# ON THE TENSOR PROPERTY OF BERNSTEIN-SATO POLYNOMIAL 

QUAN SHI AND HUAIQING ZUO

#### Abstract

We prove the multiplicative Thom-Sebastiani rule for Bernstein-Sato polynomials, answering the longstanding questions of Budur and Popa. We generalize the result to the tensor of two effective divisors on the product of two arbitrary non-singular complex varieties. This also leads to a multiplicative property related to Igusa's strong monodromy conjecture. Moreover, we propose an extension of our result to Bernstein-Sato polynomials for ideals and prove it for monomial ideals.

Convention. In this paper, we adopt multi-index. We use $\boldsymbol{x}$ to denote an array of variables or numbers depending on the context. For $\boldsymbol{x}=\left(x_{1}, \ldots, x_{n}\right)$ a sequence of variables and $\boldsymbol{\alpha}=$ $\left(\alpha_{1}, \ldots, \alpha_{n}\right) \in \mathbb{Z}^{n}$, we use $\boldsymbol{x}^{\alpha}$ to mean $\prod_{i} x_{i}^{\alpha_{i}}$. For the convention of sheaf, we use $f \in \mathcal{F}$ to mean a section in some open set. If $\mathcal{F}$ is a quasi-coherent sheaf over an affine scheme $X$, we may sometimes mix $\mathcal{F}$ with its module of global sections deliberately.

## 1. Introduction

Suppose $X$ is a non-singular complex variety and $f$ is a non-zero regular function. Let $\mathcal{D}_{X}$ be the sheaf of differential operators of $X$, which is locally the non-commutative polynomial
ring in partial derivations of $X$. The Bernstein-Sato polynomial $b_{f}(s)$ is defined as the non-zero polynomial in $s$ of the minimal degree such that

$$
\begin{equation*}
b_{f}(s) \cdot f^{s} \in \mathcal{D}_{X}[s] \cdot f^{s+1} \tag{111}
\end{equation*}
$$

where $s$ is a formal indeterminant and the $\mathcal{D}_{X}[s]$ action on the right-hand side is in the expected way. We have demonstrated the complete definition and related machinery in Subsection 2.2 The existence of $b_{f}$ is a non-trivial issue and is due to the holonomicity of $\mathcal{D}_{X_{s}}$-module $\mathcal{O}_{X_{s}}\left[\frac{1}{f}\right] \cdot f^{s}$, where $X_{s}=X \times_{\mathbb{C}} \operatorname{Spec} \mathbb{C}(s)$. The case for $X=\mathbb{A}_{\mathbb{C}}^{n}$ is proven in Ber71] and for the general case, we refer to Pop18.

The definition of $b_{f}$ can be extended to a $\log$ pair $(X, D)$, where $D$ is an effective divisor. For an affine covering $\left\{U_{i}\right\}_{i}$ and sections $f_{i} \in \Gamma\left(U_{i}, \mathcal{O}_{X}\right)$ such that $\left.D\right|_{U_{i}}=\operatorname{div} f_{i}$, we have $b_{D}(s)=$ $\operatorname{lcm}_{i} b_{f_{i}}(s) . b_{D}$ is an important invariant of the log pair $(X, D)$. It has a subtle connection with multiplier ideals (for definition, see (Laz04), and we refer to [Kol97 and ELSV04. Also, it plays a role in the classification of singularities (see [KS11, Sai93], and [Sai09]). There are numerous other applications, we refer to Pop18.

For $X=\mathbb{A}_{\mathbb{C}}^{n}$, (11,1) can be rewritten as

$$
b_{f}(s) \cdot f^{s}=P\left(s, \boldsymbol{x}, \boldsymbol{\partial}_{\boldsymbol{x}}\right) \cdot f^{s+1}
$$

where $P$ is an element in the Weyl algebra (tensoring $\mathbb{C}[s]) A_{n}(\mathbb{C})[s]$ (see [Sch19]).
For all invariants about functions, it is always natural to ask how will they change if the functions are put into some algebraic operations. For $f \in \mathbb{C}[\boldsymbol{x}]$ and $g \in \mathbb{C}[\boldsymbol{y}]=\mathbb{C}\left[y_{1} \ldots, y_{m}\right]$, Nero Budur proposed the following problem.

Problem 1.1 ( Bud12], 2.11). Is there a multiplicative Thom-Sebastiani rule for b-functions? That is, is there any relation between $b_{f}, b_{g}$, and $b_{f g}$ ?

Years later, Mihnea Popa further asked the following.
Problem 1.2 ( Pop18, page 33). Do the Bernstein-Sato polynomials of $f, g$, and $f \cdot g$ satisfy

$$
b_{f}(s) b_{g}(s)=b_{f \cdot g}(s) ?
$$

Honestly, they are the problems that everyone knows Bernstein-Sato polynomial may consider and even thought clear. However, although one side of the division i.e. $b_{f . g}(s) \mid b_{f}(s) b_{g}(s)$ is obvious, the other side is highly non-trivial.

In literature, only few clues related to this problem can be found. In Wal15, Proposition 2.6.1. tells us $b_{f} b_{g}=b_{f \cdot g}$ holds for $f$ and $g$ whose Bernstein-Sato polynomials can be attained by differential operators consisting only of $s$ and $\boldsymbol{\partial}_{\boldsymbol{x}}$ (or $\boldsymbol{\partial}_{\boldsymbol{y}}$ ). In Pop18, the formula of BernsteinSato polynomial for monomial helps prove the identity, after some works, when either $f$ or $g$ is a monomial. Apart from them, useful results can hardly be found in literature, much less complete proof.

The problems are about the tensor property of Bernstein-Sato polynomials since $f \cdot g \in \mathbb{C}[\boldsymbol{x}, \boldsymbol{y}]$ can be identified as $f \otimes g \in \mathbb{C}[\boldsymbol{x}] \otimes_{\mathbb{C}} \mathbb{C}[\boldsymbol{y}]$. One will also see that tensors appear everywhere in the later sections. In this paper, we prove a strong version of the problems.
Theorem A (Theorem (3.2). Suppose $A$ and $B$ are finitely generated integral regular $k$-algebras. $C=A \otimes_{\mathbb{C}} B$ is the tensor product, with $f \in A$ and $g \in B$ non-zero. Let $b_{f}(s), b_{g}(s), b_{f \cdot g}(s)$ be the corresponding Bernstein-Sato polynomials, then the following equality holds.

$$
b_{f \cdot g}(s)=b_{f}(s) b_{g}(s) .
$$

Generalizing to divisors, we have the following global version.

Theorem B (Theorem 3.6). Suppose $X_{1}$ and $X_{2}$ non-singular complex varieties and $D_{1}, D_{2}$ are effective Cartier divisors on $X_{1}, X_{2}$, then we have

$$
b_{D_{1} \otimes D_{2}}(s)=b_{D_{1}}(s) \cdot b_{D_{2}}(s)
$$

The theorem turns out to give a product result of the Igusa's strong monodromy conjecture.
Conjecture 2.11 (Strong Monodromy Conjecture, Igusa). Given $f \in \mathbb{Z}[\boldsymbol{x}]$, for every prime $p$ large enough, if $s_{0}$ is a pole of $Z_{p}(f ; s)$, then $\Re s_{0}$ is a root of $b_{f}(s)$. Moreover, if the order of $s_{0}$ as a pole is $m$, then $s_{0}$ is a root of $b_{f}(s)$ of multiplicity $\geq m$.
Corollary 3.4. Suppose $f \in \mathbb{Z}[\boldsymbol{x}]$ and $g \in \mathbb{Z}[\boldsymbol{y}]$ are non-zero polynomials. Suppose strong monodromy conjecture (Conjecture 2.11) holds for $f$ and $g$, then it also holds for $f \cdot g \in \mathbb{Z}[\boldsymbol{x}, \boldsymbol{y}]$.

The Bernstein-Sato polynomial can be generalized to ideals (see BMS06b and Mus22). Let $\mathfrak{a} \subset \mathbb{C}[\boldsymbol{x}]$ with non-zero generators $f_{1}, \ldots, f_{r}$, then $b_{\mathfrak{a}}(|\boldsymbol{s}|)$ is the the minimal polynomial in $|\boldsymbol{s}|$ such that

$$
b_{\mathfrak{a}}(|\boldsymbol{s}|) f_{1}^{s_{1}} f_{2}^{s_{2}} \ldots f_{r}^{s_{r}} \in \sum_{\boldsymbol{u} \in \mathbb{Z}^{r},|\boldsymbol{u}|=1} D(A)[\boldsymbol{s}] \cdot\left(\prod_{u_{i}<0}\binom{s_{i}}{-u_{i}}\right) f_{1}^{s_{1}+u_{1}} f_{2}^{s_{2}+u_{2}} \ldots f_{r}^{s_{r}+u_{r}}
$$

We write more information in Subsection 2.3. The general computation is very difficult. But in monomial ideal case, we have a combinatoric description (see BMS06c).

One may be interested in ideal analogues of Problems 1.1 and Problems $\mathbf{1 . 2}$ i.e. for $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$, whether one can find relations between $b_{\mathfrak{a}}, b_{\mathfrak{b}}$, and $b_{\mathfrak{a} \cdot \mathfrak{b}}$, or even has $b_{\mathfrak{a}} b_{\mathfrak{b}}=b_{\mathfrak{a} \cdot \mathfrak{b}}$. Unfortunately, the general answer to the second is no, even if we do not care about the multiplicity of roots (see Example 3.8). But if one of the ideals is principal, we have the following.

Proposition 3.9. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ be an ideal and $g \in \mathbb{C}[\boldsymbol{y}]$, then $b_{\mathfrak{a}} b_{g}=b_{\mathfrak{a} \cdot(g)}$.
For monomial ideals, we find $W_{\mathfrak{a}} \cup W_{\mathfrak{b}}$ is not that far from $W_{\mathfrak{a} \cdot \mathfrak{b}}$, where $W_{\mathfrak{a}}$ means the roots of $b_{\mathfrak{a}}$, not counting multiplicity.

Theorem $\mathbf{C}$ (Theorem 3.10). Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero monomial ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}} \subseteq W_{\mathfrak{a b}}
$$

Theorem $\mathbf{D}$ (Theorem 2.16). Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero monomial ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}}=W_{\mathfrak{a b}} \quad \bmod \mathbb{Z}
$$

Consequently, we conjecture the following multiplicative Thom-Sebastiani rule for all ideals.
Conjecture 3.15. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}} \subseteq W_{\mathfrak{a b}}
$$

Moreover, we have

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}}=W_{\mathfrak{a b}} \quad \bmod \mathbb{Z}
$$

The organization of this paper comes as follows.
In Section 2, we provide preliminary knowledge for our study. In Subsection 2.1, we review the general picture of algebraic $\mathcal{D}$-modules and some variations needed to the proof of the existence of Bernstein-Sato polynomial. In the subsequent subsection of Section 2, the content comes as the subsection title.

In Section 3, we discuss the proof, generalization, and some consequences of Problem 1.1 and Problem 1.2. In Subsection 3.1, we give two sound motivations. In Subsection
3.2, we prove a generalized version of the problems and give one of consequences about strong monodromy conjecture, we discuss analogous problems of Problem 1.1 and Problem 1.2 about ideals and prove two results for monomial ideals.
1.1. Announcement. This is a paper finished at the beginning of January 2024. It was first submitted to a journal on January 31. In June, we were told there was a preprint that appeared on arxiv on February 7, a week after our submission (see Lee24].https://arxiv.org/pdf/2402.04512). It also solves the problems in the abstract and has some overlaps with our paper. Two solutions are completed independently. Besides, the methods of the two papers are different. Our solution comes from a definition of $b_{f}$ from commutative algebra and seems more direct towards the original problems.

## 2. Preliminary

2.1. Algebraic $\mathcal{D}$-module over $\mathbb{C}$ and $\mathbb{C}(s)$. In this subsection, we will pay a brief review of the theory of algebraic $\mathcal{D}$-module related to our theme. Let $X$ be a $n$-dimensional nonsingular complex algebraic variety i.e. a separated scheme of finite type over $\mathbb{C}$. To make the definition explicit, the sheaf of differential operators on $X, \mathcal{D}_{X}$, is defined to be the subalgebra of $\mathcal{E} n d_{\mathbb{C}}\left(\mathcal{O}_{X}\right)$ generated by $\mathcal{O}_{X}$ and $\operatorname{Der}_{\mathbb{C}}\left(\mathcal{O}_{X}\right)$.

On an affine open subset $U$ small enough, one can choose local coordinates $x_{1}, \ldots, x_{n}$ i.e.

$$
\Omega_{U / \mathbb{C}}=\bigoplus_{i=1}^{n} \mathcal{O}_{U} \cdot d x_{i}
$$

where $d: \mathcal{O}_{X} \rightarrow \Omega_{X / \mathbb{C}}$ is the universal derivation (Kähler differential). Then on $U$, the sheaf of differential operators is defined to be the quasi-coherent $\mathcal{O}_{U}$-non-commutative algebra

$$
\left.\mathcal{D}_{X}\right|_{U}=\bigoplus_{\alpha \in \mathbb{N}^{n}} \mathcal{O}_{U} \cdot \partial^{\alpha}
$$

where $\partial_{i}: \mathcal{O}_{U} \rightarrow \mathcal{O}_{U}$ is the dual derivation of $d x_{i}$. To distinguish the action of $\partial_{i}$ on $\mathcal{O}_{U}$ and its multiplication in $\mathcal{D}_{X}$, we use $\frac{\partial f}{\partial x_{i}}$ to mean $\partial_{i}(f)$. Here $f \in \mathcal{O}_{U}$ is a local section. The multiplication of $\mathcal{D}_{X}$ is defined as

$$
\left[\partial_{i}, \partial_{j}\right]=\delta_{i j}, \quad\left[\partial_{i}, f\right]=\frac{\partial f}{\partial x_{i}}
$$

There is a natural filtration on $\mathcal{D}_{X}$, the order filtration $F_{\bullet} \mathcal{D}_{X}$. The increasing chain $\mathcal{O}_{X}=$ $F_{0} \mathcal{D}_{X} \subseteq F_{1} \mathcal{D}_{X} \subseteq \ldots$ is a sequence of quasi-coherent $\mathcal{O}_{X}$-modules (see Pop18 or HTT08]). Locally, we have

$$
\left.F_{j} \mathcal{D}_{X}\right|_{U}=\bigoplus_{\alpha \in \mathbb{N}^{n},|\alpha| \leq j} \mathcal{O}_{U} \cdot \partial^{\alpha}
$$

We can define $\mathcal{D}_{X}$ more intrinsically. Let $R$ be a ring and $A$ an $R$-algebra, we can define the (non-commutative) subalgebra $F_{j} D_{R}(A) \subseteq \operatorname{End}_{R}(A)$ inductively. Set

$$
\begin{aligned}
& F_{0} D_{R}(A):=A \\
& F_{j} D_{R}(A):=\left\{P \in \operatorname{End}_{R}(A) \mid[P, f] \in F_{j-1} D_{R}(A), \text { for all } f \in A\right\}
\end{aligned}
$$

In our case, $R=\mathbb{C}$ and $A$ is a finitely generated regular $\mathbb{C}$-algebra. In our assumption, for each multiplicative closed subset $S \subseteq A$, there is a canonical isomorphism

$$
\pi_{j}: S^{-1} F_{j} D_{\mathbb{C}}(A) \rightarrow F_{j} D_{\mathbb{C}}\left(S^{-1} A\right)
$$

Taking $S$ to be all localizations to a principal open set of $A$, one finds $F_{j} D_{\mathbb{C}}(A)$, with $A$ running through all affine open sets of $X$, defines a quasi-coherent sheaf on $X$. The sheaf is exactly the
$F_{j} \mathcal{D}_{X}$ defined before (see Sch19). In particular, we have

$$
F_{j} D_{\mathbb{C}}(A)=\operatorname{span}_{\mathbb{C}}\left\{\delta_{1} \delta_{2} \ldots \delta_{j} \mid \delta_{1}, \ldots, \delta_{j} \in F_{1} D_{\mathbb{C}}(A)=A \oplus \operatorname{Der}_{\mathbb{C}}(A)\right\}
$$

In the rest of the paper, we use $F_{j} D(A)$ instead of $F_{j} D_{\mathbb{C}}(A)$ if no confusion arises.
A (left) algebraic $\mathcal{D}_{X}$-module is a quasi-coherent $\mathcal{O}_{X}$-module $\mathcal{M}$ equipped with a (left) $\mathcal{D}_{X^{-}}$ multiplication compatible with the $\mathcal{O}_{X}$-multiplication. The quasi-coherence condition is crucial, without which we cannot deal with $\mathcal{D}_{X}$-modules locally.

The graded ring of $F_{\bullet} \mathcal{D}_{X}$ is $\operatorname{Sym}_{\mathcal{O}_{X}} \mathcal{T}_{X}$, where $\mathcal{T}_{X}=\mathcal{H o m}\left(\Omega_{X / \mathbb{C}}, \mathcal{O}_{X}\right)$ is the tangent sheaf. Hence, $\operatorname{Spec}_{X}\left(\operatorname{gr}^{F} \mathcal{D}_{X}\right)=T^{*} X$, the cotangent bundle of $X$. This fact leads to the filtration study of $\mathcal{D}$-modules.

A compatible filtration on $\mathcal{M}$ is an $\mathcal{O}_{X}$-module filtration $G_{\bullet} \mathcal{M}$ such that $F_{i} \mathcal{D}_{X} \cdot G_{j} \mathcal{M} \subseteq$ $G_{i+j} \mathcal{M}$. The graded module $\operatorname{gr}^{G} \mathcal{M}$ is a $\mathrm{gr}^{F} \mathcal{D}_{X}$-module and hence can be identified with an $\mathcal{O}_{T^{*} X}$-module. We also call this module $\mathrm{gr}^{G} \mathcal{M}$. We call the filtration $G$ • good $\mathrm{if} \mathrm{gr}^{G} \mathcal{M}$ is a coherent $\mathcal{O}_{T^{*} X}$-module. $\mathcal{M}$ is called a coherent $\mathcal{D}_{X}$-module if it admits a good filtration. From Sch19, we know $\mathcal{M}$ is coherent if and only if it is locally a finitely generated $\mathcal{D}_{X}$-module. and all good filtrations are equivalent i.e. bounded by a shift of each other.

For a coherent $\mathcal{D}_{X}$-module $\mathcal{M}$, choose a good filtration $G \cdot \mathcal{M}$. The characteristic variety of $\mathcal{M}$ is defined to be

$$
\operatorname{Ch}(\mathcal{M})=V\left(\operatorname{Ann}_{\mathcal{O}_{T^{*} X}} \operatorname{gr}^{G} \mathcal{M}\right)
$$

equipped with reduced scheme structure. $\operatorname{Ch}(\mathcal{M})$ is independent of the choice of good filtration, which follows from the fact that all good filtrations are equivalent. Through arguments of symplectic algebraic geometry or reducing to affine spaces, one can prove the dimension of $\operatorname{Ch}(\mathcal{M}) \geq n$ if $\mathcal{M} \neq 0$ (see HTT08], Pop18 or [Sch19]). As a result, $\mathcal{M}$ is called holonomic holonomic if $\operatorname{dim} \operatorname{Ch}(\mathcal{M})=n$ or $\mathcal{M}=0$. Submodules and quotient modules of holonomic modules are again holonomic since the the graded modules with induced good filtration have larger annihilators.

There are also push-forward and pulling-back operations for $\mathcal{D}$-modules. The general construction is hard to describe in a few pages since it involves many statements in derived category and the transformation between left and right $\mathcal{D}_{X}$-modules. Roughly speaking, let $f: X \rightarrow Y$ be a morphism between non-singular varieties, the push-forward is the functor $f_{+}:=R f_{*}\left(\mathcal{D}_{Y \leftarrow X} \otimes_{\mathcal{D}_{X}}-\right): D^{b}\left(\mathcal{D}_{X}\right) \rightarrow D^{b}\left(\mathcal{D}_{Y}\right)$ between derived categories (see HTT08 and Pop18).

Here, we only describe the push-forward functor of closed immersion and affine open immersion, in which the the performance of the functor is simple.

## 1. Closed immersion.

Let $i: X \rightarrow Y$ be a closed immersion of non-singular varieties and $\mathcal{M}$ be a $\mathcal{D}_{X}$-module. Restricting our attention to some small affine open set, we may assume $Y=\operatorname{Spec} A$ with local coordinate $x_{1}, \ldots, x_{n}$ with $X=\operatorname{Spec} A /\left(x_{r+1}, \ldots, r_{n}\right)$. Let $\tilde{M}=M^{\sim}$ and $i_{+} \mathcal{M}=(\bar{M})^{\sim}$ is a $\mathcal{D}_{Y}$-module such that

$$
\bar{M}=A\left[\partial_{r+1}, \ldots, \partial_{n}\right] \otimes_{A} M=\mathbb{C}\left[\partial_{r+1}, \ldots, \partial_{n}\right] \otimes_{\mathbb{C}} M
$$

The $\mathcal{D}_{Y}$-module action on $i_{+} \mathcal{M}$ (equivalent, $D(A)$-module action on $\left.\bar{M}\right)$ is described as follows.
Let $P \otimes m \in \mathbb{C}\left[\partial_{r+1}, \ldots, \partial_{n}\right] \otimes \mathbb{C} M$, we only need to describe the multiplication of (1) $\partial_{i}, 1 \leq$ $i \leq r,(2) \partial_{j}, r+1 \leq j \leq n$, and (3) $g \in A$ on $P \otimes m$. For (1), one simply defines $\partial_{i} \cdot(P \otimes m)=$ $P \otimes\left(\partial_{i} m\right)$. For (2), one defines $\partial_{j} \cdot(P \otimes m)=\left(\partial_{j} P\right) \otimes m$. (3) is a bit complicated. Suppose $A\left[\partial_{r+1}, \ldots, \partial_{n}\right] \ni f \cdot P=\sum_{\boldsymbol{\alpha}^{\prime} \in \mathbb{N}^{n-r}} \boldsymbol{\partial}^{\prime \alpha^{\prime}} f_{\boldsymbol{\alpha}^{\prime}}$, where $\boldsymbol{\alpha}^{\prime}=\left(\alpha_{r+1}, \ldots, \alpha_{n}\right)$ and $f_{\boldsymbol{\alpha}^{\prime}} \in A$. Then $f \cdot(P \otimes m)$ is defined to be $\sum_{\alpha^{\prime} \in \mathbb{N}^{n-r}} \partial^{\prime \alpha^{\prime}} \otimes f_{\alpha^{\prime}} m$.

It is easy to see $i_{+}$is an exact functor and $\mathcal{M}=0$ iff $i_{+} \mathcal{M}=0$. Moreover, for a good filtration $G_{\bullet}$ on $\mathcal{M}$, we have an induced good filtration on $i_{+} \mathcal{M}$ locally. That is,

$$
G_{l} \bar{M}:=\sum_{i+j=l}\left(\sum_{\left|\alpha^{\prime}\right| \leq i} \partial^{\prime \alpha^{\prime}}\right) \otimes G_{j} M
$$

Hence, by definition, one has $\operatorname{dim} \operatorname{Ch}\left(i_{+} \mathcal{M}\right)-\operatorname{dim} Y=\operatorname{dim} \operatorname{Ch}(\mathcal{M})-\operatorname{dim} X$. As a direct corollary, we see that $\mathcal{M}$ is holonomic iff $i_{+} \mathcal{M}$ is holonomic.

## 2. Affine open immersion

In this case, let $f: U \hookrightarrow X$ be an affine open immersion and $\mathcal{M}$ be a $\mathcal{D}_{U}$-module, then $f_{+} \mathcal{M}=f_{*} \mathcal{M}$, equipped with the natural $\mathcal{D}_{X}$-module structure given by the restriction maps of sheaves.

The general theorem tells us that holonomicity is preserved by the push-forward of an arbitrary morphism. Applied to the two special cases we introduced, it tells us that $i_{+}$and $f_{*}$ send holonomic modules to holonomic modules. (Although we have already known the result for $i_{+}$.)
Theorem 2.1 (HTT08 or Sch19). Let $X \rightarrow Y$ be a morphism of non-singular varieties, then $f_{+}: D^{b}\left(\mathcal{D}_{X}\right) \rightarrow D^{b}\left(\mathcal{D}_{Y}\right)$ induces $f_{+}: D_{h}^{b}\left(\mathcal{D}_{X}\right) \rightarrow D^{b}\left(\mathcal{D}_{X}\right)$. Here $D_{h}^{b}(\mathcal{D})$ is the subcategory in which the cohomology modules of every complex are holonomic.

For further use, we need to give a brief sketch of $\mathcal{D}_{X_{s}}$-modules. Let $\mathbb{C}(s)$ be the function field of $\mathbb{C}$ and $S=\operatorname{Spec} \mathbb{C}(s)$. Then $X \mapsto X_{s}:=X \times_{\mathbb{C}} S$ is a functor from smooth $\mathbb{C}$-varieties to smooth $\mathbb{C}(s)$-varieties of the same dimension, since flatness of morphisms, local freeness of Kählere differential, and local transcendental degree are all preserved. For $X=\operatorname{Spec} A$, one can also define $F_{j} \mathcal{D}_{X_{s}}=\left(F_{j} D_{\mathbb{C}(s)}(A(s))\right)^{\sim}$. One can compute $F_{j} D_{\mathbb{C}(s)}(A(s))$ through $F_{j} D_{\mathbb{C}} A[s]$ and using the compatibility of $F_{j} D_{\mathbb{C}}(A[s])$ with the localization $S=\mathbb{C}[s] \backslash\{0\}$. Consequently, $F_{j} D_{\mathbb{C}(s)}(A(s))=F_{j} D_{\mathbb{C}}(A) \otimes_{\mathbb{C}} \mathbb{C}(s)$. For a general variety $X$, just glue the local module and we have $\mathcal{D}_{X_{s}}$ one the induced variety $X_{s}$.

Again, a $\mathcal{D}_{X_{s}}$-module is a quasi-coherent $\mathcal{O}_{X_{s}}$-module $\mathcal{M}$ equipped with a $\mathcal{D}_{X_{s}}$-multiplication. One can easily define notions of coherence, good filtration, and characteristic varieties. Furthermore, we have $\operatorname{Spec}_{X_{s}}\left(\operatorname{gr}^{F} \mathcal{D}_{X_{s}}\right)=T^{*} X_{s}=\left(T^{*} X\right)_{s}$, we also define $\mathcal{M}$ to be holonomic if $\operatorname{dim} \operatorname{Ch}(\mathcal{M})=\operatorname{dim} X=\operatorname{dim} X_{s}$ or $\mathcal{M}$.

Suppose $f: X \rightarrow Y$ is a morphism of non-singular $\mathbb{C}$-varieties, then we can also define the functor $\left(f_{s}\right)_{+}: X_{s} \rightarrow Y_{s}$. If $f$ is a closed immersion or an affine open immersion, the construction is the same as before, just substitute $\mathbb{C}$-tensor for $\mathbb{C}(s)$-tensor. For a closed immersion, we still have $\operatorname{dim} \operatorname{Ch}\left(i_{+} \mathcal{M}\right)-\operatorname{dim} Y=\operatorname{dim} \operatorname{Ch}(\mathcal{M})-\operatorname{dim} X$ if $\mathcal{M} \neq 0$. In particular, holonomicity is preserved.

Locally, there is a closed immersion $X \hookrightarrow \mathbb{A}_{\mathbb{C}(s)}^{m}$, then we have $\operatorname{dim} \operatorname{Ch}(\mathcal{M})-\operatorname{dim} X=$ $\operatorname{dim} \operatorname{Ch}\left(i_{+} \mathcal{M}\right)-m \geq 0$, by the Bernstein inequality on $\mathbb{A}_{\mathbb{C}(s)}^{m}$ (see [Sch19]). Hence we still have $\operatorname{dim} \operatorname{Ch}(\mathcal{M}) \geq \operatorname{dim} X$. Besides, since $\left(i_{s}\right)_{+}$is exact and faithful $\left(\mathcal{M}=0 \Longleftrightarrow i_{+} \mathcal{M}=0\right)$, we have holonomic $\mathcal{D}_{X_{s}}$-module satisfies a.c.c. and d.c.c. condistion, also applying the result on $\mathbb{A}_{\mathbb{C}(s)}^{m}$ (see [Sch19]).

For $f: U \rightarrow X$ an affine open immersion, $\left(f_{s}\right)_{+}$also preserves holonomicity. Here we only sketch the proof for a principal localization $U=\operatorname{Spec} A_{g} \rightarrow X=\operatorname{Spec} A$. Suppose $A=$ $k\left[z_{1}, \ldots, z_{m}\right] / I=k[\boldsymbol{z}] / I$, then $A_{g}=k[\boldsymbol{z}, w] /(w g-1, I)$, hence we have the following commutative diagram.

Vertical arrows are both closed immersion and the arrow in the second row is the coordinate projection. Since closed immersion preserves holonomicity, the problem is reduced to $\mathbb{A}^{m+1} \rightarrow$ $\mathbb{A}^{n}$. This can be proven using the Fourier transformation for $\mathcal{D}$-modules on $\mathbb{A}_{\mathbb{C}(s)}^{m}$ (see [Sch19]).

In the next subsection, we will apply these tools to sketch the existence of Bernstein-Sato polynomial.
2.2. Bernstein-Sato polynomial, Existence, and Some Results. The Bernstein-Sato polynomial $b_{f}(s)$ is an important product of the $\mathcal{D}$-module theory. Let us first give a brief definition of it. Let $X=\operatorname{Spec} A$ be a non-singular affine complex variety (WLOG integral) and $f \in A$ be a non-zero section.

We define a $D_{\mathbb{C}(s)}(A(s))=D(A)(s)$-module $M=A_{f} \cdot f^{s}$ as follows.
(1) $M=A_{f}(s)$ as an $A$-module;
(2) the multiplication of $A(s)$ on $M$ is the natural one i.e.

$$
a\left(b \cdot f^{s}\right):=(a b) \cdot f^{s}, a \in A(s), b \in A_{f}(s)
$$

(3) the $\operatorname{Der}_{\mathbb{C}(s)}(A(s))$ multiplication is operated by considering $s$ a formal power i.e.

$$
\delta\left(c \cdot f^{s}\right)=[\delta(c)+(\delta(f) \cdot c)] \cdot f^{s}, c \in A_{f}(s), \delta \in \operatorname{Der}_{\mathbb{C}(s)}(A(s))
$$

There are some $D(A)(s)$-submodules of $M$ e.g. $D(A)(s) \cdot f^{k+s}:=D(A)(s) \cdot\left(f^{k} \cdot f^{s}\right)$ and $D(A)[s]$-submodules e.g. $D(A)[s] \cdot f^{s+k}:=D(A)[s] \cdot\left(f^{k} \cdot f^{s}\right)$. It is clear that $D(A)(s) \cdot f^{s+k} \supseteq$ $D(A)(s) \cdot f^{s+k+1}$ and $D(A)[s] \cdot f^{s+k} \supseteq D(A)[s] \cdot f^{s+k+1}$. The Bernstein-Sato polynomial of $f$ is defined to be the polynomial $b_{f}(s) \in \mathbb{C}[s] \backslash\{0\}$ such that there exists $P \in D(A)[s]$ satisfying

$$
\begin{equation*}
P \cdot f^{s+1}=b_{f}(s) \cdot f^{s} \tag{B-S}
\end{equation*}
$$

For a general non-singular variety $X$ (WLOG integral) and $0 \neq f \in \Gamma\left(X, \mathcal{O}_{X}\right)$, we can also define these two kinds of modules from this local construction. Note that $i_{*}\left(\left.\mathcal{O}_{X_{s}}\right|_{\left.\left(X_{s}\right)_{f}\right)}\right) \cdot f^{s}=\mathcal{O}_{X_{s}}\left[\frac{1}{f}\right] \cdot f^{s}$ has the natural $\mathcal{D}_{X_{s}}$-module structure, on each affine open subset of which is the same as above. For the latter, we simply glue the locally defined modules $D(A)[s] \cdot f^{s+k}$ to be a $\mathcal{D}_{X}[s]$-module. We can also define $b_{f}(s)$ to be the minimal polynomial such that $b_{f}(s) \cdot f^{s} \in \mathcal{D}_{X}[s] \cdot f^{s+1}$. In affine cases, the two definitions coincide since every module is quasi-coherent, and hence inclusion is determined by global sections. Furthermore, $b_{f}(s)$ defined on $X$ is the least common multiple of the ones on all affine open sets (if the existence is guaranteed).

Historically, Joseph Bernstein and Mikio Sato discovered $b_{f}(s)$ independently in the 1970s. Bernstein found it when studying meromorphic extension of distributions and Sato found it when studying prehomogeneous vector spaces (see AMHJNBTW22]).

In the 50 years since, $b_{f}(s)$ have been applied to many fields of mathematics, especially in singularity theory. For example, taking $X=\mathbb{A}_{\mathbb{C}}^{n}$, then the negative of the maximal root $b_{f}(s)$, $\alpha_{f}$, is equal to the $\log$ canonical threshold of $f$ (see Kol97]).

Also, we can define the analytic Bernstein-Sato polynomial, simply by substituting ring $A$ to the ring of holomorphic germ $\mathbb{C}\{\boldsymbol{x}\}$ (for definition, see GLS07]). Morihiko Saito proved $\alpha_{f}$ coincides with the minimal spectrum number (see [Sai06] and Var81). More surprisingly, roots of $b_{f}(s)$ happen to be related to two other important invariants, poles of topological zeta function $Z_{t o p, f}(s)$ and eigenvalues of monodromy action $T_{f}$ (for definition, see DL92 and vS20] respectively). This relation is the well-known Monodromy Conjecture.

Conjecture 2.2 (Monodromy Conjecture, DL92]). Assume $s_{0} \in \mathbb{C}$ is a pole of $Z_{f, t o p}(s)$, then $e^{2 \pi i s_{0}}$ is an eigenvalue of $T_{f}$ and $s_{0}$ is a zero of $b_{f}(s)$.

These are the general stories of Bernstein-Sato polynomials. Next, we will show some important properties of the Bernstein-Sato polynomials.

The existence of $b_{f}(s)$ is itself non-trivial. For $X=\mathbb{A}_{\mathbb{C}}^{n}$, the existence is proven by using the Bernstein filtration on the Weyl algebra $A_{n}(\mathbb{C}(s))$ and some holonomicity arguments (see Ber71). For a general non-singular variety $X$, there is no such filtration. But fortunately, we can use an exquisite construction to circumvent this obstacle.

Theorem 2.3 (see also Pop18). Let $X$ be a non-singular complex variety (WLOG integral) and $0 \neq f \in \Gamma\left(X, \mathcal{O}_{X}\right)$. Then the Bernstein-Sato polynomial $b_{f}(s)$ exists.

Proof. The problem is local, we may assume $X=\operatorname{Spec} A$ is affine. Let $U=D(f)$ be an open affine subset of $X$ and $j: U \hookrightarrow X$ be the open immersion. One can find $\mathcal{O}_{U} \cdot f^{s}$ is a holonomic $\mathcal{D}_{U_{s}}$-module since its characteristic variety is the zero section of $T^{*} X_{s}$. Hence, we have $\left(j_{s}\right)_{+}\left(\mathcal{O}_{U} \cdot f^{s}\right)=\mathcal{O}_{X}\left[\frac{1}{f}\right] \cdot f^{s}$ is holonomic. Considering the following descending chain of its submodules.

$$
\mathcal{D}_{X_{s}} \cdot f^{s} \supseteq \mathcal{D}_{X_{s}} \cdot f^{s+1} \supseteq \mathcal{D}_{X_{s}} \cdot f^{s+2} \supseteq \ldots
$$

Since holonomic modules satisfy d.c.c. considtion, there is some $k \geq 0$ such that $\mathcal{D}_{X_{s}} \cdot f^{s+k}=$ $\mathcal{D}_{X_{s}} \cdot f^{s+k+1}$. Apply the automorphism $s \mapsto s+k$ of $\mathcal{O}_{X}\left[\frac{1}{f}\right] \cdot f^{s}$, we have $\mathcal{D}_{X_{s}} \cdot f^{s} \supseteq \mathcal{D}_{X_{s}}$. $f^{s+1}$. Hence, there is some $P \in \Gamma\left(X, \mathcal{D}_{X_{s}}\right)=D(A)(s)$ such that $f^{s}=P \cdot f^{s+1}$. Killing the denominators of $P$ (polynomials in $\mathbb{C}[s]$ ), we are done.

More than existence, Kashiwara proved the following.
Theorem 2.4 ( Kas77]). Roots of $b_{f}(s)$ are all negative rational numbers.
We can give an explicit description of $b_{f}(s)$ in commutative algebra, as below.
The action of $F_{j} D(A)[s]$ on $A_{f}[s] f^{s}$ gives an ideal $I_{j}$ as follows.

$$
F_{j} D(A)[s] \cdot f^{s+1}=I_{j} \cdot f^{s+1-j}
$$

$I_{j} \subset A[s]$ is an ideal and it is related to $I_{j-1}$ by the identity below.

$$
I_{j}=I_{j-1} \cdot f+A[s] \cdot\left\{\delta(a) f+(s+2-j) a \delta(f) \mid a \in I_{j-1}, \delta \in \operatorname{Der}_{k}(A)\right\}
$$

This is simply because $F_{j} D(A)=F_{1} D_{k}(A) \cdot F_{j-1} D_{k}(A)=\left(A \oplus \operatorname{Der}_{\mathbb{C}}(A)\right) \cdot F_{j-1} D(A)$.
Consequently, $0 \neq b_{f}(s)$ is the polynomial with the minimal degree such that $b_{f}(s) \cdot f^{j-1} \cdot I_{j}$ for some $j$. We point out this description is useful in proving our main theorem (Theorem 3.2).

The following two propositions show $b_{f}(s)$ is invariant under the multiplication of units and can be locally glued. As a result, for an effective divisor $D$ on non-singular complex variety $X$, one can define the Bernstein-Sato polynomial of $D$ as

$$
b_{D}(s)=\operatorname{lcm}_{i} b_{f_{i}}(s)
$$

where $\left\{U_{i}\right\}_{i}$ is an affine open covering of $X, f_{i} \in \Gamma\left(U_{i}, \mathcal{O}_{X}\right)$, and $\left.D\right|_{U_{i}}=\operatorname{div}\left(f_{i}\right)$.
We will give the proof of the first proposition and only give reference to the second.
Proposition 2.5. Suppose $X=\operatorname{Spec} A$ is an integral non-singular complex affine variety. Let $0 \neq f \in A$ and $g \in A^{*}$, then $b_{f}(s)=b_{f \cdot g}(s)$.

Proof. For $f \cdot g$, we define the ideals $J_{j}$ as the $I_{j}$ above i.e.

$$
F_{j} D(A)[s] \cdot(f \cdot g)^{s+1}=J_{j} \cdot(f \cdot g)^{s+1-j}
$$

Since $g$ is invertible, it suffices to prove $I_{j}=J_{j}$ for all $j$. We prove it by induction. For $j=0$, both sides are $A[s]$. Suppose the identity holds for $j-1$. We can present $I_{j}$ by $I_{j-1}$ i.e.

$$
I_{j}=I_{j-1} \cdot f+A[s] \cdot\left\{\delta(a) f+(s+2-j) a \delta(f) \mid a \in I_{j-1}, \delta \in \operatorname{Der}_{\mathbb{C}}(A)\right\}
$$

Similar presentation holds for $J_{j}$ i.e.

$$
J_{j}=J_{j-1} \cdot g f+A[s] \cdot\left\{\delta(a) g f+(s+2-j) a[g \delta(f)+\delta(g) f] \mid a \in J_{j-1}, \delta \in \operatorname{Der}_{\mathbb{C}}(A)\right\}
$$

Since $g$ is invertible, $(s+2-j) a \delta(g) f \in J_{j-1} \cdot g f$. Then we can rewrite $J_{j}$ as

$$
J_{j}=J_{j-1} \cdot g f+A[s] \cdot\left\{\delta(a) g f+(s+2-j) a g \delta(f) \mid a \in J_{j-1}, \delta \in \operatorname{Der}_{\mathbb{C}}(A)\right\}
$$

By the induction hypothesis, $I_{j-1}=J_{j-1}$, we then have $I_{j}=J_{j}$.
Remark 2.6. The argument can also be applied to analytic $b_{f}(s)$ for $f \in \mathbb{C}\{\boldsymbol{x}\}$. Since an automorphism of $\mathbb{C}\{\boldsymbol{x}\}$ gives an isomorphism of its ring of differential operators, the result tells us in a direct way that $b_{f}(s)$ is a contact invariant of hypersurface singularity.

Proposition 2.7 (see Pop18). Suppose $X=\operatorname{Spec} A$ is an integral non-singular affine complex variety and $f \in A$, then the global and local Bernstein-Sato polynomials are related by the formula

$$
b_{f}(s)=\operatorname{lcm}_{i} b_{\left.f\right|_{U_{i}}}(s)
$$

where $\left\{U_{i}\right\}_{i}$ is an arbitrary affine open covering of $X$ and $b_{f_{U_{i}}}(s)$ the Bernstein-Sato polynomial of $\left.f\right|_{U_{i}}$ on $U_{i}$.

The computation of $b_{f}(s)$ is a rather difficult problem and there has not been a general formula so far. In the rest of this subsection, we present some computational results of $b_{f}(s)$.

Theorem 2.8 (see Pop18). Let $f=\operatorname{det}\left(x_{i j}\right) \in \mathbb{C}\left[x_{i j}\right]_{1 \leq i, j \leq n}$ be the determinant of variables, then

$$
b_{f}(s)=(s+1)(s+2) \ldots(s+n)
$$

Theorem 2.9 ( [Sai16]). The Bernstein-Sato polynomial of a generic central hyperplane arrangement $f \in \mathbb{C}[x]$ of degree $l \geq n$ is

$$
b_{f}(s)=(s+1)^{n-1} \prod_{j=0}^{2 l-n-2}\left(s+\frac{j+n}{l}\right)
$$

Theorem 2.10 (see Gra10] or Pop18). Suppose $f \in \mathbb{C}[\boldsymbol{x}]$ is a weighted homogeneous polynomial defining an isolated singularity at the origin, with weight type $\boldsymbol{w}=\left(w_{1}, \ldots, w_{n}\right)$. Let $M_{f}:=\mathbb{C}\{\boldsymbol{x}\} /\left(\frac{\partial f}{\partial x_{1}}, \ldots, \frac{\partial f}{\partial x_{1}}\right)$ be the Milnor algebra of $f$ and $\left\{\boldsymbol{x}^{\alpha_{i}}\right\}_{1 \leq i \leq \mu}$ be a monomial basis of $M_{f}$. Here $\mu=\operatorname{dim}_{\mathbb{C}} M_{f}$ is the Milnor number of $f$. Let $\Delta$ be the set (not counting multiplicity) consisting of all rational numbers $\boldsymbol{w} \cdot \boldsymbol{\alpha}_{i}$.

The Bernstein-Sato polynomial of $f$ is

$$
b_{f}(s)=(s+1) \prod_{\rho \in \Delta}(s+|\boldsymbol{w}|+\rho)
$$

2.3. Igusa Zeta Function and Strong Monodromy Conjecture. In this section, we review the $p$-adic Igusa zeta function and the strong monodromy conjecture. For a reference, we recommend Nic10].

Let $p$ be a rational prime number, then we have the $p$-adic number field $\mathbb{Q}_{p}$ is a locally compact group and admits a unique Haar measure $\mu_{p}$ up to scalar (see Wei67). After normalizing, we have $\mu_{p}\left(p^{r} \mathbb{Z}_{p}\right)=p^{-r}$ for all $r \in \mathbb{Z}$.

Suppose $f \in \mathbb{Z}[\boldsymbol{x}]$ is a non-zero polynomial, the $p$-adic Igusa zeta function is defined as

$$
Z_{p}(f ; s)=\int_{\mathbb{Z}_{p}^{n}}|f|_{p}^{s} d \mu_{p}
$$

It was shown by Igusa that $Z_{p}(f ; s)$ is a rational function of $p^{-s}$ (see Igu75). There is a well-known conjecture about the poles of $Z_{p}(f ; s)$ (see Nic10] or Mus22]).

Conjecture 2.11 (strong monodromy conjecture, Igusa). Given $f \in \mathbb{Z}[\boldsymbol{x}]$, for every prime $p$ large enough, if $s_{0}$ is a pole of $Z_{p}(f ; s)$, then $s_{0}$ is a root of $b_{f}(s)$. Moreover, if the order of $s_{0}$ as a pole is $m$, then $\Re s_{0}$ is a root of $b_{f}(s)$ of multiplicity $\geq m$.
2.4. Bernstein-Sato polynomial for Ideals. The Bernstein-Sato polynomial can be generalized to an arbitrary variety (see BMS06b or [Mus22]). Definitions in the two papers are stated differently but equivalent in fact. We first review the defintion.

Suppose $X=\operatorname{Spec} A$ is an affine non-singular complex variety. Let $\mathfrak{a}=\left(f_{1}, \ldots, f_{r}\right)\left(f_{1}, \ldots, f_{r} \neq\right.$ 0 ) be an ideal and $s=\left(s_{1}, \ldots, s_{r}\right)$ be a set of indeterminant. We consider the following equation:

The action of $D(A)$ is the natural in the same sense as (B-S) and $b_{\alpha} \in \mathbb{C}[t]$ is a polynomial. The existence and independence of choice of generators of $\alpha$ was proven in [BMS06b] or one may turn to the following result in Mus22.

Theorem 2.12 (see Mus22]). Let $X$ be a smooth complex algebraic variety. If $f_{1}, \ldots, f_{r} \in$ $\Gamma\left(X, \mathcal{O}_{X}\right)$ are nonzero, generating the ideal sheaf $\mathfrak{a}$, and if $g=\sum_{i=1}^{r} f_{i} y_{i} \in \Gamma\left(X \times \mathbb{A}^{r}, \mathcal{O}_{X \times \mathbb{A}^{r}}\right)$, then $b_{\mathfrak{a}}(s)=b_{g}(s) /(s+1)$.

The theorem also provides a method to compute $b_{\mathfrak{a}}$, but the general computation is still difficult so far. Even if we do not consider the multiplicity, the determination of roots is also a hard issue. But in monomial ideal cases, we can find the roots in a combinatoric way (see the next subsection). $b_{\mathfrak{a}}$ satisfies the following union property.
Theorem 2.13. Suppose $X$ and $Y$ are non-singular complex algebraic varieties. Let $f_{1}, . ., f_{r} \in$ $\Gamma\left(X, \mathcal{O}_{X}\right) \backslash\{0\}$ and $g_{1}, \ldots, g_{t} \in \Gamma\left(Y, \mathcal{O}_{Y}\right)$ define ideal sheaves $\mathfrak{a}$ and $\mathfrak{b}$. We have an ideal sheaf $\mathfrak{c}$ of $X \times Y$ defined by $f_{1}, \ldots, f_{r}, g_{1}, \ldots, g_{t} \in \gamma\left(X \times Y, \mathcal{O}_{X \times Y}\right)$, then their Bernsetin-Sato polynomial satiesfies the following:

$$
b_{\mathfrak{a}}(s)=\prod_{\alpha}(s+\alpha)^{n_{\alpha}}, b_{\mathfrak{b}}(s)=\prod_{\beta}(s+\beta)^{m_{\beta}}, \text { and } b_{\mathfrak{c}}(s)=\prod_{\gamma}(s+\gamma)^{n_{\gamma}} \text {, }
$$

where $q_{\gamma}=\max \left\{n_{\alpha}+m_{\beta}-1 \mid n_{\alpha}>0, m_{\beta}>0, \alpha+\beta=\gamma\right\}$.
2.5. Combinatoric Description in Monomial Ideal Case. In this subsection, we review the combinatoric description of roots of $b_{\mathfrak{a}}$ when $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ is a monomial ideal. For reference, we recommend BMS06a and BMS06c.

For a monomial ideal $\mathfrak{a} \triangleleft \mathbb{C}[\boldsymbol{x}]$, generated by $\boldsymbol{x}^{\boldsymbol{v}_{i}}, \boldsymbol{v}_{i}=\left(v_{i}^{1}, v_{i}^{2}, \ldots, v_{i}^{n}\right) \in \mathbb{N}^{n}, i=1,2 \ldots r$. Let

$$
\Gamma_{\mathfrak{a}}:=\left\{\boldsymbol{u} \in \mathbb{N}^{n} \mid \boldsymbol{x}^{\boldsymbol{u}} \in \mathfrak{a}\right\}
$$

be the semigroup associated with $\mathfrak{a}$. The Newton polyhedron of $\mathfrak{a}, P_{\mathfrak{a}}$, is defined to be the convex hull of $\Gamma_{\mathfrak{a}}$. A face $Q$ of $P_{\mathfrak{a}}$ refers to (a) $P_{\mathfrak{a}}$ itself, or (b) the intersection of an affine hyperplane $H$ and $P_{\mathfrak{a}}$ with $P_{\mathfrak{a}}$, where $P_{\mathfrak{a}}$ lie in one of the half space given $H$. We call a face of (b) type a proper face.

Let $\boldsymbol{e}=(1,1, \ldots, 1) \in \mathbb{N}^{n}$. If $Q$ is a face, let

$$
M_{Q}:=\boldsymbol{e}+\mathbb{N}\left\{\boldsymbol{u}-\boldsymbol{v} \mid \boldsymbol{u} \in \Gamma_{\mathfrak{a}}, \boldsymbol{v} \in \Gamma_{\mathfrak{a}} \cap Q\right\}
$$

be the translation of the semigroup generated by $\boldsymbol{u}-\boldsymbol{v}, \boldsymbol{u} \in \Gamma_{\mathfrak{a}}, \boldsymbol{v} \in Q \cap \Gamma_{\mathfrak{a}}$ by $\boldsymbol{e}$. Take $M_{Q}^{\prime}=\boldsymbol{v}_{0}+M_{Q}$, where $\boldsymbol{v}_{0} \in Q \cap \Gamma_{\mathfrak{a}} . M_{Q}^{\prime}$ does not depend on the choice of $\boldsymbol{v}_{0}$. If $Q$ is not contained in any coordinate hyperplane, there is some linear function $L_{Q}$ over $\mathbb{R}^{n}$ s.t. $\left.L\right|_{Q} \equiv 1$. Let $V_{Q}$ denote the linear span of $Q$, then $L_{Q}$ is uniquely determined on $V_{Q}$. Hence the set

$$
R_{Q}:=\left\{-L_{Q}(u) \mid u \in\left(M_{Q} \backslash M_{Q}^{\prime}\right) \cap V_{Q}\right\}
$$

is well-defined.
Particularly, if $Q$ is a facet i.e. $\operatorname{codim} Q=1$, then $V_{Q}=\mathbb{R}^{n}$ and hence $L_{Q}$ is unique. Let $m_{Q}$ be the minimal positive integer such that the coefficients of $m_{Q} L_{Q}$ are all integers.

The following are Theorem 1.1 and Theorem 1.2 of $\mathrm{BMS06c}$.
Theorem 2.14. The roots of the Bernstein-Sato polynomial of $\mathfrak{a}$ is the union of all $R_{Q}$, where $Q$ runs through all faces not contained in any coordinate hyperplanes.

Theorem 2.15. The set of classes in $\mathbb{Q} / \mathbb{Z}$ of the roots of the Bernstein-Sato polynomial of $\mathfrak{a}$ is equal to the union of subgroups generated by $\frac{1}{m_{Q}}$, with $Q$ running over the facets of $P_{\mathfrak{a}}$ that are not contained in any coordinate hyperplanes.

We give an example of Theorem $\mathbf{2 . 1 4}$.
Example 2.16. Let $\mathfrak{a}=\left(x^{a_{1}} y^{b_{1}}, x^{a_{2}} y^{b_{2}}\right) \subseteq \mathbb{C}[x, y]$ be a monomial ideal, where $a_{1}<a_{2}$ and $b_{1}>b_{2}$. There are five proper faces of $P_{\mathfrak{a}}$. They are $L$, the diagonal, $X$ the horizontal, $Y$ the vertical, and points $P_{1}, P_{2}$.

The linear function $L_{L}$ defined by $L$ is

$$
L_{L}(x, y)=-\frac{b_{2}-b_{1}}{b_{1} a_{2}-a_{1} b_{2}} x+\frac{a_{2}-a_{1}}{b_{1} a_{2}-a_{1} b_{2}} y
$$

We have $M_{L}=(1,1)+\mathbb{N}^{2}+\mathbb{Z}\left(a_{1}-a_{2}, b_{1}-b_{2}\right)$. After a elementary calculation, one finds $M_{L} \backslash M_{L}^{\prime}$ consisting of those points $(s+1, t+1)+\mathbb{Z}\left(a_{1}-a_{2}, b_{1}-b_{2}\right), s, t \geq 0$ such that

$$
\mathbb{Z} \cap\left[\frac{t-b_{1}}{b_{2}-b_{1}}, \frac{s-a_{1}}{a_{2}-a_{1}}\right]=\varnothing
$$

Consequently, $R_{L}$ is provided.
For $X$ and $Y$, one may find they contribute to $W_{\mathfrak{a}}$ the following roots.

$$
\frac{1}{a_{1}}, \ldots, \frac{a_{1}-1}{a_{1}}, \ldots, 1, \frac{1}{b_{2}}, \ldots, \frac{b_{2}-1}{b_{2}}, 1
$$

For $P_{1}$ and $P_{2}, L_{P_{1}}$ can be chosen as $\frac{x}{a_{1}}$. It is easy to see all $M_{P_{1}} \cap V_{Q} \cap\left\{x \geq a_{1}\right\} \subseteq M_{P_{1}}^{\prime}$. Then no new roots emerge. A similar result holds for $P_{2}$.

In particular if $\left(a_{1}, b_{1}, a_{2}, b_{2}\right)=(0, b, a, 0)$, we have

$$
\begin{aligned}
L_{L} & =\frac{x}{a}+\frac{y}{b} \\
M_{L} \backslash M_{L}^{\prime} & =\{(s+1, t+1) \mid 0 \leq s<a, 0 \leq t<b\}+\mathbb{Z}(-a, b), \\
R_{L} & =\left\{\left.-\frac{a i+b j}{a b} \right\rvert\, 1 \leq i \leq b, 1 \leq j \leq a\right\} .
\end{aligned}
$$

Hence, for $\mathfrak{a}=\left(x^{a}, y^{b}\right)$, we have

$$
W_{\mathfrak{a}}=\left\{\left.-\frac{a i+b j}{a b} \right\rvert\, 1 \leq i \leq b, 1 \leq j \leq a\right\}
$$

## 3. Tensor Property of Bernstein-Sato Polynomials

3.1. Probable Motivations. Let $f \in \mathbb{C}[\boldsymbol{x}]$ and $g \in \mathbb{C}[\boldsymbol{y}]$ be two non-zero polynomials. It is obvious that $b_{f \cdot g}(s)$ is a divisor of $b_{f}(s) \cdot b_{g}(s)$ since if $P_{f} \in \mathbb{C}\left[\boldsymbol{x}, \boldsymbol{\partial}_{\boldsymbol{x}}, s\right]$ and $P_{g} \in \mathbb{C}\left[\boldsymbol{y}, \boldsymbol{\partial}_{\boldsymbol{y}}, s\right]$ satisfies

$$
P_{f} \cdot f^{s+1}=b_{f}(s) \cdot f^{s}, P_{g} \cdot g^{s+1}=b_{g}(s) \cdot g^{s}
$$

then we have

$$
\left(P_{f} \cdot P_{g}\right) \cdot(f \cdot g)^{s+1}=b_{f}(s) b_{g}(s) \cdot(f \cdot g)^{s}
$$

So one may be interested in the converse divisibility. In our preliminary work, we proved at least $(s+1)$ timing $\operatorname{lcm}\left(b_{f}(s), b_{g}(s)\right)$ is a divisor i.e.

$$
(s+1) \operatorname{lcm}\left(b_{f}(s), b_{g}(s)\right) \mid b_{f \cdot g}(s) .
$$

Hence, if we only consider the cases when $f$ and $g$ are weighted homogeneous with isolated singularity, and all denominators of weights of $f, g$ are coprime, we have $b_{f}(s) b_{g}(s)=b_{f \cdot g}(s)$ by Theorem 2.10

Another motivation seems more profound. We further assume coefficients of $f$ and $g$ are rational integers. Then we have a trivial relation among zeta functions:

$$
Z_{p}(f \cdot g ; s)=Z_{p}(f ; s) \cdot Z_{p}(g ; s) .
$$

If the strong monodromy conjecture, especially the assertion about the multiplicity, holds, it is natural to ask if $b_{f \cdot g}(s)=b_{f}(s) \cdot b_{g}(s)$.
3.2. Proof of $b_{f}(s) b_{g}(s)=b_{f \cdot g}(s)$. In this subsection, we give a positive answer to a generalized version of " $b_{f}(s) b_{g}(s)=b_{f \cdot g}(s)$ ". More precisely, we generalized polynomials $f, g$ to effective divisors on non-singular varieties. We first prove a simple lemma below.

Lemma 3.1. Let $R$ be a PID and $M, N$ be free $R$-modules. Suppose $M_{1}, M_{2} \subseteq M$ and $N_{1}, N_{2} \subseteq$ $N$ are submodules (hence free). For free submodules $M^{\prime} \subseteq M$ and $N^{\prime} \subseteq N$, we have canonical injection $M^{\prime} \otimes N^{\prime} \rightarrow M \otimes N$, and hence identify $M^{\prime} \otimes N^{\prime}$ with its image in $M \otimes N$. In this sense, we have the following identity:

$$
\left(M_{1} \cap M_{2}\right) \otimes\left(N_{1} \cap N_{2}\right)=\bigcap_{i, j \in\{1,2\}}\left(M_{i} \otimes N_{j}\right) .
$$

Proof. Let us first prove the following:

$$
\begin{equation*}
\left(M_{1} \otimes N_{1}\right) \cap\left(M_{2} \otimes N_{1}\right)=\left(M_{1} \cap M_{2}\right) \otimes N_{1} . \tag{3.1.1}
\end{equation*}
$$

Since $N_{1}$ is free, we set $N_{1}=A^{\oplus Q}$. Take a basis $\left\{b_{i}\right\}_{i \in Q}$ of $N_{1}$, then elements of $M \otimes N_{1}$ can be uniquely written in a finite sum $\sum_{i \in Q} m_{i} \otimes b_{i}, m_{i} \in M$. Then one can easily deduce (3.1]1).

In parallel, we have

$$
\left(M_{1} \otimes N_{2}\right) \cap\left(M_{2} \otimes N_{2}\right)=\left(M_{1} \cap M_{2}\right) \otimes N_{2} .
$$

Applying the same argument to ( $M_{1} \cap M_{2}$ ) (also free), $N_{1}$, and $N_{2}$, we are done.
Theorem 3.2. Suppose $A$ and $B$ are finitely generated integral regular $k$-algebras. $C=A \otimes_{\mathbb{C}} B$ is the tensor product, with $f \in A$ and $g \in B$ non-zero. Let $b_{f}(s), b_{g}(s), b_{f \cdot g}(s)$ be the corresponding Bernstein-Sato polynomials, then the following equality holds.

$$
b_{f \cdot g}(s)=b_{f}(s) b_{g}(s) .
$$

Here we use $\cdot$ instead of $\otimes$ in the multiplication of $C$.
Remark 3.3. One side of the division i.e. $b_{f . g}(s) \mid b_{f}(s) b_{g}(s)$ is trivial since we simply need to multiplicate the operators to attain $b_{f}(s)$ and $b_{g}$. Hence, we only need to consider the other side of the division. Moreover, the case with $f$ or $g$ invertible is trivial, so we may assume $f$ and $g$ are both non-invertible.

Proof. As in Subsection 2.2, we define $I_{j} \subseteq A[s]$ to be an ideal such that

$$
F_{j} D(A) f^{s+1}=I_{j} \cdot f^{s+1-j} .
$$

Similarly, we define $J_{j} \subseteq B[s]$ and $L_{j} \subseteq C[s]$ for $F_{j} D(B) \cdot g^{s}$ and $F_{j} D(C) \cdot(f \cdot g)^{s}$ respectively. Furthermore, we define $\mathbb{C}[s]$-modules

$$
\begin{aligned}
M_{i} & :=I_{i} \cdot f^{-i+1} \subseteq A_{f}[s] \\
N_{j} & :=J_{j} \cdot g^{-j+1} \subseteq B_{g}[s] \\
\Lambda_{l} & :=L_{l} \cdot(f \cdot g)^{-l+1} \subseteq C_{f \cdot g}[s]
\end{aligned}
$$

Since $I_{j} \supseteq I_{j-1} \cdot f$, we see $M_{j} \supseteq M_{j-1}$. Similarly, we have $N_{j} \supseteq N_{j-1}$ and $L_{l} \supseteq N_{l-1}$. By definition, we obtain a way to characterize the Bernstein-Sato polynomials as

$$
\begin{aligned}
b_{f}(s) \cdot \mathbb{C}[s] & =\bigcup_{i=1}^{\infty}\left(\mathbb{C}[s] \cap M_{i}\right) \\
b_{g}(s) \cdot \mathbb{C}[s] & =\bigcup_{j=1}^{\infty}\left(\mathbb{C}[s] \cap N_{j}\right) \\
b_{f \cdot g}(s) \cdot \mathbb{C}[s] & =\bigcup_{l=1}^{\infty}\left(\mathbb{C}[s] \cap \Lambda_{l}\right)
\end{aligned}
$$

It is worth mentioning that the intersections happen in $A_{f}[s], B_{g}[s]$, and $C_{f \cdot g}[s]$, where $\mathbb{C}[s]$ can be naturally embedded. The identities tell us that for all $i, j, l \gg 0$, we have

$$
M_{i} \cap \mathbb{C}[s]=b_{f}(s) \cdot \mathbb{C}[s], \quad N_{i} \cap \mathbb{C}[s]=b_{g}(s) \cdot \mathbb{C}[s], \quad \Lambda_{l} \cap \mathbb{C}[s]=b_{f \cdot g}(s) \cdot \mathbb{C}[s]
$$

Since $\operatorname{Der}_{\mathbb{C}} C=\left(\operatorname{Der}_{\mathbb{C}}(A) \otimes \mathbb{C} B\right) \oplus\left(A \otimes_{\mathbb{C}} \operatorname{Der}_{\mathbb{C}}(B)\right)$ i.e. derivations of $C$ are induced by those of $A$ and $B$. Since derivations of $A$ and $B$ commutes, we have the following identity:

$$
F_{l} D(C)=\sum_{i+j=l} F_{i} D(A) \cdot F_{j} D(B)
$$

Here we identify $F_{i} D(A)$ and $F_{j} D(B)$ with their images under canonical embeddings $F_{i} D_{A} \hookrightarrow$ $F_{i} D_{C}$ and $F_{j} D_{B} \hookrightarrow F_{j} D_{C}$. As a result, we have a subsequent identity for $I_{i}, J_{j}$ and $L_{l}$ as below:

$$
L_{l}=\sum_{i+j=l} f^{l-i} \cdot I_{i} \cdot g^{l-j} \cdot J_{j}
$$

Dividing $(f \cdot g)^{l-1}$ on both sides, we have

$$
\Lambda_{l}=\sum_{i+j=l} M_{i} \cdot N_{j} \subseteq M_{l} \cdot N_{l} \subseteq C_{f \cdot g}[s]
$$

Take $l \in \mathbb{N}$ sufficiently large, such that

$$
\Lambda_{l} \cap \mathbb{C}[s]=b_{f \cdot g}(s) \cdot \mathbb{C}[s], \quad M_{l} \cap \mathbb{C}[s]=b_{f}(s) \cdot \mathbb{C}[s], \quad N_{l} \cap \mathbb{C}[s]=b_{g}(s) \cdot \mathbb{C}[s]
$$

It suffices to prove $\left(M_{l} \cdot N_{l}\right) \cap \mathbb{C}[s]=b_{f}(s) b_{g}(s) \cdot \mathbb{C}[s]$. As a result, we have $\Lambda_{l} \cap[s] \subseteq$ $b_{f}(s) b_{g}(s) \cdot \mathbb{C}[s]$ i.e. $b_{f}(s) b_{g}(s)$ divides $b_{f \cdot g}(s)$. Now let us focus on the category of $\mathbb{C}[s]$-modules.

The following two diagrams are Cartesian products.

All of the eight arrows are $\mathbb{C}[s]$-module injections. Tensoring ( $\mathbb{C}[s]$-module tensor) the two squares, we have a commutative diagram.

A simple observation shows $M_{l}, N_{l}, A_{f}[s]$ and $B_{g}[s]$ are all $\mathbb{C}[s]$-free modules. In fact, $A_{f}[s]=$ $A_{f} \otimes \mathbb{C}[s]$ is a linear space tensored with $\mathbb{C}[s]$, and hence free. Moreover, since $\mathbb{C}[s]$ is a PID and $M_{l}$ is a $\mathbb{C}[s]$-submodule of $A_{f}[s], M_{l}$ is also free. Similarly, $N_{l}$ and $B_{g}[s]$ are both free. Consequently, one deduce the four arrows in the diagram above are all injections.

Under the canonical isomorphism $A_{f}[s] \otimes_{\mathbb{C}[s]} B_{g}[s] \simeq C_{f \cdot g}[s]$, the diagram above is identified with the following.

Therefore, to prove Theorem 3.2, we only need to show (3.2, 1) is a Cartesian product.
Applying Lemma 3.1, we have:

$$
\left(b_{f}(s) \cdot \mathbb{C}[s]\right) \otimes_{\mathbb{C}[s]}\left(b_{g}(s) \cdot \mathbb{C}[s]\right)=\left(M_{l} \otimes_{\mathbb{C}[s]} N_{l}\right) \cap\left(\mathbb{C}[s] \otimes_{\mathbb{C}[s]} \mathbb{C}[s]\right) \cap\left(M_{l} \otimes_{\mathbb{C}[s]} \mathbb{C}[s]\right) \cap\left(\mathbb{C}[s] \otimes_{\mathbb{C}[s]} N_{l}\right)
$$

Since all arrows in (3.2.1) are injective, it suffices to show

$$
\begin{equation*}
\left(M_{l} \otimes_{\mathbb{C}[s]} N_{l}\right) \cap\left(\mathbb{C}[s] \otimes_{\mathbb{C}[s]} \mathbb{C}[s]\right) \subseteq M_{l} \otimes_{\mathbb{C}[s]} \mathbb{C}[s] \tag{3.2.2}
\end{equation*}
$$

And similarly, the corresponding containing holds for $N_{l}$. As a result (3.2, 1) is a Cartesian product.

To prove (3.2 2), we use the canonical isomorphism $A_{f}[s] \otimes_{\mathbb{C}[s]} B_{g}[s] \simeq C_{f . g}[s]$ to pass everything to $C_{f . g}[s]$. It is equivalent to show

$$
\left(M_{l} \cdot N_{l}\right) \cap \mathbb{C}[s] \subseteq M_{l} .
$$

Let $\sum_{i} a_{i} \cdot f^{-l+1} \cdot b_{i} \cdot g^{-l+1}=c$ be an element in the left-hand side, where $a_{i} \in I_{l}, b_{i} \in J_{l}$, and $c(s) \in \mathbb{C}[s]$. That is,

$$
\begin{equation*}
\sum_{i} a_{i} b_{i}=c(s)(f \cdot g)^{l-1} \tag{3.2,3}
\end{equation*}
$$

The equality happens in $C[s]$.
We will localize $B$ to show $c(s) \in M_{l}$. Let $\mathfrak{m}_{y} \subset B$ be a maximal ideal such that $g \in \mathfrak{m}_{y}$ and $\boldsymbol{y}=\left(y_{1}, \ldots, y_{m}\right)$ be a set of local coordinates of $B$ at $\mathfrak{m}_{y}$. Let $\tilde{B}=B_{\mathfrak{m}_{y}}$ be the localization and we still write $\mathfrak{m}_{y}$ the maximal ideal of $\tilde{B}$. Tensoring $A$ and $\mathbb{C}[s]$ to the natural embedding $B \hookrightarrow \tilde{B}$, we have $C[s] \hookrightarrow\left(A \otimes_{\mathbb{C}} \tilde{B}\right) \otimes_{\mathbb{C}} \mathbb{C}[s]=\left(A \otimes_{\mathbb{C}} \tilde{B}\right)[s]$. Suppose the order of $g$ in $\tilde{B}$ is $t>0$ i.e. $g \in \mathfrak{m}_{y}^{t}$ but $g \notin \mathfrak{m}_{y}^{t-1}$. Since $B$ is a regular local ring, we have

$$
\operatorname{gr}_{\mathfrak{m}_{y}} \tilde{B}=\bigoplus_{j \geq 0} \mathfrak{m}_{y}^{j} / \mathfrak{m}_{y}^{j+1}
$$

is isomorphic to the polynomial ring of $m$-variables, with indeterminants being images of $\boldsymbol{y}$ in $\operatorname{gr}_{\mathfrak{m}_{y}} \tilde{B}$. Suppose $\boldsymbol{y}^{\alpha}$ appears in $g$ i.e. in the image of $g$ in $\tilde{B} / \mathfrak{m}_{y}^{t+1}=\bigoplus_{0 \leq j \leq t} \mathfrak{m}_{y}^{j} / \mathfrak{m}_{y}^{j+1}$. We may assume the coefficient of $\boldsymbol{y}^{\alpha}$ is 1 .

Let us treat (3.2],3) in $\left(A \otimes_{k} \tilde{B}\right)[s]$. Moduling $\mathfrak{m}_{y}^{(l-1) t+1}$, we know the identity also holds in $A[s] \otimes_{\mathbb{C}[s]}\left(\tilde{B} / \mathfrak{m}_{y}^{(l-1) t+1}\right)[s]$. Since $\left(\tilde{B} / \mathfrak{m}_{y}^{(l-1) t+1}\right)[s]$ is a $\mathbb{C}[s]$-free module, we can still compare the coefficient of $\boldsymbol{y}^{(l-1) \alpha}$ on both sides (coefficients in $\left.A[s]\right)$. On one hand, the coefficient of $\boldsymbol{y}^{(l-1) \boldsymbol{\alpha}}$ in the right-hand side is $c(s) f^{l-1}$. On the other hand, suppose the coefficient of $\boldsymbol{y}^{(l-1) \boldsymbol{\alpha}}$ in $b_{i}$ is $\tilde{b}_{i}(s) \in \mathbb{C}[s]$. Hence, we have $\sum_{i} \tilde{b}_{i}(s) a_{i}=c(s) f^{l-1}$. Consequently, $c(s)=f^{-l+1} \cdot\left(\sum_{i} \tilde{b}_{i}(s) a_{i}\right) \in$ $M_{l}$. We are done.

This theorem immediately implies the following.
Corollary 3.4. Suppose $f \in \mathbb{Z}[\boldsymbol{x}]$ and $g \in \mathbb{Z}[\boldsymbol{y}]$ are non-zero polynomials. Suppose strong monodromy conjecture (Conjecture [2.11) holds for $f$ and $g$, then it also holds for $f \cdot g \in \mathbb{Z}[\boldsymbol{x}, \boldsymbol{y}]$.

As another corollary, we can generalize the theorem for affine varieties to a global theorem. We first define the tensor of divisors, as a generalization of $f \cdot g$.

Definition 3.5. Suppose $X_{1}, X_{2}$ are non-singular complex varieties and $D_{1}, D_{2}$ are effective Cartier divisors on $X_{1}, X_{2}$. We define $D_{1} \otimes D_{2}$ to be an effective Cartier divisor on $X_{1} \times X_{2}$, as follows. Take affine coverings $\left\{U_{i}\right\},\left\{V_{j}\right\}$ of $X_{1}$ and $X_{2}$ respectively, such that $D_{1}$ is represented by $f_{i}$ on $U_{i}$ and $D_{2}$ is represented by $g_{j}$ on $V_{j}$. Define $D_{1} \otimes D_{2}$ to be the Cartier divisor represented by $f_{i} \otimes g_{j}$ on each $U_{i} \times V_{j}$.

Theorem 3.6. Suppose $X_{1}$ and $X_{2}$ non-singular complex varieties and $D_{1}, D_{2}$ are effective Cartier divisors on $X_{1}, X_{2}$, then we have

$$
b_{D_{1} \otimes D_{2}}(s)=b_{D_{1}}(s) \cdot b_{D_{2}}(s) .
$$

Proof. As in Definition 3.5, take open affine coverings $\left\{U_{i}\right\},\left\{V_{j}\right\}$. By Theorem 3.2, we have

$$
b_{D_{1} \otimes D_{2} \mid U_{i} \times V_{j}}(s)=b_{D_{1} \mid U_{i}}(s) \cdot b_{\left.D_{2}\right|_{V_{j}}}(s) .
$$

Since $X_{1} \times V_{j}=\bigcup_{i} U_{i} \times V_{j}$, we have

$$
b_{\left.D_{1} \otimes D_{2}\right|_{X \times V_{j}}}(s)=\underset{i}{\operatorname{lcm}} b_{\left.D_{1}\right|_{U_{i}}}(s) \cdot b_{\left.D_{2}\right|_{V_{j}}}(s)=\left[\underset{i}{\operatorname{cm}} b_{D_{1} \mid U_{i}}(s)\right] \cdot b_{D_{2} \mid V_{j}}(s)=b_{D_{1}}(s) \cdot b_{\left.D_{2}\right|_{V_{j}}}(s) .
$$

Furthermore, by $X_{1} \times X_{2}=\bigcup_{j} X_{1} \times V_{j}$, we have

$$
b_{D_{1} \otimes D_{2}}(s)=\operatorname{lcm}_{j} b_{D_{1}}(s) \cdot b_{D_{2} \mid V_{j}}(s)=b_{D_{1}}(s) \cdot\left[\operatorname{lcm}_{j} b_{D_{2} \mid V_{j}}(s)\right]=b_{D_{1}}(s) \cdot b_{D_{2}}(s) .
$$

So we are done.
3.3. Generalization to Ideals. Having done the problem about the product of two regular functions, it is natural to ask the following.

Question 3.7. For $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$, is $b_{\mathfrak{a} \cdot \mathfrak{b}}(s)=b_{\mathfrak{a}}(s) \cdot b_{\mathfrak{b}}(s)$ ?
The general answer is no. Here is a counter-example.
Example 3.8. Consider $\mathfrak{a}=\left(x^{2}, y^{7}\right) \subseteq \mathbb{C}[x, y]$ and $\mathfrak{b}=\left(z^{14}, w\right) \subset \mathbb{C}[z, w]$. By Example [2.16. we have

$$
\begin{aligned}
W_{\mathfrak{a}} & =\left\{\left.\frac{7 i+2 j}{14} \right\rvert\, 1 \leq i \leq 2,1 \leq j \leq 7\right\}, \\
W_{\mathfrak{b}} & =\left\{\left.1+\frac{j}{14} \right\rvert\, 1 \leq j \leq 14\right\} .
\end{aligned}
$$

By Theorem 2.14, considering the product of the two diagonals, we have $\frac{15}{7}$ is contained in $W_{\mathfrak{a b}}$.

But, if $\mathfrak{a}$ or $\mathfrak{b}$ is principal, we have the following.
Proposition 3.9. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ be an ideal and $g \in \mathbb{C}[\boldsymbol{y}]$, then $b_{\mathfrak{a}} b_{g}=b_{\mathfrak{a} \cdot(g)}$.
Proof. By Theorem 2.12, $b_{\mathfrak{a}}=b_{h} /(s+1)$, where $h=\sum f_{i} z_{i}, \boldsymbol{z}$ are indeterminants. Again by Theorem 2.12, $b_{\mathfrak{a} \cdot(g)}=b_{h^{\prime}} /(s+1)$, where $h^{\prime}=\sum f_{i} g z_{i}$. Applying Theorem 3.2, we get $b_{h^{\prime}}=b_{g} b_{h}$, hence $b_{\mathfrak{a} \cdot(g)}=b_{\mathfrak{a}} b_{g}$.

If we neglect the multiplicity of roots, there are still some interesting things. Let $W_{\mathfrak{n}}$ be the roots of $b_{\mathfrak{n}}$ for an ideal $\mathfrak{n}$ contained in some polynomial ring. We find the following.

Theorem 3.10. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero monomial ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}} \subseteq W_{\mathfrak{a b}}
$$

Despite the sets of roots are not equal totally, it is surprising that they are equal when modulo $\mathbb{Z}$. More precisely, we have the following.

Theorem 3.11. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero monomial ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}}=W_{\mathfrak{a b}} \quad \bmod \mathbb{Z}
$$

We need some preparations before proving the theorem.
For the convenience of further discussion, we shall first develop some properties of Newton polyhedron of the product ideal of two monomial ideals. The ideals considered are all non-trivial.

Let $\mathfrak{a} \triangleleft \mathbb{C}\left[x_{1}, x_{2}, \ldots, x_{n}\right], \mathfrak{b} \triangleleft \mathbb{C}\left[y_{1}, y_{2}, \ldots, y_{m}\right]$ be monomial ideals. Suppose

$$
\begin{aligned}
\mathfrak{a} & =\left(\boldsymbol{x}^{\boldsymbol{v}_{i}}\right), \boldsymbol{v}_{i}=\left(v_{i}^{1}, \ldots, v_{i}^{n}\right) \in \mathbb{N}^{n}, i=1,2, \ldots, r, \text { and } \\
\mathfrak{b} & =\left(\boldsymbol{y}^{\boldsymbol{w}_{i}}\right), \boldsymbol{w}_{i}=\left(w_{i}^{1}, \ldots, w_{i}^{m}\right), i=1,2, \ldots, s
\end{aligned}
$$

We have the following lemma.
Lemma 3.12. (a) $\Gamma_{\mathfrak{a b}}=\Gamma_{\mathfrak{a}} \times \Gamma_{\mathfrak{b}}$.
(b) $P_{\mathfrak{a b}}=P_{\mathfrak{a}} \times P_{\mathfrak{b}}$.
(c) Faces of $P_{\mathfrak{a b}}$ are exactly those of $Q_{1} \times Q_{2}$, where $Q_{1}\left(\right.$ resp. $Q_{2}$ ) is a face of $P_{\mathfrak{a}}$ (resp. $P_{\mathfrak{b}}$ ).
(d) For face $Q_{1}$ of $P_{\mathfrak{a}}$ and $Q_{2}$ of $P_{\mathfrak{b}}$, we have

$$
M_{Q_{1} \times Q_{2}} \backslash M_{Q_{1} \times Q_{2}}^{\prime}=\left[\left(M_{Q_{1}} \backslash M_{Q_{1}}^{\prime}\right) \times M_{Q_{2}}\right] \cup\left[M_{Q_{1}} \times\left(M_{Q_{2}} \backslash M_{Q_{2}}^{\prime}\right)\right]
$$

Proof. We only prove (c) since (a)(b) are trivial and (d) is merely a calculation for sets.
It suffices to consider proper faces. Let $H$ be a hyperplane such that one of the corresponding half spaces contains $P_{\mathfrak{a b}}$. Suppose $H$ is defined by the equation:

$$
\lambda_{1} x_{1}+\ldots \lambda_{n} x_{n}+\mu_{1} y_{1}+\ldots+\mu_{m} y_{m}-C=0
$$

It is easy to find that all $\lambda_{i}, \mu_{j}, C \in \mathbb{Q}$ have the same sign since there exists positive integer $R$ sufficiently large s.t. $(R, R, \ldots, R)+\mathbb{Z}_{\geq 0} \subset P_{\mathfrak{a b}}$ and difference of signs among $\left\{\lambda_{i}, \mu_{j}\right\}$ implies that $P_{\mathfrak{a b}}$ does not lies in one side of $H$, a contradiction. We may assume $\lambda_{i}, \mu_{j}>0$ for all $i, j$, then the nonemptiness of $H \cap P_{\mathfrak{a b}}$ implies $C>0$. Since the minimum of $X=\lambda_{1} x_{1}+\ldots \lambda_{n} x_{n}$ and $Y=\mu_{1} y_{1}+\ldots+\mu_{m} y_{m}$ can be attained in $P_{\mathfrak{a}}$ and $P_{\mathfrak{b}}$ respectively, denoted by $C_{1}$ and $C_{2}$, then we have $C=C_{1}+C_{2}$ and $H \cap P_{\mathfrak{a b}}=H_{1} \times H_{2}$, where $H_{1}$ (resp. $H_{2}$ ) is the face determined by $X-C_{1}$ (resp. $Y-C_{2}$ ).

The following is the proof of Theorem $\mathbf{3 . 1 0}$.

Proof. For any proper face $Q$ of $P_{\mathfrak{a}}$ which is not contained in any coordinate hyperplane, $Q \times P_{\mathfrak{b}}$ is a proper face of $P_{\mathfrak{a b}}$. It is not contained in any coordinate hyperplane as well. Let $L_{Q}$ be a linear function on $\mathbb{R}^{n}$ s.t. $\left.L_{Q}\right|_{Q} \equiv 1$, then $L_{Q}$ is naturally extended to a linear function whose restriction on $Q \times P_{\mathfrak{b}}$ is 1 . One can see $M_{Q \times P_{\mathfrak{b}}}=\left(M_{Q} \backslash M_{Q}^{\prime}\right) \times \mathbb{Z}^{m}$ by Lemma 3.12 and the simple fact that $M_{P_{\mathfrak{a}}}=\mathbb{Z}^{m}$. Since the linear span of $Q \times P_{\mathfrak{b}}$ is $V_{Q} \times \mathbb{R}^{m}$, we have $R_{Q \times P_{\mathfrak{b}}}=R_{Q}$. Therefore, by Theorem $\mathbf{2 . 1 4}$ roots of $b_{\mathfrak{a}}$ are contained in those of $b_{\mathfrak{a}}$. Symmetrically, roots of $b_{\mathfrak{b}}$ are also contained in $W_{\mathfrak{a b}}$.

Remark 3.13. Through the preceding proof, we can see $b_{\mathfrak{a b}}$ can have roots other than those of $b_{\mathfrak{a}}$ and $b_{\mathfrak{b}}$ since it has faces other than those of the form $Q \times P_{\mathfrak{b}}$ and $P_{\mathfrak{a}} \times Q$. This is why we construct Example 3.8

The following is the proof of Theorem 3.11.
Proof. By Theorem 3.11, it suffices to show all facets of $P_{\mathfrak{a}} \times P_{\mathfrak{b}}$ are exactly those of the form $Q_{1} \times P_{\mathfrak{b}}$ or $P_{\mathfrak{a}} \times Q_{2}$, where $Q_{1}, Q_{2}$ are facets since we have shown in the proof of Theorem 3.10 that $R_{Q_{1} \times P_{\mathfrak{a}}}=R_{Q_{1}}$ and $R_{P_{\mathfrak{b}} \times Q_{2}}=R_{Q_{2}}$.

Suppose $Q_{1} \subseteq P_{\mathfrak{a}}$ and $Q_{2} \subseteq P_{\mathfrak{b}}$ are both proper faces. By the following lemma, we have

$$
\operatorname{dim} V_{Q_{1} \times Q_{2}} \leq \operatorname{dim} V_{Q_{1}}+\operatorname{dim} V_{Q_{2}}-1<n+m
$$

Therefore, the dimension of $V_{Q_{1} \times Q_{2}}$ is $n+m-1$. If $Q_{1} \times Q_{2}$ is a facet, it must pass through the origin. However, this tells us that $Q_{1} \times Q_{2}$ is contained in some coordinate hyperplane. Otherwise, one can see the dimension of the linear span of $\mathbb{R}_{\geq 0}^{m+n} \cap Q_{1} \times Q_{2}<m+n-1$. So we are done.

Lemma 3.14. For affine hyperplanes $Q_{1} \in \mathbb{R}^{n}$ and $Q_{2} \in \mathbb{R}^{m}$, then the dimension of the linear space generated by $Q_{1} \times Q_{2}$ is not greater than $n+m-1$.

Proof. We may assume both $Q_{1}$ and $Q_{2}$ do not pass through the origin, since otherwise we can replace the total space with $Q_{i}$. Let $Q_{i}=Q_{i}^{\prime}+w_{i}$, where $Q_{i}^{\prime}$ passes through the origin and $w_{i} \in Q_{i}$. Let $u_{1}, u_{2}, \ldots, u_{n-1}$ be a basis of $Q_{1}^{\prime}$ and $v_{1}, v_{2}, \ldots, v_{m-1}$ be a basis of $Q_{2}^{\prime}$. Then every point in $Q_{1}$ can be written uniquely in the form $\sum a_{i} u_{i}$ with $\sum a_{i}=1$. A similar result holds for $Q_{2}$. One can easily deduce that $Q_{1} \times Q_{2}$ is contained in the linear space generated by $\left(u_{i}, v_{j}\right)_{1 \leq i \leq n-1,1 \leq j \leq m-1}$. Furthermore, the following is a basis of this space:

$$
\left(u_{1}, v_{1}\right)\left(u_{2}, v_{1}\right) \ldots\left(u_{n-1}, v_{1}\right)\left(u_{n-1}, v_{2}\right) \ldots\left(u_{n-1}, v_{m-1}\right)
$$

Hence we have the result.
Taking both Proposition 3.9, Theorem 3.10, and Theorem 3.11 into consideration, we hence make the following conjecture.

Conjecture 3.15. Let $\mathfrak{a} \subseteq \mathbb{C}[\boldsymbol{x}]$ and $\mathfrak{b} \subseteq \mathbb{C}[\boldsymbol{y}]$ be non-zero ideals, then

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}} \subseteq W_{\mathfrak{a b}}
$$

Moreover, we have

$$
W_{\mathfrak{a}} \cup W_{\mathfrak{b}}=W_{\mathfrak{a} \mathfrak{b}} \quad \bmod \mathbb{Z}
$$
