Zero, Finite, and Infinite Belief History of Theory of Mind Reasoning in Large Language Models

Weizhi Tang University of Edinburgh Weizhi.Tang@ed.ac.uk

Abstract

Large Language Models (LLMs) have recently shown a promise and emergence of Theory of Mind (ToM) ability and even outperform humans in certain ToM tasks. To evaluate and extend the boundaries of the ToM reasoning ability of LLMs, we propose a novel concept, taxonomy, and framework, the ToM reasoning with Zero, Finite, and Infinite Belief History and develop a multi-round text-based game, called Pick the Right Stuff, as a benchmark. We have evaluated six LLMs with this game and found their performance on Zero Belief History is consistently better than on Finite Belief History. In addition, we have found two of the models with small parameter sizes outperform all the evaluated models with large parameter sizes. We expect this work to pave the way for future ToM benchmark development and also for the promotion and development of more complex AI agents or systems which are required to be equipped with more complex ToM reasoning ability¹.

1 Introduction

Theory of Mind (ToM) is the ability to understand, attribute, and infer the mental states of oneself and others to be able to represent how others perceive, interpret, reason, and respond to the surrounding world (Baron-Cohen et al., 1985; Premack and Woodruff, 1978; Quesque and Rossetti, 2020). In order for individuals to understand and reason about others' beliefs, intention, desires, emotions, obligations, and so on, the ability of ToM is essential (Premack and Woodruff, 1978; Frith and Frith, 2006; Quesque and Rossetti, 2020). And with the emergence and consistent advancement of Large Language Models (LLMs), they have demonstrated impressive and near-human-level capabilities in various tasks (Naveed et al., 2024; Wan et al., 2024; Vaishak Belle University of Edinburgh vbelle@ed.ac.uk

Wang et al., 2023b; Chang et al., 2023) and some studies have shown a promise and even an emergence of ToM reasoning ability in LLMs (Strachan et al., 2024; Kosinski, 2023; Jamali et al.; Moghaddam and Honey). Furthermore, since the essence of ToM is understanding and representing the mental states of others, for LLMs within its frequently mentioned and used situation, the question and answering (QA), correctly understanding the mental states, such as the intention of the users, is necessary and the key to efficiently generate appropriate, meaningful, and beneficial responses. Additionally, not only in the QA situation, LLMs are mentioned and used in various other scenarios, such as using LLMs as embodied agents (Zhang et al., 2024; Liu et al., 2023; Gallotta et al., 2024; Wang et al., 2023a), understanding the beliefs of other agents in environments is essential to act in a beneficial, safe, and helpful way for both themselves and other agents. Therefore, further exploration of the ToM ability of LLMs is necessary and meaningful.

In order to understand the ToM ability of LLMs, various benchmarks have been developed in different evaluation perspectives of the ToM ability of LLMs in previous work, such as that MindGames leverages dynamic epistemic logic to generate complex ToM problems including the k-order ToM reasoning and different problem contexts (Sileo and Lernould, 2023), Hi-ToM introduces a complex k-order ToM problems based on Sally-Anne-like stories, which further contain communications between agents (Wu et al., 2023), and FANToM introduces the ToM benchmark in a manner of interactions of agents and aligns the ToM problems more with real-world scenarios requiring ToM reasoning (Kim et al., 2023).

In this study, in order to further understand the ToM ability of LLMs, besides providing a textbased and multi-round game as a new benchmark to evaluate the ToM reasoning ability of LLMs in a complex and dynamic way, we have extended

¹Our source code of the study and benchmark is open source and available at https://anonymous.4open.science/r/Pick-the-Right-Stuff-B1F0.

the current boundaries of ToM ability evaluation range by introducing a novel concept, taxonomy, and framework of ToM evaluation, which is the ToM reasoning with Zero, Finite, and Infinite Belief History. This concept and taxonomy aim to provide a clear idea and structure for evaluating a specific aspect of ToM, the beliefs, in a more advanced and nuanced manner.

We give a brief explanation of the concept here and discuss it in more detail in Section 3. The Zero Belief History means that the test subject can identify the latest beliefs of others without needing to reason from the available or known belief history while the Finite Belief History means that the test subject should and have to utilize and reason with the known finite belief history to distinguish and identify the latest beliefs of others. In addition, since recent ToM benchmarks introduce more complex ToM problems which are even not comfortable for humans, such as the high k-order ToM problems mentioned by Sileo and Lernould (2023) and Wu et al. (2023), and because Strachan et al. (2024) shows LLMs, especially GPT-4 (OpenAI et al., 2024), sometimes can even outperform humans in ToM problems, we propose to not make the ToM evaluation of LLMs be constrained in humanlevel but to extend the boundaries to more complex ToM problems so that we may have confidence to put LLMs in situations which need more complex ToM reasoning. Thus, while we consider Zero and Finite Belief History to be reasonably solvable for humans, in addition to that, we further introduce the Infinite Belief History in which the test subject should maintain an infinite belief history, typically in the way of implicit patterns, and propose to discover and study it in future work.

In this study, we explain Zero, Finite, and Infinite Belief History in detail with examples. In addition, we have developed a game called Pick the *Right Stuff* as both a proof-of-concept benchmark and example for future work and an out-of-box benchmark to evaluate the ToM ability of LLMs in the case of Zero Belief History and Finite Belief History. We have also evaluated 6 LLMs, in which there are 3 models in large parameter sizes and 3 models in small parameter sizes. Unsurprisingly, all LLMs perform better under the condition of the Zero Belief History than the Finite Belief History case. In addition, an unexpected and supervising finding is that two of LLMs with the small parameter sizes outperform all the three LLMs with large parameter sizes in both of Zero Belief History and

Finite Belief History case, which may further bring up evidence and an answer to the question, whether increasing the sizes of the parameter of LLMs is necessary and effective to enhance model capabilities, at least in the context of ToM. Our overall contributions are listed as follows:

- 1. We propose a novel concept, taxonomy, and framework for evaluating ToM ability of LLMs.
- 2. Along with the concept we proposed, we have developed a multi-round text-based game as a new ToM benchmark to be both a proofof-concept and example benchmark for future benchmark development and an out-ofbox benchmark to evaluate the ToM ability of LLMs.
- 3. We have shown that LLMs perform better in the case of Zero Belief History than in the case of Finite Belief History and also shown that LLMs in small parameter sizes can even outperform LLMs in large parameter sizes when tackling ToM problems.

2 Related Work

2.1 ToM in LLMs

Although there has been debating around whether the ToM ability is really emerged in LLMs among previous work (Kosinski, 2023; Jamali et al.; Sap et al., 2023; Trott et al., 2023; Bubeck et al., 2023), recent work has shown a hard-to-deny promise of emergence of ToM in LLMs (Strachan et al., 2024; Kosinski, 2023; Jamali et al.), especially in the study of Strachan et al. (2024) which compares GPT-4 (OpenAI et al., 2024) and Llama 2 (Touvron et al., 2023) with human performance and demonstrates their superior performance compared to humans in certain tasks such as false beliefs and misdirection while suggesting that GPT's poor performance stems from a hyperconservative approach to committing to conclusions rather than from a genuine failure of inference. In this work, instead of focusing on discussing and debating the emergence of ToM in LLMs, we propose a novel concept and taxonomy of an evaluation direction of the ToM ability of LLMs and provide a clear framework for evaluating the ToM ability of LLMs in this direction.

Figure 1: An example of Zero Belief History in which the blue shadowed block represents the belief history which is not necessary, the red shadowed block represents a gap of beliefs between the LLM and Agent A.

2.2 ToM Benchmarks

The benchmarks for evaluating ToM ability of LLMs are recently in active development such as MindGames (Sileo and Lernould, 2023), FAN-ToM (Kim et al., 2023), Hi-ToM (Wu et al., 2023), ToMChallenges (Ma et al., 2023a), Symm-ToM (Sclar et al.), ToMi (Le et al., 2019), and so on. Each of them is proposed and developed to enhance the complexity or diversity of the ToM evaluation. In addition, Ma et al. (2023b) has proposed to taxonomize machine ToM into individual components such as belief, intentions, desires, emotions, percepts, and more, and also suggested treating LLMs as agents that are physically situated in environments and socially engaged in interactions with humans or intelligent agents. In this paper, we propose to further extend the evaluation of beliefs in terms of Zero, Finite, and Infinite Belief History and develop a benchmark as a game in which an LLM is a player to play the multi-round text-based game for evaluating its ToM reasoning ability.

3 ToM Reasoning with Zero, Finite, and Infinite Belief History

3.1 Zero Belief History

The ToM reasoning with Zero Belief History refers to a scenario where LLMs can directly search and find associated information from the context to perform ToM reasoning to directly distinguish and identify the beliefs of others without requiring any additional reasoning with prior knowledge and beliefs including but not limited to leveraging social rules, culture context, mathematical reasoning, and so on. For example, consider three agents discussing a certain topic in a room. If one agent leaves the room, the remaining two agents understand that the agent who left is unaware of any new

Figure 2: An example of Finite Belief History in which the blue shadowed block representing a finite belief history is necessary for the LLM to reason with to identify the latest belief of the Agent A.

content they will be discussing.

We have also demonstrated an example in Figure 1. The gap depicted in a red shadow block represents the belief difference between the LLM and Agent A. In order for the LLM to identify the belief of Agent A, the LLM only needs to find associated information provided in the context which is the information of the gap, without needing to use a belief history represented as a blue shadow block.

3.2 Finite Belief History

In contrast to the ToM reasoning with the Zero Belief History, under the condition of Finite Belief History, in addition to searching and finding available and associated information from the context, due to the information is not sufficient to enable it to directly identify the latest beliefs of others, it needs and has to utilize a belief history and reason with it in a certain way, such as levering mathematical reasoning, to be able to correctly identify the latest beliefs of others. In addition, a worth noting is that, in this case, the LLM only needs to reason with a finite belief history, such as a limited number and complexity of cultural background information, social rules, or mathematical formulations.

As an example shown in Figure 2, besides the condition of Zero Belief History demonstrated in Figure 1, the LLM needs to utilize and reason with a finite belief history represented in the blue shadowed block to identify the correct latest belief of Agent A.

3.3 Infinite Belief History

As a complex variant of the Finite Belief History, under the condition of Infinite Belief History, the only difference is the LLM needs and has to reason with an infinite belief history and everything else re-

Figure 3: An example of Infinite Belief History in which the LLM needs to leverage an infinite belief history represented in the blue shadowed block to reason with to identify the latest belief of the Agent A.

mains the same as in the Finite Belief History. An infinite belief history is typically implicitly held by the LLM in a certain pattern such as a function which represents the beliefs of the possible responses and actions towards different situations of environments in which since there could be infinite situations, responses, and actions, and the generated belief history could not be logged finitely, this function can be as a pattern to represent an infinite belief history.

As depicted in Figure 3, the only difference between the Finite Belief History and Infinite Belief History is that the belief history in the case of the Infinite Belief History colored in the blue shadowed block is infinite rather than finite and the LLM needs and have to utilize and reason with it to identify the latest belief of Agent A.

4 Methodology

4.1 Pick the Right Stuff

In order to evaluate the ToM reasoning ability of LLMs with each type of belief history, we develop a multi-round text-based game as a benchmark, called Pick the Right Stuff, in which an LLM plays as a warehouse manager required to correctly pick and deliver the right stuff belonging to its original owner in the condition that the position of the stuff is not the same as its original position while the users of the warehouse do not know. This game focuses on testing ToM reasoning in the cases of Zero and Finite Belief History, while leaving the Infinite Belief History as the future work. We expect this benchmark not only as an out-of-box benchmark for ToM evaluation but also as a proof-of-concept example for future benchmark development along the concept and taxonomy of Zero, Finite, and Infinite Belief History.

4.1.1 Game Logic for Zero History Belief

The game, *Pick the Right Stuff*, for the case of Zero Belief History, operates under the following logic².

There are two rooms in the game, Room 1 and Room 2. In Room 1, there is an opaque locker where the items are stored. The positions of the items in this opaque locker are randomly shuffled and reset throughout the game. Room 2 contains a monitor that allows observation of all items in the opaque locker in Room 1. An LLM is situated in this room, meaning it can observe and know the positions and owners of items at all times.

At the onset of the game, users place their items in Room 1 and both they and the LLM are aware of the initial positions of the items. During the game, some users may randomly enter Room 2 to view the monitor and they may enter the room and view the monitor more than once times, and the LLM is also able to observe the users since in the same room. Furthermore, users may enter Room 1 at any time and expect to retrieve their items. The LLM needs to think about and provide the positions of the items as believed by the users, so that the system can automatically swap the real items with those at the given positions. If the swap is correct, the user successfully retrieves their item and the LLM scores a point. If incorrect, the LLM scores no points and the system will automatically intervene to ensure the user successfully obtains their item. After retrieval, the position of the item becomes vacant, and the retrieving user will leave. The game will continue until all positions are empty. We have also demonstrated the game logic in Figure 4.

In this game under the condition of Zero Belief History, the users' beliefs are updated when they place their items at the onset of the game and when they enter Room 2 to observe the positions of the items, which means their beliefs are updated dynamically and may be changed multiple times during the game. The LLM can always know the correct positions of the items and is required to identify the false beliefs of the users in order to correctly pick and deliver the correct items to their owners to score points. Additionally, it is considered under the condition of Zero Belief History because the LLM does not need to identify the latest beliefs of the users based on a belief history but can utilize the available and associated information around the context which is whether the users enter

²An example of the game instance under the condition of Zero Belief History is shown in Appendix A.1.

Figure 4: The game logic of *Pick the Right Stuff* under the condition of Zero Belief History in which there are two rooms, (1) Room 1 is the Locker Room containing an opaque locker used for storing the items of the users, and (2) Room 2 is the Monitoring Room where the LLM is located.

the Room 2 to view the monitor to determine the latest beliefs of the users.

4.1.2 Game Logic For Finite Belief History

Under the condition of Finite History Belief, the game logic is similar to that of under the condition of Zero History Belief³. The key difference lies in the addition of a third room, Room 3. In this room, there is a screen that randomly shows a snapshot representing a random previous state of the monitor located in Room 2 which is the previous state of the positions of items. Instead of entering Room 2 to observe the current monitor, some users may randomly enter Room 3 to view the snapshot on the screen during the game. In addition, the LLM located in Room 2 is only informed about the specific previous state relative to the current state in an indirect way such as "nth-to-last" instead of directly being presented. Therefore, the LLM must utilize and reason with a finite belief history to identify the latest beliefs of the users. The game logic under the condition of Finite Belief History is shown in Figure 5.

4.2 Experiment Settings

In order to have a comprehensive view of the ToM reasoning ability of LLMs under Zero and Finite

Belief History, we have conducted evaluations with six Large Language Models, comprising three models with large parameter sizes and three models with small parameter sizes.

For the models with large parameter sizes, we choose GPT-3.5-Turbo noted as *gpt-3.5-turbo*, Llama 3 for which we select its instruct model in 70 billion parameter size noted as *llama3:70b-instruct*, and Qwen (Bai et al., 2023) for which we use its chat model in 72 billion parameter size noted as *qwen:72b-chat*.

For the models with small parameter sizes, we select Gemma (Team et al., 2024) for which we use its instruct model in 7 billion parameter size noted as *gemma:7b-instruct*, Mistral (Jiang et al., 2023) for which we choose its instruct model in 7 billion parameter size noted as *mistral:7b-instruct*, and Qwen (Bai et al., 2023) for which we use its chat model in 7 billion parameter size noted as *qwen:7b-chat*.

We then fix the temperature to 0 for all the selected LLMs to ensure the consistency of the responses. And we also fix the random seed of the game to ensure each model faces the same game states and questions. In addition, we run each model to play 60 turns of the game in the case of 5 users⁴.

³An example of the game instance under the condition of Finite Belief History is shown in Appendix A.2.

⁴Each turn consists of multiple ToM questions.

Figure 5: The game logic of *Pick the Right Stuff* under the condition of Finite Belief History in which there are three rooms, (1) Room 1 is the Locker Room containing an opaque locker, (2) Room 2 is the Monitoring Room where the LLM is located and enables the LLM to know the situations from both of Room 1 and Room 3, and (3) Room 3 is the Snapshots Room which shows a certain state of positions of items to users.

5 Results and Analyses

The average scores of the *gpt-3.5-turbo*, *llama3:70b-instruct*, *qwen:72b-chat*, *gemma:7b-instruct*, *mistral:7b-instruct*, and *qwen:7b-chat* playing the game, *Pick the Right Stuff*, under the conditions of Zero and Finite Belief History are depicted in Figure 6.

For all the evaluated models, the average score under the condition of the Zero Belief History is 32.06, while it is 26.33 under the condition of the Finite Belief History, indicating that although LLMs show an impressive promise and performance on ToM reasoning, they still struggle with it.

In addition, from the difference between the two conditions, which is 5.73, and also as shown in Figure 6, the performance of LLMs under the condition of Finite Belief History is consistently lower than the performance under the condition of Zero Belief History, which indicates that the Finite History Belief case is indeed harder for them than the Zero History Belief.

Furthermore, among the selected LLMs, the model with small parameter size, *gemma:7b-instruct*, emerged as the best-performing, achieving an average score of 43.00 under the Zero Belief History condition and 34.33 under the Finite Belief History condition, thereby outperforming all the other LLMs. In addition, *mistral:7b-instruct* also shows better performance over all the other LLMs

with large parameter sizes, like *gpt-3.5-turbo*. Although there may be differences in the training data and architectures leveraged by these models, the outstanding performance of the models with smaller parameter sizes presents evidence and an answer to a thought-provoking question, whether increasing model parameter size may effectively enhance LLMs capabilities, at least discussed in the context of ToM reasoning ability.

6 Implications

We propose a novel concept, taxonomy, and framework to evaluate the ToM reasoning ability of LLMs under the conditions of Zero, Finite, and Infinite Belief History. Although we focus primarily on LLMs as the subjects of our evaluation, this concept and evaluation approach is equally applicable to other AI agents and systems.

Additionally, since the essence and necessity of complex ToM reasoning ability in many applications such as autonomous driving, complex multi-actor story writing, embodied agents under the multi-agent case, and more, we expect this work to pave the way for more intelligent AI agents or systems which are required to equipped with more complex ToM reasoning.

7 Conclusion

In this study, we propose a novel concept, taxonomy, and framework to extend the boundaries of

Figure 6: The average scores of each model for playing the game under the condition of Zero or Finite Belief History.

evaluation of the ToM reasoning ability of LLMs, by introducing Zero, Finite, and Infinite Belief History. In addition, we develop a multi-round text-based game as both of a proof-of-concept and example benchmark for future benchmark development along the concept proposed and an out-of-box benchmark to evaluate the ToM reasoning ability of LLMs under the conditions of Zero and Finite Belief History. We choose six LLMs of which three of them are in large parameter sizes and three of them are in small parameter sizes. We have demonstrated the evaluated LLMs perform better under the condition of Zero Belief History than under the condition of Finite Belief History. In addition, we have also found that two of the models with small parameter sizes outperform all the selected models with large parameter sizes. We hope this work can pave the way for future benchmark development and also the development of more complex AI agents and systems which are required to tackle more complex ToM problems.

8 Limitations

Due to this study focusing on proposing a novel evaluation concept of ToM reasoning rather than presenting an exhaustively comprehensive comparison of all available LLMs and since the unavoidable heavy computation costs incurred by GPT-4, we do not run an evaluation of GPT-4 and other LLMs. Nevertheless, future work can leverage this out-ofbox game to evaluate GPT-4 and other LLMs.

In addition, the game we developed does not cover all possibilities and variants under the conditions of Zero and Finite Belief History such as replacing mathematical reasoning in the case of Finite Belief History with social rules or cultural background. We expect the future work can work along it to develop various benchmarks to evaluate ToM reasoning ability under the conditions of Zero, Finite, and Infinite Belief History with different kinds of belief history to prompt comprehensive evaluation.

Furthermore, since presenting implementation examples of Zero and Finite Belief History is sufficient to express and explain the concept and due to that the LLMs still struggle with handling ToM reasoning in the game under the conditions of the Zero and Finite Belief History, we leave the implementation of Infinite Belief History for future work.

A Appendix

A.1 Game Instance of Zero Belief History

Listing 1: Example of the *Pick the Right Stuff* game under the condition of Zero Belief History. Welcome to, Pick the Right Stuff!

- In this game, you will play the role of a warehouse manager. The warehouse contains two rooms. Room 1 is used for storing items, with each item stored in a certain position inside the opaque locker. You are situated in the Room 2, which contains a monitor that allows you to see the content of the opaque locker located in the Room 1 through the camera inside the opaque locker. Due to malfunctions in the locker system, it randomly resets the positions of the items in the opaque locker from time to time. To ensure that each user retrieves their stored item correctly, when a user comes to retrieve an item, you are required to predict the position of the item the user believes (the user will always retrieve their item based on the position they last believed). You only need to tell the system which position inside the locker the user will go to retrieve their item and then the locker system will automatically swap the item at that location with the one belonging to the user. During the game, users may or may not enter the Room 2 to observe the monitor. By observing the monitor, users will update their beliefs about the position of their item.
- If a user successfully retrieves their item, you score a point and the item is removed from the locker.
- If a user retrieves the wrong item, the item is returned, the user contacts the system administrator to take the correct item, and you score no points.
- Indeed, this is a problematic locker system, but you are hoped to be an excellent warehouse manager!

=================

Game Begins!

There are 3 users. User 0 stores its item at the position 0th of the locker. User 1 stores its item at the position 1st of the locker. User 2 stores its item at the position 2nd of the locker.

Now they leave the room.

- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 1.
- The position 1st stores the item of User 2.

The position 2nd stores the item of User 0.

- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 2.
- The position 1st stores the item of User 0.
- The position 2nd stores the item of User 1.
- User 1 is coming to Room 1 to take his/her item ...

You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).

- For example, if you think the user will go to position 0th to retrieve their item, you should only answer in single number '0'.
- Please make your prediction:
- Your prediction is correct! Item in the position 1st is exchanged with the correct item in the position 2nd. User 1 successfully retrieved the item from the correct position . You score a point!
- Now, from the monitor, you can see the content of the locker:
- The position 0th stores the item of User 2.
- The position 1st box is empty.
- The position 2nd stores the item of User 0.
- User 0 walks into the Room 2 and leaves the room after observing the monitor.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 0.
- The position 1st stores the item of User 2.
- The position 2nd box is empty.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...

The locker has returned to normal.

- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 2.
- The position 1st box is empty.
- The position 2nd stores the item of User 0.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...

The locker has returned to normal.

From the monitor, you can see the content of the locker:

The position 0th box is empty. The position 1st stores the item of User 0. The position 2nd stores the item of User 2.

- User 0 is coming to Room 1 to take his/her item \ldots
- You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).
- For example, if you think the user will go to position 0th to retrieve their item, you should only answer in single number '0'. Please make your prediction:
- 2
- Your prediction is correct! Item in the position 2nd is exchanged with the correct item in the position 1st. User 0 successfully retrieved the item from the correct position . You score a point!
- Now, from the monitor, you can see the content of the locker:
- The position 0th box is empty.
- The position 1st stores the item of User 2.
- The position 2nd box is empty.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th box is empty.
- The position 1st box is empty.
- The position 2nd stores the item of User 2.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 2.
- The position 1st box is empty.
- The position 2nd box is empty.
- The locker is malfunctioning and randomly resetting the positions of the items in the locker...
- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th box is empty.
- The position 1st box is empty.
- The position 2nd stores the item of User 2.
- User 2 is coming to Room 1 to take his/her item \ldots
- You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).

For example, if you think the user will go to position 0th to retrieve their item, you should only answer in single number '0'. Please make your prediction: 2 Your prediction is correct! Item in the position 2nd is exchanged with the correct item in the position 2nd. User 2 successfully retrieved the item from the correct position . You score a point! Now, from the monitor, you can see the content of the locker: The position 0th box is empty. The position 1st box is empty. The position 2nd box is empty. Correct: 3 Final score: 100

Game Over! Do you want to play another turn?(Y/n)

A.2 Game Instance of Finite Belief History

Listing 2: Example of the *Pick the Right Stuff* game under the condition of Finite Belief History.

Game client is running! Welcome to, Pick the Right Stuff!

- In this game, you will play the role of a warehouse manager. The warehouse contains three rooms. Room 1 is used for storing items, with each item stored in a certain position inside the opaque locker. You are situated in the Room 2, which contains a monitor that allows you to see the content of the opaque locker located in the Room 1 through the camera inside the opaque locker. Due to malfunctions in the locker system, it randomly resets the positions of the items in the opaque locker from time to time . To ensure that each user retrieves their stored item correctly, when a user comes to retrieve an item, you are required to predict the position of the item the user believes (the user will always retrieve their item based on the position they last believed). You only need to tell the system which position inside the locker the user will go to retrieve their item and then the locker system will automatically swap the item at that location with the one belonging to the user. Additionally, Room 3 contains a screen which will randomly show a certain previous snapshot of the monitor located in Room 2. During the game, users may or may not enter the Room 3 to observe a certain snapshot of the monitor. By observing the snapshot, users will update their beliefs about the position of their item.
- If a user successfully retrieves their item, you score a point and the item is removed from the locker.
- If a user retrieves the wrong item, the item is returned, the user contacts the system

administrator to take the correct item, and you score no points.

Indeed, this is a problematic locker system, but you are hoped to be an excellent warehouse manager!

=======

Game Begins!

There are 3 users. User 0 stores its item at the position 0th of the locker. User 1 stores its item at the position 1st of the locker. User 2 stores its item at the position 2nd of the locker.

Now they leave the room.

The locker is malfunctioning and randomly resetting the positions of the items in the locker...

- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 1.
- The position 1st stores the item of User 2.
- The position 2nd stores the item of User 0.

The locker is malfunctioning and randomly resetting the positions of the items in the locker...

- The locker has returned to normal.
- From the monitor, you can see the content of the locker:
- The position 0th stores the item of User 2.
- The position 1st stores the item of User 0.
- The position 2nd stores the item of User 1.
- User 1 is coming to Room 1 to take his/her item ...
- You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).
- For example, if you think the user will go to
 position 0th to retrieve their item, you
 should only answer in single number '0'.
 Please make your prediction:

1

Your prediction is correct! Item in the position 1st is exchanged with the correct item in the position 2nd. User 1 successfully retrieved the item from the correct position . You score a point!

Now, from the monitor, you can see the content of the locker: The position 0th stores the item of User 2. The position 1st box is empty. The position 2nd stores the item of User 0.

User 0 walks into the Room 3 and is observing the snapshot of the monitor...

User 0 observes the snapshot which depicts the 2

nd-to-last state of the monitor and leaves the room.

- User 2 is coming to Room 1 to take his/her item
- You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).
- For example, if you think the user will go to position 0th to retrieve their item, you should only answer in single number '0'.
- Please make your prediction:
- 2
- Your prediction is correct! Item in the position 2nd is exchanged with the correct item in the position 0th. User 2 successfully retrieved the item from the correct position . You score a point!
- Now, from the monitor, you can see the content of the locker:
- The position 0th stores the item of User 0.
- The position 1st box is empty.
- The position 2nd box is empty.
- User 0 is coming to Room 1 to take his/her item \ldots
- You should only answer the position of the item the user will go to retrieve their item (e.g . 0 for the 0th, 1 for the 1st, 2 for the 2 nd...).
- For example, if you think the user will go to position 0th to retrieve their item, you should only answer in single number '0'.
- Please make your prediction:
- Your prediction is correct! Item in the position 1st is exchanged with the correct item in the position 0th. User 0 successfully retrieved the item from the correct position . You score a point!

Now, from the monitor, you can see the content of the locker: The position 0th box is empty. The position 1st box is empty.

The position 2nd box is empty.

Correct: 3 Final score: 100 Game Over!

Do you want to play another turn?(Y/n)
