### Abstract

Convolutional neural networks have been successfully extended to operate on graphs, giving rise to Graph Neural Networks (GNNs). GNNs combine information from adjacent nodes by successive applications of graph convolutions. GNNs have been implemented successfully in various learning tasks while the theoretical understanding of their generalization capability is still in progress. In this paper, we leverage manifold theory to analyze the statistical generalization gap of GNNs operating on graphs constructed on sampled points from manifolds. We study the generalization gaps of GNNs on both node-level and graph-level tasks. We show that the generalization gaps decrease with the number of nodes in the training graphs, which guarantees the generalization of GNNs to unseen points over manifolds. We validate our theoretical results in multiple real-world datasets.

### <span id="page-0-0"></span>1 Introduction

Graph convolutional neural networks (GNNs) [\[1](#page-10-0)[–3\]](#page-10-1) have emerged as one of the leading tools for processing graph-structured data. There is abundant evidence of their empirical success across various fields, including but not limited to weather prediction [\[4\]](#page-10-2), protein structure prediction in biochemistry [\[5,](#page-10-3) [6\]](#page-10-4), resource allocation in wireless communications [\[7\]](#page-10-5), social network analysis in sociology [\[8\]](#page-10-6), point cloud in 3D model reconstruction [\[9\]](#page-10-7) and learning simulators [\[10\]](#page-10-8).

The effectiveness of GNNs relies on their empirical ability to *predict* over unseen data. This capability is evaluated theoretically with *statistical generalization* in deep learning theory [\[11\]](#page-10-9), which quantifies the difference between the *empirical risk* (i.e. training error) and the *statistical risk* (i.e. testing error). Despite the abundant evidence of GNNs' generalization capabilities in practice, developing concrete theories to explain their generalization is an active area of research. Many recent works have studied the generalization bounds of GNNs without any dependence on the underlying model responsible for generating the graph data [\[12–](#page-10-10)[14\]](#page-10-11). Generalization analysis on graph classification, when graphs are drawn from random limit models, is also studied in a series of works [\[15](#page-10-12)[–18\]](#page-10-13). In this work, we follow a similar methodology to formulate graph data on continuous topological spaces

The authors contribute equally.

<span id="page-1-0"></span>

Figure 1: OBGN-Arxiv accuracy and loss generalization gaps. The GNN is trained over graphs with the number of nodes indicated on the x-axis, and the generalization gap (difference between the training and loss datasets) is measured, both in terms of the accuracy (Figure [1a\)](#page-1-0), and the loss (Figure [1b\)](#page-1-0) with which we trained – the cross-entropy loss. As can be seen, in both cases the generalization gap presents a logarithmically linear behavior with respect to the number of nodes.

– specifically, manifolds – which are realistic models that enable rigorous theoretical analysis and a deeper understanding of the behaviors of GNNs.

Specifically, we explore the generalization gap of GNNs through the lens of manifold theory on both node level and graph level tasks. The graphs are constructed based on points randomly sampled from underlying manifolds, indicating that the manifold can be viewed as a statistical model for these discretely sampled points. As convolutional neural network architectures have been established over manifolds [\[19\]](#page-11-0), the convergence of GNNs to manifold neural networks (MNNs) facilitates a detailed generalization analysis over GNNs. We demonstrate that, with an appropriate graph construction (Definition [2](#page-4-0) or Definition [3\)](#page-4-1), the generalization gap between empirical and statistical risks decreases with the number of sampled points in the graphs while increasing with the manifold dimension. The main findings of this paper (Theorem [1](#page-5-0) and Theorem [2\)](#page-6-0) provide a unified approach, showing that GNNs can effectively generalize to other unseen data over the manifold.

Theorem (Informal, Node classification on Gaussian kernel based graphs). *Consider a graph constructed with* N *randomly sampled points over a* d*-dimensional manifold* M *with respect to the measure*  $\mu$  *over the manifold. Then, with probability*  $1 - \delta$  *the generalization gap (GA) of a GNN with* L *layers and* F *features in each layer trained to predict the node labels on this graph satisfies*

$$
GA \approx \mathcal{O}\left(\frac{LF^{L-1}}{\sqrt{N}}\left(\frac{\log 1/\delta}{N}\right)^{\frac{1}{d+4}} + F^{L}\left(\frac{\log N}{N}\right)^{\frac{1}{d}}\right). \tag{1}
$$

Simulations on the ArXiv dataset [\[20\]](#page-11-1) further validate our theoretical results as Figure [1](#page-1-0) shows. Both the accuracy and loss generalization gaps decrease approximately linearly with the number of nodes in the logarithmic scale. We provide generalization bounds on both node and graph levels. For node level tasks, the generalization guarantees that a GNN trained on finitely sampled points over the manifold can accurately predict the labels of other unseen points over the manifold. For graph level tasks, the generalization assures that a GNN trained to classify graphs sampled from different manifolds can predict the labels of other unseen graphs sampled from these manifolds.

#### <span id="page-1-2"></span>2.1 Generalization bounds of GNNs

Node level tasks We first give a brief recap of the generalization bounds of GNNs on node level tasks. In [\[12\]](#page-10-10), the authors give a generalization bound of GNNs with a Vapnik–Chervonenkis dimension of GNNs. The authors in [\[14\]](#page-10-11) analyze the generalization of a single-layer GNN based on stability analysis, which is further extended to a multi-layer GNN in [\[21\]](#page-11-2). In [\[22\]](#page-11-3), the authors give a novel PAC-Bayesian analysis on the generalization bound of GNNs across arbitrary subgroups of training and testing datasets. The authors derive generalization bounds for GNNs via transductive uniform stability and transductive Rademacher complexity in [\[23–](#page-11-4)[25\]](#page-11-5). The authors in [\[26\]](#page-11-6) propose a size generalization analysis of GNNs correlated to the discrepancy between local distributions of graphs. Different from these works, we consider a continuous manifold model when generating the graph data, which is theoretically powerful and realistic when characterizing real-world data.

Graph level tasks There are also related works on the generalization analysis of GNNs on graph level tasks. In [\[13\]](#page-10-14), the authors form the generalization bound via Rademacher complexity. The authors in [\[27\]](#page-11-7) build a PAC-Bayes framework to analyze the generalization capabilities of graph convolutional networks [\[28\]](#page-11-8) and message-passing GNNs [\[29\]](#page-11-9), based on which the authors in [\[30\]](#page-11-10) improve the results and prove a lower bound. The works in [\[16–](#page-10-15)[18\]](#page-10-13) are most related to ours, which also consider the generalization of GNNs on a graph limit model. Different from our setting, the authors see the graph limit as a random continuous model. They study the generalization of graph classification problems with message-passing GNNs with graphs belonging to the same category sampled from a continuous limit model. The generalization bound grows with the model complexity and decreases with the number of nodes in the graph. We show that a GNN trained on a single graph sampled from each manifold is enough, and can generalize and classify unseen graphs sampled from the manifold set.

#### <span id="page-2-0"></span>2.2 Neural networks on manifolds

Geometric deep learning has been proposed in [\[31\]](#page-11-11) with neural network architectures raised in manifold space. The authors in [\[32\]](#page-11-12) and [\[33\]](#page-11-13) provide neural network architectures for manifoldvalued data. In [\[34\]](#page-11-14) and [\[19\]](#page-11-0), the authors define convolutional operation over manifolds and see the manifold convolution as a generalization of graph convolution, which establishes the limit of neural networks on large-scale graphs as manifold neural networks (MNNs). The authors in [\[35\]](#page-11-15) further establish the relationship between GNNs and MNNs with non-asymptotic convergence results for different graph constructions.

### <span id="page-2-1"></span>3 Preliminaries

#### <span id="page-2-2"></span>3.1 Graph neural networks

Setup An undirected graph  $G = (V, E, W)$  contains a node set V with N nodes and an edge set  $\mathcal{E} \subseteq V \times V$ . The weight function  $\mathcal{W} : \mathcal{E} \to \mathbb{R}$  assigns weight values to the edges. We define the Graph Laplacian  $L = diag(A1) - A$  where  $A \in \mathbb{R}^{N \times N}$  is the adjacency matrix. Graph signals are defined as functions mapping nodes to a feature value  $\mathbf{x} \in \mathbb{R}^N$ .

**Graph convolutions and frequency response** A graph convolutional filter  $h_G$  is composed of consecutive graph shifts by graph Laplacian, defined as  $\mathbf{h}_{\mathbf{G}}(\mathbf{L})\mathbf{x} = \sum_{k=0}^{K-1} h_k \mathbf{L}^k \mathbf{x}$  with  $\{h_k\}_{k=0}^{K-1}$  as filter parameters. We replace  $\mathbf{L}$  with eigendecomposition  $\mathbf{L} = \mathbf{V}\mathbf{\Lambda}\mathbf{$ vector matrix and  $\Lambda$  is a diagonal matrix with eigenvalues  $\{\lambda_{i,N}\}_{i=1}^N$  as the entries. The spectral representation of a graph filter is

$$
\mathbf{V}^{H}\mathbf{h}_{\mathbf{G}}(\mathbf{L})\mathbf{x} = \sum_{k=1}^{K-1} h_{k}\mathbf{\Lambda}^{k}\mathbf{V}^{H}\mathbf{x} = \hat{h}(\mathbf{\Lambda})\mathbf{V}^{H}\mathbf{x}.
$$
 (2)

This leads to a point-wise frequency response of the graph convolution as  $\hat{h}(\lambda) = \sum_{k=0}^{K-1} h_k \lambda^k$ .

Graph neural networks A graph neural network (GNN) is a layered architecture, where each layer consists of a bank of graph convolutional filters followed by a point-wise nonlinearity  $\sigma : \mathbb{R} \to \mathbb{R}$ . Specifically, the l-th layer of a GNN that produces  $F_l$  output features  $\{x_l^p\}_{p=1}^{F_l}$  with  $F_{l-1}$  input

features  $\{\mathbf x_{l-1}^q\}_{q=1}^{F_{l-1}}$  is written as

$$
\mathbf{x}_l^p = \sigma \left( \sum_{q=1}^{F_{l-1}} \mathbf{h}_{\mathbf{G}}^{lpq}(\mathbf{L}) \mathbf{x}_{l-1}^q \right), \qquad (3)
$$

for each layer  $l = 1, 2 \cdots, L$ . The graph filter  $\mathbf{h}^{lpq}_\mathbf{G}(\mathbf{L})$  maps the q-th feature of layer  $l-1$  to the p-th feature of layer l. We denote the GNN as a mapping  $\Phi_G(H, L, x)$ , where  $H \in \mathcal{H} \subset \mathbb{R}^P$  denotes a set of the graph filter coefficients at all layers and  $H$  denotes the set of all possible parameter sets.

#### <span id="page-3-0"></span>3.2 Manifold neural networks

Setup We consider a d-dimensional compact, smooth and differentiable Riemannian submanifold M embedded in  $\mathbb{R}^M$  with finite volume. This induces a Hausdorff probability measure  $\mu$  over the manifold with density function  $\rho : \mathcal{M} \to (0, \infty)$ , assumed to be bounded as  $0 < \rho_{min} \leq \rho(x) \leq$  $\rho_{max} < \infty$  for all  $x \in \mathcal{M}$ . The manifold data supported on each point  $x \in \mathcal{M}$  is defined by scalar functions  $f : \mathcal{M} \to \mathbb{R}$  [\[34\]](#page-11-14). We use  $L^2(\mathcal{M})$  to denote  $L^2$  functions over M with respect to measure  $\mu$ . The manifold with probability density function  $\rho$  is equipped with a weighted Laplace operator [\[36\]](#page-11-16), generalizing the Laplace-Beltrami operator as

<span id="page-3-1"></span>
$$
\mathcal{L}_{\rho}f = -\frac{1}{2\rho} \text{div}(\rho^2 \nabla f),\tag{4}
$$

with div denoting the divergence operator of M and  $\nabla$  denoting the gradient operator of M [\[31,](#page-11-11) [37\]](#page-12-0).

Manifold convolutions and frequency responses The manifold convolution operation is defined relying on the Laplace operator  $\mathcal{L}_{\rho}$  and on the heat diffusion process over the manifold [\[34\]](#page-11-14). For a function  $f \in L^2(\mathcal{M})$  as the initial heat condition over M, the heat condition diffused by a unit time step can be explicitly written as  $e^{-\mathcal{L}_{\rho}}f$ . A manifold convolutional filter [\[34\]](#page-11-14) can be defined in a diffuse-and-sum manner as

$$
g(x) = \mathbf{h}(\mathcal{L}_{\rho})f(x) = \sum_{k=0}^{K-1} h_k e^{-k\mathcal{L}_{\rho}} f(x),
$$
 (5)

with the k-th diffusion scaled with a filter parameter  $h_k \in \mathbb{R}$ . We consider the case in which the Laplace operator is self-adjoint with respect to the inner product defined in [\(24\)](#page-15-0) and positivesemidefinite and the manifold  $\dot{M}$  is compact, in this case,  $\mathcal{L}_{\rho}$  has real, positive and discrete eigenvalues  $\{\lambda_i\}_{i=1}^{\infty}$ , written as  $\mathcal{L}_{\rho}\phi_i = \lambda_i \phi_i$  where  $\phi_i$  is the eigenfunction associated with eigenvalue  $\lambda_i$ . The eigenvalues are ordered in increasing order as  $0 = \lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \ldots$ , and the eigenfunctions are orthonormal and form an eigenbasis of  $L^2(\mathcal{M})$ . When mapping a manifold signal onto the eigenbasis  $[\hat{f}]_i = \langle f, \phi_i \rangle_{\mathcal{M}}$ , the manifold convolution can be written in the spectral domain as

$$
[\hat{g}]_i = \sum_{k=0}^{K-1} h_k e^{-k\lambda_i} [\hat{f}]_i.
$$
 (6)

Hence, the frequency response of manifold filter is given by  $\hat{h}(\lambda) = \sum_{k=0}^{K-1} h_k e^{-k\lambda}$ .

**Manifold neural networks** A manifold neural network (MNN) is constructed by cascading  $L$ layers, each of which contains a bank of manifold convolutional filters and a pointwise nonlinearity  $\sigma : \mathbb{R} \to \mathbb{R}$ . The output manifold function of each layer  $l = 1, 2 \cdots, L$  can be explicitly denoted as

<span id="page-3-2"></span>
$$
f_l^p(x) = \sigma \left( \sum_{q=1}^{F_{l-1}} \mathbf{h}_l^{pq}(\mathcal{L}_{\rho}) f_{l-1}^q(x) \right), \tag{7}
$$

where  $f_{l-1}^q$ ,  $1 \le q \le F_{l-1}$  is the q-th input feature from layer  $l-1$  and  $f_l^p$ ,  $1 \le p \le F_l$  is the p-th output feature of layer *l*. We denote MNN as a mapping  $\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)$ , where  $\mathbf{H} \in \mathcal{H} \subset \mathbb{R}^P$  is a collective set of filter parameters in all the manifold convolutional filters.

<span id="page-4-2"></span>

(a) Gaussian kernel based graphs (b)  $\epsilon$ -graphs

Figure 2: Illustration of the constructed graphs on points sampled over a chair and a table model.

### <span id="page-4-6"></span>4 Generalization analysis of GNNs based on manifold

We consider a manifold M as defined in Section [3.2,](#page-3-0) with a weighted Laplace operator  $\mathcal{L}_{\rho}$  as [\(4\)](#page-3-1). Since functions  $f \in L^2(\mathcal{M})$  characterize information over manifold M, we restrict our analysis to a finite-dimensional subset of  $L^2(\mathcal{M})$  up to some eigenvalue of  $\mathcal{L}_{\rho}$ , defined as a bandlimited signal.

<span id="page-4-3"></span>**Definition 1.** A manifold signal  $f \in L^2(\mathcal{M})$  is bandlimited if there exists some  $\lambda > 0$  such that for *all eigenpairs*  $\{\lambda_i, \phi_i\}_{i=1}^{\infty}$  *of the weighted Laplacian*  $\mathcal{L}_{\rho}$  *when*  $\lambda_i > \lambda$ *, we have*  $\langle f, \phi_i \rangle_{\mathcal{M}} = 0$ *.* 

Suppose we are given a set of N i.i.d. randomly sampled points  $X_N = \{x_i\}_{i=1}^N$  over M, with  $x_i \in \mathcal{M}$  sampled according to measure  $\mu$ . We construct a graph  $\mathbf{G}(\mathcal{V}, \mathcal{E}, \mathcal{W})$  on these N sampled points  $X_N$ , where each point  $x_i$  is a vertex of graph G, i.e.  $\mathcal{V} = X_N$ . Each pair of vertices  $(x_i, x_j)$ is connected with an edge while the weight attached to the edge  $\mathcal{W}(x_i, x_j)$  is determined by a kernel function  $K_{\epsilon}$ . The kernel function is decided by the Euclidean distance  $||x_i - x_j||$  between these two points. The graph Laplacian denoted as  $L<sub>N</sub>$  can be calculated based on the weight function [\[38\]](#page-12-1). The constructed graph Laplacian with an appropriate kernel function has been proved to approximate the Laplace operator  $\mathcal{L}_{\rho}$  of M [\[39](#page-12-2)[–41\]](#page-12-3). We present the following two definitions of  $K_{\epsilon}$ .

<span id="page-4-0"></span>**Definition 2** (Gaussian kernel based graph [\[40\]](#page-12-4)). *The graph*  $G(X_N, \mathcal{E}, \mathcal{W})$  *can be constructed as a dense graph degree when the kernel function is defined as*

<span id="page-4-4"></span>
$$
\mathcal{W}(x_i, x_j) = K_{\epsilon} \left( \frac{\|x_i - x_j\|^2}{\epsilon} \right) = \frac{1}{N} \frac{1}{\epsilon^{d/2 + 1} (4\pi)^{d/2}} e^{-\frac{\|x_i - x_j\|^2}{4\epsilon}}, \quad (x_i, x_j) \in \mathcal{E}.
$$
 (8)

The weight function of a Gaussian kernel based graph is defined on unbounded support (i.e.  $[0, \infty)$ ), which connects  $x_i$  and  $x_j$  regardless of the distance between them. This results in a dense graph with  $N^2$  edges. In particular, this Gaussian kernel based graph has been widely used to define the weight value function due to the good approximation properties of the corresponding graph Laplacians to the manifold Laplace operator [\[40](#page-12-4)[–42\]](#page-12-5).

<span id="page-4-1"></span>**Definition 3** ( $\epsilon$ -graph [\[39\]](#page-12-2)). *The graph*  $G(X_N, \mathcal{E}, \mathcal{W})$  *can be constructed as an*  $\epsilon$ -graph with the *kernel function defined as*

<span id="page-4-5"></span>
$$
\mathcal{W}(x_i, x_j) = K_{\epsilon} \left( \frac{\|x_i - x_j\|^2}{\epsilon} \right) = \frac{1}{N} \frac{d+2}{\epsilon^{d/2+1} \alpha_d} \mathbb{1}_{[0,1]} \left( \frac{\|x_i - x_j\|^2}{\epsilon} \right), \quad (x_i, x_j) \in \mathcal{E}, \quad (9)
$$

*where*  $\alpha_d$  *is the volume of a unit ball of dimension d and*  $\mathbb{1}$  *is the characteristic function.* 

The weight function of an  $\epsilon$ -graph is defined on a bounded support, i.e., only nodes that are within a certain distance of one another can be connected by an edge. It has also been shown to provide a good approximation of the manifold Laplace operator [\[39\]](#page-12-2). Figure [2](#page-4-2) gives an illustration of both Gaussian kernel based graphs and  $\epsilon$ -graphs sampled from point cloud models [\[43\]](#page-12-6).

### <span id="page-4-7"></span>4.1 Manifold label prediction via node label prediction

Suppose we have an input manifold signal  $f \in L^2(\mathcal{M})$  and a label (i.e. target) manifold signal  $g \in L^2(\mathcal{M})$  over M. With an MNN  $\Phi(\mathbf{H}, \mathcal{L}_{\rho}, \cdot)$ , we predict the target value  $g(x)$  based on input  $f(x)$  at each point  $x \in M$ . By sampling N points  $X_N$  over this manifold, we can approximate this problem in a discrete graph domain. Consider a graph  $G(X_N, \mathcal{E}, \mathcal{W})$  constructed with  $X_N$  as either a Gaussian kernel based graph (Definition [2\)](#page-4-0) or an  $\epsilon$ -graph (Definition [3\)](#page-4-1) equipped with the graph Laplacian  $\mathbf{L}_N$ . Suppose we are given graph signal  $\{\mathbf{x}, \mathbf{y}\}\$  sampled from  $\{f, g\}$  to train a GNN  $\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \cdot)$ , explicitly written as

$$
[\mathbf{x}]_i = f(x_i), \qquad [\mathbf{y}]_i = g(x_i) \quad \text{for all } x_i \in X_N. \tag{10}
$$

We assume that the filters in MNN  $\Phi(H, \mathcal{L}_{\rho}, \cdot)$  and GNN  $\Phi_{\mathbf{G}}(H, L_N, \cdot)$  are low-pass filters, which are defined explicitly as follows.

<span id="page-5-2"></span>Definition 4. *A filter is a low-pass filter if its frequency response satisfies*

$$
\left|\hat{h}(\lambda)\right| = \mathcal{O}\left(\lambda^{-d}\right), \quad \left|\hat{h}'(\lambda)\right| \le C_L \lambda^{-d-1}, \quad \lambda \in (0, \infty). \tag{11}
$$

To introduce the first of our two main results, we require the introduction of two assumptions.

<span id="page-5-1"></span>AS 1. *(Normalized Lipschitz nonlinearity) The nonlinearity* σ *is normalized Lipschitz continuous, i.e.,*  $|\sigma(a) - \sigma(b)| \leq |a - b|$ *, with*  $\sigma(0) = 0$ *.* 

<span id="page-5-3"></span>AS 2. *(Normalized Lipschitz loss function) The loss function* ℓ *is normalized Lipschitz continuous, i.e.*,  $|\ell(y_i, y) - \ell(y_j, y)| \le |y_i - y_j|$ , with  $\ell(y, y) = 0$ .

Assumption [1](#page-5-1) is satisfied by most activations used in practice such as ReLU, modulus and sigmoid.

The generalization gap is evaluated between the *empirical risk* over the discrete graph model and the *statistical risk* over manifold model, with the manifold model viewed as a statistical model since the expectation of the sampled point is with respect to the measure  $\mu$  over the manifold. The empirical risk over the sampled graph that we trained to minimize is therefore defined as

$$
R_{\mathbf{G}}(\mathbf{H}) = \frac{1}{N} \sum_{i=1}^{N} \ell\left( [\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i} \right).
$$
 (12)

The statistical risk over the manifold is defined as

$$
R_{\mathcal{M}}(\mathbf{H}) = \int_{\mathcal{M}} \ell(\mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x).
$$
 (13)

The generalization gap is defined to be

$$
GA = \sup_{\mathbf{H} \in \mathcal{H}} |R_{\mathcal{M}}(\mathbf{H}) - R_{\mathbf{G}}(\mathbf{H})|.
$$
 (14)

<span id="page-5-0"></span>Theorem 1. *Suppose the GNN and MNN with low-pass filters (Definition [4\)](#page-5-2) have* L *layers with* F *features in each layer and the input signal is bandlimited (Definition [1\)](#page-4-3). Under Assumptions [1](#page-5-1) and [2](#page-5-3) it holds in probability at least* 1 − δ *that*

$$
GA \le LF^{L-1} \left( C_1 \frac{\epsilon}{\sqrt{N}} + C_2 \frac{\sqrt{\log(1/\delta)}}{N} \right) + F^L C_3 \left( \frac{\log N}{N} \right)^{\frac{1}{d}} \tag{15}
$$

*1.* When the graph is constructed with a Gaussian kernel [\(8\)](#page-4-4), then  $\epsilon \sim \left(\frac{\log(C/\delta)}{N}\right)$  $\frac{(C/\delta)}{N}\bigg)^{\tfrac{1}{d+4}}.$ 

2. When the graph is constructed as an  $\epsilon$ -graph as [\(9\)](#page-4-5), then  $\epsilon \sim \left(\frac{\log(CN/\delta)}{N}\right)$  $\frac{CN(\delta)}{N}\bigg)^{\frac{1}{d+4}}.$ 

*Proof.* See Appendix [D](#page-21-0) for proof and the definitions of  $C_1$ ,  $C_2$  and  $C_3$ .

Theorem [1](#page-5-0) shows that the generalization gap decreases approximately linearly with the number of nodes  $N$  in the logarithmic scale. It also increases with the dimension of the underlying manifold d. Another observation is that the generalization gap scales with the size of GNN architectures. Specifically, it scales polynomially with the number of features  $F$ , while the exponent depends on the number of layers L. This generalization result attests that when the graph is supported on a manifold, a GNN trained on this discrete graph model can approximate the MNN performance. GNNs trained on these finite sampled points can generalize to predict the labels of other unseen points over the manifold with large enough nodes in the graph. To generalize effectively over a manifold with a higher dimension, we need more sampled points to construct the graph to guarantee the generalization.

 $\Box$ 

#### <span id="page-6-1"></span>4.2 Manifold classification via graph classification

Suppose we have a set of manifolds  $\{M_k\}_{k=1}^K$ , each of which is  $d_k$ -dimensional, smooth, compact, differentiable and embedded in  $\mathbb{R}^M$  with measure  $\mu_k$ . Each manifold  $\mathcal{M}_k$  equipped with a weighted Laplace operator  $\mathcal{L}_{\rho,k}$  is labeled with  $y_k \in \mathbb{R}$ . We assume to have access to  $N_k$  randomly sampled points according to measure  $\mu_k$  over each manifold  $\mathcal{M}_k$  and construct K graphs  $\{G_k\}_{k=1}^K$  with graph Laplacian  ${\bf L}_{N,k}$ . The GNN  $\pmb{\Phi_G}({\bf H},{\bf L}_{N,\cdot},{\bf x})$  is trained on this set of graphs with  ${\bf x}_k$  as the input graph signal sampled from the manifold signal  $f_k \in L^2(\mathcal{M}_k)$  and  $y_k \in \mathbb{R}$  as the scalar target label. The final output of the GNN is set to be the average of the output signal values on each node while the output of MNN  $\Phi(H, \mathcal{L}_{\rho, \cdot}, f_{\cdot})$  is the statistical average value of the output signal over the manifold. A loss function  $\ell$  evaluates the difference between the output of GNN and MNN with the target label. The empirical risk of the GNN is

$$
R_{\mathbf{G}}(\mathbf{H}) = \sum_{k=1}^{K} \ell \left( \frac{1}{N_k} \sum_{i=1}^{N_k} [\mathbf{\Phi}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_k)]_i, y_k \right).
$$
 (16)

While the output of MNN is the average value over the manifold, the statistical risk is defined based on the loss evaluated between the MNN output and the label as

$$
R_{\mathcal{M}}(\mathbf{H}) = \sum_{k=1}^{K} \ell \left( \int_{\mathcal{M}_k} \Phi(\mathbf{H}, \mathcal{L}_{\rho, k}, f_k)(x) d\mu_k(x), y_k \right).
$$
 (17)

The generalization gap is therefore

$$
GA = \sup_{\mathbf{H} \in \mathcal{H}} |R_{\mathcal{M}}(\mathbf{H}) - R_{\mathbf{G}}(\mathbf{H})|.
$$
 (18)

<span id="page-6-0"></span>Theorem 2. *Suppose the GNN and MNN with low-pass filters (Definition [4\)](#page-5-2) have* L *layers with* F *features in each layer and the input signal is bandlimited (Definition [1\)](#page-4-3). Under Assumptions [1](#page-5-1) and [2](#page-5-3) it holds in probability at least* 1 − δ *that*

$$
GA \le LF^{L-1} \sum_{k=1}^{K} \left( \frac{C_1}{\sqrt{N_k}} \epsilon + C_2 \frac{\sqrt{\log(1/\delta)}}{N_k} \right) + F^L C_3 \sum_{k=1}^{K} \left( \frac{\log N_k}{N_k} \right)^{\frac{1}{d_k}}
$$
(19)

*1.* When the graph is constructed with a Gaussian kernel [\(8\)](#page-4-4), then  $\epsilon \sim \left(\frac{\log(C/\delta)}{N}\right)$  $\frac{d(C/\delta)}{N_k}$ <sup> $\frac{1}{d_k+4}$ </sup>.

2. When the graph is constructed as an  $\epsilon$ -graph as [\(9\)](#page-4-5), then  $\epsilon \sim \left(\frac{\log(CN_k/\delta)}{N_k}\right)$  $\frac{CN_k/\delta)}{N_k}$   $\frac{1}{d_k+4}$ .

*Proof.* See Appendix [E](#page-23-0) for proof and the definitions of  $C_1$ ,  $C_2$  and  $C_3$ .

 $\Box$ 

Theorem [2](#page-6-0) shows that a single graph sampled from the underlying manifold with large enough sampled points  $N$  can provide an effective approximation to classify the manifold itself. The generalization gap also attests that the trained GNN can generalize to classify other unseen graphs sampled from the same manifold. Similar to the generalization result in node-level tasks, the generalization gap decreases with the number of points sampled over each manifold while increasing with the manifold dimension. A higher dimensional manifold, i.e. higher complexity, needs more samples to guarantee the generalization. The generalization gap also scales with the size of GNN architecture polynomially with the number of features and exponentially with the number of layers.

### <span id="page-6-2"></span>5 Experiments

Node classification In this section, we empirically study the generalization gap in 8 real-world datasets. The task is to predict the label of a node given a set of features. The datasets vary in the number of nodes from 169, 343 to 3, 327, and in the number of edges from 1, 166, 243 to 9, 104. The feature dimension also varies from 8, 415 to 300 features, and the number of classes of the node label from 40 to 3. We consider the following datasets: *OGBN-Arxiv* [\[20,](#page-11-1) [44\]](#page-12-7), *Cora* [\[45\]](#page-12-8), *CiteSeer* [\[45\]](#page-12-8),

<span id="page-7-0"></span>

Figure 3: In the top row, we plot the difference in the accuracy and loss for columns [3a, 3b](#page-7-0) and [3c,](#page-7-0) [3d,](#page-7-0) respectively. On the bottom row, we plot the actual train and test values of the accuracy [\(3a, 3b\)](#page-7-0), and the loss [\(3c, 3d\)](#page-7-0). The plots are for the Arxiv dataset and {64, 128, 256, 512} hidden units. For the bottom row, we also calculate the linear fit for the values whose training accuracy is below 95%, showing that our linear bound on the logarithm of the generalization gap for the logarithm of the number of nodes shares the same rate shown in Theorem [1.](#page-5-0)

*PubMed* [\[45\]](#page-12-8), *Coauthors CS* [\[46\]](#page-12-9), *Coauthors Physics* [\[46\]](#page-12-9), *Amazon-rating* [\[47\]](#page-12-10), and *Roman-Empire* [\[47\]](#page-12-10), details of the datasets can be found in Table [2.](#page-25-0) In all cases, we vary the number of nodes in the training set by partitioning it in  $\{1, 2, 4, 8, 16, 32, 64, 32, 64, 128, 256, 512, 1024\}$  partitions when possible. For both the training and testing sets, we computed the loss in *cross-entropy loss*, and the accuracy in percentage  $(\%)$ .

Our main goal is to show that the rate presented in Theorem [1](#page-5-0) holds in practice. That is to say, if we plot the logarithm of the generalization gap as a function of the logarithm of the number of nodes we see a linear rate. To be consistent with the theory, we also want to show that if the number of layers or the size of the features increases, so does the generalization gap.

In Figure [3,](#page-7-0) we plot the generalization gap of the accuracy in the logarithmic scale for a two-layered GNN (Figure [3a\)](#page-7-0), and for a three-layered GNN (Figure [3b\)](#page-7-0). On the upper side, we can see that the generalization bound decreases with the number of nodes and that outside of the strictly overfitting regime (when the training loss is below 95%), the generalization gap shows a linear decay, as depicted in the dashed line. The same behavior can be seen in plots [3c,](#page-7-0) and [3d](#page-7-0) which correspond to the loss for 2 and 3 layered GNNs. As predicted by our theory, the generalization gap increases with the

(a) Differences of the outputs of 3-layer GNNs. (b) Differences of the outputs of 4-layer GNNs.

Figure 6: Generalization gap as a function of number of nodes for average GNN output differences for graph classification over ModelNet10.

number of features and layers in the GNN (see also Figure [1\)](#page-1-0). The behavior of the training and testing accuracy as a function of the number of nodes is intuitive. For the training loss, when the number of nodes in the training set is small, the GNN can overfit the training data. As the number of features increases, the GNN's capacity to overfit also increases.

In Figures [4,](#page-7-1) and [5](#page-8-0) we present the accuracy generalization gaps for 2 and 3 layers with 32 and 64 features. In the overfitting regime, the rate of our generalization bound seems to hold – decreases linearly with the number of nodes in the logarithmic scale. In the non-overfitting regime, our rate holds for the points whose training accuracy is below 95%. Also, we validate that the bound increases both with the number of features, as well as the number of layers.

In Table [1](#page-8-1) we present the Pearson correlation coefficient to measure the linear relationships in the generalization gaps of a 2 layers GNN with 64 hidden units in all datasets considered. In almost every case, the coefficient is above 0.95 which translates into a strong linear correlation. In Appendix [F](#page-24-0) we explain how we computed these values. As seen in the experiment, the GNN generalization gap experiences a linear decay with respect to the number of nodes in the logarithmic scale. The bound presented in Theorem [1](#page-5-0) is an upper bound on the generalization

<span id="page-8-1"></span>

Amazon	$-0.99\overline{72}$
Roman	$-1.0000$

Table 1: Pearson correlation for 2 layer, 64 hidden units GNNs measured on the accuracy generalization gap.

gap, whose rate can be seen to match the one seen in practice both for the loss, as well as the accuracy gaps.

**Graph classification** We evaluate the generalization gap on graph prediction using the ModelNet10 dataset [\[43\]](#page-12-6). We set the coordinates of each point as input graph signals, and the weights of the edges are calculated based on the Euclidean distance between the nodes. The generalization gap is calculated by training GNNs on graphs with  $N = 10, 20, \ldots, 80$  sampled points, and plotting the

differences between the average output of the trained GNNs on the trained graph and a testing graph with size  $N = 100$ . Figure [6a](#page-8-2) shows the generalization gaps for GNNs with 3 layers and Figure [6b](#page-8-2) shows the results of GNNs with 4 layers. We can see that the output differences between the GNNs decrease with the number of nodes and scale with the size of the GNN architectures. This verifies the claims of Theorem [2.](#page-6-0) In Appendix [F,](#page-24-0) we present experiment results on more model datasets.

# <span id="page-9-0"></span>6 Conclusion

We study the statistical generalization of GNNs from a manifold perspective. We considered graphs sampled from manifolds and proved that GNNs can effectively generalize to unseen data from the manifolds when the number of sampled points is large enough. We validate our results both on node-level and graph-level classification tasks with real-world datasets. The impact of this paper is to show a better understanding of GNN generalization capabilities from a statistical perspective relying on a continuous model. Our work also motivates the practical design of large-scale GNNs. For future work, we will study the switching behavior between the over-fitting, and non-over-fitting regimes of node classification.

### <span id="page-15-1"></span>A Induced manifold signals

The graph signal attached to this constructed graph G can be seen as the discretization of the continuous function over the manifold. Suppose  $f \in L^2(\mathcal{M})$ , the graph signal  $\mathbf{x}_N$  is composed of discrete data values of the function f evaluated at  $X_N$ , i.e.  $[\mathbf{x}_N]_i = f(x_i)$  for  $i = 1, 2 \cdots, N$ . With a sampling operator  $\mathbf{P}_N : L^2(\mathcal{M}) \to L^2(X_N)$ , the discretization can be written as

$$
\mathbf{x}_N = \mathbf{P}_N f. \tag{20}
$$

Let  $\mu_N$  be the empirical measure of the random sample as

$$
\mu_N = \frac{1}{N} \sum_{i=1}^N \delta_{x_i}.\tag{21}
$$

Let  $\{V_i\}_{i=1}^N$  be the decomposition [\[48\]](#page-12-11) of M with respect to  $X_N$  with  $V_i \subset B_r(x_i)$ , where  $B_r(x_i)$ denoted the closed metric ball of radius r centered at  $x_i \in \mathcal{M}$ . The decomposition can be achieved by the optimal transportation map  $T : \mathcal{M} \to X_N$ , which is defined by the  $\infty$ -Optimal Transport distance between  $\mu$  and  $\mu_N$ .

$$
d_{\infty}(\mu, \mu_N) := \min_{T: T_{\#}\mu = \mu_N} \operatorname{esssup}_{x \in \mathcal{M}} d(x, T(x)),
$$
\n(22)

where  $T_{\#}\mu = \mu_N$  indicates that  $\mu(T^{-1}(V)) = \mu_N(V)$  for every  $V_i$  of M. This transportation map T induces the partition  $V_1, V_2, \cdots V_N$  of M, where  $V_i := T^{-1}(\{x_i\})$  with  $\mu(V_i) = \frac{1}{N}$  for all  $i = 1, \cdots N$ . The radius of  $V_i$  can be bounded as  $r \leq A(\log N/N)^{1/d}$  with A related to the geometry of  $M$  [\[48,](#page-12-11) Theorem 2].

The manifold function induced by the graph signal  $x_N$  over the sampled graph G is defined by

$$
(\mathbf{I}_N \mathbf{x}_N)(x) = \sum_{i=1}^N [\mathbf{x}]_i \mathbb{1}_{x \in V_i}, \text{ for all } x \in \mathcal{M}
$$
 (23)

where we denote  $I_N: L^2(X_N) \to L^2(\mathcal{M})$  as the inducing operator.

### <span id="page-15-2"></span>B Convergence of GNN to MNN

The convergence of GNN on sampled graphs to MNN provides the support for the generalization analysis. We first introduce the inner product over the manifold. The inner product of signals  $f, g \in L^2(\mathcal{M})$  is defined as

<span id="page-15-0"></span>
$$
\langle f, g \rangle_{\mathcal{M}} = \int_{\mathcal{M}} f(x)g(x) \mathrm{d}\mu(x),\tag{24}
$$

where  $d\mu(x)$  is the volume element with respect to the measure  $\mu$  over M. Similarly, the norm of the manifold signal  $f$  is

$$
||f||_{\mathcal{M}}^2 = \langle f, f \rangle_{\mathcal{M}}.\tag{25}
$$

<span id="page-15-3"></span>**Proposition 1.** Let  $M \subset \mathbb{R}^M$  be an embedded manifold with weighted Laplace operator  $\mathcal{L}_{\rho}$  and *a bandlimited manifold signal f. Graph*  $\mathbf{G}_N$  *is constructed based on a set of* N *i.i.d. randomly sampled points*  $X_N = \{x_1, x_2, \dots, x_N\}$  *according to measure*  $\mu$  *over* M. A graph signal **x** *is the sampled manifold function values at*  $X_N$ *. The graph Laplacian*  $\mathbf{L}_N$  *is calculated based on* [\(8\)](#page-4-4) *or* [\(9\)](#page-4-5) *with*  $\epsilon$  *as the graph parameter. Let*  $\Phi(H, \mathcal{L}_{\rho}, \cdot)$  *be a MNN on*  $\mathcal{M}$  [\(7\)](#page-3-2) *with L layers and F features in each layer. Let*  $\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \cdot)$  *be the GNN with the same architecture applied to the graph*  $\mathbf{G}_N$ *. Then, with the filters as low-pass and nonlinearities as normalized Lipschitz continuous, it holds in probability at least*  $1 - \delta$  *that* 

$$
\frac{1}{N} \sum_{i=1}^{N} \|\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x}) - \mathbf{P}_N \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_\rho, \mathbf{I}_N \mathbf{x})\|_2 \leq L F^{L-1} \left( C_1 \epsilon + C_2 \sqrt{\frac{\log(1/\delta)}{N}} \right) \tag{26}
$$

*where*  $C_1$ ,  $C_2$  *are constants defined in the following proof.* 

<span id="page-16-2"></span>Proposition 2. *[\[35,](#page-11-15) Proposition 2, Proposition 4] Let* M ⊂ R <sup>M</sup> *be equipped with Laplace operator*  $\mathcal{L}_\rho$ , whose eigendecomposition is given by  $\{\lambda_i, \phi_i\}_{i=1}^\infty$ . Let  $\mathbf{L}_N$  be the discrete graph Laplacian  $of$  graph weights defined as [\(8\)](#page-4-4) (or [\(9\)](#page-4-5)), with spectrum  $\{\lambda_{i,N},\phi_{i,N}\}_{i=1}^N$ . Fix  $K\in\mathbb{N}^+$  and assume *that*  $\epsilon = \epsilon(N) \geq (\log(C/\delta)/N)^{1/(d+4)}$  (or  $\epsilon = \epsilon(N) \geq (\log(CN/\delta)/N)^{1/(d+4)}$ ). Then, with *probability at least* 1 − δ*, we have*

$$
|\lambda_i - \lambda_{i,N}| \le C_{\mathcal{M},1} \lambda_i \epsilon, \quad \|a_i \phi_{i,N} - \phi_i\| \le C_{\mathcal{M},2} \frac{\lambda_i}{\theta_i} \epsilon,
$$
 (27)

*with*  $a_i \in \{-1, 1\}$  *for all*  $i < K$  *and*  $\theta$  *the eigengap of*  $\mathcal{L}$ *, i.e.,*  $\theta_i = \min\{\lambda_i - \lambda_{i-1}, \lambda_{i+1} - \lambda_i\}$ *. The constants*  $\ddot{C}_{\mathcal{M},1}$ ,  $\ddot{C}_{\mathcal{M},2}$  depend on d and the volume, the injectivity radius and sectional curvature of M*.*

*Proof.* Because  $\{x_1, x_2, \dots, x_N\}$  is a set of randomly sampled points from M, based on Theorem 19 in [\[49\]](#page-12-12) we can claim that

$$
|\langle \mathbf{P}_N f, \mathbf{P}_N \boldsymbol{\phi}_i \rangle - \langle f, \boldsymbol{\phi}_i \rangle_{\mathcal{M}}| = O\left(\sqrt{\frac{\log(1/\delta)}{N}}\right).
$$
 (28)

This also indicates that

$$
\left|\|\mathbf{P}_N f\|^2 - \|f\|_{\mathcal{M}}^2\right| = O\left(\sqrt{\frac{\log(1/\delta)}{N}}\right),\tag{29}
$$

<span id="page-16-0"></span> $\parallel$ II II II  $\frac{1}{2}$ 

<span id="page-16-1"></span>.

which indicates  $\|\mathbf{P}_N f\| = \|f\|_{\mathcal{M}} + O((\log(1/\delta)/N)^{1/4})$ . We suppose that the input manifold signal is  $\lambda_M$ -bandlimited with M spectral components. We first write out the filter representation as

$$
\|\mathbf{h}(\mathbf{L}_{N})\mathbf{P}_{N}f - \mathbf{P}_{N}\mathbf{h}(\mathcal{L}_{\rho})f\| = \left\|\sum_{i=1}^{N}\hat{h}(\lambda_{i,N})\langle\mathbf{P}_{N}f, \phi_{i,N}\rangle\phi_{i,N} - \sum_{i=1}^{M}\hat{h}(\lambda_{i})\langle f, \phi_{i}\rangle_{\mathcal{M}}\mathbf{P}_{N}\phi_{i}\right\|
$$
\n(30)\n
$$
\leq \left\|\sum_{i=1}^{M}\hat{h}(\lambda_{i,N})\langle\mathbf{P}_{N}f, \phi_{i,N}\rangle\phi_{i,N} - \sum_{i=1}^{M}\hat{h}(\lambda_{i})\langle f, \phi_{i}\rangle_{\mathcal{M}}\mathbf{P}_{N}\phi_{i} + \sum_{i=M+1}^{N}\hat{h}(\lambda_{i,N})\langle\mathbf{P}_{N}f, \phi_{i,N}\rangle\phi_{i,N}\right\|
$$
\n(31)\n
$$
\leq \left\|\sum_{i=1}^{M}\hat{h}(\lambda_{i,N})\langle\mathbf{P}_{N}f, \phi_{i,N}\rangle\phi_{i,N} - \sum_{i=1}^{M}\hat{h}(\lambda_{i})\langle f, \phi_{i}\rangle_{\mathcal{M}}\mathbf{P}_{N}\phi_{i}\right\| + \left\|\sum_{i=M+1}^{N}\hat{h}(\lambda_{i,N})\langle\mathbf{P}_{N}f, \phi_{i,N}\rangle\phi_{i,N} - \sum_{i=1}^{M}\hat{h}(\lambda_{i,N})\langle f, \phi_{i}\rangle_{\mathcal{M}}\mathbf{P}_{N}\phi_{i}\right\|
$$
\n(32)

The first part of [\(32\)](#page-16-0) can be decomposed with the triangle inequality as

$$
\left\| \sum_{i=1}^{M} \hat{h}(\lambda_{i,N}) \langle \mathbf{P}_{N} f, \phi_{i,N} \rangle \phi_{i,N} - \sum_{i=1}^{M} \hat{h}(\lambda_{i}) \langle f, \phi_{i} \rangle_{\mathcal{M}} \mathbf{P}_{N} \phi_{i} \right\|
$$
  

$$
\leq \left\| \sum_{i=1}^{M} \left( \hat{h}(\lambda_{i,N}) - \hat{h}(\lambda_{i}) \right) \langle \mathbf{P}_{N} f, \phi_{i,N} \rangle \phi_{i,N} \right\| + \left\| \sum_{i=1}^{M} \hat{h}(\lambda_{i}) \left( \langle \mathbf{P}_{N} f, \phi_{i,N} \rangle \phi_{i,N} - \langle f, \phi_{i} \rangle_{\mathcal{M}} \mathbf{P}_{N} \phi_{i} \right) \right\|
$$
(33)

In equation [\(33\)](#page-16-1), the first part relies on the difference of eigenvalues and the second part depends on the eigenvector difference. The first term in [\(33\)](#page-16-1) is bounded with Cauchy-Schwartz inequality as

$$
\left\| \sum_{i=1}^{M} (\hat{h}(\lambda_{i,n}) - \hat{h}(\lambda_i)) \langle \mathbf{P}_N f, \phi_{i,N} \rangle \phi_{i,N} \right\| \leq \sum_{i=1}^{M} \left| \hat{h}(\lambda_{i,N}) - \hat{h}(\lambda_i) \right| |\langle \mathbf{P}_N f, \phi_{i,N} \rangle|
$$
(34)

$$
\leq \|\mathbf{P}_N f\| \sum_{i=1}^M |\hat{h}'(\lambda_i)| |\lambda_{i,N} - \lambda_i| \tag{35}
$$

<span id="page-17-0"></span>
$$
\leq \|\mathbf{P}_N f\| \sum_{i=1}^M C_{\mathcal{M},1} C_L \epsilon \lambda_i^{-d} \tag{36}
$$

<span id="page-17-1"></span>
$$
\leq \|\mathbf{P}_N f\| C_L C_{\mathcal{M},1} \epsilon \sum_{i=1}^M i^{-2}
$$
\n(37)

<span id="page-17-2"></span>
$$
\leq \left( \|f\|_{\mathcal{M}} + \left(\frac{\log(1/\delta)}{N}\right)^{\frac{1}{4}} \right) C_{\mathcal{M},1} \epsilon \frac{\pi^2}{6} := A_1(N) \quad (38)
$$

In [\(36\)](#page-17-0), it depends on the low-pass filter assumption in Definition [4.](#page-5-2) In [\(37\)](#page-17-1), we implement Weyl's law [\[50\]](#page-12-13) which indicates that eigenvalues of Laplace operator scales with the order  $\lambda_i \sim i^{2/d}$ . The last inequality comes from the fact that  $\sum_{i=1}^{\infty} i^{-2} = \frac{\pi^2}{6}$  $\frac{6}{6}$ . The second term in [\(33\)](#page-16-1) can be bounded with the triangle inequality as

$$
\left\| \sum_{i=1}^{M} \hat{h}(\lambda_i) \left( \langle \mathbf{P}_N f, \phi_{i,N} \rangle \phi_{i,N} - \langle f, \phi_i \rangle_{\mathcal{M}} \mathbf{P}_N \phi_i \right) \right\|
$$
  

$$
\leq \left\| \sum_{i=1}^{M} \hat{h}(\lambda_i) \left( \langle \mathbf{P}_N f, \phi_{i,N} \rangle \phi_{i,N} - \langle \mathbf{P}_N f, \phi_{i,N} \rangle \mathbf{P}_N \phi_i \right) \right\|
$$
  

$$
+ \left\| \sum_{i=1}^{M} \hat{h}(\lambda_i) \left( \langle \mathbf{P}_N f, \phi_{i,N} \rangle \mathbf{P}_N \phi_i - \langle f, \phi_i \rangle_{\mathcal{M}} \mathbf{P}_N \phi_i \right) \right\|
$$
(39)

The first term in [\(39\)](#page-17-2) can be bounded with inserting the eigenfunction convergence result in Proposition [2](#page-16-2) as

$$
\left\| \sum_{i=1}^{M} \hat{h}(\lambda_i) \left( \langle \mathbf{P}_N f, \phi_{i,N} \rangle \phi_{i,N} - \langle \mathbf{P}_N f, \phi_{i,N} \rangle_{\mathcal{M}} \mathbf{P}_N \phi_i \right) \right\|
$$
  

$$
\leq \sum_{i=1}^{M} \left| \hat{h}(\lambda_i) \right| \| \mathbf{P}_N f \| \| \phi_{i,N} - \mathbf{P}_N \phi_i \|
$$
 (40)

$$
\leq \sum_{i=1}^{M} (\lambda_i^{-d}) \frac{C_{\mathcal{M},2} \epsilon}{\theta_i} \left( \|f\|_{\mathcal{M}} + \left(\frac{\log(1/\delta)}{N}\right)^{\frac{1}{4}} \right) \tag{41}
$$

$$
\leq C_{\mathcal{M},2}\epsilon \frac{\pi^2}{6} \max_{i=1,\cdots,M} \theta_i^{-1} \left( \|f\|_{\mathcal{M}} + \left(\frac{\log(1/\delta)}{N}\right)^{\frac{1}{4}} \right) \tag{42}
$$

$$
:= A_2(M, N). \tag{43}
$$

Considering the low-pass filter assumption, the second term in [\(39\)](#page-17-2) can be written as

$$
\left\| \sum_{i=1}^{M} \hat{h}(\lambda_{i,N}) (\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle \mathbf{P}_{N} \phi_{i} - \langle f, \phi_{i} \rangle_{\mathcal{M}} \mathbf{P}_{N} \phi_{i}) \right\|
$$
  

$$
\leq \sum_{i=1}^{M} \left| \hat{h}(\lambda_{i,N}) \right| |\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle - \langle f, \phi_{i} \rangle_{\mathcal{M}}| \left\| \mathbf{P}_{N} \phi_{i} \right\|
$$
(44)

$$
\leq \sum_{i=1}^{M} (\lambda_{i,N}^{-d}) \left| \left\langle \mathbf{P}_N f, \phi_{i,N} \right\rangle - \left\langle f, \phi_i \right\rangle_{\mathcal{M}} \right| \left( 1 + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right) \tag{45}
$$

$$
\leq \sum_{i=1}^{M} (1 + C_{\mathcal{M},1} \epsilon)^{-d} (\lambda_i^{-d}) \left| \langle \mathbf{P}_N f, \phi_{i,N} \rangle - \langle f, \phi_i \rangle_{\mathcal{M}} \right| \left( 1 + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right) \tag{46}
$$

$$
\leq \frac{\pi^2}{6} |\langle \mathbf{P}_N f, \phi_{i,N} \rangle - \langle f, \phi_i \rangle_{\mathcal{M}}| \left( 1 + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right) := A_3(N) \tag{47}
$$

The term  $|\langle \mathbf{P}_N f, \phi_{i,N} \rangle - \langle f, \phi_i \rangle_{\mathcal{M}}|$  can be decomposed by inserting a term  $\langle \mathbf{P}_N f, \mathbf{P}_N \phi_i \rangle$  as  $|\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle - \langle f, \phi_i \rangle_{\mathcal{M}}| \leq |\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle - \langle \mathbf{P}_{N} f, \mathbf{P}_{N} \phi_i \rangle + \langle \mathbf{P}_{N} f, \mathbf{P}_{N} \phi_i \rangle - \langle f, \phi_i \rangle_{\mathcal{M}}|$ 

<span id="page-18-0"></span>
$$
(48)
$$

$$
\leq |\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle - \langle \mathbf{P}_{N} f, \mathbf{P}_{N} \phi_{i} \rangle| + |\langle \mathbf{P}_{N} f, \mathbf{P}_{N} \phi_{i} \rangle - \langle f, \phi_{i} \rangle_{\mathcal{M}}|
$$
\n(49)

$$
\leq \|\mathbf{P}_N f\| \|\boldsymbol{\phi}_{i,N} - \mathbf{P}_N \boldsymbol{\phi}_i\| + |\langle \mathbf{P}_N f, \mathbf{P}_N \boldsymbol{\phi}_i \rangle - \langle f, \boldsymbol{\phi}_i \rangle_{\mathcal{M}}| \tag{50}
$$

$$
\leq \left( \|f\|_{\mathcal{M}} + \left(\frac{\log(1/\delta)}{N}\right)^{\frac{1}{4}} \right) \frac{C_{\mathcal{M},2} \lambda_i \epsilon}{\theta_i} + \sqrt{\frac{\log(1/\delta)}{N}} \tag{51}
$$

Then equation [\(46\)](#page-18-0) can be bounded as

$$
\left\| \sum_{i=1}^{M} \hat{h}(\lambda_{i,N}) (\langle \mathbf{P}_{N} f, \phi_{i,N} \rangle \mathbf{P}_{N} \phi_{i} - \langle f, \phi_{i} \rangle_{\mathcal{M}} \mathbf{P}_{N} \phi_{i}) \right\|
$$
  
\n
$$
\leq \sum_{i=1}^{M} (1 + C_{\mathcal{M},1} \epsilon)^{-d} (\lambda_{i}^{-d}) \left( \left( \|f\|_{\mathcal{M}} + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right) \frac{C_{\mathcal{M},2} \lambda_{i} \epsilon}{\theta_{i}} + \sqrt{\frac{\log(1/\delta)}{N}} \right) \left( 1 + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right)
$$
  
\n(52)

$$
\leq \frac{\pi^2}{6} \max_{i=1,\cdots,M} \frac{C_{\mathcal{M},2}\epsilon}{\theta_i} \left( \|f\|_{\mathcal{M}} + \left(\frac{\log(1/\delta)}{N}\right)^{\frac{1}{4}} \right) + \frac{\pi^2}{6} \sqrt{\frac{\log(1/\delta)}{N}} \tag{53}
$$

The second term in [\(32\)](#page-16-0) can be bounded with the eigenvalue difference bound in Proposition [2](#page-16-2) as

$$
\left\| \sum_{i=M+1}^{N} \hat{h}(\lambda_{i,N}) \langle \mathbf{P}_N f, \phi_{i,N} \rangle \phi_{i,N} \right\| \leq \sum_{i=M+1}^{N} (\lambda_{i,N}^{-d}) \left( \|f\|_{\mathcal{M}} + \left( \frac{\log(1/\delta)}{N} \right)^{\frac{1}{4}} \right) \tag{54}
$$
\n
$$
\leq \sum_{i=M+1}^{\infty} (\lambda_{i,N}^{-d}) \|f\|_{\mathcal{M}}
$$

$$
\leq \sum_{i=M+1} (\lambda_{i,N}^{-d}) \|f\|_{\mathcal{M}}
$$
\n(55)

$$
\leq (1 + C_{\mathcal{M},1}\epsilon)^{-d} \sum_{i=M+1}^{\infty} (\lambda_i^{-d}) \|f\|_{\mathcal{M}}
$$
 (56)

<span id="page-18-1"></span>
$$
\leq M^{-1} \|f\|_{\mathcal{M}} := A_4(M). \tag{57}
$$

We note that the bound is made up by terms  $A_1(N) + A_2(M, N) + A_3(N) + A_4(M)$ , related to the bandwidth of manifold signal  $\overline{M}$  and the number of sampled points  $\overline{N}$ . This makes the bound scale with the order

$$
\|\mathbf{h}(\mathbf{L}_N)\mathbf{P}_N f - \mathbf{P}_N \mathbf{h}(\mathcal{L}_\rho) f\| \le C_1' \epsilon + C_2' \epsilon \theta_M^{-1} + C_3' \sqrt{\frac{\log(1/\delta)}{N}} + C_4' M^{-1},\tag{58}
$$

with  $C_1' = C_L C_{\mathcal{M},1} \frac{\pi^2}{6}$  $\frac{\pi^2}{6} \| f \|_{\mathcal{M}}, C'_2 = C_{\mathcal{M}, 2} \frac{\pi^2}{6}$  $\frac{\pi^2}{6}, C'_3 = \frac{\pi^2}{6}$  $\frac{\pi^2}{6}$  and  $C'_4 = ||f||_{\mathcal{M}}$ . As N goes to infinity, for every  $\delta > 0$ , there exists some  $M_0$ , such that for all  $\check M > M_0$  it holds that  $A_4(M) \le \delta/2$ . There also exists  $n_0$ , such that for all  $N > n_0$ , it holds that  $A_1(N) + A_2(M_0, N) + A_3(N) \le \delta/2$ . We can conclude that the summations converge as  $N$  goes to infinity. We see  $M$  large enough to have  $M^{-1} \leq \delta'$ , which makes the eigengap  $\theta_M$  also bounded by some constant. We combine the first two terms as

$$
\|\mathbf{h}(\mathbf{L}_N)\mathbf{P}_N f - \mathbf{P}_N \mathbf{h}(\mathcal{L}_\rho) f\| \le C_1 \epsilon + C_2 \sqrt{\frac{\log(1/\delta)}{N}},\tag{59}
$$

with  $C_1 = C_1' + C_2' \theta_{\delta'^{-1}}^{-1}$  and  $C_2 = C_3'$  To bound the output difference of MNNs, we need to write in the form of features of the final layer

$$
\|\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{P}_N f) - \mathbf{P}_N \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_\rho, f))\| = \left\|\sum_{q=1}^F \mathbf{x}_{n,L}^q - \sum_{q=1}^F \mathbf{P}_N f_L^q \right\| \le \sum_{q=1}^F \left\|\mathbf{x}_{n,L}^q - \mathbf{P}_N f_L^q \right\|.
$$
\n(60)

By inserting the definitions, we have

$$
\left\| \mathbf{x}_{n,l}^p - \mathbf{P}_N f_l^p \right\| = \left\| \sigma \left( \sum_{q=1}^F \mathbf{h}_l^{pq} (\mathbf{L}_N) \mathbf{x}_{n,l-1}^q \right) - \mathbf{P}_N \sigma \left( \sum_{q=1}^F \mathbf{h}_l^{pq} (\mathcal{L}_\rho) f_{l-1}^q \right) \right\| \tag{61}
$$

with  $\mathbf{x}_{n,0} = \mathbf{P}_N f$  as the input of the first layer. With a normalized point-wise Lipschitz nonlinearity, we have

$$
\|\mathbf{x}_{n,l}^p - \mathbf{P}_N f_l^p\| \le \left\|\sum_{q=1}^F \mathbf{h}_l^{pq} (\mathbf{L}_N) \mathbf{x}_{n,l-1}^q - \mathbf{P}_N \sum_{q=1}^F \mathbf{h}_l^{pq} (\mathcal{L}_\rho) f_{l-1}^q\right\| \tag{62}
$$

$$
\leq \sum_{q=1}^{F} \left\| \mathbf{h}_l^{pq}(\mathbf{L}_N) \mathbf{x}_{n,l-1}^q - \mathbf{P}_N \mathbf{h}_l^{pq}(\mathcal{L}_\rho) f_{l-1}^q \right\| \tag{63}
$$

The difference can be further decomposed as

$$
\|\mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{x}_{n,l-1}^q - \mathbf{P}_N\mathbf{h}_l^{pq}(\mathcal{L}_\rho)f_{l-1}^q\|
$$
  
\n
$$
\leq \|\mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{x}_{n,l-1}^q - \mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{P}_Nf_{l-1}^q + \mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{P}_Nf_{l-1}^q - \mathbf{P}_N\mathbf{h}_l^{pq}(\mathcal{L}_\rho)f_{l-1}^q\|
$$
(64)

$$
\leq \left\| \mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{x}_{n,l-1}^q - \mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{P}_N f_{l-1}^q \right\| + \left\| \mathbf{h}_l^{pq}(\mathbf{L}_N)\mathbf{P}_N f_{l-1}^q - \mathbf{P}_N \mathbf{h}_l^{pq}(\mathcal{L}_\rho) f_{l-1}^q \right\| \tag{65}
$$

The second term can be bounded with [\(58\)](#page-18-1) and we denote the bound as  $\Delta_N$  for simplicity. The first term can be decomposed by Cauchy-Schwartz inequality and non-amplifying of the filter functions as

$$
\left\| \mathbf{x}_{n,l}^p - \mathbf{P}_N f_l^p \right\| \le \sum_{q=1}^F \Delta_N \|\mathbf{x}_{n,l-1}^q\| + \sum_{q=1}^F \|\mathbf{x}_{l-1}^q - \mathbf{P}_N f_{l-1}^q\|.
$$
 (66)

To solve this recursion, we need to compute the bound for  $\|\mathbf{x}_l^p\|$ . By normalized Lipschitz continuity of  $\sigma$  and the fact that  $\sigma(0) = 0$ , we can get

$$
\|\mathbf{x}_{l}^{p}\| \leq \left\|\sum_{q=1}^{F} \mathbf{h}_{l}^{pq}(\mathbf{L}_{N})\mathbf{x}_{l-1}^{q}\right\| \leq \sum_{q=1}^{F} \|\mathbf{h}_{l}^{pq}(\mathbf{L}_{N})\| \|\mathbf{x}_{l-1}^{q}\| \leq \sum_{q=1}^{F} \|\mathbf{x}_{l-1}^{q}\| \leq F^{l-1} \|\mathbf{x}\|.
$$
 (67)

Insert this conclusion back to solve the recursion, we can get

$$
\left\|\mathbf{x}_{n,l}^p - \mathbf{P}_N f_l^p\right\| \le lF^{l-1} \Delta_N \|\mathbf{x}\|.\tag{68}
$$

Replace  $l$  with  $L$  we can obtain

$$
\|\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{P}_N f) - \mathbf{P}_N \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_\rho, f))\| \le L F^{L-1} \Delta_N,
$$
\n(69)

when the input graph signal is normalized. By replacing  $f = I_N x$ , we can conclude the proof.  $\Box$ 

# <span id="page-20-0"></span>C Local Lipschitz continuity of MNNs

We propose that the outputs of MNN defined in [\(7\)](#page-3-2) are locally Lipschitz continuous within a certain area, which is stated explicitly as follows.

<span id="page-20-1"></span>Proposition 3. *(Local Lipschitz continuity of MNNs) Let MNN be* L *layers with* F *features in each layer, suppose the manifold filters are nonamplifying with*  $|\hat{h}(\lambda)| \leq 1$  *and the nonlinearities normalized Lipschitz continuous, then there exists a constant* C *such that*

$$
|\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(y)| \le F^{L}C'dist(x - y), \quad \text{for all } x, y \in B_{r}(\mathcal{M}), \tag{70}
$$

*where*  $B_r(\mathcal{M})$  *is a ball with radius r over*  $\mathcal{M}$ *.* 

*Proof.* The output of MNN can be written explicitly as

$$
|\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(y)| = \left| \sigma \left( \sum_{q=1}^{F} \mathbf{h}_L^q(\mathcal{L}_{\rho}) f_{L-1}^q(x) \right) - \sigma \left( \sum_{q=1}^{F} \mathbf{h}_L^q(\mathcal{L}_{\rho}) f_{L-1}^q(y) \right) \right|
$$
\n(71)

$$
\leq \left| \sum_{q=1}^{F} \mathbf{h}_{L}^{q}(\mathcal{L}_{\rho}) f_{L-1}^{q}(x) - \sum_{q=1}^{F} \mathbf{h}_{L}^{q}(\mathcal{L}_{\rho}) f_{L-1}^{q}(y) \right| \leq F \max_{q=1,\cdots,F} \left| \mathbf{h}_{L}^{q}(\mathcal{L}_{\rho}) f_{L-1}^{q}(x) - \mathbf{h}_{L}^{q}(\mathcal{L}_{\rho}) f_{L-1}^{q}(y) \right|
$$
\n(72)

We have  $f_{L-1}^q(x) = \sigma\left(\sum_{p=1}^F \mathbf{h}_{L-1}^p f_{L-2}^p(x)\right)$ . The process can be repeated recursively, and finally, we can have

$$
|\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(y)| \leq F^{L}|\mathbf{h}_{L}(\mathcal{L}_{\rho})\cdots\mathbf{h}_{1}(\mathcal{L}_{\rho})f(x) - \mathbf{h}_{L}(\mathcal{L}_{\rho})\cdots\mathbf{h}_{1}(\mathcal{L}_{\rho})f(y)|.
$$
\n(73)

With f as a  $\lambda$ -bandlimited manifold signal, we suppose  $g = b \cdot b \cdot L(\mathcal{L}_{\rho}) \cdots h_1(\mathcal{L}_{\rho}) f$ . As  $\langle f, \phi_i \rangle = 0$ for all  $i > M$ , g is also bandlimited and possesses M spectral components. The gradient can be bounded according to [\[51\]](#page-12-14) combined with the non-amplifying property of the filter function as

$$
\|\nabla g\|_{\infty} \le C \sum_{\lambda_i \le \lambda} \left|\hat{h}(\lambda_i)\right|^L \lambda_i^{\frac{d+1}{2}} \|f\|_{\mathcal{M}} \le C \sum_{\lambda_i \le \lambda} \lambda_i^{\frac{d+1}{2}} \|f\|_{\mathcal{M}}
$$
(74)

.

 $\Box$ 

From Theorem 4.5 in [\[52\]](#page-12-15),  $q$  is locally Lipschitz continuous as

$$
|g(x) - g(y)| \le C' \text{dist}(x - y), \quad \text{with } x, y \in B_r(\mathcal{M}), \tag{75}
$$

where  $B_r(\mathcal{M})$  is a closed ball with radius r.

Combining the above, we have the continuity of the output of MNN as

$$
|\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(y)| \le F^{L}C' \text{dist}(x - y), \quad \text{with } x, y \in B_{r}(\mathcal{M}), \qquad (76)
$$

which concludes the proof.

# <span id="page-21-0"></span>D Proof of Theorem [1](#page-5-0)

*Proof.* To analyze the difference between the empirical risk and statistical risk, we introduce an intermediate term which is the induced version of the sampled MNN output. We define  $I_N$  as the inducing operator based on the Voronoi decomposition  $\{V_i\}_{i=1}^N$  defined in Section [A.](#page-15-1) This intermediate term is written explicitly as

<span id="page-21-4"></span>
$$
\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) = \mathbf{I}_N \mathbf{P}_N \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) = \sum_{i=1}^N \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x_i) \mathbb{1}_{x \in V_i}, \text{ for all } x \in \mathcal{M}, \quad (77)
$$

where  $x_i \in X_N$  are sampled points from the manifold.

Suppose  $\mathbf{H} \in \arg \min_{\mathbf{H} \in \mathcal{H}} R_{\mathcal{M}}(\mathbf{H})$ , we have

<span id="page-21-1"></span>
$$
GA = \sup_{\mathbf{H} \in \mathcal{H}} |R_{\mathbf{G}}(\mathbf{H}) - R_{\mathcal{M}}(\mathbf{H})|
$$
\n(78)

The difference between  $R_G(H)$  and  $R_M(H)$  can be decomposed as

$$
|R_{\mathbf{G}}(\mathbf{H}) - R_{\mathcal{M}}(\mathbf{H})|
$$
  
\n
$$
= \left| \frac{1}{N} \sum_{i=1}^{N} \ell([\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \int_{\mathcal{M}} \ell(\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) \right|
$$
(79)  
\n
$$
= \left| \frac{1}{N} \sum_{i=1}^{N} \ell([\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \int_{\mathcal{M}} \ell(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) \right|
$$

$$
\begin{aligned}\n& \left| \frac{1}{N} \sum_{i=1}^{N} \ell([\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \int_{\mathcal{M}} \ell\left(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) d\mu(x) \right. \\
&\left. + \int_{\mathcal{M}} \ell\left(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) d\mu(x) - \int_{\mathcal{M}} \ell\left(\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) d\mu(x) \right| \tag{80}\n\end{aligned}
$$

$$
\leq \left| \frac{1}{N} \sum_{i=1}^{N} \ell([\Phi_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \int_{\mathcal{M}} \ell(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) \right| + \left| \int_{\mathcal{M}} \ell(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) - \int_{\mathcal{M}} \ell(\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) \right|
$$
(81)

We analyze the two terms in  $(81)$  separately, with the first term bounded based on the convergence of GNN to MNN and the second term bounded with the smoothness of manifold functions.

The first term in [\(81\)](#page-21-1) can be written as

<span id="page-21-2"></span>
$$
\left| \frac{1}{N} \sum_{i=1}^{N} \ell([\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \int_{\mathcal{M}} \ell(\overline{\mathbf{\Phi}}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)) d\mu(x) \right| \tag{82}
$$

<span id="page-21-3"></span>
$$
= \frac{1}{N} \left| \sum_{i=1}^{N} \ell([\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N}, \mathbf{x})]_{i}, [\mathbf{y}]_{i}) - \sum_{i=1}^{N} \ell(\mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x_{i}), g(x_{i})) \right| \tag{83}
$$

$$
\leq \frac{1}{N} \sum_{i=1}^{N} |\ell([\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x})]_i, [\mathbf{y}]_i) - \ell(\mathbf{\Phi}(\mathbf{H}, \mathcal{L}_\rho, f)(x_i), g(x_i))|
$$
(84)

<span id="page-21-7"></span><span id="page-21-6"></span><span id="page-21-5"></span>
$$
\leq \frac{1}{N} \sum_{i=1}^{N} \left| [\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x})]_i - \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x_i) \right| \tag{85}
$$

$$
\leq \frac{1}{N} \|\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x}) - \mathbf{P}_N \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_\rho, \mathbf{I}_N \mathbf{x})\|_1
$$
\n(86)

<span id="page-21-8"></span>
$$
\leq \frac{1}{\sqrt{N}} L F^{L-1} \left( C_1 \epsilon + C_2 \sqrt{\frac{\log(1/\delta)}{N}} \right) \tag{87}
$$

From [\(82\)](#page-21-2) to [\(83\)](#page-21-3), we use the definition of induced manifold signal defined in [\(77\)](#page-21-4). We utilize the Lipschitz continuity assumption on loss function from [\(84\)](#page-21-5) to [\(85\)](#page-21-6). From [\(85\)](#page-21-6) to [\(86\)](#page-21-7), it depends on the fact that x is a single-entry vector and that  $[y]_i$  is the value sampled from target manifold function

 $g$  evaluated on  $x_i$ . Finally the bound depends on the convergence of GNN on the sampled graph to the MNN as stated in Proposition [1.](#page-15-3)

The second term is decomposed as

$$
\left| \int_{\mathcal{M}} \ell \left( \overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x) \right) d\mu(x) - \int_{\mathcal{M}} \ell \left( \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x) \right) d\mu(x) \right| \tag{88}
$$

$$
\leq \left| \sum_{i=1}^{N} \int_{V_i} \ell\left(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) d\mu(x) - \sum_{i=1}^{N} \int_{V_i} \ell\left(\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) d\mu(x) \right| \tag{89}
$$

$$
\leq \sum_{i=1}^{N} \int_{V_i} \left| \ell\left(\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) - \ell\left(\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x), g(x)\right) \right| d\mu(x) \tag{90}
$$

$$
\leq \sum_{i=1}^{N} \int_{V_i} \left| \overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x) \right| d\mu(x) \tag{91}
$$

$$
\leq \sum_{i=1}^{N} \int_{V_i} |\mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x_i) - \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)(x)| d\mu(x) \tag{92}
$$

From [\(88\)](#page-22-0) to [\(89\)](#page-22-1), it relies on the decomposition of the MNN output over  $\{V_i\}_{i=1}^N$ . From [\(90\)](#page-22-2) to [\(91\)](#page-22-3), we use the Lipschitz continuity of loss function. From [\(91\)](#page-22-3) to [\(92\)](#page-22-4), we use the definition of  $\overline{\Phi}(\mathbf{H}, \mathcal{L}_{\rho}, f)$ . Proposition [3](#page-20-1) indicates that the MNN outputs are Lipschitz continuous within a certain range, which leads to

$$
\sum_{i=1}^{N} \int_{V_i} |\Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x_i) - \Phi(\mathbf{H}, \mathcal{L}_{\rho}, f)(x)| d\mu(x)
$$
  

$$
\leq \sum_{i=1}^{N} \int_{V_i} F^L C_3 \left(\frac{\log N}{N}\right)^{\frac{1}{d}} d\mu(x)
$$
(93)

$$
=F^{L}C_{3}\left(\frac{\log N}{N}\right)^{\frac{1}{d}}\sum_{i=1}^{N}\int_{V_{i}}\mathrm{d}\mu(x)\tag{94}
$$

$$
\leq F^L C_3 \left(\frac{\log N}{N}\right)^{\frac{1}{d}}.\tag{95}
$$

Combining [\(87\)](#page-21-8) and [\(93\)](#page-22-5), we can conclude the proof.

<span id="page-22-5"></span><span id="page-22-4"></span><span id="page-22-3"></span><span id="page-22-2"></span><span id="page-22-1"></span><span id="page-22-0"></span> $\Box$ 

# <span id="page-23-0"></span>E Proof of Theorem [2](#page-6-0)

*Proof.* We can write the difference as

$$
\begin{aligned} &|R_{\mathbf{G}}(\mathbf{H}) - R_{\mathcal{M}}(\mathbf{H})| \\ &\leq \sum_{k=1}^{K} \left| \ell \left( \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_{k})]_{i}, y_{k} \right) - \ell \left( \int_{\mathcal{M}_{k}} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k}) d\mu_{k}(x), y_{k} \right) \right| \end{aligned} \tag{96}
$$

Based on the property of absolute value inequality and the Lipschitz continuity assumption of loss function (Assumption [2\)](#page-5-3), we have

$$
\left| \ell \left( \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_{k})]_{i}, y_{k} \right) - \ell \left( \int_{\mathcal{M}_{k}} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k}) d\mu_{k}(x), y_{k} \right) \right|
$$
  

$$
\leq \left| \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_{k})]_{i} - \int_{\mathcal{M}_{k}} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k}) d\mu_{k}(x) \right|
$$
(97)

We insert an intermediate term  $\Phi(H, \mathcal{L}_{\rho,k}, f_k)(x_i)$  as the value evaluated on the sampled point  $x_i$ , which leads to

$$
\left| \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_{k})]_{i} - \int_{\mathcal{M}_{k}} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k}) d\mu_{k}(x) \right|
$$
\n
$$
\leq \left| \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_{k})]_{i} - \frac{1}{N} \sum_{i=1}^{N} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k})(x_{i}) \right| + \left| \frac{1}{N} \sum_{i=1}^{N} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k})(x_{i}) - \int_{\mathcal{M}_{k}} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_{k}) d\mu_{k}(x) \right|
$$
\n(99)

The first term in [\(99\)](#page-23-1) can be bounded similarly as [\(86\)](#page-21-7), which is explicitly written as

$$
\left| \frac{1}{N} \sum_{i=1}^{N} [\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_{N,k}, \mathbf{x}_k)]_i - \frac{1}{N} \sum_{i=1}^{N} \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x_i) \right| \tag{100}
$$

$$
\leq \frac{1}{N} \|\boldsymbol{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x}_k) - \mathbf{P}_N \boldsymbol{\Phi}(\mathbf{H}, \mathcal{L}_\rho, f_k)\|_1
$$
\n(101)

$$
\leq \frac{1}{\sqrt{N}} \|\mathbf{\Phi}_{\mathbf{G}}(\mathbf{H}, \mathbf{L}_N, \mathbf{x}_k) - \mathbf{P}_N \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_\rho, f_k)\|_2
$$
\n(102)

$$
\leq \frac{1}{\sqrt{N}} \left( C_1 \epsilon + C_2 \sqrt{\frac{\log(1/\delta)}{N}} \right) \tag{103}
$$

<span id="page-23-1"></span> $\overline{a}$ 

The second term is

$$
\left| \frac{1}{N} \sum_{i=1}^{N} \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x_i) - \int_{\mathcal{M}_k} \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k) d\mu_k(x) \right| \tag{104}
$$

$$
= \left| \sum_{i=1}^{N} \int_{V_i} \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x_i) d\mu_k(x) - \sum_{i=1}^{N} \int_{V_i} \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x) d\mu_k(x) \right| \tag{105}
$$

$$
\leq \sum_{i=1}^{N} \int_{V_i} |\mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x_i) - \mathbf{\Phi}(\mathbf{H}, \mathcal{L}_{\rho,k}, f_k)(x)| d\mu_k(x) \tag{106}
$$

$$
\leq F^L C_3 \left(\frac{\log N}{N}\right)^{\frac{1}{d}} \tag{107}
$$

This depends on the Lipschitz continuity of the output manifold function in Proposition [3.](#page-20-1)  $\Box$ 

# <span id="page-24-0"></span>F Experiment details and further experiments

All experiments were done using a *NVIDIA GeForce RTX 3090*, and each set of experiments took at most 10 hours to complete. In total, we run 10 datasets, which amounts for around 100 hours of GPU use. All datasets used in this paper are public, and free to use. They can be downloaded using the pytorch package ([https://pytorch-geometric.readthedocs.io/en/latest/modules/](https://pytorch-geometric.readthedocs.io/en/latest/modules/datasets.html) [datasets.html](https://pytorch-geometric.readthedocs.io/en/latest/modules/datasets.html)), the *ogb* package (<https://ogb.stanford.edu/docs/nodeprop/>) and the Princeton ModelNet project (<https://modelnet.cs.princeton.edu/>). In total, the datasets occupy around 5 gb. However, they do not need to be all stored at the same time, as the experiments that we run can be done in series.

### <span id="page-24-1"></span>F.1 ModelNet10 and ModelNet40 graph classificationtasks

ModelNet10 dataset [\[43\]](#page-12-6) includes 3,991 meshed CAD models from 10 categories for training and 908 models for testing as Figure [7](#page-24-2) shows. ModelNet40 dataset includes 38,400 training and 9,600 testing models as Figure [8](#page-24-3) shows. In each model, N points are uniformly randomly selected to construct graphs to approximate the underlying model, such as chairs, tables.

<span id="page-24-2"></span>

Figure 7: Point cloud models in ModelNet10 with  $N = 300$  sampled points in each model, corresponding to bathtub, chair, desk, table, toiler, and bed.

<span id="page-24-3"></span>

Figure 8: Point cloud models from ModelNet40 with  $N = 300$  sampled points in each model, corresponding to airplane, person, car, guitar, plant, and bottle.

(a) Differences of the outputs of 3-layer GNNs.

(b) Differences of the outputs of 4-layer GNNs.

Figure 9: Graph outputs differences of GNNs with different architectures on ModelNet40 dataset.

The weight function of the constructed graph is determined as [\(8\)](#page-4-4) with  $\epsilon = 0.1$ . We calculate the Laplacian matrix for each graph as the input graph shift operator. In this experiment, we implement

GNNs with different numbers of layers and hidden units with  $K = 5$  filters in each layer. All the GNN architectures are trained by minimizing the cross-entropy loss. We implement an ADAM optimizer with the learning rate set as 0.005 along with the forgetting factors 0.9 and 0.999. We carry out the training for 40 epochs with the size of batches set as 10. We run 5 random dataset partitions and show the average performances and the standard deviation across these partitions.

### <span id="page-25-1"></span>F.2 Node classification training details and datasets

In this section, we present the results for node classification. In this paragraph we present the common details for all datasets, we will next delve into each specific detail inside the dataset subsection that follows.

<span id="page-25-0"></span>

Table 2: Details of the datasets considered in the experiments.

In all datasets, we used the graph convolutional layer GCN, and trained for 1000 epochs. For the optimizer, we used AdamW, with using a learning rate of 0.01, and 0 weight decay. We trained using the graph convolutional layer, with a varying number of layers and hidden units. For dropout, we used 0.5. We trained using the cross-entropy loss. In all cases, we trained 2 and 3 layered GNNs.

To compute the linear approximation in the plots, we used the mean squared error estimator of the form

$$
y = s * \log(n) + p. \tag{108}
$$

Where s is the slope, p is the point, and  $\bf{n}$  is the vector with the nodes in the training set for each experiment. Note that we repeated each experiment for 10 independent runs. In all experiments, we compute the value of s and p that minimize the mean square error over the mean of the experiment runs, and we compute the Pearson correlation index over those values.

Our experiment shows that our bound shows the same rate dependency as the experiments. That is to say, in the logarithmic scale, the generalization gap of GNNs is linear with respect to the logarithm of the number of nodes. In most cases, the Pearson correlation index is above  $\overline{0.9}$  in absolute value, which indicates a strong linear relationship. We noticed that the linear relationship changes the slope in the overfitting regime, and in the non-overfitting regime. That is to say, when the GNN is overfitting the training set, the generalization gap decreases at a much slower rate than it does with the GNN does not have the capacity to do so. Therefore, in the case in which the GNN overfits the training set for all nodes when computed s using all the samples in the experiment. On the other hand, when the number of nodes is large enough that the GNN cannot overfit the training set, then we computed the s and p with the nodes in the non overfitting regime.

### <span id="page-25-2"></span>F.2.1 Arxiv dataset

For this datasets, we trained 2, 3, 4 layered GNN. We also used a learning rate scheduler ReduceLROnPlateau with mode min, factor 0.5, patience 100 and a minimum learning rate of 0.001.

### <span id="page-25-3"></span>F.2.2 Cora dataset

For the Cora dataset, we used the standard one, which can be obtained running torch\_geometric.datasets.Planetoid(root="./data",name='Cora').

## <span id="page-29-0"></span>G Further references

Graphon theory Different from the manifold model we are using, some research constructs graphs derived from graphons, which can be viewed as a random limit graph model. This research has focused on their convergence, stability, as well as transferability [\[53–](#page-12-16)[55\]](#page-12-17). In [\[56\]](#page-13-0), graphon is used as a pooling tool in GNNs. Despite its utility, the graphon presents several limitations compared to the manifold model we use. Firstly, the graphon model assumes an infinite degree at every node [\[57\]](#page-13-1), which is not the case in the manifold model. Additionally, graphons offer limited insight into the underlying model; visualizing a graphon is challenging, except in the stochastic block model case. Manifolds, however, are more interpretable, especially when based on familiar shapes like spheres and 3D models (see Figure [2\)](#page-4-2). Finally, the manifold model supports a wider range of characterizable models, making it a more realistic choice.

Manifold Theory Some studies have used graph samples to infer properties of the underlying manifold itself. These properties include the validity of the manifold assumption [\[58\]](#page-13-2), the manifold dimension [\[59\]](#page-13-3) and the complexity of these inferences [\[60,](#page-13-4) [61\]](#page-13-5). Other research has focused on

Table 10: Details of the linear approximation of the Roman Dataset. Note that in this case we used only the values of the generalization gap whose training error is below 95%

Transferability of GNNs The transferability of GNNs has been extensively studied by examining the differences in GNN outputs across graphs of varying sizes as they converge to a limit model.

Figure 23: Generalization Gaps as a function of the number of nodes in the training set in the Roman dataset.

This analysis, however, often lacks statistical generalization. Several studies have explored GNN transferability with graphon models, proving bounds on the differences in GNN outputs [\[15,](#page-10-12) [53,](#page-12-16) [54\]](#page-12-18). Other research has demonstrated how increasing graph size during GNN training can improve generalization to large-scale graphs [\[66\]](#page-13-9). The transferability of GNNs has also been investigated in the context of graphs generated from general topological spaces [\[67\]](#page-13-10) and manifolds [\[35\]](#page-11-15). Furthermore, a novel graphop operator has been proposed as a limit model for both dense and sparse graphs, with proven transferability results [\[68\]](#page-13-11). Further research has focused on transfer learning for GNNs by measuring distances between graphs without assuming a limit model [\[69,](#page-13-12) [70\]](#page-13-13). Finally, a transferable graph transformer has been proposed and empirically validated [\[71\]](#page-13-14).

### <span id="page-34-0"></span>H Low Pass Filter Assumption

In the main results, we assume that the GNN and MNN are low-pass filters. This is a reasonable assumption because high-frequency signals on graphs or manifolds can fluctuate significantly between adjacent entries, leading to instability and learning challenges. We expect a degree of local homogeneity, which translates to low-frequency signals. This assumption is supported by empirical evidence in various domains, including opinion dynamics, econometrics, and graph signal processing [\[72](#page-13-15)[–74\]](#page-13-16).

Moreover, several other effective learning techniques, such as Principal Component Analysis (PCA) and Isomap, implicitly employ low-pass filtering. Therefore, we believe that the low-pass filter assumption is not restrictive and is well-supported by both practical applications and theoretical considerations.
