Abstract

Nonlinear transports (NLTs) have garnered broad attention based on their topological origin in quantum geometry. When quantum geometry meets magnetic geometry in magnets, their crossover excites diverse phenomena particularly related to antiferromagnetic spintronics. However, very few material platforms have been predicted and experimentally verified to date, where spin-orbit coupling (SOC) plays an indispensable role in generating NLTs. Therefore, to boost antiferromagnetic spintronics affected by the dual effect of quantum geometry and magnetic geometry, a material database of antiferromagnets (AFMs) with magnetic geometry driven quantum geometry and more significant NLT effects is urgently needed. Here, we integrate the *state-of-the-art* spin space group theory into the symmetry analysis of NLT tensors. By completely disentangling SOC effects, we find that collinear and coplanar magnetic geometry can only induce NLT driven by Berry curvature dipole, and noncoplanar one may trigger NLT driven by dipoles of Berry curvature, inverse mass, and quantum metric. Remarkably, a materials database of 260 AFMs with SOC-free NLT effects is established. Several prototypical material candidates are presented by first-principle calculations, including collinear AFM VNb_3S_6 with NLT driven by Berry curvature dipole, and a room-temperature noncoplanar AFM CrSe with NLTs driven by quantum metric dipole. Our work not only provides a universal theoretical framework for studying various magnetism-driven transport effects, but also predicts broad, experimentally accessible material platforms for antiferromagnetic spintronics.

Introduction

Nonlinear effects are widespread in various fields of modern physics, spanning from second harmonic generation in optics¹ to chaos in classical and quantum dynamics². Spotlighting condensed matter systems, electrical nonlinear transport (NLT) is not only the foundation of next-generation devices such as full-wave rectification^{3,4}, but also a generic method to measure the distribution of the quantum geometry of states in momentum space⁵⁻¹². In crystals, the quantum geometry, including Berry curvature and quantum metric, characterizes the curving and distances between neighboring Bloch states and is tightly related to the topological properties of the system¹³. More intriguingly, in magnetic crystals, the crossover between the quantum geometry in momentum space with the magnetic geometry in real space excites a diversity of phenomena. Recently, it has been pointed out that the efficient detection of the Néel vector orientation makes the second-order transports desirable for antiferromagnetic spintronics¹⁴⁻¹⁸. Despite the promising applications, however, very few antiferromagnets (AFMs) have been theoretically predicted^{9,10,17-21} and experimentally proven^{11,12,22} to generate NLT so far. Therefore, there is an urgent need for a comprehensive database of AFMs with NLT toward antiferromagnetic spintronics.

One step before the AFMs database, we would wonder what driving forces may produce more significant NLT. Focusing on the second-order transport, the transport effects can be intrinsically driven by the asymmetric quantum geometry^{5,9,10,21,23-25} in crystals without spatial inversion symmetry (P). Hence, it has long been assumed that quantum geometry accompanied by band anti-crossings originates from spin-orbit coupling (SOC)²⁶⁻²⁸. However, in magnetic systems, the contributions from exchange interactions and relativistic SOC always entangle with each other. It has been pointed out that complex magnetic geometry can inherently produce anomalous Hall effect^{29,30}, spin splitting³¹⁻³⁶, and spin-resolved transports³⁷⁻⁴². Nevertheless, it is unclear for NLT whether magnetic geometry can trigger quantum geometry without the assistance of SOC, and if yes, it may generate more significant NLT due to the strong exchange interactions. Unfortunately, the conventional framework, where the NLT tensors are constrained by the magnetic space group of the magnetic geometry^{10,43,44}, provides no answer to this question. In magnetic space groups, rotational operations of spin and lattice are completely locked, thus highly entangling the magnetic geometry and SOC contributions on any effect. Therefore, separating their contributions relies on extensive computations *post factum*.

Here, we propose an efficient, symmetry-based framework to uncover the link connecting magnetic geometry and quantum geometry, and establish an NLT database in AFM without tedious calculations. We employ the *state-of-the-art* spin space group (SSG) theory⁴⁵⁻⁵¹ to disentangle the contributions of magnetic geometry and SOC toward quantum geometry and NLT. The central result is that magnetic geometry generally triggers the quantum geometry and so do the second-order transports unless the effective symmetry suppresses all the components, as listed in Table I. By our framework, we deduce that collinear and coplanar magnetic geometry can only produce effects contributed by Berry curvature dipole (BCD), as the combined symmetry of time-reversal (T) and spin rotation serving as the effective time-reversal T_{eff} (see Fig. 1a-b) to eliminate quantum metric dipole (QMD) and inversed mass dipole (IMD). In contrast, noncoplanar magnetic geometry may, in general, produce all geometry quantities for both the longitudinal and transversal second-order transport once T_{eff} and PT_{eff} symmetries are absent (see Table I).

Within our SSG framework, we *a priori* single out 260 experimentally verified AFMs (120 collinear, 71 coplanar, and 69 noncoplanar magnetic configurations) from MAGNDATA database^{52,53} with magnetic geometry triggered NLT. To demonstrate the accuracy of our framework, we present specific material candidates with density functional theory (DFT) calculations, including a collinear AFM VNb_3S_6 with T_{eff} exhibiting NLT induced by BCD, a *room-temperature* noncoplanar AFM CrSe with PT_{eff} exhibiting NLT induced by QMD, and other materials such as coplanar AFM $\text{Ca}_2\text{Cr}_2\text{O}_5$, noncoplanar AFMs CuB_2O_4 , and strain-engineered Mn_3CoGe with NLTs driven by all three types of quantum geometric dipoles. Remarkably, we find that the magnitudes of NLT triggered by magnetic geometry are comparable to or even larger than those triggered by SOC, paving a new avenue for the material discovery of nonlinear physics in magnetic-ordered solids.

Effective time-reversal symmetry in antiferromagnets

Let us first describe how the effective symmetries relevant to NLT emerged without SOC. Despite the breaking of T in magnets, magnetic geometry may emerge effective time-reversal symmetry T_{eff} to constrain the NLT, where a well-known example is the combined symmetry of time-reversal and fractional lattice translation in the so-called $T\tau$ -AFMs, *e.g.* MnBi_2Te_4 . More importantly, the magnetic geometry without SOC proceeds richer T_{eff} symmetry as the spin and lattice space are partially decoupled. Indeed, all the symmetries of the magnetic geometry form a

SSG, where each symmetry operation takes the form $\{u||r|\boldsymbol{\tau}\}$ with u and r are the spin and lattice rotation, respectively, and $\boldsymbol{\tau}$ the lattice translation. Notice that the role of T in spin space is analogous to that of inversion P in lattice space. Then the key point is that without SOC, the charge transports is blind of proper spin rotation but affected by the *improper* one. Therefore, in any collinear AFM, the improper spin rotation $u = U_{\perp}(\pi)T$ maintains the magnetic geometry and serves as the T_{eff} symmetry (Fig. 1a), provided $U_{\perp}(\pi)$ a two-fold spinful rotation about an axis perpendicular to the Néel vector. Similarly, T_{eff} also emerges in any coplanar AFM since $u = U'_{\perp}(\pi)T$ always exists (Fig. 1b), with $U'_{\perp}(\pi)$ the two-fold spinful rotation along the axis normal to all magnetic moments. On the contrary, noncoplanar AFMs do not respect spin-only rotational symmetry, while some of them contain $T\boldsymbol{\tau}$ as T_{eff} (Fig. 1c). These effective time-reversal symmetries of the magnetic geometry constrain the T -odd charge transport tensors.

Besides T symmetry, the combination of spatial inversion and time-reversal, PT , is also a crucial symmetry for NLT, as it suppresses the nonlinear Hall effect⁵, where the collinear AFM CuMnAs is a famous instance^{9,18} (Fig. 1d). For coplanar and noncoplanar AFMs, however, the exact PT symmetry is generally missing owing to the complex magnetic geometry. Nevertheless, the absence of SOC allows the magnetic geometry to carry out the combined symmetry of improper spin rotation and spatial inversion as the effective PT_{eff} . For example, a coplanar AFM shown in Fig. 1e is invariant under spatial inversion P followed by spin rotation $U_y(\pi)T$ with $U_y(\pi)$ the two-fold spin rotation along the y axis, and so does the noncoplanar AFM with $U_z(\pi)TP$, as presented in Fig. 1f. These PT_{eff} symmetries emerged from magnetic geometry constrain the PT -odd charge transport tensors.

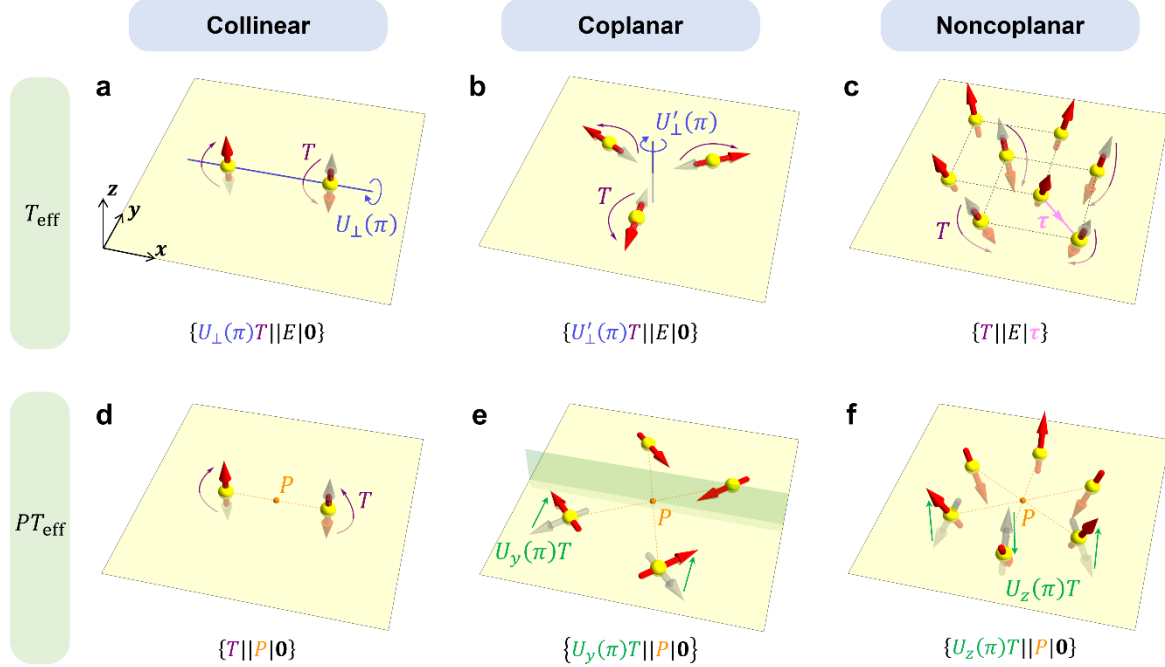

Fig. 1 | Effective time-reversal symmetry. **a-c**, Effective time-reversal symmetries always emerge in collinear **(a)** and coplanar AFMs **(b)**, with $U_{\perp}(\pi)T$ and $U'_{\perp}(\pi)T$, respectively, and may emerge in certain noncoplanar AFMs **(c)** with $T\tau$. **d-f**, Combined symmetry of spatial inversion and time-reversal PT is available in certain collinear AFMs **(d)**, while effective combined symmetry can emerge in coplanar **(e)** and noncoplanar AFMs **(f)** with $U_{\mathbf{n}}(\pi)TP$. T : time-reversal; P : spatial inversion; $U_{\perp}(\pi)$: two-fold spin rotation along an axis normal to the Néel vector; $U'_{\perp}(\pi)$: two-fold spin rotation along the axis normal to all in-plane magnetic moments; $U_{\mathbf{n}}(\pi)$: two-fold spin rotation along \mathbf{n} axis; τ : fractional lattice translation. Red arrows and yellow balls denote magnetic moments and atoms, respectively, and shadowed arrows represent the intermediate state of magnetic moments operated by part of the combined symmetry, *i.e.* T in **a-c** and P in **d-f**.

Second-order transport tensor and their symmetry constrain

With the crucial effective symmetries of magnetic geometry, we next consider the NLTs, especially the second-order transports, originated from distinct geometric quantities. In general, the current density \mathbf{J} driven quadratically by electric field \mathbf{E} is given by $J^{\alpha} = \sigma^{\alpha\beta\gamma} E^{\beta} E^{\gamma}$ (Fig. 2a), where $\sigma^{\alpha\beta\gamma}$ is the second-order conductivity tensor of rank-three with spatial indices $\alpha, \beta, \gamma = x, y, z$, and the summation over repeated indices is implied. Finite second-order conductivity demands necessarily the breaking of P , resulting in dipole terms to generate NLT. Using the

quantum kinetic theory^{24,54} in weak scattering regime (ignoring disorder effects^{55,56}), we deduce that three dipole terms contribute to the conductivity tensor with different polynomial dependences on relaxation time²⁰ (τ_r): IMD contribution $\sigma_{\text{IMD}} \propto \tau_r^2$; BCD contribution $\sigma_{\text{BCD}} \propto \tau_r^1$; QMD contribution $\sigma_{\text{QMD}} \propto \tau_r^0$ (see Methods and Supplementary Information). All these dipole terms have geometric significances. Specifically, the inverse mass tensor¹⁸ $w_l^{\alpha\beta} = \hbar^{-2} \partial_\alpha \partial_\beta \varepsilon_l$, known as a Hessian tensor with $\partial_\alpha \equiv \partial / \partial k_\alpha$, describes the local curvature of the l -th energy band manifold ε_l . In the meanwhile, quantum metric $G_l^{\alpha\beta}$ and Berry curvature $\Omega_l^{\alpha\beta}$, forming the quantum geometry tensor¹³ $Q_l^\alpha = G_l^{\alpha\beta} - i\Omega_l^{\alpha\beta} / 2 = \sum_{n(\neq l)} A_{ln}^\alpha A_{nl}^\beta$, depict the geometric properties of the l -th Bloch state $|u_l\rangle$, where $A_{ln}^\alpha = i\langle u_l | \partial_\alpha u_n \rangle$ is the interband Berry connection. In second-order conductivity, the quantum metric is normalized to $\mathcal{G}_l^{\alpha\beta} = \text{Re} \left[\sum_{n(\neq l)} A_{ln}^\alpha A_{nl}^\beta / (\varepsilon_l - \varepsilon_n) \right]$, also known as the Berry connection polarizability^{10,23}. All three dipole terms can be considered as the electrons on the Fermi surface carrying special charges of $w_l^{\alpha\beta}$, $\Omega_l^{\alpha\beta}$, and $\mathcal{G}_l^{\alpha\beta}$, and transporting with group velocity v_l^γ , as shown in Fig. 2b-d.

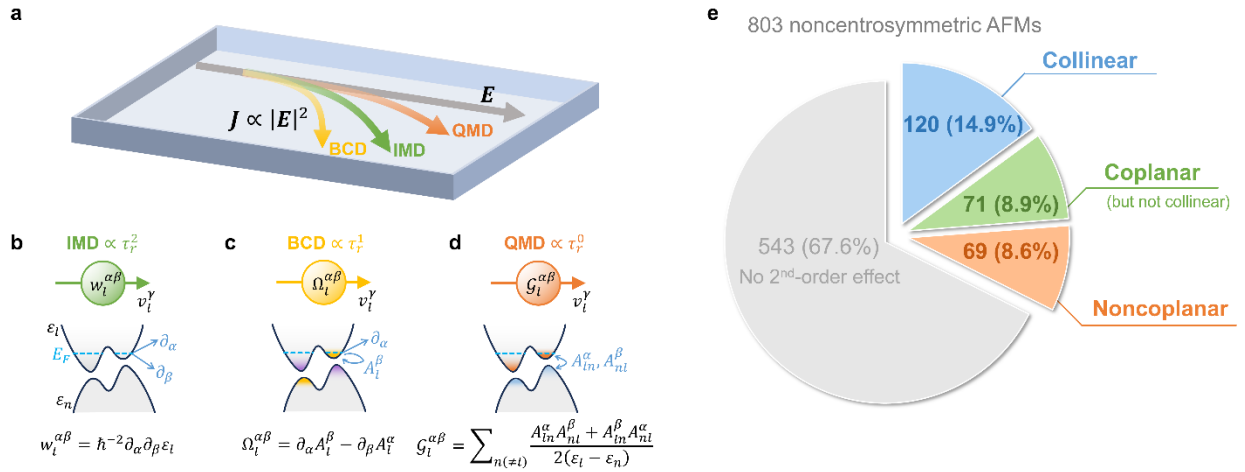

Fig. 2 | Second-order transports and statistics of AFM material database. **a**, Schematic of nonlinear charge current $\mathbf{J} \propto |\mathbf{E}|^2$ driven by the electric field \mathbf{E} , where the current is contributed by three geometric quantities as IMD, BCD, and QMD. **b-d**, Physical mechanisms and formulae for IMD (**b**), BCD (**c**), and QMD (**d**), and their polynomial dependence on relaxation time τ_r . **e**, Among 803 noncentrosymmetric AFMs, 543 AFMs have no second-order transport effects.

Among the remaining 260 materials, 120 and 71 AFMs with collinear and coplanar antiferromagnetic geometry, respectively, are found to have BCD-contributed second-order transport effect, while 69 AFMs with noncoplanar antiferromagnetic geometry are found to allow second-order transport effect contributed by at least one geometry quantity. IMD: inverse mass dipole, BCD: Berry curvature dipole, QMD: quantum metric dipole.

We now employ symmetry analysis to restrict NLT tensors. First for general symmetries P and T , all the dipole terms are P -odd and so does the second-order conductivity, while the conductivity tensors contributed by IMD and QMD are T -odd and that by BCD is T -even. Combining them yields that IMD and QMD contributions are PT -even and BCD contributions is PT -odd. These relations are also valid for effective symmetries of T_{eff} and PT_{eff} emerged in AFM, and the general symmetry constrain on NLT conductivities are collected in Table I. As one can see, IMD and QMD share the same symmetry constrain. Two consequences are concluded: (i) in noncentrosymmetric AFM with collinear and coplanar magnetic geometry, only the BCD-contributed transversal (Hall type) current is allowed if no PT_{eff} emerges. (ii) only noncentrosymmetric AFM of noncoplanar magnetic geometry allow longitudinal and transversal current contributed by IMD and QMD if no T_{eff} emerges, and the BCD contribution is additionally allowed if no PT_{eff} exists. Note here that the allowance by T_{eff} or PT_{eff} does not necessarily imply the existence of NLT, as other spin group symmetry constraints still need to be considered. Given any spin group symmetry $\{u||r|\boldsymbol{\tau}\}$, the BCD and IMD/QMD tensors are transformed by

$$\sigma_{\text{BCD}}^{\alpha\beta\gamma} = \mathcal{R}^{\alpha\mu}\mathcal{R}^{\beta\nu}\mathcal{R}^{\gamma\eta}\sigma_{\text{BCD}}^{\mu\nu\eta}, \quad (1)$$

$$\sigma_{\text{IMD/QMD}}^{\alpha\beta\gamma} = \det(\mathcal{U})\mathcal{R}^{\alpha\mu}\mathcal{R}^{\beta\nu}\mathcal{R}^{\gamma\eta}\sigma_{\text{IMD/QMD}}^{\mu\nu\eta}, \quad (2)$$

where \mathcal{R} and \mathcal{U} are the representation matrices of r and u under Cartesian coordinate. Considering the BCD contributed tensors as vector $\{\sigma_{\text{BCD}}^{xxx}, \dots, \sigma_{\text{BCD}}^{zzz}\}$, Eq. (1) provides the linear transformation of it and the eigenvectors of the transformation solves the $\{u||r|\boldsymbol{\tau}\}$ -allowed BCD contributed tensors (see Supplementary Information), where the procedure for allowed tensors contributed by IMD/QMD is same. Hence, provided the SSG of an AFM, the symmetry-allowed conductivity tensors of any magnetic geometry can be predicted by Eqs. (1) and (2). Notice that

BCD contribution bears one extra constrain of $\sigma_{\text{BCD}}^{xyz} + \sigma_{\text{BCD}}^{yzz} + \sigma_{\text{BCD}}^{zxy} = 0$, due to the solenoidal nature of Berry curvature (see Methods).

Table I. | Magnetic geometry induced second-order conductivities by symmetry analysis. All the AFMs are supposed to be noncentrosymmetric. In the column of T_{eff} and PT_{eff} , ✓ and ✗ represent the presence and absence of the specific effective symmetry, respectively. In the column of “IMD & QMD” and “BCD”, ✓ and ✗ denote the corresponding nonlinear transport to be allowed and disallowed by T_{eff} and/or PT_{eff} , respectively.

Diagnosis of realistic materials

To materialize the magnetic-geometry-induced NLT, we construct a complete database of validated AFMs with second-order conductivity tensors allowed by SSG symmetry. Starting from ~1700 experimentally validated AFMs in MAGNDATA database^{52,53} on the Bilbao Crystallographic Server (BCS; <http://www.cryst.ehu.es>), we selected 803 noncentrosymmetric AFMs as material pool. Subsequently, the SSG of each AFM was recognized by our online program FINDSPINGROUP⁴⁸ (<https://findspingroup.com>). With the SSG for any AFM at hand, we predicted which NLT contributions are possible by checking T_{eff} and PT_{eff} according to Table I, and further solved which tensor components are allowed under the constrain by SSG using Eqs. (1) and (2). Finally, a database of 260 AFMs with geometric NLT tensors induced by magnetic geometry is established, where 120 collinear and 71 coplanar AFMs allow BCD-contributed NLT.

We also found 69 noncoplanar AFMs with SSG-allowed NLT, 21 among which feature all NLT contributed by both IMD, BCD, and QMD. Our comprehensive database includes large fraction about 32.4% of the 803 noncentrosymmetric AFMs, revising the previous consensus that nontrivial transports are generally triggered by SOC. A snapshot of the AFM database is presented in Fig. 2e, and the full list is provided in Supplementary Information Table S1-S3 as well as the online database (<https://findspingroup.com/>).

Material examples

Below we choose two candidates from our database and performed DFT level calculations on the second-order transport tensors (Methods). The first example is the transition metal VNb_3S_6 crystallized by 1H-NbS₂ layers with V inserted at interlayer positions as shown in Fig. 3a, where the magnetic moments in the same (adjacent) V layer are parallel (anti-parallel) with the Néel vector orientated along a axis⁵⁷. The SSG is recognized as $P^{-1}6_3^{-1}2^{12}\infty m1$, which is generated by spatial rotations $\{T||R_{[100]}(\pi)|(1/2)\boldsymbol{\tau}_c\}$, $\{E||R_{[120]}(\pi)|\mathbf{0}\}$, skew rotations $\{T||R_z(\pi/3)|(1/2)\boldsymbol{\tau}_c\}$ with $\boldsymbol{\tau}_c = (0,0,1)$ the lattice translation, and the spin-only subgroup $\infty m1$ of infinite spin rotation along the Néel vector. The band structure without SOC, as shown in Fig. 3b, exhibits the SOC-free spin splitting due to the breaking of T . By the newly definition of altermagnetism, collinear AFM VNb_3S_6 is a so-called g -wave altermagnet⁵⁸. By Table I, we predict that the T_{eff} symmetry of $U_z(\pi)T$ naturally forbid the IMD/QMD contributions, while the absence of PT_{eff} symmetry implies the BCD-contributed conductivity tensor to be allowed. From our database (Supplementary Information Table S1), the allowed BCD-contributed tensor components of VNb_3S_6 , constrained by SSG with Eq. (1), are $\sigma_{\text{BCD}}^{xyz} = -\sigma_{\text{BCD}}^{yzx}$. To verify this, the BCD-contributed tensor components are computed without SOC in Fig. 3c, showcasing that the quantum-geometry-driven NLT effect can be inherently induced by magnetic geometry. Moreover, the maximum value of $\sigma_{\text{BCD}}^{xyz}$ approaching $75 \text{ S}^2/\text{A}$ (with relaxation time set $\tau_r = 1 \text{ ns}$) at $\sim 0.25 \text{ eV}$ above the Fermi energy, which is comparable to the nonlinear Hall conductivity of CuMnSb ¹⁷. Such a large conductivity originates from the BCD hot spot (Fig. 3d) at the corresponding energy. Note that considering SOC barely changes the BCD contribution around the Fermi energy but decreases the peak by $\sim 50\%$ (Supplementary Information Fig. S2),

indicating the opposite contributions from magnetic geometry and SOC in this system. Our results show that magnetic geometry is the dominate driving force of NLT in VNb_3S_6 even with SOC counted.

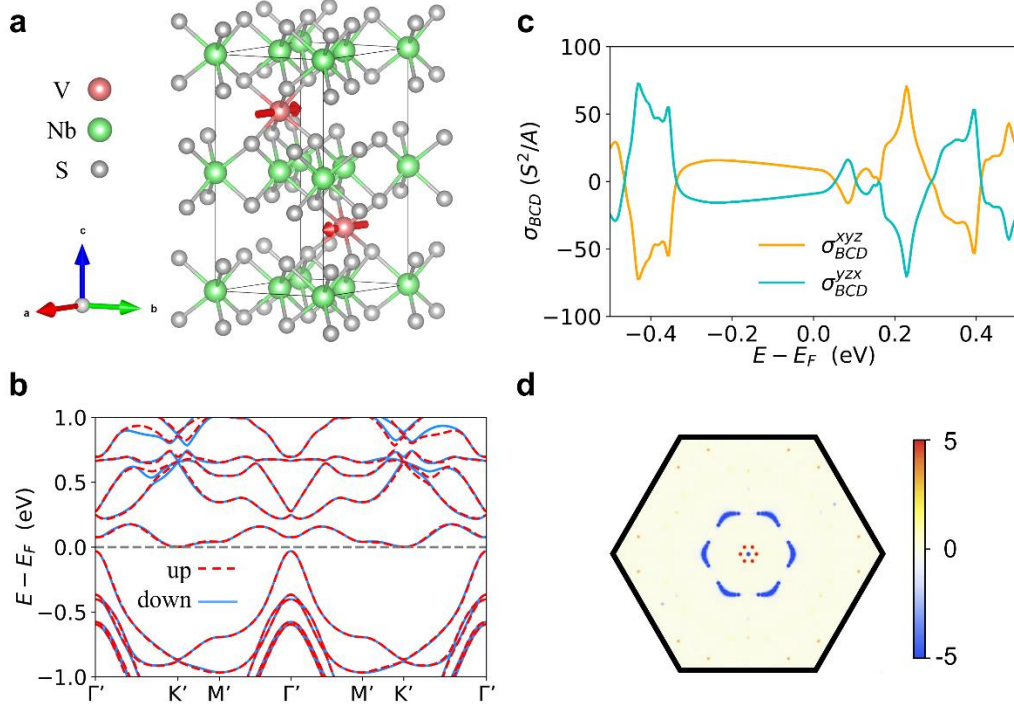

Fig. 3 | Collinear AFM VNb_3S_6 . **a**, Crystal structure and collinear magnetic geometry of VNb_3S_6 . **b**, DFT-calculated band structures with the projection onto opposite spin components. Spin-orbit coupling is turned off. **c**, Nonlinear conductivity tensor contributed by BCD with relaxation time set $\tau_r = 1$ ns. **d**, Distribution of the BCD $\partial^z \Omega^{xy}(k_x, k_y)$ in the slice of Brillouin zone $k_z = 0$ at ~ 0.25 eV above the Fermi energy.

Our next example is CrSe of room temperature (Néel temperature 290 K) noncoplanar antiferromagnetic geometry^{59,60}, as shown in Fig. 4a. Separated by Se layers, Cr atoms form layers of trigonal sublattice in ab plane, where the in-plane magnetic components inside each Cr layer are related by spin rotation $U_z\left(\frac{2\pi}{3}\right)$ with alternating out-of-plane (along c) magnetic components between neighboring layers. The SSG of CrSe is $P^{2_010}6_3/-1m^{m_010}m^{-1}c|(3_{001}^2, 3_{001}^2, 1)$, which is generated by $\{U_{[010]}(\pi)||R_z(\pi/3)|(1/2)\tau_c\}$, $\{U_{[010]}(\pi)T||P|\mathbf{0}\}$, $\{E||R_{[210]}(\pi)|\mathbf{0}\}$, and spin

screw rotation $\left\{U_z\left(\frac{2\pi}{3}\right)\parallel E\right\}(1/3)\boldsymbol{\tau}_a + (2/3)\boldsymbol{\tau}_b}$ and $\left\{U_z\left(-\frac{2\pi}{3}\right)\parallel E\right\}(2/3)\boldsymbol{\tau}_a + (1/3)\boldsymbol{\tau}_b}$ with $\boldsymbol{\tau}_a = (1,0,0)$ and $\boldsymbol{\tau}_b = (0,1,0)$. We find that CrSe contains $\left\{U_{[010]}(\pi)T\parallel P\right\}\mathbf{0}$ as PT_{eff} protecting the four-fold and six-fold band degeneracy at Γ and K , respectively⁴⁸ (Fig. 4b). Besides band degeneracy, PT_{eff} further eliminates the BCD contribution of NLT as seen from Table I. By referring to the database (Supplementary Information Table S3), we predict the SSG-allowed conductivity tensor components, contributed by QMD, are $\sigma_{\text{QMD}}^{xyz} = -\sigma_{\text{QMD}}^{yxz}$. Once again, our DFT calculations on QMD-contributed tensor components in Fig. 4c are consistent with the spin group analysis, where the maximum is $23.4 \text{ S}^2/\text{A}$ at $\sim 0.19 \text{ eV}$ above Fermi energy, corresponding to the significant QMD (Fig. 4d). Such QMD contribution triggered by magnetic geometry is much larger than that of $\sim 0.01 \text{ S}^2/\text{A}$ in MnBi_2Te_4 thin film^{12,21}, which is purely triggered by SOC. We note that SOC induces opposite contributions on $\sigma_{\text{IMD}}^{xyz}$, resulting in a net value of $\sim 0.2 \text{ S}^2/\text{A}$ (Supplementary Information Fig. S4).

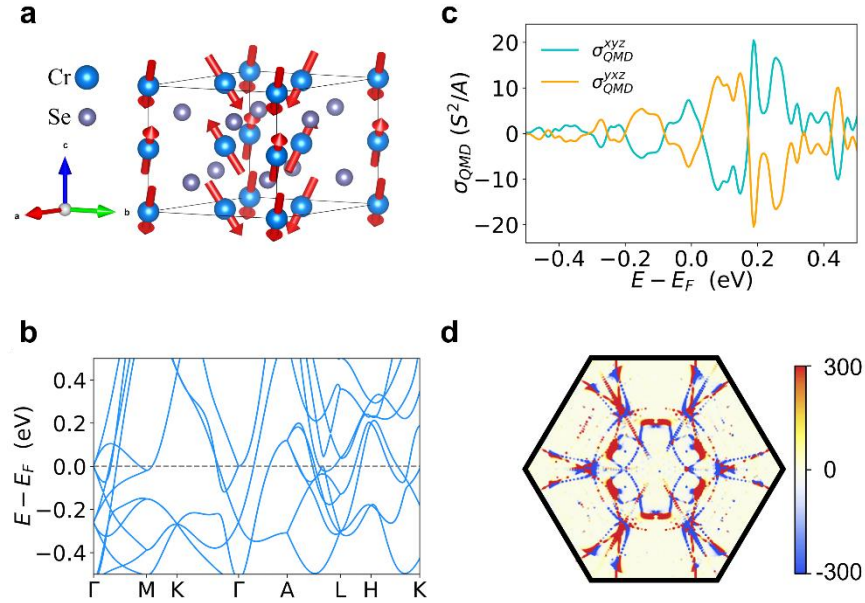

Fig. 4 | Noncoplanar AFM CrSe. **a**, Crystal structure and noncoplanar magnetic geometry of CrSe. **b**, DFT-calculated band structures without spin-orbit coupling. **c**, Nonlinear conductivity tensor contributed by QMD. **d**, Distribution of the QMD $\partial^x \mathcal{G}^{yz}(k_x, k_y)$ in $k_z = 0$ plane at $\sim 0.19 \text{ eV}$ above Fermi energy.

Besides VNb_3S_6 and CrSe , we also perform DFT calculations on $\text{Ca}_2\text{Co}_2\text{O}_5$ ⁶¹, CuB_2O_4 ⁶², and Mn_3CoGe ⁶³, and the results are summarized as follows: the coplanar magnetic geometry of $\text{Ca}_2\text{Co}_2\text{O}_5$ forbids the T -odd effects, leaving two independent BCD components to be finite; CuB_2O_4 with noncoplanar magnetic geometry allows both T -odd and T -even conductivity components due to the absence of T_{eff} and PT_{eff} ; Mn_3CoGe with noncoplanar magnetic geometry should allow two independent T -odd and T -even conductivity components, *i.e.*, $\sigma^{xyz} = \sigma^{yzx} = \sigma^{zxy}$ and $\sigma^{yxz} = \sigma^{zyx} = \sigma^{xzy}$. However, the extra constrain on BCD components $\sigma_{\text{BCD}}^{xyz} + \sigma_{\text{BCD}}^{yzx} + \sigma_{\text{BCD}}^{zxy} = 0$ eliminates all the BCD contributions, where a uniaxial strain ϵ_z breaks the three-fold rotation along $[111]$ direction and also the identity $\sigma^{xyz} = \sigma^{yzx} = \sigma^{zxy}$. Hence, uniaxial strain can induce BCD-contributed NLT in Mn_3CoGe . All these results are consistent with our *a priori* predictions in Table S1-S3 and the details are provided in Supplementary Information.

Discussion

We propose an efficient framework to search for AFMs with magnetic geometry driven quantum geometry and second-order charge transport. Our diagnosis of magnetic geometry triggered second-order transport is based on the complete symmetry analysis of SSG rather than the conventional magnetic space group. Within magnetic space group, the symmetry-allowed NLT tensors could be triggered by both of magnetic geometry and relativistic SOC. One can only disentangle their contributions *post factum* by performing time-consuming first-principles calculations on NLT tensors with and without SOC. Nevertheless, with the help of SSG, we *a priori* predict which NLT tensors are triggered by magnetic geometry for any AFM. After that, the SOC contributions can be immediately extracted by comparing the allowed NLT tensors constrained by the SSG and magnetic space group. For instance, we can directly point out that the experimentally observed NLT of MnBi_2Te_4 induced by QMD is a pure SOC effect^{12,21}. Furthermore, our framework is universal for other magnetic-geometry-induced nonlinear effects like photovoltaic effects⁶⁴ and current-induced spin polarization^{65,66}. It can also be easily extended for the third order transport effects⁶⁷⁻⁷¹, which could be the leading order of electrical transport effects in certain centrosymmetric magnets.

Methods

Nonlinear charge transport

In general, the current density \mathbf{J} driven quadratically by electric field \mathbf{E} is given by $J^\alpha = \sigma^{\alpha\beta\gamma} E^\beta E^\gamma$. Here $\sigma^{\alpha\beta\gamma}$ is the second-order conductivity tensor. The conductivity tensor can be derived within the quantum kinetic theory^{24,54}. Here we concentrate on the weak scattering limit, *i.e.*, ignoring disorder contributions^{55,56}. Under the relaxation time approximation, the dynamic of the density matrix is encoded by quantum Liouville-von Neumann equation:

$$\frac{i}{\hbar} [H_0, \rho^{(N)}]_{ln} + \frac{\rho_{ln}^{(N)}}{\tau_r/N} = -i \frac{e\mathbf{E}}{\hbar} \cdot [\mathbf{r}, \rho^{(N-1)}]_{ln}, \quad (3)$$

where H_0 is the field-free Hamiltonian, $\rho^{(N)} \propto E^N$ is the field-perturbed density matrix, τ_r is the relaxation time, \mathbf{r} is the position operator, l, n are the band indices. After tedious derivation, we obtain three distinct conductivity tensors contributed by IMD, BCD, and QMD, respectively, reads

$$\sigma_{\text{IMD}}^{\alpha\beta\gamma}(\tau_r^2) = \tau_r^2 \frac{e^3}{2\hbar^2} \sum_{\mathbf{k}, l} v_l^\alpha w_l^{\beta\gamma} \frac{\partial f_l}{\partial \varepsilon_l}, \quad (4)$$

$$\sigma_{\text{BCD}}^{\alpha\beta\gamma}(\tau_r^1) = -\tau_r \frac{e^3}{2\hbar^2} \sum_{\mathbf{k}, l} (v_l^\gamma \Omega_l^{\alpha\beta} + v_l^\beta \Omega_l^{\alpha\gamma}) \frac{\partial f_l}{\partial \varepsilon_l}, \quad (5)$$

$$\sigma_{\text{QMD}}^{\alpha\beta\gamma}(\tau_r^0) = -\frac{e^3}{\hbar^2} \sum_{\mathbf{k}, l} [2(v_l^\gamma \mathcal{G}_l^{\alpha\beta} + v_l^\beta \mathcal{G}_l^{\alpha\gamma}) - v_l^\alpha \mathcal{G}_l^{\beta\gamma}] \frac{\partial f_l}{\partial \varepsilon_l}, \quad (6)$$

Here $w_l^{\alpha\beta} = \hbar^{-2} \partial_\alpha \partial_\beta \varepsilon_l$ is the inverse mass tensor, $\Omega_l^{\alpha\beta} = -2\text{Im}[\sum_{n(\neq l)} A_{ln}^\alpha A_{nl}^\beta]$ is the Berry curvature tensor, $\mathcal{G}_l^{\alpha\beta} = \text{Re}[\sum_{n(\neq l)} A_{ln}^\alpha A_{nl}^\beta / (\varepsilon_l - \varepsilon_n)]$ is the band-normalized quantum metric tensor (also called Berry connection polarizability), v_l^γ is the group velocity of l -th band ε_l of γ component, and $f_l = \{1 + \exp[(\varepsilon_l - \mu)/k_B T]\}^{-1}$ is the Fermi distribution function of band ε_l . For full derivation, please see Supplementary Information. We note that $\sigma_{\text{IMD}}^{\alpha\beta\gamma}$ is symmetric under any permutation of all three indices α, β , and γ , where $\sigma_{\text{BCD}}^{\alpha\beta\gamma}$ and $\sigma_{\text{QMD}}^{\alpha\beta\gamma}$ are symmetric under

permutation of the last two indices $\beta \leftrightarrow \gamma$. Moreover, we find that $\sigma_{\text{BCD}}^{\alpha\alpha\beta} = -\sigma_{\text{BCD}}^{\beta\alpha\alpha}/2$ and $\sigma_{\text{BCD}}^{\alpha\alpha\alpha} = 0$, indicating the pure Hall-type nature of the BCD contributions.

Besides Eq. (1) BCD contribution bears one extra constrain⁷². Notice that $\Omega^x \equiv \Omega^{yz}$, $\Omega^y \equiv \Omega^{zx}$, $\Omega^z \equiv \Omega^{xy}$ as Berry curvature is an anti-symmetric tensor. Since Berry curvature can be written as the curl of the intraband Berry connection: $\Omega = \nabla \times A$, it is solenoidal, *i.e.*, $\nabla \cdot \Omega = 0$, and hence $\partial^x \Omega^x + \partial^y \Omega^y + \partial^z \Omega^z = 0$. Back to the conductivity tensor, it brings an extra constrain $\sigma_{\text{BCD}}^{xyz} + \sigma_{\text{BCD}}^{yzx} + \sigma_{\text{BCD}}^{zxy} = 0$.

Density functional theory calculations.

All DFT calculations herein are performed using projector augmented wave method⁷³, implemented in Vienna ab initio simulation package (VASP)⁷⁴. The generalized gradient approximation of the Perdew-Burke-Ernzerhof-type exchange-correlation potential⁷⁵ is adopted. All the verified AFMs are collected in the MAGNDATA database (<https://www.cryst.ehu.es/magndata/>). For 20-atom collinear AFM VNb_3S_6 , #0.712 in MAGNDATA, (lattice parameter of the magnetic unit cell $a = b = 5.73 \text{ \AA}$, $c = 12.11 \text{ \AA}$), we solve (3p,4s,3d) electrons for V, (4p,5s,4d) electrons for Nb, (3s, 3p) electrons for S, with $E_{\text{cut}} = 400\text{eV}$ and a k-point mesh of $13 \times 13 \times 5$. For 12-atom non-coplanar AFM CrSe, #2.35 in MAGNDATA, (lattice parameter of the magnetic unit cell $a = b = 6.37 \text{ \AA}$, $c = 6.02 \text{ \AA}$), we solve (3p,4s,3d) electrons for Cr, (4s,4p) electrons for Se, with $E_{\text{cut}} = 500\text{eV}$ and a k-point mesh of $13 \times 13 \times 9$. Tight-binding models are constructed from DFT bands using the WANNIER90 package⁷⁶, and NLT tensors in gauge-covariant form⁷² are calculated within WannierBerri code⁷⁷. Crystal structures are plotted by VESTA⁷⁸. The SSGs of materials, labeled by the international notation⁴⁸, are diagnosed by the self-developed program FINDSPINGROUP at <https://findspingroup.com>.
