boldsymbol{v}_{2n+2s}=\boldsymbol{u}_y).
$$

We similarly denote the marginal and conditional distributions of  $\tilde{X}_s$  and  $\tilde{Y}_s | \tilde{X}_s$  by  $Q_{\tilde{X}_s, \Psi, \tau, \mathcal{D}_n}(x)$  and  $Q_{\tilde{Y}_s, \tilde{X}_s, \Psi, \tau, \mathcal{D}_n}(y)$ . Table [2](#page-19-1) shows the overview of the input and output tokens sequentially input to transformers.

<span id="page-19-1"></span>

	Input								Output			
Index $s$   1   2   3									4 $2n-1$ $2n$   $2n+2s-1$ $2n+2s$			
									Token $\begin{array}{ccccccccc} h_1^X & h_1^Y & h_2^X & h_2^Y & \cdots & h_n^X & h_n^Y & \cdots & h_{2n+2s-1} & h_{2n+2s} & \cdots \end{array}$			
						Datum $X_1$ $Y_1$ $X_2$ $Y_2$ $\cdots$ $X_n$ $Y_n$ $\cdots$			$X_s$	$Y_s$	$\ddotsc$ .	
$(p_{s,n})_1$   1   1   2   2   $\cdots$   n							$\,n$	$\ldots$ .	$n+s$ $n+s$		$\ldots$	
$(p_{s,n})_2$   0   1   0   1   $\cdots$   0								$\cdots$	$\overline{0}$		$\cdots$	

Table 2: An overview of the input and output tokens.

# <span id="page-19-0"></span>B Proofs for Section [3.1](#page-4-4)

In this section, we restate the theoretical results for oversampling in Section [3.1](#page-4-4) in a more rigorous way, then provide the detailed proofs.

### B.1 General theory for oversampling

We first see how oversampling improves the performance on minority group in general. Let  $n_g$  be the number of raw samples observed for group  $g \in \mathcal{G}$ . For each group g, we generate  $m_g$  synthetic data  $m_g$ . Denote  $n_{\text{total}} := \sum_g n_g$  and  $m_{\text{total}} := \sum_g m_g$  by the total number of raw data and the total number of synthetic data, respectively.

Denote the observed raw data as  $\{(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_{n_g})\}_{g\in\mathcal{G}}$  and generated synthetic data as  $\{(\tilde{x}_1,\ldots,\tilde{x}_{m_g})\}_{g\in\mathcal{G}}$ . We assume the independence between raw data and synthetic data. When directly using raw data as a reference to synthetic data, the independence does not hold. However, we can always split the raw data, with one half used as raw data, and the other half used as a reference. Given a loss function  $\ell(\theta; x, y) \in \mathbb{R}$  we define the empirical risk with raw and synthetic data as follows

$$
\widehat{\mathcal{R}}_{\text{syn}}(\boldsymbol{\theta}) = \frac{1}{n_{\text{total}} + m_{\text{total}}}\sum_{g \in \mathcal{G}}\sum_{i \in [n_g]} \ell(\boldsymbol{\theta}; \boldsymbol{x}_i^{(g)}, y_i^{(g)}) + \frac{1}{n_{\text{total}} + m_{\text{total}}}\sum_{g \in \mathcal{G}}\sum_{i \in [m_g]} \ell(\boldsymbol{\theta}; \tilde{\boldsymbol{x}}_i^{(g)}, \tilde{y}_i^{(g)}).
$$

Let  $\mathcal{R}_{syn}(\theta) = \mathbb{E}[\hat{\mathcal{R}}_{syn}(\theta)]$  be the population version of  $\hat{\mathcal{R}}_{syn}$ . We also define the balanced risk

$$
\mathcal{R}_{\mathrm{bal}}(\boldsymbol{\theta}) = \frac{1}{|\mathcal{G}|} \sum_{g \in \mathcal{G}} \mathcal{R}_g(\boldsymbol{\theta}),
$$

where  $\mathcal{R}_g(\boldsymbol{\theta}) = \mathbb{E}[\ell(\boldsymbol{\theta};\boldsymbol{x}_1^{(g)})]$  $\binom{g}{1}, y_1^{(g)}$  $\binom{10}{1}$  is the group specific risk. Let the minimizers of  $\mathcal{R}_{syn}$ ,  $\mathcal{R}_{syn}$ , and  $\mathcal{R}_{bal}$  be  $\hat{\theta}_{syn}$ ,  $\theta_{syn}$ ,  $\theta_{bal}$  respectively. Define the bias term for group g as

$$
\mathcal{B}_g(\boldsymbol{\theta}):=\mathbb{E}[\ell(\boldsymbol{\theta};\tilde{\boldsymbol{x}}_1^{(g)},\tilde{y}_1^{(g)})]-\mathbb{E}[\ell(\boldsymbol{\theta};\boldsymbol{x}_1^{(g)},y_1^{(g)})].
$$

Note that  $\theta_{\text{bal}}$  is the ideal estimator, balancing out the parameters over all groups present in the dataset.

Our goal is to see the effect of bias present in the synthetic data to the estimator  $\hat{\theta}_{syn}$ by measuring the risk of group  $g$ :

$$
\mathcal{R}_g(\hat{\bm{\theta}}_\text{syn}) - \mathcal{R}_g(\bm{\theta}_\text{bal}).
$$

<span id="page-19-2"></span>Here we formally introduce standard assumptions that are commonly used in asymptotic theory [Van der Vaart](#page-15-8) [\(2000\)](#page-15-8).

**Assumption B.1.** Assume that  $\sup_{\theta \in \Theta} |\mathcal{B}_{g}(\theta)| \vee ||\nabla \mathcal{B}_{g}(\theta)|| = o(1)$  for all  $g \in \mathcal{G}$ .

<span id="page-20-5"></span>Assumption B.2. Assume that

$$
\sup_{\theta \in \Theta} |\widehat{\mathcal{R}}_{\text{syn}}(\theta) - \mathcal{R}_{\text{syn}}(\theta)| = o_p(1),
$$

<span id="page-20-4"></span>**Assumption B.3** (Identifiability of  $\theta_{syn}$ ). Assume that

$$
\inf_{\boldsymbol{\theta}: \|\boldsymbol{\theta}-\boldsymbol{\theta}_\mathrm{syn}\| \geq \epsilon} \mathcal{R}_\mathrm{syn}(\boldsymbol{\theta}) > \mathcal{R}_\mathrm{syn}(\boldsymbol{\theta}_\mathrm{syn})
$$

and

$$
\inf_{\boldsymbol{\theta}:\|\boldsymbol{\theta}-\boldsymbol{\theta}_\mathrm{bal}\|\geq\epsilon} \mathcal{R}_\mathrm{bal}(\boldsymbol{\theta}) > \mathcal{R}_\mathrm{bal}(\boldsymbol{\theta}_\mathrm{bal}).
$$

<span id="page-20-6"></span>**Assumption B.4.**  $\mathcal{B}_g$  and  $\mathcal{R}_g$  are twice differentiable around  $\theta_{bal}$  with bounded Lipschitz Hessian, and  $\sum_{g} \nabla^2 \mathcal{R}_g(\boldsymbol{\theta})$  is strictly positive definite around  $\boldsymbol{\theta}_{bal}$ .

<span id="page-20-1"></span>**Assumption B.5.** Assume that  $\ell(\theta; x, y)$  and  $\ell(\theta; \tilde{x}, \tilde{y})$  are differentiable around  $\theta_{bal}$ almost surely under the distributions for raw data  $(x, y)$  and synthetic data  $(\tilde{x}, \tilde{y})$ . Also assume that  $\Sigma_g$  and  $\tilde{\Sigma}_g$  are Lipschitz around  $\boldsymbol{\theta}_{bal}$ , and  $\sup_{\boldsymbol{\theta} \in \Theta} ||\Sigma_g(\boldsymbol{\theta}) - \tilde{\Sigma}_g(\boldsymbol{\theta})|| = o(1)$ .

Denote the covariance matrices of gradients for each group  $g \in \mathcal{G}$  by

$$
\Sigma_g(\boldsymbol{\theta}) = \mathbb{E}\bigg[\Big(\nabla \ell(\boldsymbol{\theta}; \boldsymbol{x}_1^{(g)}, y_1^{(g)})\Big) \Big(\nabla \ell(\boldsymbol{\theta}; \boldsymbol{x}_1^{(g)}, y_1^{(g)})\Big)^\top\bigg],
$$
  

$$
\tilde{\Sigma}_g(\boldsymbol{\theta}) = \mathbb{E}\bigg[\Big(\nabla \ell(\boldsymbol{\theta}; \tilde{\boldsymbol{x}}_1^{(g)}, \tilde{y}_1^{(g)})\Big) \Big(\nabla \ell(\boldsymbol{\theta}; \tilde{\boldsymbol{x}}_1^{(g)}, \tilde{y}_1^{(g)})\Big)^\top\bigg].
$$

<span id="page-20-2"></span>**Theorem [B.1](#page-19-2)** (Restatement of Theorem [3.1\)](#page-4-3). Under Assumptions B.1[-B.5,](#page-20-1) for any  $q \in \mathcal{G}$ ,

$$
\mathcal{R}_{g}(\widehat{\theta}_{syn}) = \mathcal{R}_{g}(\theta_{bal}) - \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} b_{g,g'} + O_p\left(\frac{1}{\sqrt{n_{\text{total}} + m_{\text{total}}}} v_g + \frac{1}{m_{\text{total}} \wedge n_{\text{total}}} + \left\|\sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}}\nabla \mathcal{B}_{g'}(\theta_{bal})\right\|^2\right),
$$

where  $v_g$  and  $b_{g,g'}$  are defined as

$$
v_g^2 := \{\nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}})\}^\top \{\nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}})\}^{-1} \left(\frac{1}{G} \sum_{g' \in \mathcal{G}} \Sigma_{g'}(\boldsymbol{\theta}_{\text{bal}})\right) \{\nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}})\}^{-1} \nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}}),
$$
\n(7)

$$
b_{g,g'} := \{\nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}})\}^\top \{\nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}})\}^{-1} \nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_{\text{bal}}). \tag{8}
$$

*Proof of Theorem [B.1.](#page-20-2)* To ease notation we define  $H_{syn} = \nabla^2 \mathcal{R}_{syn}(\theta_{syn})$  and  $H_{bal} =$  $\nabla^2 \mathcal{R}_{\rm bal}(\boldsymbol{\theta}_{\rm bal})$ . We note that

<span id="page-20-3"></span><span id="page-20-0"></span>
$$
\mathcal{R}_{syn}(\boldsymbol{\theta}) = \mathcal{R}_{bal}(\boldsymbol{\theta}) + \sum_{g \in \mathcal{G}} \frac{m_g}{n_{total} + m_{total}} \mathcal{B}_g(\boldsymbol{\theta}). \tag{9}
$$

We divide the proof into two parts. In the first part we derive the bias between  $\theta_{\text{bal}}$  and  $\theta_{syn}$ . In the second part we show the convergence of  $\theta_{syn}$  to  $\theta_{syn}$ .

**Part 1.** Note that  $\sup_{\theta} |\mathcal{R}_{syn}(\theta) - \mathcal{R}_{bal}(\theta)| = o_p(1)$  follows from Assumption [B.1](#page-19-2) and equation [9.](#page-20-3) Then, the convergence  $\|\boldsymbol{\theta}_{syn} - \boldsymbol{\theta}_{bal}\| = o(1)$  follows by a standard Taylor expansion argument, using Assumption [B.3.](#page-20-4) (See, for example, Theorem 5.7 of [Van der](#page-15-8) [Vaart](#page-15-8) [\(2000\)](#page-15-8).) From equation [9,](#page-20-3) we obtain

$$
\nabla \mathcal{R}_{syn}(\boldsymbol{\theta}_{bal}) = \sum_{g' \in \mathcal{G}} \nabla \mathcal{R}_{g'}(\boldsymbol{\theta}_{bal}) + \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{total} + m_{total}} \nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_{bal})
$$
(10)

<span id="page-21-1"></span><span id="page-21-0"></span>
$$
=\sum_{g'\in\mathcal{G}}\frac{m_{g'}}{n_{\text{total}}+m_{\text{total}}}\nabla\mathcal{B}_{g'}(\theta_{\text{bal}}),\tag{11}
$$

where we used  $\sum_{g'} \nabla \mathcal{R}_{g'}(\theta_{bal}) = 0$ . By Taylor expansion, there exists some  $\theta'$  in a line segment between  $\ddot{\theta}_{\text{bal}}$  and  $\theta_{\text{syn}}$  such that

$$
\nabla \mathcal{R}_{syn}(\boldsymbol{\theta}_{bal}) = \underbrace{\nabla \mathcal{R}_{syn}(\boldsymbol{\theta}_{syn})}_{=0} + \nabla^2 \mathcal{R}_{syn}(\boldsymbol{\theta}')(\boldsymbol{\theta}_{bal} - \boldsymbol{\theta}_{syn}).
$$
\n(12)

This yields

$$
\{\nabla \mathcal{R}_{syn}(\pmb{\theta}_{bal})\}^\top (\pmb{\theta}_{bal} - \pmb{\theta}_{syn}) = (\pmb{\theta}_{bal} - \pmb{\theta}_{syn})^\top \nabla^2 \mathcal{R}_{syn}(\pmb{\theta}')(\pmb{\theta}_{bal} - \pmb{\theta}_{syn}).
$$

Since  $\|\boldsymbol{\theta}_{\text{bal}} - \boldsymbol{\theta}_{\text{syn}}\| = o(1)$ , and  $\nabla^2 \mathcal{R}_{\text{syn}}(\boldsymbol{\theta})$  is Lipschitz contniuous around  $\boldsymbol{\theta}_{\text{bal}}$  with its smallest eigenvalue bounded below, we have

$$
\begin{aligned} \|\pmb\theta_{\rm bal} - \pmb\theta_{\rm syn}\| &\leq \frac{1}{\lambda_{\rm min}(\nabla^2\mathcal{R}_{\rm syn}(\pmb\theta_{\rm bal}))+o(1)}\|\nabla\mathcal{R}_{\rm syn}(\pmb\theta_{\rm bal})\|\\ &\lesssim \|\nabla\mathcal{R}_{\rm syn}(\pmb\theta_{\rm bal})\|. \end{aligned}
$$

Using equation [11](#page-21-0) and equation [12,](#page-21-1) we have

$$
\theta_{\text{bal}} - \theta_{\text{syn}} = \{ \nabla^2 \mathcal{R}_{\text{syn}}(\theta') \}^{-1} \nabla \mathcal{R}_{\text{syn}}(\theta_{\text{bal}}) \n= H_{\text{syn}}^{-1} \nabla \mathcal{R}_{\text{syn}}(\theta_{\text{bal}}) + R_1 \n= \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} H_{\text{syn}}^{-1} \nabla \mathcal{B}_{g'}(\theta_{\text{bal}}) + R_1,
$$

where  $||R_1|| = O(||\nabla \mathcal{R}_{syn}(\boldsymbol{\theta}_{bal})||^2)$ .

**Part 2.** The consistency  $\|\widehat{\theta}_{syn} - \theta_{syn}\| = o_p(1)$  follows by a standard argument of Mestimators combined with Assumptions [B.2](#page-20-5) and [B.3.](#page-20-4) (Theorem 5.7 in [Van der Vaart](#page-15-8) [\(2000\)](#page-15-8).) We follow the argument in the proof of Proposition 3.1 of [Jain et al.](#page-14-4) [\(2024\)](#page-14-4). By a modification to Theorem 5.23 in [Van der Vaart](#page-15-8) [\(2000\)](#page-15-8) combined with Assumptions [B.4](#page-20-6) and [B.5,](#page-20-1) and  $||\boldsymbol{\theta}_{bal} - \boldsymbol{\theta}_{syn}|| = o(1)$ , we have

$$
\widehat{\boldsymbol{\theta}}_{\text{syn}} = \boldsymbol{\theta}_{\text{syn}} - H_{\text{syn}}^{-1} \nabla \widehat{\mathcal{R}}_{\text{syn}}(\boldsymbol{\theta}_{\text{syn}}) + R_2,
$$

where  $||R_2|| = O_p(1/m + 1/n)$ .

Part 3. Combining the results from Part 1 and Part 2, we have

$$
\widehat{\theta}_{\text{syn}} - \theta_{\text{bal}} = -H_{\text{syn}}^{-1} \nabla \widehat{\mathcal{R}}_{\text{syn}}(\theta_{\text{syn}}) - \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} H_{\text{syn}}^{-1} \nabla \mathcal{B}_{g'}(\theta_{\text{bal}}) + R_3,
$$

where

$$
||R_3|| = O_p\bigg(\frac{1}{m} + \frac{1}{n} + ||\nabla \mathcal{R}_{syn}(\boldsymbol{\theta}_{bal})||^2\bigg).
$$

Now we measure the performance of  $\hat{\theta}_{syn}$  for group g. From Assumption [B.4,](#page-20-6)  $\|\nabla^2 \mathcal{R}_g(\theta')\| =$  $O(1)$  for any  $\theta'$  in the line segment between  $\theta_{syn}$  and  $\theta_{bal}$ , since  $\|\theta_{bal} - \theta_{syn}\| = o(1)$  by Part 1. Using Taylor expansion, we have

$$
\mathcal{R}_{g}(\theta_{\text{syn}}) - \mathcal{R}_{g}(\theta_{\text{bal}})
$$
\n
$$
= \{\nabla \mathcal{R}_{g}(\theta_{\text{bal}})\}^{\top}(\widehat{\theta}_{\text{syn}} - \theta_{\text{bal}}) + O(\|\widehat{\theta}_{\text{syn}} - \theta_{\text{bal}}\|^{2})
$$
\n
$$
=: -\{\nabla \mathcal{R}_{g}(\theta_{\text{bal}})\}^{\top}H_{\text{syn}}^{-1}\nabla \widehat{\mathcal{R}}_{\text{syn}}(\theta_{\text{syn}}) - \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} \{\nabla \mathcal{R}_{g}(\theta_{\text{bal}})\}^{\top}H_{\text{syn}}^{-1}\nabla \mathcal{B}_{g'}(\theta_{\text{bal}}) + R,
$$

where

$$
R = O_p \bigg( \frac{1}{m_{\text{total}}} + \frac{1}{n_{\text{total}}} + \|\nabla \mathcal{R}_{\text{syn}}(\boldsymbol{\theta}_{\text{bal}})\|^2 + \|\nabla \widehat{\mathcal{R}}_{\text{syn}}(\boldsymbol{\theta}_{\text{syn}})\|^2 \bigg)
$$
  
= 
$$
O_p \bigg( \frac{1}{m_{\text{total}}} + \frac{1}{n_{\text{total}}} + \|\nabla \mathcal{R}_{\text{syn}}(\boldsymbol{\theta}_{\text{bal}})\|^2 \bigg).
$$

Recall that  $v_g$  and  $b_{g,g'}$  are defined as

$$
v_g^2 = \{\nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}})\}^\top H_{\text{bal}}^{-1} \left(\frac{1}{G} \sum_{g' \in \mathcal{G}} \Sigma_{g'}(\boldsymbol{\theta}_{\text{bal}})\right) H_{\text{bal}}^{-1} \nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}}),
$$
  

$$
b_{g,g'} = \{\nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{bal}})\}^\top H_{\text{bal}}^{-1} \nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_{\text{bal}}).
$$

Again from Assumptions [B.4](#page-20-6) and [B.5,](#page-20-1) we have  $||H_{syn} - H_{bal}|| = O(||\boldsymbol{\theta}_{syn} - \boldsymbol{\theta}_{bal}||), ||\tilde{\Sigma}_g(\boldsymbol{\theta}_{syn}) \Sigma_g(\boldsymbol{\theta}_{syn})$ || =  $o(1)$  and  $\|\Sigma_g(\boldsymbol{\theta}_{syn}) - \Sigma_g(\boldsymbol{\theta}_{bal})\| = o(1)$ . Therefore, we have

$$
\mathcal{R}_{g}(\hat{\theta}_{syn}) - \mathcal{R}_{g}(\theta_{bal}) = -\sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} b_{g,g'}
$$

$$
+ O_p\left(\frac{1}{\sqrt{n_{\text{total}} + m_{\text{total}}}} v_g + \frac{1}{m_{\text{total}} \wedge n_{\text{total}}} + \|\nabla \mathcal{R}_{syn}(\theta_{bal})\|^2\right),
$$

where  $O_p$  hides constants in the assumption. The conclusion follows from equation [11,](#page-21-0) which completes the proof of Theorem [B.1.](#page-20-2)  $\Box$ 

#### B.2 Imbalanced Data

We specifically consider the binary classification task with the label set  $\mathcal{Y} = \{0, 1\}$ . Let  $\mathcal{G} = \mathcal{Y}$ . Here group 0 is the minority group and group 1 is the majority group. For imbalanced data classification, we add synthetic data only to minority group  $q = 0$  such that the total number of samples for each group becomes equal, i.e.,  $n_0 + m_0 = n_1$ .

<span id="page-22-0"></span>Corollary B.1 (Restatement of Corollary [3.1\)](#page-5-0). Under Assumptions [B.1-](#page-19-2)[B.5,](#page-20-1) if there exists some constant  $c \in (0,1)$  such that  $n_0/n_1 \leq c$  holds, then,

$$
\mathcal{R}_0(\widehat{\theta}_{\text{syn}}) = \mathcal{R}_0(\boldsymbol{\theta}_{\text{bal}}) - \frac{n_1 - n_0}{2n_1} b_{0,0} + O_p\bigg(\frac{1}{\sqrt{n_1}}v_0 + \|\nabla \mathcal{B}_0(\boldsymbol{\theta}_{\text{bal}})\|^2\bigg),
$$

where

$$
v_0^2 := \{\nabla \mathcal{R}_0(\boldsymbol{\theta}_{\text{bal}})\}^\top \{\nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}})\}^{-1} \frac{\Sigma_0(\boldsymbol{\theta}_{\text{bal}}) + \Sigma_1(\boldsymbol{\theta}_{\text{bal}})}{2} \{\nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}})\}^{-1} \nabla \mathcal{R}_0(\boldsymbol{\theta}_{\text{bal}}),
$$
\n(13)

$$
b_{0,0} := \{ \nabla \mathcal{R}_0(\boldsymbol{\theta}_{\text{bal}}) \}^\top \{ \nabla^2 \mathcal{R}_{\text{bal}}(\boldsymbol{\theta}_{\text{bal}}) \}^{-1} \nabla \mathcal{B}_0(\boldsymbol{\theta}_{\text{bal}}). \tag{14}
$$

Proof of Corollary [B.1.](#page-22-0) Directly applying Theorem [B.1](#page-20-2) completes the proof of Corollary B.1.  $\Box$ 

# B.3 Spurious Correlation

Let  $\mathcal{G} = \mathcal{Y} \times \mathcal{A}$ . We specifically consider binary label and discrete spurious features,  $\mathcal{Y} = \{-1,1\}$  and  $\mathcal{A} = \{-\gamma,\gamma\}$  with some  $\gamma \in \mathbb{R}^q$ . We observe  $\mathbf{x}_i = (\mathbf{z}_i, \mathbf{a}_i)$  and  $y_i$ ,  $z_i \in \mathbb{R}^p$  is the core feature and  $a_i \in \mathcal{A}$  is the spurious feature. We assume the conditional independence of  $a_i$  and  $z_i$  given  $y_i$ . For simplicity, assume  $n_{(-1,\gamma)} = n_{(1,-\gamma)} = n_{\min}$  $n_{\text{maj}} = n_{(1,\gamma)} = n_{(-1,-\gamma)}$  so that groups  $(-1,-\gamma)$  and  $(1,\gamma)$  are the majority groups. We choose the synthetic data size for group  $g = (y, a) \in \mathcal{G}$  by  $m_{(y, a)} = (n_{\text{maj}} - n_{\text{min}}) \mathbb{I} \{y = a\}$ to equalize the raw and synthetic data size for each group. Define the reweighted risk as

<span id="page-23-0"></span>
$$
\mathcal{R}_{\text{rw}}(\boldsymbol{\theta}) := \frac{1}{2} \sum_y \mathbb{E}[\ell(\boldsymbol{\theta};\boldsymbol{x}_i',y_i)|y_i = y].
$$

where  $x'_i = (z_i, a'_i)$  with  $a'_i \sim \text{Unif}(\{-\gamma, \gamma\})$  independent of  $y_i$ .

We are interested in the performance of  $\hat{\theta}_{syn}$  against the minimizer  $\theta_{rw}$  of  $\mathcal{R}_{rw}$ , measured in minority group risk  $\mathcal{R}_{(-1,1)}(\boldsymbol{\theta}) := \mathbb{E}[\ell(\boldsymbol{\theta}; (\boldsymbol{z}_1, \boldsymbol{a}_1), \boldsymbol{y}_1)|y_1 = -1, \boldsymbol{a}_1 = \boldsymbol{\gamma}].$ 

<span id="page-23-2"></span>**Corollary B.2** (Restatement of Corollary [3.2\)](#page-5-1). Under Assumptions [B.1](#page-19-2)[-B.5,](#page-20-1) if  $n_{min}/n_{maj} \leq$ c holds for some constant  $c \in (0,1)$ , then,

$$
\max_{g \in \mathcal{G}} \mathcal{R}_{g}(\widehat{\theta}_{syn}) = \max_{g \in \mathcal{G}} \mathcal{R}_{g}(\theta_{rw}) + O_p\left(\frac{n_{maj} - n_{min}}{n_{maj}}(\|\nabla \mathcal{B}_{(1, -\gamma)}(\theta_{rw})\| + \|\nabla \mathcal{B}_{(-1, \gamma)}(\theta_{rw})\|) + \frac{1}{\sqrt{n_{maj}}}\max_{g \in \mathcal{G}} v_g\right),
$$

where

$$
v_g^2 := \{\nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{rw}})\}^\top \{\nabla^2 \mathcal{R}_{\text{rw}}(\boldsymbol{\theta}_{\text{rw}})\}^{-1} \left(\frac{1}{4} \sum_{g' \in \mathcal{G}} \Sigma_{g'}(\boldsymbol{\theta}_{\text{rw}})\right) \{\nabla^2 \mathcal{R}_{\text{rw}}(\boldsymbol{\theta}_{\text{rw}})\}^{-1} \nabla \mathcal{R}_g(\boldsymbol{\theta}_{\text{rw}}). (15)
$$

*Proof of Corollary [B.2.](#page-23-2)* We first show that  $\theta_{bal} = \theta_{rw}$ . Let  $a'_i$  be an independent copy of  $a_i$  independent of  $z_i$ . The conditional independence between  $z_i$  and  $a_i$  given  $y_i$  yields

<span id="page-23-1"></span>
$$
\mathcal{R}_{bal}(\boldsymbol{\theta}) = \frac{1}{4} \sum_{y,a} \mathbb{E}[\ell(\boldsymbol{\theta}; (\boldsymbol{z}_i, \boldsymbol{a}_i')^\top, y_i)]
$$
  
=\frac{1}{4} \sum\_{y,a} \mathbb{E}[\ell(\boldsymbol{\theta}; (\boldsymbol{z}\_i, \boldsymbol{a}\_i)^\top, y\_i)|y\_i = y, \boldsymbol{a}\_i = \boldsymbol{a}]  
=\frac{1}{2} \sum\_{y} \mathbb{E}[\ell(\boldsymbol{\theta}; (\boldsymbol{z}\_i, \boldsymbol{a}\_i')^\top, y\_i)|y\_i = y] = \mathcal{R}\_{\text{rw}}(\boldsymbol{\theta}).

Thus  $\theta_{\text{bal}} = \theta_{\text{rw}}$  by definition. For any  $g \in \mathcal{G}$ , Theorem [B.1](#page-20-2) gives

$$
\mathcal{R}_{g}(\widehat{\theta}_{syn}) = \mathcal{R}_{g}(\theta_{rw}) - \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} b_{g,g'} + O_p\left(\frac{1}{\sqrt{n_{\text{total}} + m_{\text{total}}}} v_g + \frac{1}{m_{\text{total}} \wedge n_{\text{total}}} + \left\|\sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}}\nabla \mathcal{B}_{g'}(\theta_{rw})\right\|^2\right).
$$

Since  $|\mathcal{G}| = 4$ , using  $|\max(a, b) - \max(a, c)| \leq |b - c|$  for any  $a, b, c \in \mathbb{R}$  repeatedly, we obtain

$$
\begin{split} &\mid \max_{g \in \mathcal{G}} \mathcal{R}_{g}(\pmb{\theta}_{\text{syn}}) - \max_{g \in \mathcal{G}} \mathcal{R}_{g}(\pmb{\theta}_{\text{rw}}) \vert \\ & = O_{p} \bigg( \max_{g \in \mathcal{G}} \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} b_{g,g'} + \max_{g \in \mathcal{G}} \frac{1}{\sqrt{n_{\text{total}} + m_{\text{total}}}} v_{g} \\ & + \frac{1}{m_{\text{total}} \wedge n_{\text{total}}} + \bigg\| \sum_{g' \in \mathcal{G}} \frac{m_{g'}}{n_{\text{total}} + m_{\text{total}}} \nabla \mathcal{B}_{g'}(\pmb{\theta}_{\text{rw}}) \bigg\|^{2} \bigg) \\ & = O_{p} \bigg( \frac{n_{\text{maj}} - n_{\text{min}}}{n_{\text{maj}}} (\|\nabla \mathcal{B}_{(1, -\gamma)}(\pmb{\theta}_{\text{rw}})\| + \|\nabla \mathcal{B}_{(-1, \gamma)}(\pmb{\theta}_{\text{rw}})\|) + \frac{1}{\sqrt{n_{\text{maj}}}} \max_{g \in \mathcal{G}} v_{g} \bigg), \end{split}
$$

where the last inequality follows since  $n_1 \leq cn_2$  for some  $c < 1$ , and  $|b_{g,g'}| \leq ||\nabla \mathcal{B}_{g'}(\boldsymbol{\theta}_{rw})||$ . This completes the proof of Corollary [B.2.](#page-23-2)

# <span id="page-24-0"></span>C Proofs for Section [3.2](#page-6-1)

In this section, we prove the results for transformers in Section [3.2.](#page-6-1)

For the prove the results for transformers in Section 3.2.<br>Recall that  $\eta \geq (1/\sqrt{r}) \log d$ . Assume that  $||z^{(t)}|| = 1$  for all  $t \in \mathcal{T}$ ,  $|\mathcal{F}| \lesssim d^{\alpha}$  for some positive constant  $\alpha = O(1)$ , and  $\sup_{\mathbf{u} \in \mathbb{B}_r(\log d)} ||f^{(m)}(\mathbf{u})|| \leq 1$ . We introduce several assumptions. Note that in the main body we only use Assumption [C.3,](#page-25-0) which is weaker than Assumptions [C.1](#page-24-1) and [C.2.](#page-24-2)

<span id="page-24-1"></span>Assumption C.1. Assume that  $\mathbb{E}[\|f^{(m)}(\mathbf{u}_{X_1})\|^2 | T=t, U, \eta] = N_{t,U,\eta}^2$  for all  $m \in \mathcal{M}$  for some  $N_{t,U,\eta} > 0$  allowed to be dependent on  $t \in \mathcal{T}$ , U, and  $\eta$ .

This assumption can be easily satisfied when functions  $(f^{(m)})_{m\in\mathcal{M}}$  take values on the same sphere in  $\mathbb{R}^r$  on average.

Define  $\xi_{\mathcal{T}}$  and  $\xi_{\mathcal{M}}$  as

$$
\xi_{\mathcal{T}} := 1 - \max_{t \neq t'} \langle \mathbf{z}^{(t)}, \mathbf{z}^{(t')} \rangle,
$$
  

$$
\xi_{\mathcal{M}}(U) := \min_{m \neq m'} \mathbb{E} \big[ D_{\mathrm{KL}}(\mathbb{P}(Y_i | X_i, M = m, U, \eta) \| \mathbb{P}(Y_i | X_i, M = m', U, \eta)) \big| T = t, U, \eta \big].
$$
 (16)

Note that  $\xi_{\mathcal{T}}$  measures the smallest cosine dissimilarity between different subject embeddings, and  $\xi_{\mathcal{M}}(U)$  is the KL divergence between distributions of  $Y_i$  given different M. We introduce the following identifiability condition for  $(z^{(t)})_{t\in\mathcal{T}}$  and  $(f^{(m)})_{m\in\mathcal{M}}$ , which is used to prove the perfect recovery of distribution. Recall that  $\xi_{\mathcal{T}}$  and  $\xi_{\mathcal{M}}$  defined in equation [16](#page-24-3) are responsible for the identifiability.

<span id="page-24-2"></span>**Assumption C.2.** Assume that there exist sufficiently large constants  $C_T$  and  $C_M$  such that

<span id="page-24-3"></span>
$$
\xi_{\mathcal{T}} \geq C_T \frac{\eta r}{\min_{t \in \mathcal{T}} \| \mathbf{z}^{(t)} \|} \bigg( \frac{\log^2 d}{\sqrt{nr}} + \frac{\log d}{\sqrt{dr}} \bigg),
$$

$$
\mathbb{P}\bigg(\xi_{\mathcal{M}}(U) \ge C_M\bigg(\frac{\log^2 d}{\eta\sqrt{nr}} + \frac{\log d}{\sqrt{d}}\bigg)\bigg) = 1 - \exp\big(\big(\log^2 d)\big),
$$

where the probability is taken with respect to U.

We introduce another identifiability condition for the function class  $\mathcal{F}$ .

<span id="page-25-0"></span>**Assumption C.3.** There exists a constant  $C > 0$  and  $\epsilon > 0$  such that for any  $\epsilon' \leq \epsilon$  and  $m,m' \in {\cal M}, \ \text{if} \ \vert \mathbb{E}[f^{(m')}(\bm{u}_{X_1})^{\top}f^{(m)}(\bm{u}_{X_1}) \vert T=t,U,\eta] - \mathbb{E}[\Vert f^{(m)}(\bm{u}_{X_1}) \Vert^2 \vert T=t,U,\eta] \vert \leq \epsilon',$ then  $|\mathbb{E}[\|f^{(m')}(\boldsymbol{u}_{X_1})-f^{(m)}(\boldsymbol{u}_{X_1})\|^2]T = t, U, \eta]|\leq C\epsilon'$  holds with high probability with respect to  $U$ .

We then provide Lemmas [C.1](#page-25-1) and [C.2](#page-27-0) to show that selecting the subject or function embeddings by maximizing the cosine similarity gives the ground-truth subject or function with high probability.

## C.1 A Lemma for generative capacity of LLMs

Given observed covariates  $(X_i)_{i\in[n]}$  and token embeddings U, we define the estimator of T as

<span id="page-25-5"></span>
$$
\widehat{T} = \underset{t' \in \mathcal{T}}{\arg \max} \frac{1}{n} \sum_{i \in [n]} \langle \mathbf{z}^{(t')}, \mathbf{u}_{X_i} \rangle. \tag{17}
$$

<span id="page-25-1"></span>**Lemma C.1.** For any  $t \in \mathcal{T}$  and  $\eta \geq (1/\sqrt{r}) \log d$ , it holds that

$$
\mathbb{P}\left(\max_{t'\in\mathcal{T}}\left| \boldsymbol{z}^{(t')\top}\left(\frac{1}{n}\sum_{i\in[n]} \boldsymbol{u}_{X_i}\right) - \frac{1}{\eta r} \boldsymbol{z}^{(t')\top}\boldsymbol{z}^{(t)}\right| \lesssim \frac{\log^2 d}{\sqrt{n}r} + \frac{\log d}{\sqrt{dr}}\middle| T = t, U, \eta\right) = 1 - \exp\left(-\Omega(\log^2 d)\right).
$$

Furthermore, under Assumption [C.2,](#page-24-2)

$$
\mathbb{P}(\widehat{T} \neq t | T = t, U, \eta) = \exp(-\Omega(\log^2 d)),
$$
  

$$
\mathbb{P}\left(\frac{1}{n}\sum_{i \in [n]} \langle \mathbf{z}^{(\widehat{T})}, \mathbf{u}_{X_i} \rangle - \max_{t' \neq \widehat{T}} \frac{1}{n} \sum_{i \in [n]} \langle \mathbf{z}^{(t')}, \mathbf{u}_{X_i} \rangle \leq \frac{\xi \tau}{2\eta r} \middle| T = t, U, \eta \right) = \exp(-\Omega(\log^2 d))
$$

hold with high probability with respect to U. Here  $\Omega$ 's do not depend on t.

*Proof of Lemma [C.1.](#page-25-1)* Define  $E_i^{(t')}$  $\mathbf{z}_{i}^{(t')} := \sum_{x \in \mathcal{X}} \mathbf{z}^{(t')}^\top \mathbf{u}_x \mathbb{I} \{\underline{X}_i = x\}.$  From Lemma [D.1,](#page-40-0) there exists an event  $\mathcal E$  for a random matrix  $\overline{U} = [\boldsymbol{u}_1; \dots; \boldsymbol{u}_d]^\top$  with  $\mathbb P(\mathcal E) = 1 - \exp(-\Omega(\log^2 d))$ such that on this event,

<span id="page-25-2"></span>
$$
\max_{T \in \mathcal{T}, x \in \mathcal{X}} |\mathbf{z}^{(t)\top} \mathbf{u}_x| \lesssim \frac{1}{\sqrt{r}} \log d, \quad \max_{t \in \mathcal{T}} \left| \frac{d \mathbb{E}[C_x^{(t)}]}{\sum_{x \in \mathcal{X}} C_x^{(t)}} - 1 \right| \lesssim \frac{1}{\sqrt{d}} \log d,
$$
 (18)

<span id="page-25-3"></span>
$$
\max_{t,t' \in \mathcal{T}} \left| \sum_{x \in \mathcal{X}} (D_x^{(t,t')} - \mathbb{E}[D_x^{(t,t')}] ) \right| \lesssim \sqrt{\frac{d}{r}} \log d \tag{19}
$$

<span id="page-25-4"></span>
$$
\max_{t,t' \in \mathcal{T}} \left| \sum_{x \in \mathcal{X}} \frac{D_x^{(t,t')}}{\sum_{x' \in \mathcal{X}} C_{x'}^{(t)}} - \frac{\mathbb{E}[D_x^{(t,t')}]}{\mathbb{E}[C_x^{(t)}]} \right| \lesssim \frac{1}{\sqrt{dr}} \log d,
$$
\n(20)

hold, where  $C_x^{(t)} = \sum_{x \in \mathcal{X}} \exp(\eta^{-1} \mathbf{z}^{(t)\top} \mathbf{u}_x)$  and  $D_x^{(t,t')} = \sum_{x \in \mathcal{X}} \mathbf{z}^{(t')\top} \mathbf{u}_x \exp(\eta^{-1} \mathbf{z}^{(t)\top} \mathbf{u}_x)$ . For now we fix any U satisfying equation [18](#page-25-2) and equation [19.](#page-25-3) We also fix any  $t \in \mathcal{T}$ 

and  $\eta \geq (1/\sqrt{r}) \log d$ . Then, there exists some constant  $C > 0$  such that  $|E_i^{(t)}|$  $\left|\frac{i^{(l)}}{i}\right| \leq$  $\lim_{x \to \infty} \frac{f(z)}{z^{(t')} \tau}$   $\mathbf{u}_x \leq (C/\sqrt{r}) \log d$  holds. From Hoeffding's inequality, it follows that

$$
\mathbb{P}\left(\left|\sum_{i\in[n]}(E_i^{(t')} - \mathbb{E}[E_i^{(t')}|U,T=t,\eta])\right| \ge \epsilon \middle| U,T=t,\eta\right) \le 2\exp\left(-\frac{r\epsilon^2}{2C^2n\log^2 d}\right).
$$

Choosing  $\epsilon \leftarrow \sqrt{n/r} \log^2 d$ , and using  $(1/n) \sum_{i \in [n]} z^{(t')}^{\top} \mathbf{u}_{X_i} = (1/n) \sum_{i \in [n]} E_i^{(t')}$  $i^{(i)}$ , we have

$$
\mathbb{P}\left(\left| \boldsymbol{z}^{(t')\top}\left(\frac{1}{n}\sum_{i\in[n]} \boldsymbol{u}_{X_i}\right) - \sum_{x\in\mathcal{X}}\frac{D_x^{(t,t')}}{\sum_{x'\in\mathcal{X}}C_{x'}^{(t)}}\right| \leq \frac{\log^2 d}{\sqrt{nr}}\middle| U, T = t, \eta \right) = 1 - \exp\left(-\Omega(\log^2 d)\right),
$$

where we used

$$
\mathbb{E}[E_i^{(t)}|U,T=t,\eta] = \sum_{x\in\mathcal{X}} \mathbf{z}^{(t')\top} \mathbf{u}_x \mathbb{P}(X_i=x|U,T=t,\eta) = \frac{\sum_{x\in\mathcal{X}} D_x^{(t,t')}}{\sum_{x'\in\mathcal{X}} C_{x'}^{(t)}}.
$$

By a union bound argument,

$$
\mathbb{P}\left(\max_{t'\in\mathcal{T}}\left| \boldsymbol{z}^{(t')\top}\left(\frac{1}{n}\sum_{i\in[n]} \boldsymbol{u}_{X_i}\right) - \sum_{x\in\mathcal{X}}\frac{D_x^{(t,t')}}{\sum_{x'\in\mathcal{X}}C_{x'}^{(t)}}\right| \le \frac{\log^2 d}{\sqrt{nr}}\middle| U, T = t, \eta \right) = 1 - \exp\left(-\Omega(\log^2 d)\right)
$$
\n(21)

<span id="page-26-1"></span><span id="page-26-0"></span>.

Notice that equation [64](#page-43-0) and  $\mathbb{E}[C_{x'}^{(t)}] = \exp\left(\Vert \mathbf{z}^{(t)} \Vert^2 / (2\eta^2 r)\right)$  yield

$$
\frac{\mathbb{E}[D_x^{(t,t')}] }{\mathbb{E}[C_x^{(t)}]} = \frac{1}{\eta r} \boldsymbol{z}^{(t')\top} \boldsymbol{z}^{(t)}.
$$

Therefore, combining equation [21](#page-26-0) and equation [20,](#page-25-4) we have

$$
\mathbb{P}\left(\max_{t' \in \mathcal{T}} |\Delta^{(t,t')}| \lesssim \frac{\log^2 d}{\sqrt{nr}} + \frac{\log d}{\sqrt{dr}} \middle| U, T = t, \eta \right) = 1 - \exp\left(-\Omega(\log^2 d)\right),\tag{22}
$$

where  $\Delta^{(t,t')} := (1/n) \sum_{i \in [n]} z^{(t')}^\top u_{X_i} - (1/nr) z^{(t')}^\top z^{(t)}$ . This gives the first claim. The second claim follows since

$$
\mathbb{P}(\widehat{T} \neq t | T = t, U, \eta) = \mathbb{P}\left(\frac{1}{n} \sum_{i \in [n]} \mathbf{z}^{(t)\top} \mathbf{u}_{X_i} < \max_{t': t' \neq t} \frac{1}{n} \sum_{i \in [n]} \mathbf{z}^{(t')\top} \mathbf{u}_{X_i} \middle| T = t, U, \eta\right) \tag{23}
$$

$$
\leq \mathbb{P}\left(\frac{1}{\eta r} < \max_{t':t'\neq t} \frac{\mathbf{z}^{(t')\top}\mathbf{z}^{(t)}}{\eta r} + 2\max_{t'\in\mathcal{T}} |\Delta^{(t,t')}| \middle| T = t, U, \eta\right) \tag{24}
$$

$$
= \mathbb{P}\left(\max_{t' \in \mathcal{T}} |\Delta^{(t,t')}| > \frac{\xi\tau}{2\eta r} \middle| T = t, U, \eta\right)
$$
\n(25)

<span id="page-26-2"></span>
$$
= \exp(-\Omega(\log^2 d)),\tag{26}
$$

where the last equality follows from equation [22](#page-26-1) and by assumption for  $\xi_{\mathcal{T}}$ .

Next we prove the third claim. We already know that  $\max_{t \in \mathcal{T}} \mathbb{P}(\hat{T} \neq t | T = t, U, \eta) =$  $1 - \exp(-\Omega(\log^2 d))$ . Thus by a union bound argument we only need to bound

$$
\delta_n^{(t)} := \frac{1}{n} \sum_{i \in [n]} \langle \mathbf{z}^{(t)}, \mathbf{u}_{X_i} \rangle - \max_{t': t' \neq t} \frac{1}{n} \sum_{i \in [n]} \langle \mathbf{z}^{(t')}, \mathbf{u}_{X_i} \rangle \tag{27}
$$

given  $T = t$  and U. By the same argument as in equation [26,](#page-26-2)

$$
\mathbb{P}\left(\delta_n^{(t)} < \delta' \middle| T = t, U, \eta\right) \le \mathbb{P}\left(\frac{1}{\eta r} < \max_{t': t' \ne t} \frac{\mathbf{z}^{(t')\top} \mathbf{z}^{(t)}}{\eta r} + 2 \max_{t' \in \mathcal{T}} |\Delta^{(t, t')}| + \delta' \middle| T = t, U, \eta\right) \tag{28}
$$

$$
= \mathbb{P}\left(\max_{t' \in \mathcal{T}} |\Delta^{(t,t')}| > \frac{\xi_{\mathcal{T}}}{2\eta r} - \frac{\xi_{\mathcal{T}}}{4\eta r} \middle| T = t, U, \eta\right)
$$
(29)

$$
= \exp(-\Omega(\log^2 d))
$$
\n(30)

This completes the proof of Lemma [C.1.](#page-25-1)

# C.2 A Lemma for discriminative capacity of LLMs

Given observed pairs  $(X_i, Y_i)_{i \in [n]}$ , we define the estimator of M as

$$
\widehat{M} := \underset{m' \in \mathcal{M}}{\arg \max} \frac{1}{n} \sum_{i \in [n]} \langle f^{(m')}(\boldsymbol{u}_{X_i}), \boldsymbol{u}_{Y_i} \rangle. \tag{31}
$$

We first provide a lemma stating that  $M$  can be estimated perfectly with high probability under the identifiability condition on  $\xi_M$ .

<span id="page-27-0"></span>**Lemma C.2.** For any  $m \in \mathcal{M}$ ,  $t \in \mathcal{T}$  and  $\eta \geq (1/\sqrt{r}) \log d$ , it holds that

$$
\mathbb{P}\left(\max_{m'\in\mathcal{M}}\left|\frac{1}{n}\sum_{i\in[n]}\langle f^{(m')}(\boldsymbol{u}_{X_i}),\boldsymbol{u}_{Y_i}\rangle-\mathbb{E}\Big[\langle f^{(m')}(\boldsymbol{u}_{X_1}),\boldsymbol{u}_{Y_1}\rangle|M=m,T=t,U,\eta\Big]\right|\\>\frac{\log^2 d}{\sqrt{nr}}\bigg|M=m,T=t,U,\eta\right)
$$
\n
$$
=\exp(-\Omega(\log^2 d)).
$$

with high probability. Furthermore, under Assumptions [C.1](#page-24-1) and [C.2,](#page-24-2)

$$
\mathbb{P}(\widehat{M} \neq m | M = m, T = t, U, \eta) = \exp(-\Omega(\log^2 d)),
$$
  

$$
\mathbb{P}\left(\frac{1}{n}\sum_{i\in[n]} \langle f^{(\widehat{M})}(\mathbf{u}_{X_i}), \mathbf{u}_{Y_i}\rangle - \max_{m'\neq \widehat{M}} \frac{1}{n}\sum_{i\in[n]} \langle f^{(m')}(\mathbf{u}_{X_i}), \mathbf{u}_{Y_i}\rangle \leq \frac{\eta \xi_M}{2} \middle| M = m, T = t, U, \eta \right)
$$
  
=  $\exp(-\Omega(\log^2 d)).$ 

holds with high probability with respect to U.

*Proof of Lemma [C.2.](#page-27-0)* To ease notation we let  $p_x^{(t)} := \mathbb{P}(X_1 = x | T = t, U, \eta)$ . We divide the proof into two parts.

**Part 1.** In this part we bound the quantity  $\min_{m' \in \mathcal{M}} (\mathbb{E}[H_{X_1}^{(m)}])$  $X_{1, Y_{1}}^{(m)} |M = m, T = t, U, \eta] \mathbb{E}[H_{X,Y}^{(m')}$  $X_{X_1,Y_1}^{(m)}|M=m,T=t,U,\eta]$ . Note that for any  $t\in\mathcal{T}, m\in\mathcal{M}, U$  and  $\eta$ ,

$$
\mathbb{E}[\{f^{(m')}(\boldsymbol{u}_{X_1})\}^\top \boldsymbol{u}_{Y_1}|M = m, T = t, U, \eta] \n= \eta \sum_{x \in \mathcal{X}} p_x^{(t)} \sum_{y \in \mathcal{X}} \log \left( \frac{\exp \left( \eta^{-1} \{f^{(m')}(\boldsymbol{u}_x)\}^\top \boldsymbol{u}_y \right)}{\sum_{y' \in \mathcal{X}} \exp \left( \eta^{-1} \{f^{(m')}(\boldsymbol{u}_x)\}^\top \boldsymbol{u}_{y'} \right)} \right) \frac{\exp \left( \eta^{-1} \{f^{(m)}(\boldsymbol{u}_x)\}^\top \boldsymbol{u}_y \right)}{\sum_{y' \in \mathcal{X}} \exp \left( \eta^{-1} \{f^{(m)}(\boldsymbol{u}_x)\}^\top \boldsymbol{u}_{y'} \right)}
$$

<span id="page-27-1"></span> $\Box$ 

$$
+\eta\sum_{x\in\mathcal{X}}p_{x}^{(t)}\log\left(\sum_{y'\in\mathcal{X}}C_{y'}\Big(f^{(m')}(\boldsymbol{u}_{x})\Big)\right),\,
$$

where  $C_x(z) := \exp(\eta^{-1} z^{\top} u_x)$ . Then,

$$
\mathbb{E}[\{f^{(m)}(\mathbf{u}_{X_1})\}^\top \mathbf{u}_{Y_1}|M = m, T = t, U, \eta] - \mathbb{E}[\{f^{(m')}(\mathbf{u}_{X_1})\}^\top \mathbf{u}_{Y_1}|M = m, T = t, U, \eta] \n= \eta \mathbb{E}[D_{\mathrm{KL}}(\mathbb{P}(Y_i|X_i, M = m, U) || \mathbb{P}(Y_i|X_i, M = m', U)) | T = t, U, \eta] \n+ \eta \sum_{x \in \mathcal{X}} p_x^{(t)} \log \left( \frac{\sum_{y' \in \mathcal{X}} C_{y'}(f^{(m)}(\mathbf{u}_x))}{\sum_{y' \in \mathcal{X}} C_{y'}(f^{(m')}(\mathbf{u}_x))} \right).
$$
\n(32)

We first show that there exists a high probability event with respect to  $U$  such that the second term on the right hand side in equation [32](#page-28-0) is small. Fix any  $x \in \mathcal{X}$ . Note that  $||u_x|| \lesssim (1/\sqrt{r})\log d$  holds with high probability from Lemma [D.1.](#page-40-0) Thus  $\max_{m \in [m], x \in \mathcal{X}} ||f^{(m)}(\boldsymbol{u}_x)|| \leq 1$  holds with high probability by assumption. Again from Lemma [D.1](#page-40-0) with the choice  $\mathcal{X} \leftarrow \mathcal{X} \setminus \{x\}$ , we have

<span id="page-28-0"></span>
$$
\max_{m \in \mathcal{M}} \left| \sum_{y \in \mathcal{X} \setminus \{x\}} \left\{ C_y(f^{(m)}(\boldsymbol{u}_x)) - \exp\left(\frac{\|f^{(m)}(\boldsymbol{u}_x)\|^2}{2\eta^2 r} \right) \right\} \right| \lesssim \sqrt{d} \log d
$$

with high probability. By a union bound, we have

$$
\max_{x \in \mathcal{X}} \max_{m \in \mathcal{M}} \left| \sum_{y \in \mathcal{X} \setminus \{x\}} \left\{ C_y(f^{(m)}(\boldsymbol{u}_x)) - \exp\left(\frac{\|f^{(m)}(\boldsymbol{u}_x)\|^2}{2\eta^2 r} \right) \right\} \right| \lesssim \sqrt{d} \log d
$$

with probability  $1 - d \exp(-\Omega(\log^2 d)) = 1 - \exp(-\Omega(\log^2 d))$ . This gives

$$
\log \left( \frac{\sum_{y' \in \mathcal{X}} C_{y'} (f^{(m)}(\boldsymbol{u}_x))}{\sum_{y' \in \mathcal{X}} C_{y'} (f^{(m')}(\boldsymbol{u}_x))} \right) = \log \left( \frac{C_x (f^{(m)}(\boldsymbol{u}_x)) + \sum_{y' \neq x} C_{y'} (f^{(m)}(\boldsymbol{u}_x))}{C_x (f^{(m')}(\boldsymbol{u}_x)) + \sum_{y' \neq x} C_{y'} (f^{(m')}(\boldsymbol{u}_x))} \right)
$$
  
= 
$$
\log \left( \frac{O(1) + O(\sqrt{d} \log d) + (d - 1) \exp(\|f^{(m)}(\boldsymbol{u}_x)\|^2/(2\eta^2 r))}{O(1) + O(\sqrt{d} \log d) + (d - 1) \exp(\|f^{(m)}(\boldsymbol{u}_x)\|^2/(2\eta^2 r))} \right)
$$
  
= 
$$
\frac{\|f^{(m)}(\boldsymbol{u}_x)\|^2 - \|f^{(m')}(\boldsymbol{u}_x)\|^2}{2\eta^2 r} + O\left(\frac{\log d}{\sqrt{d}}\right)
$$

with high probability, where we used  $C_x(f^{(m)}(\boldsymbol{u}_x)) = O(1)$  with high probability in the second equality. Here O's do not depend on  $m, m'$  and x. To ease notation, we define  $H_{x,y}^{(m)} := \langle f^{(m)}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle$ . Then,

$$
\mathbb{E}\Big[H_{X_1,Y_1}^{(m)}|M=m,T=t,U,\eta\Big]-\mathbb{E}\Big[H_{X_1,Y_1}^{(m')}|M=m,T=t,U,\eta\Big]
$$
  
=\eta\mathbb{E}\big[D\_{\text{KL}}(\mathbb{P}(Y\_i|X\_i,M=m,U)||\mathbb{P}(Y\_i|X\_i,M=m',U))|T=t,U,\eta]\n+ \eta\frac{\mathbb{E}[\|f^{(m)}(\mathbf{u}\_{X\_1})\|^2-\|f^{(m')}(\mathbf{u}\_{X\_1})\|^2|T=t,U,\eta\}}{2\eta^2r}+O\bigg(\frac{\eta\log d}{\sqrt{d}}\bigg)\n= \eta\mathbb{E}\big[D\_{\text{KL}}(\mathbb{P}(Y\_i|X\_i,M=m,U)||\mathbb{P}(Y\_i|X\_i,M=m',U))|T=t,U,\eta\big]+O\bigg(\frac{\eta\log d}{\sqrt{d}}\bigg)

 $\mathbf{h}$  holds with high probability, where the last equality follows by assumption that  $\mathbb{E}[\|f^{(m)}(\bm{u}_{X_1})\|^2 |T=0]$  $[t, U, \eta] = N_{t, U, \eta}^2$  for all  $m \in \mathcal{M}$ . This gives

$$
\min_{m' \in \mathcal{M}} \left( \mathbb{E} \Big[ H_{X_1, Y_1}^{(m)} | M = m, T = t, U, \eta \Big] - \mathbb{E} \Big[ H_{X_1, Y_1}^{(m')} | M = m, T = t, U, \eta \Big] \right) = \eta \xi_{\mathcal{M}} + O \left( \frac{\eta \log d}{\sqrt{d}} \right)
$$
\n(33)

with high probability.

**Part 2.** Next we show the convergence of  $(1/n) \sum_{i \in [n]} H_{X_i, Y_i}^{(m')}$  $X_{i_1}^{(m')}$  for all  $m' \in \mathcal{M}$  given U. For now we fix any  $m' \in M$ . We fix any  $t \in \mathcal{T}$ ,  $m \in \mathcal{M}$  and  $\eta \geq (1/\sqrt{r}) \log d$ . From Lemma [D.1,](#page-40-0)

<span id="page-29-2"></span><span id="page-29-1"></span><span id="page-29-0"></span>
$$
\max_{m' \in \mathcal{M}} \max_{x,y \in \mathcal{X}} |H_{x,y}^{(m')}| \le \max_{y \in \mathcal{X}} \|\mathbf{u}_y\| \le C(1/\sqrt{r}) \log d \tag{34}
$$

holds for some constant  $C > 0$ . For any U satisfying equation [33](#page-29-0) and equation [34,](#page-29-1) Hoeffding's inequality gives

$$
\mathbb{P}\left(\left|\sum_{i\in[n]} \left(H_{X_i,Y_i}^{(m')} - \mathbb{E}\left[H_{X_1,Y_1}^{(m')}\middle|M=m,T=t,U,\eta\right]\right)\right| > \epsilon \middle|M=m,T=t,U,\eta\right)
$$
  

$$
\leq 2 \exp\left(-\frac{r\epsilon^2}{2nC^2\log^2 d}\right).
$$

Choosing  $\epsilon \leftarrow \sqrt{n/r} \log^2 d$  and a union bound argument gives

$$
\mathbb{P}\left(\max_{m'\in\mathcal{M}}\left|\frac{1}{n}\sum_{i\in[n]}H_{X_i,Y_i}^{(m')} - \mathbb{E}\left[H_{X_1,Y_1}^{(m')}\middle|M=m,T=t,U,\eta\right]\right| > \frac{\log^2 d}{\sqrt{nr}}\left|M=m,T=t,U,\eta\right\}
$$
(35)  

$$
\lesssim |\mathcal{M}||\mathcal{T}|\exp(-\Omega(\log^2 d)) = \exp(-\Omega(\log^2 d)),
$$

where we used  $|\mathcal{M}| = d^{\alpha}$  for some constant  $\alpha = O(1)$ . This yields the first claim. Therefore,

$$
\mathbb{P}(\widehat{M} \neq m | M = m, T = t, U, \eta)
$$
\n
$$
= \mathbb{P}\left(\frac{1}{n} \sum_{i \in [n]} H_{X_i, Y_i}^{(m)} < \max_{m' \in \mathcal{M}} \frac{1}{n} \sum_{i \in [n]} H_{X_i, Y_i}^{(m')} \middle| M = m, T = t, U, \eta\right)
$$
\n
$$
\leq \mathbb{P}\left(\mathbb{E}\left[H_{X_1, Y_1}^{(m)} | M = m, T = t, U, \eta\right] - \max_{m' \in \mathcal{M}} \mathbb{E}\left[H_{X_1, Y_1}^{(m')} | M = m, T = t, U, \eta\right]
$$
\n
$$
< 2 \max_{m' \in \mathcal{M}} \left| \frac{1}{n} \sum_{i \in [n]} H_{X_i, Y_i}^{(m')} - \mathbb{E}\left[H_{X_1, Y_1}^{(m')} | M = m, T = t, U, \eta\right] \right| \middle| M = m, T = t, U \right).
$$

Note that when  $\xi_{\mathcal{M}} \gg (1/$ √  $\overline{d}$ ) log  $d + (1/(\eta\sqrt{nr})) \log^2 d$ ,

$$
\mathbb{P}\bigg(\mathbb{E}\Big[H_{X_1,Y_1}^{(m)}|M=m,T=t,U,\eta\Big]-\max_{m'\in\mathcal{M}}\mathbb{E}\Big[H_{X_1,Y_1}^{(m')}|M=m,T=t,U,\eta\Big] \n<2\max_{m'\in\mathcal{M}}\bigg|\frac{1}{n}\sum_{i\in[n]}H_{X_i,Y_i}^{(m')}-\mathbb{E}[H_{X_1,Y_1}^{(m')}|M=m,T=t,U,\eta]\bigg|\bigg|M=m,T=t,U\bigg) \n\leq \mathbb{P}\bigg(\frac{\log^2 d}{\sqrt{nr}}<\max_{m'\in\mathcal{M}}\bigg|\frac{1}{n}\sum_{i\in[n]}H_{X_i,Y_i}^{(m')}-\mathbb{E}[H_{X_1,Y_1}^{(m')}|M=m,T=t,U,\eta]\bigg|\bigg|M=m,T=t,U\bigg)
$$

$$
= \exp(-\Omega(\log^2 d)),
$$

where we used equation [36.](#page-29-2) In summary,

$$
\mathbb{P}(\widehat{M} \neq m | M = m, T = t, U, \eta) = \exp(-\Omega(\log^2 d))
$$

holds with high probability.

By the same argument as in the proof of Lemma [C.1,](#page-25-1) we obtain

$$
\mathbb{P}\left(\frac{1}{n}\sum_{i\in[n]}H^{(m)}_{X_i,Y_i}-\max_{m'\in\mathcal{M}}\frac{1}{n}\sum_{i\in[n]}H^{(m')}_{X_i,Y_i}<\frac{\eta\xi_{\mathcal{M}}}{2}\middle|M=m,T=t,U,\eta\right)=\exp\left(-\Omega(\log^2 d)\right),
$$

This completes the proof of Lemma [C.2.](#page-27-0)

#### C.3 Construction of transformer layers

In this section, we construct a transformer that outputs synthetic covariates or labels depending on the current task. We only consider the case where  $|\mathcal{M}| \geq |\mathcal{T}|$ . Otherwise the proof follows by a similar argument.

Before the proof, we define identity feed forward neural neural networks and transformers.

**Definition C.1.** Define the identity attention  $Attn_{\mu_{id}}$  and identity feed forward neural network  $FFN_{\nu_{\rm id}}$  as  $\mu_{\rm id} = \{(O, O, O)\}$  and  $\nu_{\rm id} = \{O, O\}.$ 

We also introduce a useful function that combines the product and indicator functions. Define  $\phi_B : \mathbb{R}^3 \to \mathbb{R}$  as

$$
\phi_B(x;s,t) := -4B\sigma \left(\frac{1}{4B}x + t - s + \frac{1}{2}\right) + 8B\sigma \left(\frac{1}{4B}x + t - s + \frac{1}{4}\right) - 8B\sigma \left(\frac{1}{4B}x + t - s - \frac{1}{4}\right) + 4B\sigma \left(\frac{1}{4B}x + t - s - \frac{1}{2}\right).
$$
 (37)

We provide the following lemma without proof to help implement an attention layer that filters some input tokens.

**Lemma C.3.** For any  $B > 0$  and  $x \in [-B, B]$ , and  $s, t \in \mathbb{Z}$ ,

<span id="page-30-1"></span>
$$
\phi_B(x; s, t) = x \mathbb{I}\{s = t\}.
$$

We then introduce the notation to simplify the statement. We omit the second subscript n from  $p_{s,n}$  for the positional encoding. Define  $h_{2i-1} = h_i^X$  and  $h_{2i} = h_i^Y$  for all  $i \in [n]$ . Let  $(\tilde{X}_s, \tilde{Y}_s)$   $(s \ge 1)$  be the synthetic pair of data generated as the  $(2s-1)$ -th and  $(2s)$ -th output from the transformer. Let  $X_{n+s} := \tilde{X}_s$  and  $Y_{n+s} := \tilde{Y}_s$ . Define

$$
\boldsymbol{h}_{2n+2s-1} = \begin{pmatrix} \boldsymbol{u}_{X_{n+s}} \\ \boldsymbol{0} \\ \boldsymbol{p}_{2n+2s-1} \end{pmatrix}, \ \boldsymbol{h}_{2n+2s-1} = \begin{pmatrix} \boldsymbol{u}_{Y_{n+s}} \\ \boldsymbol{0} \\ \boldsymbol{p}_{2n+2s} \end{pmatrix}
$$
(38)

for  $s \geq 1$ . In summary, we have input tokens  $H_n = [\mathbf{h}_1, \mathbf{h}_2, \dots, \mathbf{h}_{2n}]$  and previously generated tokens  $[\mathbf{h}_{2n+1}, \mathbf{h}_{2n+2}, \dots, \mathbf{h}_{2n+\ell}]$  for some  $\ell \in \{0\} \cup \mathbb{N}^+$ .

<span id="page-30-0"></span>**Proposition C.1.** Fix any  $d, r, r_0, L_0 \in \mathbb{N}^+$ ,  $\omega > 0$ ,  $(\mathbf{z}^{(t)})_{t \in \mathcal{T}}$  and  $(f^{(m)})_{m \in \mathcal{M}} \subset \mathcal{F}(L_0, r_0)$ . Then, there exist transformer layers  $TF_{\Psi^*}$  with  $\Psi^* = \Psi^*((\mathbf{z}^{(t)})_{t \in \mathcal{T}}, (f^{(m)})_{m \in \mathcal{M}}, d, r, \omega, L_0, r_0)$ such that

<span id="page-30-2"></span> $\Box$ 

- the dimension of token embeddings is  $r + r|\mathcal{M}| + |\mathcal{M}| + 4$ ,
- it consists of  $L_0 + 9$  transformer layers with the width of FNN  $O(|\mathcal{M}|^2 \vee |\mathcal{M}|r_0)$ , and the number of heads of attention layers  $O(|\mathcal{M}|)$ .
- given inputs  $H_n$  and  $h_{2n+1}, \ldots, h_{2n+\ell}$  defined in equation [38,](#page-30-1) it outputs

$$
\mathrm{TF}_{\Psi^*}([H_n; \boldsymbol{h}_{2n+1}; \ldots; \boldsymbol{h}_{2n+\ell}])_{2n+\ell} = \begin{cases} (\widehat{f}(\boldsymbol{u}_{X_{n+s}})^\top, \boldsymbol{0}^\top)^\top & \text{if } \ell = 2s - 1, \\ (\widehat{\boldsymbol{z}}^\top, \boldsymbol{0}^\top)^\top & \text{if } \ell = 2s, \end{cases}
$$

for all  $s \in \mathbb{N}^+$ , where  $\widehat{f}(\boldsymbol{u}_{X_{n+s}})$  and  $\widehat{\boldsymbol{z}}$  satisfy

$$
\hat{f}(\boldsymbol{u}_{X_{n+s}}) \in \text{conv}\bigg\{f^{(m')}(\boldsymbol{u}_{X_{n+s}}): m' \in \mathcal{M}, \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{Y_i}, f^{(m')}(\boldsymbol{u}_{X_i}) \rangle
$$
\n
$$
\geq \max_{m'' \in \mathcal{M}} \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{Y_i}, f^{(m'')}(\boldsymbol{u}_{X_i}) \rangle - \frac{\omega}{n} \bigg\},
$$
\n
$$
\hat{\boldsymbol{z}} \in \text{conv}\bigg\{ \boldsymbol{z}^{(t')} : t' \in \mathcal{T}, \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t')} \rangle \geq \max_{t'' \in \mathcal{T}} \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t'')} \rangle - \frac{\omega}{n} \bigg\}.
$$

<span id="page-31-0"></span>**Theorem C.1.** Suppose that Assumption [C.3](#page-25-0) holds. Fix any  $d, r, r_0, L_0 \in \mathbb{N}^+, (z^{(t)})_{t \in \mathcal{T}}$  and **Theorem C.1.** Suppose that Assumption C.S holds. The any  $a, 1, 1, 0, L_0 \in \mathbb{N}^+$ ,  $(z^{\vee})_{t \in I}$  and  $(f^{(m)})_{m \in \mathcal{M}} \subset \mathcal{F}(L_0, r_0)$ . Choose  $\omega = \log^2 d/\sqrt{r}$ . Let  $\Psi^* = \Psi^*((z^{(t)})_{t \in \mathcal{T}}, (f^{(m)})_{m \in \mathcal{M}}, d, r, \omega, L_0, r$ be the parameter of transformer layers as in Proposition [C.1.](#page-30-0) Then, for any  $m \in \mathcal{M}$ ,  $t \in \mathcal{T}$ ,  $\eta \geq (1/\sqrt{r}) \log d$ , and any  $P_{X_1,Y_1|M=m,T=t,U,\eta}$  described in Section [3.2.1,](#page-6-2) with the choice  $\tau = \eta$ ,

<span id="page-31-3"></span><span id="page-31-2"></span>
$$
D_{\text{KL}}(P_{X_1;T=t,U,\eta} \| Q_{\tilde{X}_s; \Psi^*, \tau, \mathcal{D}_n}) \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}},\qquad(39)
$$

$$
\mathbb{E}\Big[D_{\mathrm{KL}}(P_{Y_1|X_1;M=m,U,\eta}\|Q_{\tilde{Y}_s|X_1;\Psi^*,\tau,\mathcal{D}_n})|M=m,T=t,U,\eta\Big] \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}}\tag{40}
$$

hold for all  $s \in \mathbb{N}^+$  with high probability. Hence,

$$
D_{\mathrm{KL}}(P_{X_1,Y_1;T=t,M=m,U,\eta}||Q_{\tilde{X}_s,\tilde{Y}_s;\Psi^*,\tau,\mathcal{D}_n}) \lesssim \frac{1}{\sqrt{d}} + \frac{\log d}{\sqrt{n}}
$$

holds for all  $s \in \mathbb{N}^+$  with high probability.

The following corollary states that transformer can perfectly recover the input distribution with sufficiently large number of samples under stronger identifiability conditions.

<span id="page-31-1"></span>Corollary C.1. Suppose that Assumptions [C.1](#page-24-1) and [C.2](#page-24-2) hold. For the transformer layers  $TF_{\Psi^*}$  in Proposition [C.1,](#page-30-0) if

$$
n \geq 2\omega \left(\frac{\xi \tau}{\eta r} \wedge \eta \xi \mathcal{M}\right)^{-1},
$$

then, given  $H_n$  and  $h_{2n+1}, \ldots, h_{2n+\ell}$  defined in equation [38,](#page-30-1) it outputs

$$
\mathrm{TF}_{\Psi^*}([H_n; \boldsymbol{h}_{2n+1}; \ldots; \boldsymbol{h}_{2n+\ell}])_{2n+\ell} = \begin{cases} (f^{(\widehat{M})}(\boldsymbol{u}_{X_{n+s}})^\top, \boldsymbol{0}^\top)^\top & \text{ if } \ell = 2s - 1, \\ (z^{(\widehat{T})\top}, \boldsymbol{0}^\top)^\top & \text{ if } \ell = 2s \end{cases}
$$

for all  $s \in \mathbb{N}^+$  with high probability, where  $\widehat{T}$  and  $\widehat{M}$  are defined in equation [17](#page-25-5) and equation [31.](#page-27-1)

Corollary [C.1](#page-31-1) states the with sufficiently large number of in-context samples pre-trained transformers can perfectly recover the distribution of  $(X_1, Y_1)$  under identifiability conditions. Corollary [C.1](#page-31-1) follows directly from Proposition [C.1,](#page-30-0) Lemma [C.1](#page-25-1) and Lemma [C.2,](#page-27-0) and its proof is omitted.

We next provide the proofs.

*Proof of Theorem [3.2.](#page-8-1)* We only focus on the first two steps to generate  $\tilde{X}_1$  and  $\tilde{Y}_1$ . We construct a transformer with the following properties: (1) For the  $(2i - 1)$ -th tokens, it performs the argmax operation  $\hat{f} = \arg \max_{f^{(m)} : m \in \mathcal{M}} \sum_{i' \in [n]} \langle \boldsymbol{u}_{Y_{i'}}, f^{(m)}(\boldsymbol{u}_{X_{i'}}) \rangle$  approximately, and outputs  $f(\boldsymbol{u}_{X_i})$ . For the tokens with even index, it performs the argmax operation  $\hat{\mathbf{z}} = \arg \max_{\mathbf{z}(t), t \in \mathcal{T}} \sum_{i' \in [n]} \langle \mathbf{u}_{Y_{i'}}, \mathbf{z}^{(t)} \rangle$  approximately, and outputs  $\hat{\mathbf{z}}$ .

We then sample from  $u_1, \ldots, u_d$  with a softmax probability applied on the last output token. When the current task is to generate  $\tilde{X}_1$ , i.e., the length of the input is  $2n$ , the last output token is  $\hat{\mathbf{z}}$ ; otherwise it is  $\hat{f}(\mathbf{u}_{\tilde{X}_1})$ . Thus we we can sample  $\tilde{X}_1, \tilde{Y}_1$  sequentially from a distribution also to that of  $Y$ ,  $\tilde{Y}_1$ . By bounding the error that error from approximati distribution close to that of  $X_1, Y_1$ . By bounding the error that comes from approximating the argmax operation and sampling variation of seed data, we obtain the desired result. This completes the proof of Theorem [3.2.](#page-8-1)  $\Box$ 

Proof of Proposition [C.1.](#page-30-0) We choose  $B = \max_{x \in \mathcal{X}} ||u_x||$  so that  $\sup_{\mathbf{z} : ||\mathbf{z}|| = 1} |\mathbf{z}^\top u_x| \leq B$ holds for all  $x \in \mathcal{X}$ . For brevity, define  $\overline{m} = |\mathcal{M}|$ ,  $\overline{t} = |\mathcal{T}|$  and write  $\mathcal{M} = [\overline{m}], \mathcal{T} = [\overline{t}]$ . Recall that  $\bar{m} \geq \bar{t}$  by assumption. Fix  $\ell \in \{0\} \cup \mathbb{N}^+$ . To ease notation, let  $N := 2n + \ell$ ,  $D := r + r \bar m + \bar m + 4 \text{ and } H_n^{(\ell)} := [\bm h_1; \ldots; \bm h_{2n}; \bm h_{2n+1}; \ldots; \bm h_{2n+\ell}] := [H_n; \bm h_{2n+1}; \ldots; \bm h_{2n+\ell}].$ 

We show the existence of transformer layers TF<sub>Ψ<sup>\*</sup></sub> such that for any  $\ell \geq 0$ , given the input  $H_n^{(\ell)} \in \mathbb{R}^{D \times (2n+\ell)}$  at the  $\ell$ -th step, the last token is transformed to :

$$
(\mathrm{TF}_{\Psi^*}(H_n^{(\ell)}))_{2n+\ell} = \begin{cases} \begin{pmatrix} \widehat{f}(\boldsymbol{u}_{X_i}) \\ * \end{pmatrix} & \text{if } \ell \text{ is even,} \\ \begin{pmatrix} \widehat{z} \\ * \end{pmatrix} & \text{if } \ell \text{ is odd.} \end{cases}
$$

Define  $\mathbf{z}^{(m)} = 0$  for  $m \in [\bar{m}] \setminus [\bar{t}]$ . We divide the proof into 4 steps.

**Step 1.** Here we aim to construct transformer layers with parameter  $\Psi_1^*$  such that it outputs

$$
\operatorname{TF}_{\Psi_1^*}(H_n^{(\ell)})_{2i-1} = \begin{pmatrix} \boldsymbol{u}_{X_i} \\ f^{(1)}(\boldsymbol{u}_{X_i}) \\ \vdots \\ f^{(\bar{m})}(\boldsymbol{u}_{X_i}) \\ \boldsymbol{0}_{\bar{m}} \\ \boldsymbol{p}_{2i-1} \end{pmatrix}, \quad \operatorname{TF}_{\Psi_1^*}(H_n^{(\ell)})_{2i} = \begin{pmatrix} \boldsymbol{u}_{Y_i} \\ \boldsymbol{z}^{(1)} \\ \vdots \\ \boldsymbol{z}^{(\bar{m})} \\ \boldsymbol{0}_{\bar{m}} \\ \boldsymbol{p}_{2i} \end{pmatrix}.
$$

Note that by assumption, there exist weights  $\{W_{\text{pre}}^{(m)}\}$  $\{p_{\text{pre},k,1}^{(m)}, W_{\text{pre},k,2}^{(m)}\}\}_{k\in [L_0], m\in [\bar{m}]}\subset \mathbb{R}^{r_0\times r}\times \mathbb{R}^{r_0\times r}$  $\mathbb{R}^{r \times r_0}$  such that

$$
f^{(m)}(\mathbf{u})=g_{L_0}^{(m)}\circ g_{L_0-1}^{(m)}\circ \cdots \circ g_1^{(m)}(\mathbf{u}),\ \ g_k^{(m)}(\mathbf{u})=W_{\text{pre},k,2}^{(m)}\sigma(W_{\text{pre},k,1}^{(m)}\mathbf{u}).
$$

For  $k \in [L_0]$ , choose parameters  $\nu_{1,k}^* = (W_{1,k,1}^*, W_{1,k,2}^*) \in \mathbb{R}^{(\bar{m}r_0) \times D} \times \mathbb{R}^{D \times (\bar{m}r_0)}$  with

$$
W_{1,k,1}^* = \begin{bmatrix} W_{\text{pre},k,1}^{(1)} & O_{r_0 \times (D-r)} \\ \vdots & & \\ W_{\text{pre},k,1}^{(\bar{m})} & O_{r_0 \times (D-r)} \end{bmatrix}, \quad W_{1,k,2}^* = \begin{bmatrix} O_{r \times (\bar{m}r_0)} & & \\ & W_{\text{pre},k,2}^{(1)} & O_{r \times ((\bar{m}-1)r_0)} \\ & & W_{\text{pre},k,2}^{(2)} & O_{r \times ((\bar{m}-2)r_0)} \\ \vdots & & \vdots \\ O_{r \times ((\bar{m}-1)r_0)} & W_{\text{pre},k,2}^{(\bar{m})} \\ & & O_{(D-r(1+\bar{m})) \times (\bar{m}r_0)} \end{bmatrix}
$$

.

.

Let  $\psi_{1,k}^* = (\mu_{\text{id}}, \nu_{1,k}^*)$  and  $H_n^{(\ell)[0.5]} = [\mathbf{h}_1^{[0.5]}]$  $\bm{h}^{[0.5]}_1; \ldots; \bm{h}^{[0.5]}_N$  $[N^{[0.5]}] := \text{TF}_{(\psi_{1,1}^*,...,\psi_{1,L_0}^*)} (H_n^{(\ell)})$ . Notice that

$$
\boldsymbol{h}_{2i-1}^{[0.5]} = \begin{pmatrix} \boldsymbol{u}_{X_i} \\ f^{(1)}(\boldsymbol{u}_{X_i}) \\ \vdots \\ f^{(\bar{m})}(\boldsymbol{u}_{X_i}) \\ \boldsymbol{0}_{\bar{m}} \\ \boldsymbol{p}_{2i-1} \end{pmatrix}, \quad \boldsymbol{h}_{2i}^{[0.5]} = \begin{pmatrix} \boldsymbol{u}_{Y_i} \\ f^{(1)}(\boldsymbol{u}_{Y_i}) \\ \vdots \\ f^{(\bar{m})}(\boldsymbol{u}_{Y_i}) \\ \boldsymbol{0}_{\bar{m}} \\ \boldsymbol{p}_{2i} \end{pmatrix}
$$

Choose  $\psi_{1,L_0+1}^* = (\mu_{L_0+1}^*, \nu_{\text{id}})$  with  $\mu_{L_0+1}^* := \{(Q_{1,L_0+1,j}^*, K_{1,L_0+1,j}^*, V_{1,L_0+1,j}^*)\}_{j \in [4]}$  such that

$$
Q_{1,L_0+1,1}^*[h]_s^{[0,5]} = \begin{pmatrix} (p_s)_2/4 \\ -2(p_s)_1 - (p_s)_2 \\ 1 \\ 0 \\ 0_{D-4} \end{pmatrix}, \quad K_{1,L_0+1,1}^*[h]_s^{[0,5]} = \begin{pmatrix} 1 \\ 2(p_s)_1 + (p_s)_2 \\ 1/2 \\ 0_{D-4} \end{pmatrix},
$$
  
\n
$$
Q_{1,L_0+1,2}^*[h]_s^{[0,5]} = \begin{pmatrix} (p_s)_2/4 \\ -2(p_s)_1 - (p_s)_2 \\ 1 \\ 1 \end{pmatrix}, \quad K_{1,L_0+1,2}^*[h]_s^{[0,5]} = \begin{pmatrix} 1 \\ 2(p_s)_1 + (p_s)_2 \\ 1/4 \\ 0_{D-4} \end{pmatrix},
$$
  
\n
$$
Q_{1,L_0+1,3}^*[h]_s^{[0,5]} = \begin{pmatrix} (p_s)_2/4 \\ -2(p_s)_1 - (p_s)_2 \\ 1 \\ 1 \end{pmatrix}, \quad K_{1,L_0+1,3}^*[h]_s^{[0,5]} = \begin{pmatrix} 1 \\ 2(p_s)_1 + (p_s)_2 \\ 1 \\ -1/4 \\ 0_{D-4} \end{pmatrix},
$$
  
\n
$$
Q_{1,L_0+1,4}^*[h]_s^{[0,5]} = \begin{pmatrix} (p_s)_2/4 \\ -2(p_s)_1 - (p_s)_2 \\ 1 \\ 1 \\ 0_{D-4} \end{pmatrix}, \quad K_{1,L_0+1,4}^*[h]_s^{[0,5]} = \begin{pmatrix} 1 \\ 2(p_s)_1 + (p_s)_2 \\ -1/2 \\ 0_{D-4} \end{pmatrix},
$$

and

$$
V_{1,L_0+1,1}^* \mathbf{h}_s^{[0.5]} = -4 \bar{\mathbf{h}}_s^{[0.5]}, \quad V_{1,L_0+1,2}^* \mathbf{h}_s^{[0.5]} = 8 \bar{\mathbf{h}}_s^{[0.5]},
$$
  

$$
V_{1,L_0+1,3}^* \mathbf{h}_s^{[0.5]} = -8 \bar{\mathbf{h}}_s^{[0.5]}, \quad V_{1,L_0+1,4}^* \mathbf{h}_s^{[0.5]} = 4 \bar{\mathbf{h}}_s^{[0.5]},
$$

where

$$
\bar{\boldsymbol{h}}_{s}^{[0.5]} = \begin{pmatrix} \mathbf{0}_{r} \\ z^{(1)} - (\boldsymbol{h}_{s'}^{[0.5]})_{(r+1):(2r)} \\ \vdots \\ z^{(\bar{m})} - (\boldsymbol{h}_{s'}^{[0.5]})_{(r\bar{m}+1):(r\bar{m}+r)} \\ \mathbf{0}_{\bar{m}+4} \end{pmatrix} . \tag{41}
$$

Then,

$$
\begin{split} & \mathrm{TF}_{\psi_{1,L_0+1}^*}(H_n^{(\ell)[0.5]})_s \\ & = \pmb{h}_s^{[0.5]} + \sum_{s' \in [N]} \phi_1((\pmb{p}_s)_2; 2(\pmb{p}_s)_1 + (\pmb{p}_s)_2, 2(\pmb{p}_{s'})_1 + (\pmb{p}_{s'})_2) \begin{pmatrix} \pmb{0}_r \\ z^{(1)} - (\pmb{h}_{s'}^{[0.5]})_{(r+1):(2r)} \\ \vdots \\ z^{(\bar{m})} - (\pmb{h}_{s'}^{[0.5]})_{(r\bar{m}+1):(r\bar{m}+r)} \\ \pmb{0}_{\bar{m}+4} \end{pmatrix} \\ & = \pmb{h}_s^{[0.5]} + (\pmb{p}_s)_2 \begin{pmatrix} \pmb{0}_r \\ z^{(1)} - (\pmb{h}_s^{[0.5]})_{(r+1):(2r)} \\ \vdots \\ z^{(\bar{m})} - (\pmb{h}_s^{[0.5]})_{(r\bar{m}+1):(r\bar{m}+r)} \\ \pmb{0}_{\bar{m}+4} \end{pmatrix}, \end{split}
$$

where we used  $2(p_s)_1 + (p_s)_2 = 2(p_{s'})_1 + (p_{s'})_2$  if and only if  $s = s'$ . Hence  $TF_{\Psi_1^*}$  with  $\Psi_1^* = (\psi_{1,1}^*, \ldots, \psi_{1,L_0}^*, \psi_{1,L_0+1}^*)$  is the desired transformer.

 $\textbf{Step 2.} \quad \text{Let} \ H^{(\ell)[1]}_{n} = [\bm{h}_{1}^{[1]}]$  $\bm{h}_1^{[1]};\ldots;\bm{h}_N^{[1]}$  $\mathbb{E}[X] = \mathrm{TF}_{\Psi_1^*}(H_n^{(\ell)})$  be the output from  $\mathrm{TF}_{\Psi_1^*}$  constructed in Step 1. In Step 2, we aim to construct transformer layers with parameter  $\Psi_2^*$  satisfying

$$
\operatorname{TF}_{\Psi_2^*}(H_n^{(\ell)[1]})_{2i-1} = \begin{pmatrix} \bm u_{X_i} \\ f^{(1)}(\bm u_{X_i}) \\ \vdots \\ \bm u_{Y_i}^\top f^{(1)}(\bm u_{X_i}) \\ \vdots \\ \bm u_{Y_i}^\top f^{(m)}(\bm u_{X_i}) \\ \bm p_{2i-1} \end{pmatrix}, \quad \operatorname{TF}_{\Psi_2^*}(H_n^{(\ell)[1]})_{2i} = \begin{pmatrix} \bm u_{Y_i} \\ \bm z^{(1)} \\ \vdots \\ \bm u_{X_i}^\top \bm z^{(1)} \\ \vdots \\ \bm u_{X_i}^\top \bm z^{(m)} \\ \bm p_{2i} \end{pmatrix}.
$$

Let  $\phi_B$  be a function defined in equation [37.](#page-30-2) Let  $\text{Attn}_{\mu_2^*}$  be an attention layer with parameters  $\mu_2^* = \{ (Q_{2,j,j'}^*, K_{2,j,j'}^*, V_{2,j,j'}^*) \}_{j \in [\bar{m}], j' \in [4]}$  defined as

$$
Q_{2,j,1}^{*}\boldsymbol{h}_s^{[1]} = \begin{pmatrix} (\boldsymbol{h}_s^{[1]})_{1:r}/(4B) \\ -2(\boldsymbol{p}_s)_1 - (\boldsymbol{p}_s)_2 \\ 1 \\ 1/2 \\ \boldsymbol{0}_{D-3-r} \end{pmatrix}, \ \ Q_{2,j,2}^{*}\boldsymbol{h}_s^{[1]} = \begin{pmatrix} (\boldsymbol{h}_s^{[1]})_{1:r}/(4B) \\ -2(\boldsymbol{p}_s)_1 - (\boldsymbol{p}_s)_2 \\ 1 \\ 1/4 \\ \boldsymbol{0}_{D-3-r} \end{pmatrix},
$$

$$
Q_{2,j,3}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{1:r}/(4B) \\ -2(\boldsymbol{p}_{s})_{1} - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 1 \\ 0_{D-3-r} \end{pmatrix}, \quad Q_{2,j,4}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{1:r}/(4B) \\ -2(\boldsymbol{p}_{s})_{1} - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 0_{D-3-r} \end{pmatrix},
$$
\n
$$
K_{2,j,1}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{(jr+1):(1+j)r)} \\ 2(\boldsymbol{p}_{s})_{1} + 1 - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 0_{D-3-r} \end{pmatrix}, \quad K_{2,j,2}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{(jr+1):(1+j)r)} \\ 2(\boldsymbol{p}_{s})_{1} + 1 - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 0_{D-3-r} \end{pmatrix},
$$
\n
$$
K_{2,j,3}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{(jr+1):(1+j)r)} \\ 2(\boldsymbol{p}_{s})_{1} + 1 - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 0_{D-3-r} \end{pmatrix}, \quad K_{2,j,4}^{*} \boldsymbol{h}_{s}^{[1]} = \begin{pmatrix} (\boldsymbol{h}_{s}^{[1]})_{(jr+1):(1+j)r)} \\ 2(\boldsymbol{p}_{s})_{1} + 1 - (\boldsymbol{p}_{s})_{2} \\ 1 \\ 0_{D-3-r} \end{pmatrix},
$$
\n
$$
V_{2,j,1}^{*} \boldsymbol{h}_{s}^{[1]} = -4Be_{r(1+\bar{m})+j}, V_{2,j,2}^{*} \boldsymbol{h}_{s}^{[1]} = 8Be_{r(1+\bar{m})+j},
$$
\n
$$
V_{2,j,3}^{*} \boldsymbol{h}_{s}^{[1]} = -8Be_{r(1+\bar{m})+j}, V_{2,j,4}^{*} \bold
$$

Then, the s-th column of the output of  $\text{Attn}_{\mu_2^*}$  is

$$
Attn_{\mu_{2}^{*}}(H_{n}^{(\ell)[1]})_{s}
$$
\n
$$
= \mathbf{h}_{s}^{[1]} + \sum_{j \in [\bar{m}]}\sum_{j' \in [4]} \sum_{s' \in [N]} \sigma(\langle Q_{2,j,j'}^{*} \mathbf{h}_{s}^{[1]}, K_{2,j,j'}^{*} \mathbf{h}_{s'}^{[1]}) \mathcal{V}_{2,j,j'}^{*} \mathbf{h}_{s'}^{[1]}
$$
\n
$$
= \mathbf{h}_{s}^{[1]} + \sum_{j \in [\bar{m}]} \sum_{s' \in [N]} \phi_{B}((\mathbf{h}_{s}^{[1]})_{1:r}^{T}(\mathbf{h}_{s'}^{[1]})_{(jr+1):(1+j)r)}; 2(\mathbf{p}_{s})_{1} + (\mathbf{p}_{s})_{2}, 2(\mathbf{p}_{s'})_{1} + 1 - (\mathbf{p}_{s'})_{2})e_{r(1+\bar{m})+j}.
$$

Since  $2(\bm{p}_s)_1 + (\bm{p}_s)_2 = 2(\bm{p}_{s'})_1 + 1 - (\bm{p}_{s'})_2$  if and only if  $(\bm{p}_s)_1 = (\bm{p}_{s'})_1$  and  $(\bm{p}_s)_2 = 1 - (\bm{p}_{s'})_2$ ,

$$
\text{Attn}_{\mu_2^*}(H_n^{(\ell)[1]})_s = \boldsymbol{h}_s^{[1]} + \sum_{s' \in [N]} \begin{pmatrix} \mathbf{0}_{r(1+\bar{m})} \\ (\boldsymbol{h}_s^{[1]})_{1:r}^{\top} (\boldsymbol{h}_{s'}^{[1]})_{(jr+1):(1+j)r} \\ \vdots \\ (\boldsymbol{h}_s^{[1]})_{1:r}^{\top} (\boldsymbol{h}_{s'}^{[1]})_{(jr+1):(1+j)r} \\ \mathbf{0}_4 \end{pmatrix} \mathbb{I}\{(\boldsymbol{p}_s)_1 = (\boldsymbol{p}_{s'})_1, (\boldsymbol{p}_s)_2 = 1 - (\boldsymbol{p}_{s'})_2\},
$$

where we used  $|(\boldsymbol{h}^{[1]}_{s})_{1:r}^{\top}(\boldsymbol{h}^{[1]}_{s'})$  $\left| \sum_{s'}^{[1]}(j_{r+1}):(1+j)_{r}\right| \leq B$ . The desired transformer is obtained by choosing parameter  $\Psi_2^* = (\psi_2^*)$ , where  $\psi_2^* = (\mu_2^*, \nu_{\text{id}})$ . Define  $H_n^{(\ell)[2]} = [\mathbf{h}_1^{[2]}]$  $\bm{h}^{[2]}_1; \ldots; \bm{h}^{[2]}_n] =$  $\mathrm{TF}_{\Psi_2^*}(H_n^{(\ell)[1]}).$ 

**Step 3.** In this step, we aim to construct transformer layers  $TF_{\Psi_3^*}$  satisfying

$$
\operatorname{TF}_{\Psi_3^*}(H_n^{(\ell)[2]})_{2i-1} = \begin{pmatrix} (\boldsymbol{h}_{2i-1}^{[2]})_{1:(r(\bar{m}+1))} \\ \sum_{i' \in [n]} \boldsymbol{u}_{Y_{i'}}^{\top} f^{(1)}(\boldsymbol{u}_{X_{i'}}) \\ \vdots \\ \sum_{i' \in [n]} \boldsymbol{u}_{Y_{i'}}^{\top} f^{(\bar{m})}(\boldsymbol{u}_{X_{i'}}) \\ (\boldsymbol{h}_{2i-1}^{[2]})_{(D-3):D} \end{pmatrix}, \quad \operatorname{TF}_{\Psi_3^*}(H_n^{(\ell)[2]})_{2i} = \begin{pmatrix} (\boldsymbol{h}_{2i}^{[2]})_{1:(r(\bar{m}+1))} \\ \sum_{i' \in [n]} \boldsymbol{u}_{X_{i'}}^{\top} \boldsymbol{z}^{(1)} \\ \vdots \\ \sum_{i' \in [n]} \boldsymbol{u}_{X_{i'}}^{\top} \boldsymbol{z}^{(\bar{m})} \\ (\boldsymbol{h}_{2i}^{[2]})_{(D-3):D} \end{pmatrix}.
$$

Note that the summations are over all  $i' \in [n]$ . We choose the parameter  $\psi_3^* = (\mu_{id}, \nu_3^*)$ with  $\nu_3^* = (W_{3,1}^*, W_{3,2}^*)$  defined as

$$
W_{3,2}^{*}\sigma(W_{3,1}^{*}\mathbf{h}_{s}) = W_{3,2}^{*}\begin{pmatrix} \sigma((\mathbf{p}_{s})_{2}) \\ \sigma((\mathbf{p}_{s})_{3}) \\ \sigma(2(\mathbf{p}_{s})_{1} - (\mathbf{p}_{s})_{3}) \end{pmatrix}
$$
  
= 
$$
\begin{pmatrix} \mathbf{0}_{D-2} \\ -\sigma((\mathbf{p}_{s})_{3}) + \sigma((\mathbf{p}_{s})_{2}) + \sigma(2(\mathbf{p}_{s})_{1} - (\mathbf{p}_{s})_{3}) \\ 0 \end{pmatrix}.
$$

Then, it follows that

$$
\operatorname{TF}_{\psi_3^*}(H_n^{(\ell)[2]})_{2i-1} = \begin{pmatrix} (\boldsymbol{h}_{2i-1}^{[2]})_{1:(D-4)} \\ i \\ 0 \\ \sigma(2(i-n)) \\ 1 \end{pmatrix} =: \begin{pmatrix} (\boldsymbol{h}_{2i-1}^{[2]})_{1:(D-4)} \\ \tilde{p}_{2i-1} \end{pmatrix},
$$

$$
\operatorname{TF}_{\psi_3^*}(H_n^{(\ell)[2]})_{2i} = \begin{pmatrix} (\boldsymbol{h}_{2i}^{[2]})_{1:(D-4)} \\ i \\ 1 \\ 1 + \sigma(2(i-n)) \end{pmatrix} =: \begin{pmatrix} (\boldsymbol{h}_{2i}^{[2]})_{1:(D-4)} \\ \tilde{p}_{2i} \end{pmatrix}.
$$

Let  $H_n^{(\ell)[2.5]}=[\bm{h}_1^{[2.5]}]$  $\bm{h}^{[2.5]}_1, \dots, \bm{h}^{[2.5]}_N$  $\binom{[2.5]}{N} := \mathrm{TF}_{\psi_3^*}(H_n^{(\ell)[2]})$ . By a similar argument as in Part 1 and Part 2, we can choose  $\psi_4^* = (\mu_4^*, \nu_{\text{id}})$  with  $\mu_4^* = \{ (Q_{4,j}^*, K_{4,j}^*, V_{4,j}^*) \}_{j \in [8]}$  such that

$$
\begin{split} \text{TF}_{\psi_{4}^{*}}(H_{n}^{(\ell)[2.5]})_{s} &= \mathbf{h}_{s}^{[2.5]} + \sum_{s' \in [N]} \phi_{1}(1; (\tilde{\mathbf{p}}_{s})_{2}, (\tilde{\mathbf{p}}_{s'})_{3}) \left( (\mathbf{h}_{s'}^{[2.5]})_{(r(\bar{m}+1)+1):(D-4)} \right) \\ &- \sum_{s' \in [N]} \phi_{1}(1; 2(\tilde{\mathbf{p}}_{s})_{1} + (\tilde{\mathbf{p}}_{s})_{2}, 2(\tilde{\mathbf{p}}_{s'})_{1} + (\tilde{\mathbf{p}}_{s'})_{2}) \left( (\mathbf{h}_{s'}^{[2.5]})_{(r(\bar{m}+1)+1):(D-4)} \right) \\ &= \begin{pmatrix} (\mathbf{h}_{s}^{[2.5]})_{1:(r(\bar{m}+1))} \\ \mathbf{0}_{r\bar{m}} \\ (\mathbf{h}_{s}^{[2.5]})_{(D-3):D} \end{pmatrix} + \sum_{s' \in [N]} \phi_{1}(1; (\tilde{\mathbf{p}}_{s})_{2}, (\tilde{\mathbf{p}}_{s'})_{3}) \left( (\mathbf{h}_{s'}^{[2.5]})_{(r(\bar{m}+1)+1):(D-4)} \right) \\ &\quad \left( \mathbf{0}_{r\bar{m}} \right)_{0} \\ \text{Note that } (\tilde{\mathbf{p}}_{s})_{s} &= (\mathbf{p}_{s})_{s} \in \{0, 1\} \quad (\tilde{\mathbf{p}}_{s})_{s} = (\tilde{\mathbf{p}}_{s})_{s} \text{ for } s < 2n \text{ and } (\tilde{\mathbf{p}}_{s})_{s} > 2 \text{ for } s > 2n+1 \end{split}
$$

Note that  $(p_s)_2 = (p_s)_2 \in \{0, 1\}, \ (p_s)_3 = (p_s)_2$  for  $s \le 2n$ , and  $(\tilde{p}_s)_3 \ge 2$  for  $s \ge 2n + 1$ . Thus,

$$
\operatorname{TF}_{\psi_4^*}(H_n^{(\ell)[2.5]})_s = \begin{pmatrix} (\boldsymbol{h}_s^{[2.5]})_{1:(r(\bar{m}+1))} \\ \boldsymbol{0}_{r\bar{m}} \\ (\boldsymbol{h}_s^{[2.5]})_{(D-3):D} \end{pmatrix} + \sum_{s' \in [2n]} \phi_1(1;(\boldsymbol{p}_s)_2,(\boldsymbol{p}_{s'})_3) \begin{pmatrix} \boldsymbol{0}_{r(\bar{m}+1)} \\ (\boldsymbol{h}_{s'}^{[2.5]})_{(r(\bar{m}+1)+1):(D-4)} \\ \boldsymbol{0}_4 \end{pmatrix}.
$$

This gives

$$
\operatorname{TF}_{\psi_4^*}(H_n^{(\ell)[2.5]})_{2i-1} = \begin{pmatrix} (\boldsymbol{h}_{2i-1}^{[2.5]})_{1:(r(\bar{m}+1))} \\ \sum_{i' \in [n]} \boldsymbol{u}_{Y_{i'}}^{\top} f^{(1)}(\boldsymbol{u}_{X_{i'}}) \\ \vdots \\ \sum_{i' \in [n]} \boldsymbol{u}_{Y_{i'}}^{\top} f^{(\bar{m})}(\boldsymbol{u}_{X_{i'}}) \\ (\boldsymbol{h}_{2i-1}^{[2.5]})_{(D-3):D} \end{pmatrix}, \quad \operatorname{TF}_{\psi_4^*}(H_n^{(\ell)[2.5]})_{2i} = \begin{pmatrix} (\boldsymbol{h}_{2i}^{[2.5]})_{1:(r(\bar{m}+1))} \\ \sum_{i' \in [n]} \boldsymbol{u}_{X_{i'}}^{\top} z^{(1)} \\ \vdots \\ \sum_{i' \in [n]} \boldsymbol{u}_{X_{i'}}^{\top} z^{(\bar{m})} \\ (\boldsymbol{h}_{2i}^{[2.5]})_{(D-3):D} \end{pmatrix}.
$$

 $TF_{\Psi_3^*}$  with  $\Psi_3^* = (\psi_3^*, \psi_4^*)$  is the desired transformer. Let  $H_n^{(\ell)[3]} = TF_{\Psi_3^*}(H_n^{(\ell)[2]})$ .

Step 4. In this step, we aim to construct transformer layers satisfying

$$
\mathrm{TF}_{\Psi_4^*}(H_n^{(\ell)[3]})_{2i-1} = \begin{pmatrix} \widehat{f}(\boldsymbol{u}_{X_i}) \\ \boldsymbol{0}_{(r+1)\bar{m}} \\ \boldsymbol{p}_{2i-1} \end{pmatrix}, \ \ \mathrm{TF}_{\Psi_4^*}(H_n^{(\ell)[3]})_{2i} = \begin{pmatrix} \widehat{z} \\ \boldsymbol{0}_{(r+1)\bar{m}} \\ \boldsymbol{p}_{2i} \end{pmatrix}.
$$

where  $\widehat{f}$  and  $\widehat{\boldsymbol{z}}$  satisfy

$$
\widehat{f}(\boldsymbol{u}_{X_i}) \in \text{conv}\left\{f^{(m')}(\boldsymbol{u}_{X_i}) : \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{Y_i}, f^{(m')}(\boldsymbol{u}_{X_i}) \rangle \ge \max_{m'' \in [\bar{m}]} \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{Y_i}, f^{(m'')}(\boldsymbol{u}_{X_i}) \rangle - \frac{\omega}{n} \right\},\
$$

$$
\widehat{\boldsymbol{z}} \in \text{conv}\left\{\boldsymbol{z}^{(t')} : \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t')} \rangle \ge \max_{t'' \in [\bar{t}]} \frac{1}{n} \sum_{i \in [n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t'')} \rangle - \frac{\omega}{n} \right\}.
$$

To this aim, we directly apply Lemma [D.2.](#page-44-0) Let  $\Psi_4^* = \Psi^{\min}$ . The desired transformer is  $TF_{\Psi_4^*} \circ TF_{\Psi_3^*} \circ TF_{\Psi_2^*} \circ TF_{\Psi_1^*}$ . This completes the proof of Proposition [C.1.](#page-30-0)

*Proof of Theorem [C.1.](#page-31-0)* Fix any distributions  $P_{X_1;T=t,U,\eta}$  and  $P_{Y_1|X_1;M=m,U,\eta}$  introduced in Section [3.2.1.](#page-6-2) Let  $\bar{m} = |\mathcal{M}|$ ,  $\bar{t} = |\mathcal{T}|$  and write  $\mathcal{M} = [\bar{m}], \mathcal{T} = [\bar{t}]$ . Recall that  $\bar{m} \geq \bar{t}$  by assumption. We divide the proof into three parts.

**Part 1.** In this part we prove equation [39.](#page-31-2) For any  $T = t$  and U, from Proposition [C.1,](#page-30-0) there exists some  $\mathcal{T}' \subset \mathcal{T} = [\bar{t}]$  such that

$$
\widehat{\mathbf{z}} = \sum_{t' \in \mathcal{T}'} \alpha^{(t')} \mathbf{z}^{(t')},\tag{42}
$$

where  $\alpha^{(t')}\geq 0$  for any  $t'\in\mathcal{T}',\sum_{t'\in\mathcal{T}'}\alpha^{(t')}=1$ , and

$$
\frac{1}{n}\sum_{i\in[n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t')} \rangle \ge \max_{t''\in[\bar{t}]} \frac{1}{n}\sum_{i\in[n]} \langle \boldsymbol{u}_{X_i}, \boldsymbol{z}^{(t'')} \rangle - \frac{\omega}{n}
$$
(43)

holds for all  $t' \in \mathcal{T}'$ . From Lemma [C.1,](#page-25-1) there exists some constant  $C > 0$  such that

$$
\max_{t \in [\bar{t}]} \mathbb{P}\left(\max_{t' \in \mathcal{T}} \left| \boldsymbol{z}^{(t')}^\top \left( \frac{1}{n} \sum_{i \in [n]} \boldsymbol{u}_{X_i} \right) - \frac{1}{\eta r} \boldsymbol{z}^{(t')}^\top \boldsymbol{z}^{(t)} \right| \leq C\epsilon \middle| T = t, U, \eta \right) = 1 - \exp\left(-\Omega(\log^2 d)\right),
$$

where  $\epsilon := \log^2 d / \sqrt{nr} + \log d / \sqrt{dr}$ . This gives

$$
\frac{1}{\eta r} \langle \mathbf{z}^{(t)}, \mathbf{z}^{(t')} \rangle + C\epsilon \ge \max_{t'' \in [\bar{t}]} \frac{1}{\eta r} \langle \mathbf{z}^{(t)}, \mathbf{z}^{(t'')} \rangle - C\epsilon - \frac{\omega}{n}
$$

$$
= \frac{1}{\eta r} - C\epsilon - \frac{\omega}{n}
$$

with high probability for all  $t' \in \mathcal{T}'$ . Thus we have

<span id="page-37-0"></span>
$$
\min_{t' \in \mathcal{T}'} \mathbf{z}^{(t')}^\top \mathbf{z}^{(t)} \ge 1 - 2C\eta r \epsilon - \frac{\eta r \omega}{n} \tag{44}
$$

with high probability. We next bound  $D_{KL}(P_{X_1;T=t,U,\eta}||Q_{\tilde{X}_s;\Psi^*,\tau,\mathcal{D}_n})$ . We specifically choose  $\tau \leftarrow \eta$ . To this aim, we first bound the difference between log normalizing constants of two distributions:

$$
\log \sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \langle \boldsymbol{u}_{x'}, \widehat{\boldsymbol{z}} \rangle) - \log \sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \langle \boldsymbol{u}_{x'}, \boldsymbol{z}^{(t)} \rangle).
$$

From Lemma [D.1,](#page-40-0) we have

<span id="page-38-0"></span>
$$
\sup_{\mathbf{z}: \|\mathbf{z}\| \le 1} \left| \frac{d \exp\big(\|\mathbf{z}\|^2 / (2r\eta^2)\big)}{\sum_{x' \in \mathcal{X}} \exp\big(\eta^{-1} \mathbf{z}^\top \mathbf{u}_{x'}\big)} - 1 \right| \lesssim \frac{1}{\sqrt{d}} \log d \tag{45}
$$

with high probability. Hereafter we focus on the event for  $U$  where equation [45](#page-38-0) holds. Using  $||z^{(t)}||=1$ , we obtain

$$
\log \sum_{x' \in \mathcal{X}} \exp \left( \eta^{-1} \langle \boldsymbol{u}_{x'}, \widehat{\boldsymbol{z}} \rangle \right) - \log \sum_{x' \in \mathcal{X}} \exp \left( \eta^{-1} \langle \boldsymbol{u}_{x'}, \boldsymbol{z}^{(t)} \rangle \right) \tag{46}
$$

$$
= \log \frac{\exp(\|\hat{z}\|^2/(2r\eta^2))}{\exp(\|z^{(t)}\|^2/(2r\eta^2))} + O\left(\frac{\log d}{\sqrt{dr}} + \frac{\log d}{\eta r \sqrt{d}}\right)
$$
(47)

<span id="page-38-1"></span>
$$
= \frac{1}{2\eta^2 r} (\Vert \widehat{\mathbf{z}} - \mathbf{z}^{(t)} \Vert^2 + 2(\widehat{\mathbf{z}}^\top \mathbf{z}^{(t)} - 1)) + O\left(\frac{\log d}{\sqrt{dr}}\right)
$$
(48)

$$
\lesssim \frac{\|\hat{\boldsymbol{z}} - \boldsymbol{z}^{(t)}\|^2}{r\eta^2} + \frac{\log d}{\sqrt{dr}},\tag{49}
$$

where we used  $\hat{\boldsymbol{z}}^{\top} \boldsymbol{z}^{(t)} \leq 1$  and  $\eta \sqrt{r} \geq \log d$ . Therefore,

$$
D_{\text{KL}}(P_{X_1;T=t,U,\eta}||Q_{\tilde{X}_s;\Psi^*,\tau,\mathcal{D}_n})
$$
\n
$$
= \sum_{x \in \mathcal{X}} P_{X_1=x|T=t,U,\eta} \left( \log \frac{\exp(\eta^{-1} \mathbf{z}^{(t)}\mathbf{u}_x)}{\sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \mathbf{z}^{(t)}\mathbf{u}_{x'})} - \log \frac{\exp(\eta^{-1} \hat{\mathbf{z}}^\top \mathbf{u}_x)}{\sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \hat{\mathbf{z}}^\top \mathbf{u}_{x'})} \right)
$$
\n
$$
= \eta^{-1} \mathbb{E}[(\mathbf{z}^{(t)} - \hat{\mathbf{z}})^\top \mathbf{u}_{X_1}|T=t,U,\eta] + \log \sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \langle \mathbf{u}_{x'},\hat{\mathbf{z}} \rangle) - \log \sum_{x' \in \mathcal{X}} \exp(\eta^{-1} \langle \mathbf{u}_{x'},\mathbf{z}^{(t)} \rangle)
$$
\n
$$
= \frac{1}{\eta^2 r} (\mathbf{z}^{(t)} - \hat{\mathbf{z}})^\top \mathbf{z}^{(t)} + \frac{||\hat{\mathbf{z}} - \mathbf{z}^{(t)}||^2}{r\eta^2} + \frac{\log d}{\sqrt{dr}} + \frac{\log d}{\eta r \sqrt{d}}
$$
\n
$$
\lesssim \frac{1}{\eta} \left( \epsilon + \frac{\omega}{n} \right) + \frac{\log d}{\sqrt{dr}}
$$

holds with high probability, where we used Lemma [D.1,](#page-40-0) equation [44](#page-37-0) and equation [49.](#page-38-1) equation [39](#page-31-2) follows from  $\eta \ge (1/\sqrt{r}) \log d$  and  $\omega = \log^2 d/\sqrt{r}$ .

**Part 2.** In this part we prove equation [40.](#page-31-3) For any fixed  $M = m$  and U, from Proposition [C.1,](#page-30-0) there exists some  $\mathcal{M}' \subset \mathcal{M} = [\bar{m}]$  such that

<span id="page-38-2"></span>
$$
\widehat{f}(\boldsymbol{u}_x) = \sum_{m' \in \mathcal{M}'} \beta^{(m')} f^{(m')}(\boldsymbol{u}_x),\tag{50}
$$

where  $\beta^{(m')} \ge 0$  for any  $m' \in \mathcal{M}'$ ,  $\sum_{m' \in \mathcal{M}'} \beta^{(m')} = 1$ , and

$$
\frac{1}{n}\sum_{i\in[n]} \langle \boldsymbol{u}_{Y_i}, f^{(m')}(\boldsymbol{u}_x) \rangle \ge \max_{m''\in[\bar{m}]} \frac{1}{n}\sum_{i\in[n]} \langle \boldsymbol{u}_{Y_i}, f^{(m'')}(\boldsymbol{u}_x) \rangle - \frac{\omega}{n}
$$

$$
\ge \frac{1}{n}\sum_{i\in[n]} \langle \boldsymbol{u}_{Y_i}, f^{(m)}(\boldsymbol{u}_x) \rangle - \frac{\omega}{n}
$$

holds for all  $m' \in \mathcal{M}'$ . From Lemma [D.1](#page-40-0) and equation [64,](#page-43-0) Note that  $||u_x|| \lesssim (1/\sqrt{r}) \log d$ holds with high probability from Lemma [D.1.](#page-40-0) Thus  $\max_{m \in [\bar{m}], x \in \mathcal{X}} ||f^{(m)}(\boldsymbol{u}_x)|| \leq 1$  holds with high probability by assumption.

$$
\sup_{\mathbf{z},\mathbf{z}'\in\mathbb{B}_r(1)}\left|\sum_{x\in\mathcal{X}}\mathbf{z}'^\top\mathbf{u}_x\exp\left(\eta^{-1}\mathbf{z}^\top\mathbf{u}_x\right)-\frac{1}{\eta r}\mathbf{z}'^\top\mathbf{z}\exp\left(\frac{\|\mathbf{z}\|^2}{2\eta^2r}\right)\right|\lesssim\sqrt{\frac{d}{r}}\log d,\qquad(51)
$$

<span id="page-39-0"></span>
$$
\sup_{\mathbf{z}\in\mathbb{B}_r(1),x\in\mathcal{X}}\left|\mathbf{z}^\top\mathbf{u}_x\right|\lesssim\frac{\log d}{\sqrt{r}},\quad\sup_{\mathbf{z}\in\mathbb{B}_r(1)}\left|\frac{d\exp\left(\|\mathbf{z}\|^2/(2\eta^2r)\right)}{\sum_{x'\in\mathcal{X}}\exp(\eta^{-1}\mathbf{z}^\top\mathbf{u}_{x'})}-1\right|\lesssim\frac{1}{\sqrt{d}}\log d\tag{52}
$$

hold with high probability with respect to  $U$ . Hereafter we focus on the event for  $U$ , where equation [51](#page-38-2) and equation [52](#page-39-0) hold, and  $\max_{m \in [m], x \in \mathcal{X}} ||f^{(m)}(\boldsymbol{u}_x)|| \leq 1$  holds. From Lemma [C.2,](#page-27-0) we have

$$
\max_{m \in \mathcal{M}, t \in \mathcal{T}} \mathbb{P}\bigg(\max_{m' \in \mathcal{M}} \left| \frac{1}{n} \sum_{i \in [n]} \langle f^{(m')}(\boldsymbol{u}_{X_i}), \boldsymbol{u}_{Y_i} \rangle - \mathbb{E}\bigg[ \langle f^{(m')}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle | M = m, T = t, U, \eta \bigg] \right|
$$
  
> 
$$
\frac{\log^2 d}{\sqrt{nr}} \bigg| M = m, T = t, U, \eta \bigg)
$$
  
= 
$$
\exp(-\Omega(\log^2 d)).
$$

Thus, we have

$$
\mathbb{E}\Big[\langle f^{(m')}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle | M = m, T = t, U, \eta \Big]
$$
  
\n
$$
\geq \max_{m'' \in [\bar{m}]} \mathbb{E}\Big[\langle f^{(m'')}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle | M = m, T = t, U, \eta \Big] - \frac{\omega}{n} - \frac{2 \log^2 d}{\sqrt{nr}}
$$
  
\n
$$
\geq \mathbb{E}\Big[\langle f^{(m)}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle | M = m, T = t, U, \eta \Big] - \frac{\omega}{n} - \frac{2 \log^2 d}{\sqrt{nr}}
$$

and hence

$$
\mathbb{E}\Big[\langle f^{(m)}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1}\rangle \big| M = m, T = t, U, \eta\Big] - \mathbb{E}\Big[\langle \widehat{f}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1}\rangle \big| M = m, T = t, U, \eta\Big] \leq \frac{\omega}{n} + \frac{2\log^2 d}{\sqrt{nr}}
$$

with high probability for all  $m' \in \mathcal{M}'$ . By the same argument as in Part 1 combined with equation [51](#page-38-2) and equation [52,](#page-39-0)

$$
\mathbb{E}\Big[\langle f^{(m)}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1}\rangle - \langle f^{(m')}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1}\rangle | X_1 = x, T = t, M = m, U\Big]
$$
(53)

$$
-\frac{1}{\eta r}\left(\|f^{(m)}(\boldsymbol{u}_x)\|^2 - f^{(m')}(\boldsymbol{u}_x)^\top f^{(m)}(\boldsymbol{u}_x)\right) \le \frac{\log d}{\sqrt{dr}}\tag{54}
$$

holds for all  $m' \in \mathcal{M}$  with high probability. Therefore,

$$
\left|\mathbb{E}\Big[\|f^{(m)}(\boldsymbol{u}_{X_1})\|^2 - f^{(m')}(\boldsymbol{u}_{X_1})^\top f^{(m)}(\boldsymbol{u}_{X_1})\|T=t, U, \eta\Big]\right| \lesssim \eta r \left(\frac{\omega}{n} + \frac{\log^2 d}{\sqrt{nr}} + \frac{\log d}{\sqrt{dr}}\right) =: \epsilon
$$
\n(55)

holds with high probability.

 $\mathbf{r}$ 

We next bound  $\mathbb{E}[D_{\text{KL}}(P_{Y_1|X_1;M=m,U,\eta}||Q_{\tilde{Y}_s|X_1;\Psi^*,\tau,\mathcal{D}_n})|M=m,T=t,U,\eta]$  with the choice  $\tau \leftarrow \eta$ . Then,

$$
\mathbb{E}[D_{\text{KL}}(P_{Y_1|X_1;M=m,U,\eta}||Q_{\tilde{X}_s;\Psi^*,\tau,\mathcal{D}_n})|M=m,T=t,U,\eta]
$$
  
= 
$$
\sum_{x \in \mathcal{X}} p_x^{(t)} \sum_{y \in \mathcal{X}} P_{Y_1|X_1=x,M=m,U,\eta}(y) \log \frac{P_{Y_1|X_1=x,M=m,U,\eta}(y)}{Q_{\tilde{X}_s;\Psi^*,\tau,\mathcal{D}_n}(y)},
$$

where  $p_x^{(t)} := \mathbb{P}(X_1 = x | T = t, U, \eta)$ . Observe that

$$
\mathbb{E}[D_{\mathrm{KL}}(P_{Y_1|X_1;M=m,U,\eta}||Q_{\tilde{Y}_s|X_1;\Psi^*,\mathcal{D}_n})|M=m,T=t,U,\eta]
$$

$$
= \sum_{x \in \mathcal{X}} p_x^{(t)} \sum_{y \in \mathcal{X}} P_{Y_1|X_1=x,M=m,U,\eta}(y) \Big( \eta^{-1} \langle f^{(m)}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle - \eta^{-1} \langle \widehat{f}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle \Big)
$$
  
- 
$$
\sum_{x \in \mathcal{X}} p_x^{(t)} \sum_{y \in \mathcal{X}} P_{Y_1|X_1=x,M=m,U,\eta}(y) \log \frac{\sum_{y' \in \mathcal{X}} \exp(\eta^{-1} \langle f^{(m)}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle)}{\sum_{y' \in \mathcal{X}} \exp(\eta^{-1} \langle \widehat{f}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle)}
$$
  
= 
$$
\eta^{-1} \mathbb{E} [\langle f^{(m)}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle - \langle \widehat{f}(\boldsymbol{u}_{X_1}), \boldsymbol{u}_{Y_1} \rangle | M = m, T = t, U, \eta]
$$
  
- 
$$
\sum_{x \in \mathcal{X}} p_x^{(t)} \log \frac{\sum_{y' \in \mathcal{X}} \exp(\eta^{-1} \langle f^{(m)}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle)}{\sum_{y' \in \mathcal{X}} \exp(\eta^{-1} \langle \widehat{f}(\boldsymbol{u}_x), \boldsymbol{u}_y \rangle)}
$$
  

$$
\lesssim \frac{\log^2 d}{\eta \sqrt{nr}} + \frac{\omega}{\eta n} + \frac{\mathbb{E}[\|\widehat{f}(\boldsymbol{u}_x)\|^2 - \|f^{(m)}(\boldsymbol{u}_x)\|^2 | T = t, U, \eta]}{\eta^2 r}
$$

holds with high probability, where the last inequality follows from the same argument as in the proof of Lemma [C.2.](#page-27-0) Note that

$$
\mathbb{E}[\|\hat{f}(\mathbf{u}_{X_1})\|^2 - \|f^{(m)}(\mathbf{u}_{X_1})\|^2 |T = t, U, \eta] \n= \mathbb{E}[\|\hat{f}(\mathbf{u}_{X_1}) - f^{(m)}(\mathbf{u}_{X_1})\|^2 |T = t, U, \eta] + 2\mathbb{E}[\hat{f}(\mathbf{u}_{X_1})^\top f^{(m)}(\mathbf{u}_{X_1}) - \|f^{(m)}(\mathbf{u}_{X_1})\|^2 |T = t, U, \eta] \n\leq \max_{m' \in \mathcal{M}'} \mathbb{E}[\|f^{(m')}(\mathbf{u}_{X_1}) - f^{(m)}(\mathbf{u}_{X_1})\|^2 |T = t, U, \eta] \n+ 2\mathbb{E}[\hat{f}(\mathbf{u}_{X_1})^\top f^{(m)}(\mathbf{u}_{X_1}) - \|f^{(m)}(\mathbf{u}_{X_1})\|^2 |T = t, U, \eta] \n\leq \frac{\log^2 d}{\eta \sqrt{nr}} + \frac{\omega}{\eta n} + \frac{\epsilon}{\eta^2 r} \leq \frac{1}{\eta} \left(\frac{\omega}{n} + \frac{\log^2 d}{\sqrt{nr}} + \frac{\log d}{\sqrt{dr}}\right)
$$

holds with high probability, where the inequalities follow from Assumption [C.3.](#page-25-0) The second claim follows from  $\eta \ge (1/\sqrt{r}) \log d$  and  $\omega = \log^2 d/\sqrt{r}$ .

Part 3. The last claim follows since

$$
D_{\text{KL}}(P_{X_1, Y_1; T=t, M=m, U, \eta} || Q_{\tilde{X}_s; \Psi^*, \tau, \mathcal{D}_n})
$$
  
= 
$$
D_{\text{KL}}(P_{X_1; T=t, U, \eta} || Q_{\tilde{X}_s; \Psi^*, \tau, \mathcal{D}_n}) + \mathbb{E}[D_{\text{KL}}(P_{Y_1 | X_1; M=m, U, \eta} || Q_{\tilde{Y}_s | X_1; \Psi^*, \tau, \mathcal{D}_n}) | M = m, T = t, U, \eta].
$$

This completes the proof of Theorem [C.1.](#page-31-0)

# D Additional Auxiliary Results in Support of the Proofs

# D.1 Existence of good word embeddings

Here we provide a lemma for the existence of a good event for the prior of  $U = [\boldsymbol{u}_1,\dots,\boldsymbol{u}_x]^\top$ .

<span id="page-40-0"></span>**Lemma D.1.** Let  $u_x \sim N(0, (1/r)I_r)$  i.i.d. Suppose that  $\eta \ge (1/\sqrt{r}) \log d$ . If  $r = o(\log d)$ , then

$$
\max_{x \in \mathcal{X}} \|\boldsymbol{u}_x\| \lesssim \frac{\log d}{\sqrt{r}},
$$

and

$$
\sup_{\mathbf{z}\in\mathbb{B}_r(1)}\left|\sum_{x\in\mathcal{X}}\left\{\exp\left(\eta^{-1}\mathbf{z}^\top\mathbf{u}_x\right)-\exp\left(\frac{\|\mathbf{z}\|^2}{2\eta^{2}r}\right)\right\}\right|\lesssim\sqrt{d}\log d,\qquad(56)
$$

<span id="page-40-1"></span> $\Box$ 

<span id="page-41-3"></span><span id="page-41-2"></span><span id="page-41-1"></span>
$$
\sup_{\mathbf{z}\in\mathbb{B}_r(1)}\left|\frac{d\exp\big(\|\mathbf{z}\|^2/(2\eta^2r)\big)}{\sum_{x'\in\mathcal{X}}\exp(\eta^{-1}\mathbf{z}^\top\mathbf{u}_{x'})}-1\right|\lesssim\frac{1}{\sqrt{d}}\log d,\qquad(57)
$$

$$
\sup_{\mathbf{z},\mathbf{z}'\in\mathbb{B}_r(1)}\left|\sum_{x\in\mathcal{X}}\left\{\mathbf{z}'^\top\mathbf{u}_x\exp\left(\eta^{-1}\mathbf{z}^\top\mathbf{u}_x\right)-\mathbb{E}\left[\mathbf{z}'^\top\mathbf{u}_x\exp\left(\eta^{-1}\mathbf{z}^\top\mathbf{u}_x\right)\right]\right\}\right|\lesssim\sqrt{\frac{d}{r}}\log d,\quad(58)
$$

$$
\sup_{\mathbf{z},\mathbf{z}'\in\mathbb{B}_r(1)}\left|\sum_{x\in\mathcal{X}}\frac{\mathbf{z}'^{\top}\mathbf{u}_x\exp(\eta^{-1}\mathbf{z}^{\top}\mathbf{u}_x)}{\sum_{x'\in\mathcal{X}}\exp(\eta^{-1}\mathbf{z}^{\top}\mathbf{u}_{x'})}-\frac{\mathbb{E}\left[\mathbf{z}'^{\top}\mathbf{u}_x\exp(\eta^{-1}\mathbf{z}^{\top}\mathbf{u}_x)\right]}{\exp(\|\mathbf{z}\|^2/(2\eta^2r))}\right|\lesssim\frac{1}{\sqrt{dr}}\log d,\quad(59)
$$

hold with probability  $1 - \exp(-\Omega(\log^2 d)).$ 

*Proof of Lemma [D.1.](#page-40-0)* We first derive the concentration for  $(\|\mathbf{u}_x\|)_{x\in\mathcal{X}}$ . Fix any  $x \in \mathcal{X}$ . Note that  $r||u_x||^2 \sim \chi_2(r)$ . The concentration inequality for chi-squared distribution (see, for example, Lemma 1 in [Laurent and Massart](#page-15-16) [\(2000\)](#page-15-16)) gives

$$
\mathbb{P}(r||\boldsymbol{u}_x\|^2 \ge r + 2\sqrt{r\epsilon} + 2\epsilon) \le \exp(-\epsilon).
$$

Choosing  $\epsilon \leftarrow \log^2 d$  gives  $r||\boldsymbol{u}_x||^2 \leq (\sqrt{r} + 2\log d)^2$  with high probability. By a union bound argument, we have

<span id="page-41-0"></span>
$$
\max_{x \in \mathcal{X}} \|\mathbf{u}_x\| \le \frac{\sqrt{r} + 2\log d}{\sqrt{r}} \le \frac{C\log d}{\sqrt{r}}\tag{60}
$$

for some constant  $C > 0$  with probability  $1 - |\mathcal{X}| \exp(-\Omega(\log^2 d)) = 1 - \exp(-\Omega(\log^2 d)),$ where we used  $r = o(\log d)$ . Let  $\mathcal E$  be the event where equation [60](#page-41-0) holds. Let  $z_1, z_2, \ldots, z_J \in$  $\mathbb{B}_r(1)$  be the centers of a  $\delta$ -covering  $(\delta > 0)$  of a ball in  $\mathbb{R}^r$  with radius 1, that is,

$$
\mathbb{B}_r(1) \subset \bigcup_{j \in [J]} \{ \boldsymbol{z} \in \mathbb{R}^r : ||\boldsymbol{z} - \boldsymbol{z}_j|| \leq \delta \}.
$$

From a standard argument of covering number, we can take the  $\delta$ -covering  $(z_j)_{j\in[J]}$  with  $\log J = O(r \log(1 + 1/\delta))$ . We specifically choose  $\delta = 1/\sqrt{d}$ .

Part 1: Proof of equation [56](#page-40-1) and equation [57.](#page-41-1) In this part we first derive the uniform convergence of  $\sup_{\boldsymbol{z}\in\mathbb{B}_r(1)}|\tilde{C}_x(\boldsymbol{z})-\mathbb{E}[\tilde{C}_x(\boldsymbol{z})]|$ , where  $\tilde{C}_x(\boldsymbol{z}) := \exp(\eta^{-1}\boldsymbol{z}^\top\boldsymbol{u}_x)\mathbb{I}_{\mathcal{E}}$ . Since  $\eta^2 r \geq \log^2 d$ , we have

$$
\max_{x \in \mathcal{X}} \max_{j \in [J]} |\tilde{C}_x(z_j)| \le \exp\left(\frac{C \log d}{\eta \sqrt{r}}\right) \le e^C.
$$

Now fix any  $j \in [J]$ . From Hoeffding's inequality,

$$
\mathbb{P}\Bigg(\Bigg|\sum_{x\in\mathcal{X}}(\tilde{C}_x(z_j)-\mathbb{E}[\tilde{C}_x(z_j)])\Bigg|>\epsilon\Bigg)\leq 2\exp\bigg(-\frac{\epsilon^2}{2de^{2C}}\bigg).
$$

Choosing  $\epsilon \leftarrow$ √  $\overline{d} \log d$  gives  $|\sum_{x \in \mathcal{X}} (\tilde{C}_x(z_j) - \mathbb{E}[\tilde{C}_x(z_j)])| \leq \sqrt{d} \log d$  with probability  $1 - \exp(-\Omega(\log^2 d))$ . By a union bound, we have  $\max_{j \in [J]} |\sum_{x \in \mathcal{X}} (\tilde{C}_x(z_j) - \mathbb{E}[\tilde{C}_x(z_j)])| \le$  $\sqrt{d} \log d$  with probability

$$
1 - J \exp(-\Omega(\log^2 d)) = 1 - \exp(-\Omega(\log^2 d) + O(r \log d)) = 1 - \exp(-\Omega(\log^2 d)).
$$

Let  $C_x(z) := \exp(\eta^{-1} z^\top u_x)$ . For any fixed  $z \in \mathbb{B}_r(1)$ , there exists some  $j' \in [J]$  such that  $||z - z_{j'}|| \le \delta$ . Note that on the event  $\mathcal{E}, C_x(z) = \tilde{C}_x(z)$  and thus

$$
|C_x(\boldsymbol{z}) - \tilde{C}_x(\boldsymbol{z}_j)| \leq \left| \exp\left( \eta^{-1} \boldsymbol{z}^\top \boldsymbol{u}_x \right) - \exp\left( \eta^{-1} \boldsymbol{z}_j^\top \boldsymbol{u}_x \right) \right|
$$
  
\n
$$
= \exp\left( \eta^{-1} \boldsymbol{z}_j^\top \boldsymbol{u}_x \right) \left| \exp\left( \eta^{-1} (\boldsymbol{z} - \boldsymbol{z}_j)^\top \boldsymbol{u}_x \right) - 1 \right|
$$
  
\n
$$
\leq 2e\eta^{-1} |(\boldsymbol{z}_j - \boldsymbol{z})^\top \boldsymbol{u}_x|
$$
  
\n
$$
\leq \delta \frac{\log d}{\eta \sqrt{r}} \leq \frac{1}{\sqrt{d}},
$$

where we used  $\exp\left(\eta^{-1}\boldsymbol{z}_{j}^{\top}\boldsymbol{u}_{x}\right) \leq \exp\left(\eta^{-1}\max_{x \in \mathcal{X}}\|\boldsymbol{u}_{x}\|\right) \lesssim 1$  by equation [60,](#page-41-0)  $|1-e^{x}| \leq 2|x|$ for  $x \in [-1,1]$  and  $|\eta^{-1}(z-z_j)^\top u_x| \leq \eta^{-1} \delta \max_{x \in \mathcal{X}} ||u_x|| \leq 1$  for sufficiently large d in the second inequality. Furthermore, a similar argument combined with Cauchy-Schwarz inequality gives

$$
|\mathbb{E}[C_x(\boldsymbol{z})] - \mathbb{E}[\tilde{C}_x(\boldsymbol{z}_{j'})]| \leq |\mathbb{E}[C_x(\boldsymbol{z})] - \mathbb{E}[C_x(\boldsymbol{z}_{j'})]| + |\mathbb{E}[C_x(\boldsymbol{z}_{j'})] - \mathbb{E}[\tilde{C}_x(\boldsymbol{z}_{j'})]|
$$
  
\n
$$
= \left| \exp\left(\frac{\|\boldsymbol{z}\|^2}{2\eta^2 r}\right) - \exp\left(\frac{\|\boldsymbol{z}_{j'}\|^2}{2\eta^2 r}\right) \right| + \mathbb{E}\left[ \exp\left(\eta^{-1} \boldsymbol{z}_{j'}^\top \boldsymbol{u}_x\right) \mathbb{I}_{\mathcal{E}^c} \right]
$$
  
\n
$$
\leq \exp\left(\frac{\|\boldsymbol{z}\|^2}{2\eta^2 r}\right) \left| 1 - \exp\left(\frac{\|\boldsymbol{z}_{j'}\|^2 - \|\boldsymbol{z}\|^2}{2\eta^2 r}\right) \right| + \sqrt{\mathbb{E}\left[ \exp\left(2\eta^{-1} \boldsymbol{z}_{j'}^\top \boldsymbol{u}_x\right) \right] \mathbb{P}(\mathcal{E}^c)}
$$
  
\n
$$
\leq \exp\left(\frac{\|\boldsymbol{z}\|^2}{2\eta^2 r}\right) \left| 1 - \exp\left(\frac{(\|\boldsymbol{z}_{j'}\| - \|\boldsymbol{z}\|)(\|\boldsymbol{z}_{j'}\| + \|\boldsymbol{z}\|)}{2\eta^2 r}\right) \right| + \exp\left(\frac{\|\boldsymbol{z}_{j'}\|^2}{\eta^2 r}\right) \exp(-\Omega(\log^2 d))
$$
  
\n
$$
\leq \frac{2\sqrt{e}\delta}{\eta^2 r} + \exp(-\Omega(\log^2 d))
$$
  
\n
$$
\leq \frac{1}{\sqrt{d}\log^2 d} + \exp(-\Omega(\log^2 d)).
$$

Hence by a union bound argument,

$$
\sup_{\mathbf{z}\in\mathbb{B}_r(1)}\left|\sum_{x\in\mathcal{X}}(C_x(\mathbf{z})-\mathbb{E}[C_x(\mathbf{z})])\right|\lesssim d\left(\frac{1}{\sqrt{d}}+\frac{1}{\sqrt{d}\log^2 d}+\exp(-\Omega(\log^2 d))\right)+\sqrt{d}\log d\tag{61}
$$

<span id="page-42-0"></span>
$$
\lesssim \sqrt{d} \log d \tag{62}
$$

holds with high probability.

Using  $\mathbb{E}[C_x(z)] = \exp(\|z\|^2/(2\eta^2 r)) \ge 1$  and equation [62,](#page-42-0) we obtain

$$
\sup_{\boldsymbol{z}\in\mathbb{B}_r(1)}\left|\frac{1}{d\mathbb{E}[C_x(\boldsymbol{z})]}\sum_{x\in\mathcal{X}}C_x(\boldsymbol{z})-1\right|\lesssim\frac{1}{\sqrt{d}}\log d.\tag{63}
$$

Thus

$$
\sup_{\boldsymbol{z}\in\mathbb{B}_r(1)}\left|\frac{d\mathbb{E}[C_x(\boldsymbol{z})]}{\sum_{x\in\mathcal{X}}C_x(\boldsymbol{z})}-1\right|\lesssim\frac{1}{\sqrt{d}}\log d
$$

holds with high probability for sufficiently large d.

 $\textbf{Part 2: Proof of equation 58} \quad \text{We first derive a concentration inequality for } \sum_{x \in \mathcal{X}} \bm{z}_{j'}^\top \bm{u}_x \exp\! \left( \eta^{-1} \bm{z}_j^\top \bm{u}_x \right)$  $\textbf{Part 2: Proof of equation 58} \quad \text{We first derive a concentration inequality for } \sum_{x \in \mathcal{X}} \bm{z}_{j'}^\top \bm{u}_x \exp\! \left( \eta^{-1} \bm{z}_j^\top \bm{u}_x \right)$  $\textbf{Part 2: Proof of equation 58} \quad \text{We first derive a concentration inequality for } \sum_{x \in \mathcal{X}} \bm{z}_{j'}^\top \bm{u}_x \exp\! \left( \eta^{-1} \bm{z}_j^\top \bm{u}_x \right)$ uniformly over all  $j, j' \in [J]$ . Fix any  $j, j' \in [J]$ . Define  $D_x(\mathbf{z}, \mathbf{z}') := \mathbf{z}'^\top \mathbf{u}_x \exp(\eta^{-1} \mathbf{z}^\top \mathbf{u}_x)$ and  $\tilde{D}_x(z, z') := z'^{\top} u_x \exp(\eta^{-1} z^{\top} u_x) \, \llbracket \varepsilon$ . Note that since  $\eta \geq \log d/\sqrt{r}$ ,

$$
|\tilde{D}_x(\boldsymbol{z}_j,\boldsymbol{z}_{j'})|\leq \frac{1}{2\sqrt{r}}\exp\biggl(\frac{1}{2\eta\sqrt{r}}\log d\biggr)\log d\leq \frac{\sqrt{e}}{2\sqrt{r}}\log d
$$

holds for  $d \geq 4$ . Furthermore,

<span id="page-43-0"></span>
$$
\mathbb{E}[\tilde{D}_x(z_j, z_{j'})] \leq \mathbb{E}[D_x(z_j, z_{j'})] = z_{j'}^\top \mathbb{E}\Big[\mathbf{u}_x \exp\Big(\eta^{-1} z_j^\top \mathbf{u}_x\Big)\Big] \n= \eta z_{j'}^\top \mathbb{E}\Big[\frac{d}{dz} \exp\Big(\eta^{-1} z^\top \mathbf{u}_x\Big)\Big|_{z=z_j}\Big] \n= \eta z_{j'}^\top \frac{d}{dz} \mathbb{E}\Big[\exp\Big(\eta^{-1} z^\top \mathbf{u}_x\Big)\Big]\Big|_{z=z_j} \n= \eta z_{j'}^\top \frac{d}{dz} \exp\Big(\frac{\|z\|^2}{2\eta^2 r}\Big)\Big|_{z=z_j} \n= \frac{1}{\eta r} z_{j'}^\top z_j \exp\Big(\frac{\|z_j\|^2}{2\eta^2 r}\Big), \tag{64}
$$

and

$$
\mathbb{E}[\tilde{D}_x(z_j, z_{j'})^2] \leq \mathbb{E}[D_x(z_j, z_{j'})^2] = \mathbb{E}\Big[(z_{j'}^\top u_x)^2 \exp\Big(2\eta^{-1}z_j^\top u_x\Big)\Big]
$$
\n
$$
= \mathbb{E}\Big[\mathrm{tr}\Big(z_{j'}z_{j'}^\top u_x u_x^\top \exp\Big(2\eta^{-1}z_j^\top u_x\Big)\Big)\Big]
$$
\n
$$
= \frac{\eta^2}{4} \mathbb{E}\Big[\mathrm{tr}\Big(z_{j'}z_{j'}^\top \frac{d}{dz}\frac{d}{dz^\top} \exp\Big(2\eta^{-1}z^\top u_x\Big)\Big|_{z=z_j}\Big)\Big]
$$
\n
$$
= \frac{\eta^2}{4} \mathrm{tr}\Big(z_{j'}z_{j'}^\top \frac{d}{dz}\frac{d}{dz^\top} \mathbb{E}\Big[\exp\Big(2\eta^{-1}z^\top u_x\Big)\Big|\Big|_{z=z_j}\Big)
$$
\n
$$
= \frac{\eta^2}{4} \mathrm{tr}\Big(z_{j'}z_{j'}^\top \frac{d}{dz}\frac{d}{dz^\top} \exp\Big(\frac{2\|z\|^2}{\eta^2r}\Big)\Big|_{z=z_j}\Big)
$$
\n
$$
= \frac{\eta^2}{4} \mathrm{tr}\Big(z_{j'}z_{j'}^\top \Big(\frac{4}{\eta^2r}I + \frac{16}{\eta^4r^2}z_jz_j^\top\Big)\exp\Big(\frac{2\|z_j\|^2}{\eta^2r}\Big)\Big)
$$
\n
$$
= \frac{\eta^2}{4} \Big(\frac{4}{\eta^2r} + \frac{16}{\eta^4r^2}(z_jz_j)^2\Big)\exp\Big(\frac{2\|z_{j'}\|}{\eta^2r}\Big)
$$
\n
$$
\leq \frac{5e^2}{r}, \tag{65}
$$

where we used  $\eta^2 r \geq \log^2 d \geq 1$  for  $d \geq 4$ , and  $||z_j|| \leq 1$  in the last inequality. From Bernstein inequality, we obtain

<span id="page-43-1"></span>
$$
\mathbb{P}\Bigg(\Bigg|\sum_{x\in\mathcal{X}}(\tilde{D}_x(z_j,z_{j'})-\mathbb{E}[\tilde{D}_x(z_j,z_{j'}))\Bigg|\geq \epsilon\Bigg)\leq 2\exp\Bigg(-\frac{(1/2)\epsilon^2}{5de^2/r+(1/6)\sqrt{e/r}\log d\epsilon}\Bigg).
$$

Choosing  $\epsilon \leftarrow \sqrt{d/r} \log d$  gives

$$
\mathbb{P}\Bigg(\Bigg|\sum_{x\in\mathcal{X}}(\tilde{D}_x(z_j,z_{j'})-\mathbb{E}[\tilde{D}_x(z_j,z_{j'})])\Bigg|\leq \sqrt{\frac{d}{r}}\log d\Bigg)\leq \exp\bigg(-\Omega\bigg(\frac{(d/r)\log^2 d}{d/r+(\sqrt{d}/r)\log^2 d}\bigg)\bigg)
$$

$$
= \exp(-\Omega(\log^2 d)).
$$

By a union bound argument, we have  $\max_{j,j'\in[J]}|\sum_{x\in\mathcal{X}}(\tilde{D}_x(z_j,z_{j'})-\mathbb{E}[\tilde{D}_x(z_j,z_{j'})])|\leq$  $\sqrt{d/r} \log d$  with high probability. From Cauchy-Schwarz inequality, we have

$$
0 \leq \mathbb{E}[D_x(z_j, z_{j'})] - \mathbb{E}[\tilde{D}_x(z_j, z_{j'})] = \mathbb{E}\Big[z_{j'}^\top u_x \exp\Big(\eta^{-1} z_j^\top u_x\Big) \mathbb{I}_{\mathcal{E}^c}\Big] \leq \sqrt{\mathbb{E}[D_x(z_j, z_{j'})^2] \mathbb{P}(\mathcal{E}^c)} \leq \sqrt{\frac{5e^2}{r}} \exp\big(\text{Im}(\log^2 d)\big),
$$

where the last inequality follows from equation [65.](#page-43-1) Since  $\tilde{D}_x(z_j, z_{j'}) = D_x(z_j, z_{j'})$  on the event  $\mathcal{E}$ , we have

$$
\max_{j,j'\in[J]}\left|\sum_{x\in\mathcal{X}}(D_x(z_j,z_{j'})-\mathbb{E}[D_x(z_j,z_{j'})])\right|\lesssim\sqrt{\frac{d}{r}}\log d+\frac{1}{\sqrt{r}}\exp(-\Omega(\log^2 d))\lesssim\sqrt{\frac{d}{r}}\log d\tag{66}
$$

with probability  $1 - \exp(-\Omega(\log^2 d)) - \mathbb{P}(\mathcal{E}^c) = 1 - \exp(-\Omega(\log^2 d))$ . A similar argumet as in Part 1 gives equation [58.](#page-41-2)

Part 3: Proof of equation [59.](#page-41-3) Fix any  $z, z' \in \mathbb{B}_r(1)$ . equation [57](#page-41-1) and equation [58](#page-41-2) yield

$$
\left| \sum_{x \in \mathcal{X}} \frac{D_x(z, z')}{\sum_{x' \in \mathcal{X}} C_{x'}(z)} - \frac{\mathbb{E}[D_x(z, z')]}{\mathbb{E}[C_x(z)]} \right|
$$
\n
$$
\leq \frac{1}{d \mathbb{E}[C_{x'}(z)]} \left| \sum_{x \in \mathcal{X}} D_x(z, z') \left( 1 - \frac{d \mathbb{E}[C_{x'}(z)]}{\sum_{x' \in \mathcal{X}} C_{x'}(z)} \right) \right| + \frac{1}{d \mathbb{E}[C_{x'}(z)]} \left| \sum_{x \in \mathcal{X}} (D_x(z, z') - \mathbb{E}[D_x(z, z')]) \right|
$$
\n
$$
\leq \left| \frac{1}{d} \sum_{x \in \mathcal{X}} D_x(z, z') \right| \left| 1 - \frac{d \mathbb{E}[C_{x'}(z)]}{\sum_{x' \in \mathcal{X}} C_{x'}(z)} \right| + \frac{1}{d} \left| \sum_{x \in \mathcal{X}} (D_x(z, z') - \mathbb{E}[D_x(z, z')]) \right|
$$
\n
$$
\leq \left( \frac{z'^{\top} z}{\eta r} \exp\left( \frac{\|z\|^2}{2\eta^2 r} \right) + \frac{1}{\sqrt{dr}} \log d \right) \left( \frac{1}{\sqrt{d}} \log d \right) + \frac{1}{\sqrt{dr}} \log d
$$
\n
$$
\leq \frac{1}{\sqrt{dr}} \log d,
$$

where we used  $\mathbb{E}[C_{x'}(z)] \geq 1$  in the second inequality, and equation [64](#page-43-0) in the third inequality. The last inequality follows since  $||z||^2 \leq 1$ ,  $|z^{j\top}z| \leq 1$  and  $\eta^2 r \geq \log^2 d$ . Since  $z, z' \in \mathbb{B}_r(1)$ are arbitrary, this gives equation [59.](#page-41-3)

This completes the proof of Lemma [D.1.](#page-40-0)

 $\Box$ 

## D.2 Construction of selection layers

We implement the delection layer that performs argmin operation. The lemma is a direct application of Proposition M.2 of [Bai et al.](#page-13-0) [\(2023\)](#page-13-0).

<span id="page-44-0"></span>**Lemma D.2** (Minimum by Transformer). Fix  $\omega > 0$ ,  $r \in \mathbb{N}^+$  and  $\bar{m} \geq 2$ . Then, there exist transformer layers  $TF_{\Psi^{\min}}$  with  $\Psi^{\min} = \Psi^{\min}(\omega, \bar{m}, r)$  satisfying that

• it consists of 5 transformer layers with the width of FNN  $O(\bar{m}^2)$ , and the number of heads of attention layers  $O(\bar{m})$ ,

• for any  $N \in \mathbb{N}^+$  and  $H = [\mathbf{h}_1, \dots, \mathbf{h}_N] \in \mathbb{R}^{r(\bar{m}+1)+\bar{m}+4}$  of the form

$$
h_s = \begin{pmatrix} x_0 \\ x_1 \\ \vdots \\ x_{\bar{m}} \\ v_1 \\ \vdots \\ v_{\bar{m}} \\ p_s \end{pmatrix},
$$

where  $\mathbf{x}_m \in \mathbb{R}^r$  for  $m \in \{0\} \cup [\bar{m}], v_m \in [-1,1]$  for  $m \in [\bar{m}],$  and  $\mathbf{p}_s$  is defined in Section [3.2.1,](#page-6-2)  $TF_{\Psi^{\min}}$  outputs

$$
\mathrm{TF}_{\Psi^{\min}}(H)_s = (\boldsymbol{x}^\top, \boldsymbol{0}^\top)^\top,
$$

where  $\mathbf{x} \in \text{conv}\{\mathbf{x}_m : m \in [\bar{m}], v_m \leq \min_{m' \in [\bar{m}]} v_{m'} + \omega\}.$ 

*Proof of Lemma [D.2.](#page-44-0)* To ease notation we write  $D = r + r\overline{m} + \overline{m} + 4$ . We divide the proof into 4 parts.

**Part 1.** Let  $FFN_{\nu_1^{\min}}$  be a feed-forward neural network with  $\nu_1^{\min} = (W_{1,1}^{\min}, W_{1,2}^{\min})$  such that

$$
W_{1,2}^{\min} \sigma(W_{1,1}^{\min} \mathbf{h}) = W_{1,2}^{\min} \left( \begin{array}{c} \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+2}) \\ \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+3}) \\ \vdots \\ \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+m}) \\ \vdots \\ \sigma((\mathbf{h})_{r(1+\bar{m})+\bar{m}} - (\mathbf{h})_{r(1+\bar{m})+1}) \\ \vdots \\ \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+m-1}) \\ \sigma((\mathbf{h})_{(r(1+\bar{m})+1):(r(1+\bar{m})+m)}) \\ \sigma(-(\mathbf{h})_{(r(1+\bar{m})+1):(r(1+\bar{m})+m)}) \end{array} \right) = \left( \begin{array}{c} \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+1} \\ - (\mathbf{h})_{r(1+\bar{m})+1} + \sum_{m':m'\neq 1} \sigma((\mathbf{h})_{r(1+\bar{m})+1} - (\mathbf{h})_{r(1+\bar{m})+m'}) \\ \vdots \\ - (\mathbf{h})_{r(1+\bar{m})+\bar{m}} + \sum_{m':m'\neq \bar{m}} \sigma((\mathbf{h})_{r(1+\bar{m})+\bar{m}} - (\mathbf{h})_{r(1+\bar{m})+m'}) \\ \mathbf{0}_{4} \end{array} \right).
$$

Then,

$$
\text{FFN}_{\nu^{\min}_1}(\boldsymbol{h}_s) = \begin{pmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \\ \vdots \\ \boldsymbol{x}_{\bar{m}} \\ v^{(1)}_1 \\ \vdots \\ v^{(1)}_{\bar{m}} \\ \boldsymbol{p}_s \end{pmatrix},
$$

where  $v_m^{(1)} = \sum_{m':m'\neq m} \sigma(v_m - v_{m'})$ . Note that  $v_m^{(1)} \leq \omega$  implies  $v_m \leq \min_{m':m'\neq m} v_{m'} + \omega$ . Choose  $\psi_1^{\min} := (\mu_{id}, \nu_1^{\min}).$ 

**Part 2.** Define  $\text{FFN}_{\nu_2^{\text{min}}}$  as a feed-forward neural network with  $\nu_2^{\text{min}} = (W_{2,1}^{\text{min}}, W_{2,2}^{\text{min}})$  such that

$$
W_{2,2}^{\min} \sigma(W_{2,1}^{\min} \mathbf{h}) = W_{2,2}^{\min} \left( \begin{array}{c} \sigma((\mathbf{h})_{r(1+\bar{m})+1}) \\ \vdots \\ \sigma((\mathbf{h})_{r(1+\bar{m})+1}) \\ \sigma(-(h)_{r(1+\bar{m})+1}) \\ \vdots \\ \sigma(-(h)_{r(1+\bar{m})+1}) \\ \sigma((\mathbf{h})_{D}-(\mathbf{h})_{r(1+\bar{m})+1}) \end{array} \right) \\ = \left( \begin{array}{c} \sigma((\mathbf{h})_{D}-(\mathbf{h})_{r(1+\bar{m})+1}) \\ \vdots \\ \sigma((\mathbf{h})_{D}-(\mathbf{h})_{r(1+\bar{m})+1}) \\ \vdots \\ \sigma((\mathbf{h})_{D}-(\mathbf{h})_{r(1+\bar{m})+1}) \end{array} \right) \\ = \left( \begin{array}{c} \mathbf{0}_{r(1+\bar{m})} \\ -(\mathbf{h})_{r(1+\bar{m})+1}+\sigma((\mathbf{h})_{D}-(\mathbf{h})_{r(1+\bar{m})+1}) \end{array} \right),
$$

Then,

$$
\text{FFN}_{\nu^{\min}_2}(\boldsymbol{h}_s) = \begin{pmatrix} x_0 \\ x_1 \\ \vdots \\ x_{\bar{m}} \\ v_1^{(2)} \\ \vdots \\ v_{\bar{m}}^{(2)} \\ p_s \end{pmatrix},
$$

where  $v_m^{(2)} = \sigma(1 - v_m^{(1)}/\omega)$ . Let  $\psi_2^{\min} := (\mu_{\text{id}}, \nu_2^{\min})$ .

**Part 3.** Define  $\text{FFN}_{\nu_3^{\text{min}}}$  as a feed-forward neural network with  $\nu_3^{\text{min}} = (W_{3,1}^{\text{min}}, W_{3,2}^{\text{min}})$  such that

$$
W_{3,2}^{\min}\sigma(W_{3,1}^{\min}\boldsymbol{h}) = W_{3,2}^{\min}\begin{pmatrix}\sigma((\boldsymbol{h})_{r(1+\bar{m})+1})\\ \vdots\\ \sigma((\boldsymbol{h})_{r(1+\bar{m})+\bar{m}})\\ \sigma(-(h)_{r(1+\bar{m})+1})\\ \vdots\\ \sigma(-(h)_{r(1+\bar{m})+1})\\ \sigma((\boldsymbol{h})_{D})\\ \sigma((\boldsymbol{h})_{D}-(\boldsymbol{h})_{r(1+\bar{m})+1})\\ \vdots\\ \sigma((\boldsymbol{h})_{D}-(\boldsymbol{h})_{r(1+\bar{m})+1}-(\boldsymbol{h})_{r(1+\bar{m})+2})\\ \vdots\\ \sigma((\boldsymbol{h})_{D}-(\boldsymbol{h})_{r(1+\bar{m})+1}-(\boldsymbol{h})_{r(1+\bar{m})+2}-\cdots-(\boldsymbol{h})_{r(1+\bar{m})+\bar{m}})\end{pmatrix}
$$

$$
= \begin{pmatrix} \mathbf{0}_{r(1+\bar{m})} & \\ -(h)_{r(1+\bar{m})+1} + V_1^{(3)}(h) \\ -(h)_{r(1+\bar{m})+2} + V_2^{(3)}(h) \\ \vdots \\ -(h)_{r(1+\bar{m})+\bar{m}} + V_{\bar{m}}^{(3)}(h) \\ \mathbf{0}_4 \end{pmatrix},
$$

where

$$
V_m^{(3)}(\boldsymbol{h}) := \sigma((\boldsymbol{h})_D - (\boldsymbol{h})_{r(1+\bar{m})+1} - \cdots - (\boldsymbol{h})_{r(1+\bar{m})+m-1}) - \sigma((\boldsymbol{h})_D - (\boldsymbol{h})_{r(1+\bar{m})+1} - \cdots - (\boldsymbol{h})_{r(1+\bar{m})+m}).
$$

Then,

$$
\text{FFN}_{\nu^{\text{min}}_3}(\boldsymbol{h}_s) = \boldsymbol{h}_s + W^{\text{min}}_{3,2} \sigma(W^{\text{min}}_{3,1} \boldsymbol{h}_s) = \begin{pmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \\ \vdots \\ \boldsymbol{x}_{\bar{m}} \\ v_1^{(3)} \\ \vdots \\ v_{\bar{m}}^{(3)} \\ \boldsymbol{0} \\ * \end{pmatrix},
$$

where  $v_m^{(3)} = \sigma(1 - \sum_{m' \in [m-1]} v_{m'}^{(2)}) - \sigma(1 - \sum_{m' \in [m]} v_{m'}^{(2)})$ . Note that since there always exists some  $m^* \in [\bar{m}]$  with  $v_{m^*} = \min_{m \in [\bar{m}]} v_m$ ,  $v_{m^*}^{(1)} = 0$  and  $v_{m^*}^{(2)} = 1$ . This implies  $v_{\bar{m}}^{(2)} = 0$ . Thus

$$
\sum_{m \in [\bar{m}]} v_m^{(3)} = \sigma(1) - \sigma \left( 1 - \sum_{m' \in [\bar{m}]} v_{m'}^{(2)} \right) = 1 - 0 = 1.
$$

We also have  $v_m^{(3)} \geq 0$  for all  $m \in [\bar{m}]$ . Furthermore,  $v_m^{(3)} > 0$  implies  $v_m^{(1)} < \omega$  and thus  $v_m \leq \min_{m' \in [\bar{m}]} v_{m'} + \omega$ . Then,  $\sum_m v_m^{(3)} x_m$  is a convex combination of  $\{x_m : v_m \leq \omega_m\}$  $\min_{m' \in [\bar{m}]} v_{m'} + \omega$ . Let  $\psi_{\min,3} := (\mu_{\text{id}}, \nu_3^{\min}).$ 

**Part 4.** Define  $TF_{\mu_4^{\min}}$  with a parameter  $\mu_4^{\min} = \{ (Q_{4,j,j'}^{\min}, K_{4,j,j'}^{\min}, V_{4,j,j'}^{\min}) \}_{j \in [\bar{m}], j' \in [8]}$  such that

$$
Q_{4,j,1}^{\min}\boldsymbol{h} = \begin{pmatrix} (\boldsymbol{h})_{r(1+\bar{m})+j}/4 \\ -2(\boldsymbol{h})_{D-3} - (\boldsymbol{h})_{D-2} \\ (\boldsymbol{h})_{D} \\ (\boldsymbol{h})_{D}/2 \\ 0_{D-4} \end{pmatrix}, Q_{4,j,2}^{\min}\boldsymbol{h} = \begin{pmatrix} (\boldsymbol{h})_{r(1+\bar{m})+j}/4 \\ -2(\boldsymbol{h})_{D-3} - (\boldsymbol{h})_{D-2} \\ (\boldsymbol{h})_{D}/4 \\ 0_{D-4} \end{pmatrix},
$$

$$
Q_{4,j,3}^{\min}\boldsymbol{h} = \begin{pmatrix} (\boldsymbol{h})_{r(1+\bar{m})+j}/4 \\ (\boldsymbol{h})_{D}/4 \\ -2(\boldsymbol{h})_{D-3} - (\boldsymbol{h})_{D-2} \\ (\boldsymbol{h})_{D} \\ -(\boldsymbol{h})_{D}/4 \\ 0_{D-4} \end{pmatrix}, Q_{4,j,4}^{\min}\boldsymbol{h} = \begin{pmatrix} (\boldsymbol{h})_{r(1+\bar{m})+j}/4 \\ -2(\boldsymbol{h})_{D-3} - (\boldsymbol{h})_{D-2} \\ (\boldsymbol{h})_{D} \\ -(\boldsymbol{h})_{D}/2 \\ 0_{D-4} \end{pmatrix},
$$

$$
Q_{4,j,5}^{\min}h = \begin{pmatrix} (h)_{D}/4 \\ -2(h)_{D-3} - (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \end{pmatrix}, Q_{4,j,6}^{\min}h = \begin{pmatrix} (h)_{D}/4 \\ -2(h)_{D-3} - (h)_{D-2} \\ (h)_{D} \\ (h)_{D}/4 \\ 0_{D-4} \end{pmatrix},
$$
\n
$$
Q_{4,j,7}^{\min}h = \begin{pmatrix} (h)_{D}/4 \\ -2(h)_{D-3} - (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \end{pmatrix}, Q_{4,j,8}^{\min}h = \begin{pmatrix} (h)_{D}/4 \\ -2(h)_{D-3} - (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \end{pmatrix},
$$
\n
$$
R_{4,j,1}^{\min}h = \begin{pmatrix} (h)_{D} \\ 2(h)_{D-3} + (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \end{pmatrix},
$$
\n
$$
K_{4,j,3}^{\min}h = \begin{pmatrix} (h)_{D} \\ 2(h)_{D-3} + (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \end{pmatrix},
$$
\n
$$
K_{4,j,3}^{\min}h = \begin{pmatrix} (h)_{D} \\ 2(h)_{D-3} + (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \end{pmatrix},
$$
\n
$$
K_{4,j,3}^{\min}h = \begin{pmatrix} (h)_{D} \\ 2(h)_{D-3} + (h)_{D-2} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \\ (h)_{D} \end{pmatrix},
$$
\n
$$
K_{4,j,6}^{\min} = K_{4,j,1}^{\min},
$$
\n
$$
K_{4,j,6}^{\min} = K_{4,j,2}^{\min},
$$
\n
$$
K_{4,j,6}^{\min} = K_{4,j,1}^{\min},
$$
\n
$$
V_{4,j,4}^{\min}h = 4 \begin{pmatrix} (h)(j_{
$$

Let  $\tilde{H} = [\tilde{\boldsymbol{h}}_1; \ldots; \tilde{\boldsymbol{h}}_N] := \mathrm{TF}_{(\psi_1^{\min}, \psi_2^{\min}, \psi_3^{\min})}(H)$ . Then,

$$
\begin{split}\n &\text{Attn}_{\mu_{4}^{\min}}(\tilde{H})_{s} \\
 &= \tilde{\boldsymbol{h}}_{s} + \sum_{s' \in [N]} \phi_{1}((\tilde{\boldsymbol{h}}_{s})_{r(1+\bar{m})+j}; 2(\tilde{\boldsymbol{h}}_{s})_{D-3} + (\tilde{\boldsymbol{h}}_{s})_{D-2}, 2(\tilde{\boldsymbol{h}}_{s'})_{D-3} + (\tilde{\boldsymbol{h}}_{s'})_{D-2}) \begin{pmatrix} (\tilde{\boldsymbol{h}}_{s'})_{(jr+1):(j+1)r} \\ \mathbf{0}_{D-r} \end{pmatrix} \\
 &- \sum_{s' \in [N]} \phi_{1}(1; 2(\tilde{\boldsymbol{h}}_{s})_{D-3} + (\tilde{\boldsymbol{h}}_{s})_{D-2}, 2(\tilde{\boldsymbol{h}}_{s'})_{D-3} + (\tilde{\boldsymbol{h}}_{s'})_{D-2}) \begin{pmatrix} (\tilde{\boldsymbol{h}}_{s'})_{1:(r(1+\bar{m}))} \\ \mathbf{0}_{D-r} \end{pmatrix} \\
 &= \begin{pmatrix} \sum_{m \in [\bar{m}]} v_{m}^{(3)} \boldsymbol{x}_{m} \\ \mathbf{0}_{(r+1)\bar{m}} \\ \boldsymbol{p}_{s} \end{pmatrix} .\n\end{split}
$$

Define  $\psi_4^{\min} = (\mu_4^{\min}, \nu_{\text{id}})$ . We can easily implement a transformer layer  $\text{TF}_{\psi_5^{\min}}$  such that  $\mathrm{TF}_{\psi_5^{\min}}(H)_s = ((\boldsymbol{h}_s)_{1:D-4}^\top, \mathbf{0}_4^\top)^\top$ . The desired transformer is obtained by TF<sub>Ψ</sub>min with  $\Psi^{\min} = (\psi_1^{\min}, \psi_2^{\min}, \psi_3^{\min}, \psi_4^{\min}, \psi_5^{\min}).$ 

This completes the proof of Lemma [D.2.](#page-44-0)

#### <span id="page-50-1"></span>E.2 More details about the spurious correlation experiment

We evaluate spurious correlations across three datasets: Diabetes, Heart Failure, and Gender, and invetigate four groups: the minority group, the majority group, the overall group, and the worst group. Among them, the worst group identifies the subgroup of subjects with the highest errors in predictions, and the overall group includes all subjects.

For the Diabetes data,  $(y, a) = (class, skin)$ . The minority group includes patients diagnosed with diabetes who have no triceps skinfold thickness measurements, i.e.,  $\{class =$ 1, skin  $= 0$ , and those without diabetes but with positive measurements, i.e.,  $\{\text{class} =$  $(0, \text{skin} > 0)$ , reflecting negative correlations. The majority group includes patients with diabetes and measured skin thickness, i.e.,  $\{class = 1, skin > 0\}$ , and those without diabetes and no skin thickness measurements, i.e.,  ${class = 0, skin = 0}$ , reflecting positive correlations.

For the HeartFailure data,  $(y, a) =$  (deatherent, sex). The minority group includes female patients who have death events, i.e., {death event = 1, sex = 0}, and those male patients who have not experienced death events, i.e.,  $\{\text{death event} = 0, \text{sex} = 1\}$ . The majority group includes male patients with death events, i.e., {death event = 1, sex = 1}, as well as those female patients without death events, i.e., {death event =  $0$ , sex =  $0$ }.

For the Gender data,  $(y, a) = ($ gender, longhair). The minority group include female subjects without long hair, i.e.,  $\{\text{gender} = 1, \text{long hair} = 0\}$ , and male subjects with long hire, i.e.,  $\{\text{gender} = 0, \text{long hair} = 1\}$ . The majority group includes female subjects with long hair, i.e., { $\mathsf{gender} = 1, \mathsf{long}$  hair  $= 1$ }, and male subjects without long hair, i.e., {gender = 0, long hair = 1}.

We determine the spurious correlation by two main criteria: the meaning in practice, and the correlation in the whole data. For the Diabetes data, a skin value of 0 indicates missing the skinfold measurement. If the data trend reveals a strong positive correlation between skin and class, then there exists a risk of under-representation for those without skinfold measurement who have diabetes. For the Heart Failure data, an apparent correlation between sex and the death event indicator may suggest a potential gender bias in predictions. For the Gender data, while the gender does not inherently correlate with hair length, the observed data suggests that females typically have long hair and males typically have short hair, which could potentially lead to a biased classifier. Finally, we select the  $(y, a)$  pairs such that they exhibit minimal correlations in the complete dataset, and we ensure that neither positive nor negative correlations dominate.

#### <span id="page-50-0"></span>E.3 Ablation studies

We show through simulations that the generated synthetic data remains effective even without contextual information, and GPT-4 learns the distribution of the tabular data, and does not memorize the individual samples, when asked to generate the synthetic data.

We consider the following simulation model with 9 features  $X_1, \ldots, X_9$ .

$$
X_1 \sim \mathcal{N}(0, 1), \quad X_2 \sim \mathcal{N}(0, 1), \quad X_3 = 0.5X_1 + 0.3X_2 + \epsilon_3, \epsilon_3 \sim \mathcal{N}(0, 0.5),
$$

<span id="page-51-0"></span>

Figure 4: Imbalanced classification: comparison of OPAL, SMOTE, and duplication, with the simulated data, and the three classifiers, logistic regression, CatBoost, and random forest. The red line represents the mean error of the classifier trained with the raw data.

$$
X_4 = X_1 \cdot \epsilon_4, \ \epsilon_4 \sim \mathcal{N}(0, 1), \quad X_5 = 0.5X_3 + \epsilon_5, \ \epsilon_5 \sim \mathcal{N}(0, 1), \quad X_6 \sim \mathcal{N}(0, 1),
$$
  

$$
X_7 \sim \mathcal{N}(0, 1), \quad X_8 = X_2 \cdot X_3, \quad X_9 = X_1 \cdot X_2,
$$

Let  $f(X_1, X_2, X_3, X_9) = 1.5 + 0.7X_1 - 0.6X_2 + 0.8X_3 + 0.4X_9$ , and  $Z_i = f(X_1^i, X_2^i, X_3^i, X_9^i) +$  $\epsilon_i$ , with  $\epsilon_i \sim \mathcal{N}(0, 0.5)$ , we generate the response

$$
Y_i = \mathbb{I}\{Z_i > \text{median}(\{Z_j\}_{j\geq 1})\}.
$$

To show that OPAL remains effective without contextual information, we generate a total of 1000 samples, with 400 as the testing samples. Among the remaining 600 samples, we randomly select 100 samples as the raw data, in which labels '0' and '1' are treated as the minority and majority groups, respectively, with a ratio of  $1:9$  between the two groups. We then use Algorithm [1](#page-3-1) to perform LLM-based oversampling. Figure [4](#page-51-0) reports the misclassification error rate based on 5 data replications with the tree classifiers. We see that OPAL consistently outperforms the benchmark solutions, and the improvement is more evident for nonlinear classifiers.

To show that GPT-4 learns the distribution of the tabular data, rather than memorizing the individual samples, we compute the median distance to the closest records (DCR) for our data. DCR quantifies the proximity between each synthetic sample and the nearest sample in the original data. A larger DCR suggests an enhanced diversity of the synthetic data compared to the original data [Xu et al.](#page-16-7) [\(2019\)](#page-16-7). Table [3](#page-51-1) reports the DCR results for the three datasets, Diabetes, HeartFailure, and Gender. We see that OPAL achieves a comparable DCR to the DCR when using the rest of real samples not fed into GPT-4. Meanwhile, the DCR of OPAL is better or comparable to that of SMOTE.

<span id="page-51-1"></span>

<b>Dataset</b>			Real OPAL SMOTE
<b>Diabetes</b>	0.160	0.153	0.088
HeartFailure	0.361	0.304	0.242
Gender	0.049	0.056	0.070

Table 3: Median DCR across Real, OPAL, and SMOTE data.

We acknowledge the possibility that publicly available data might have been included in OpenAI's pre-training, which is a common issue for all LLM-based synthetic data generators. Our simulation here seems to suggest that GPT-4 learns the underlying data pattern rather than memorizing the data, because it has not seen this simulated data before.

## <span id="page-52-0"></span>E.4 More numerical results

This section contains additional results for the numerical experiments in Section [4.](#page-9-0)

In particular, Figure [5](#page-52-1) and Figure [6](#page-52-2) report the results for imbalanced classification with logistic regression and CatBoost, which show similar qualitative patterns as Figure [2](#page-10-0) in Section [4.2.](#page-10-1) Figure [7](#page-53-0) and Figure [8](#page-53-1) report the results for spurious correlations with logistic regression and CatBoost, which again show similar qualitative patterns as Figure [3](#page-11-0) in Section [4.3.](#page-10-2)

<span id="page-52-1"></span>

Figure 5: Imbalanced classification: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, and Gender, and the logistic regression classifier. The red line represents the mean error of the classifier trained with the raw data.

<span id="page-52-2"></span>

Figure 6: Imbalanced classification: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, and Gender, and the CatBoost classifier. The red line represents the mean error of the classifier trained with the raw data.

<span id="page-53-0"></span>

Figure 7: Spurious correlations: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, Gender, and the logistic regression classifier. The red line represents the mean error of the classifier trained with the raw data

<span id="page-53-1"></span>

Figure 8: Spurious correlations: comparison of OPAL, SMOTE, and duplication, with three datasets, Diabetes, Heart Failure, Gender, and the CatBoost classifier. The red line represents the mean error of the classifier trained with the raw data.
