

SOLVING THE INDEX PROBLEM FOR (CURVED) BERNSTEIN-GELFAND-GELFAND SEQUENCES

MAGNUS GOFFENG

ABSTRACT. We study the index theory of curved Bernstein-Gelfand-Gelfand (BGG) sequences in parabolic geometry and their role in K -homology and noncommutative geometry. The BGG-sequences fit into K -homology, and we solve their index problem. We provide a condition for when the BGG-complex on the flat parabolic geometry G/P of a semisimple Lie group G fits into G -equivariant K -homology by means of Heisenberg calculus. For higher rank Lie groups, we prove a no-go theorem showing that the approach fails.

1. INTRODUCTION

In this paper we study curved Bernstein-Gelfand-Gelfand sequences in noncommutative geometry and index theory with the purpose of forming a global perspective on parabolic geometries. Parabolic geometry [10] can be seen as a vast generalization of Riemannian geometry, describing a plethora of geometric structures such as contact or CR structures, hyper-Kähler structures and the geometry of flag manifolds G/P , for examples see [10, Chapter 4] and [9, 12, 44]. In noncommutative geometry [13], parabolic geometries arising from CR-structures and quaternionic analogues thereof have been of interest in the study of the Baum-Connes conjecture [32, 33]. In representation theory function spaces on flat parabolic geometries play an important role in parabolic induction and Langlands classification of admissible representations [35, 48], for instance through the Casselman-Wallach theorem.

Parabolic geometries arise as a special case of Cartan geometries. Its name is derived from Fefferman's work [21] on the relation between parabolic invariant theory and local invariants on the boundary of pseudoconvex domains in complex manifolds, see [19]. In the spirit of geometric analysis and noncommutative geometry, a natural starting point to study the global aspects of a geometry is to study its geometric differential operators, e.g. the role that Laplace operators, the de Rham or Dirac operators play to Riemannian geometry. As pioneered by Čap-Slovák-Souček [11], building on work by Bernstein-Gelfand-Gelfand (BGG) [8] and Lepowsky [37], the natural geometric differential operators on a parabolic geometry arise from curved BGG sequences. We study such geometric operators in this paper standing on the shoulders of the recently developed Heisenberg calculus on Carnot manifolds [2, 16, 20, 24, 46].

The idea to describe parabolic geometry by means of curved BGG-sequences is well studied in the literature, for instance in [15, 16, 17, 26]. The special case of Rumin complexes arising on contact manifolds, as introduced by Rumin [43], are studied in more detail [32]. BGG-sequences have been used for applications in the Baum-Connes conjecture [6] in operator K -theory, most notably by Yuncken [49] for $SL(3, \mathbb{C})$, by Julg-Kasparov [32] for $SU(n, 1)$ and by Julg as an approach towards $Sp(n, 1)$ [33]. An important feature needed in the applications to the Baum-Connes conjecture is equivariance, for non-compact groups this causes substantial analytic subtleties. Furthermore, BGG-sequences hold hope for extending the ideas of noncommutative geometry to quantum groups through Heckenberger-Kolb's [27] quantized BGG-sequence, first described by

Date: June 12, 2024.

Rosso [42]. Such ideas saw applications in work of Voigt-Yuncken [47] to the equivariant index theory of $SU_q(3)$ and its Drinfeld double, notably proving the Baum-Connes with trivial coefficients for $\widehat{SU_q(3)}$.

A curved BGG-sequence often arises from compressing a de Rham or Dolbeault type complex to a subquotient complex, leaving the Fredholm index unaltered. The analytic machinery for studying curved BGG-sequences was set up by Dave-Haller [16] and refined in [24] to show that curved BGG-sequences define elements in K -homology. This line of thought opens up two natural questions:

- (1) The Fredholm index is unaltered by BGG-compression. Does the same statement hold for the associated K -homology classes?
- (2) A curved BGG-sequence captures the differential geometric features of a parabolic geometry, does it fit into Connes' program for spectral noncommutative geometry?

We study and solve the first problem in this paper with a view towards the equivariant case as needed for application to the Baum-Connes conjecture. This solves the index problem for curved BGG-sequences in the Baum-Douglas sense of describing the associated K -homology classes geometrically. Further clarifying the construction of K -homology classes from [24] will indeed provide us with a better grasp on equivariance properties. The solution to the index problem for curved BGG-sequences can be seen as the first step towards incorporating methods of noncommutative local index theorems [14] and its associated spectral geometric invariants into the study of parabolic geometry, and would be of relevance for better understanding a potential solution to the second listed problem above. The problem can be set up also in the larger generality of graded Rockland sequences, and in the equivariant setting there is an additional abstract existence assumption that we in this paper only can guarantee for real rank one or less.

2. MAIN RESULTS

The geometric objects we study in this paper are Carnot manifolds \mathfrak{X} . The precise definition is reviewed below in Definition 3.1 and further context can be found in Section 3. For now, the reader unacquainted with this notion should think of \mathfrak{X} carrying a filtration of the tangent bundle by sub-bundles such that the Lie bracket of vector fields induces a fibrewise structure of a nilpotent Lie algebra on the associated graded bundle $\mathfrak{t}_H\mathfrak{X}$ integrating to a bundle $T_H\mathfrak{X} \rightarrow \mathfrak{X}$ of osculating Lie groups in each fibre. We also consider group actions on a Carnot manifold \mathfrak{X} , i.e. groups acting by diffeomorphisms preserving the filtration, and therefore lifts to fibrewise Lie algebra isomorphisms on $\mathfrak{t}_H\mathfrak{X}$. The bundle of osculating Lie groups $T_H\mathfrak{X} \rightarrow \mathfrak{X}$ and the affiliated Heisenberg calculus will play a prominent role in this work, for more details see Section 4.

The main results of the paper concern curved BGG-complexes, and to some extent we work in the generality of graded Rockland sequences. To describe the main results of the paper, we will provide a colloquial description of a low-dimensional example showcasing the overall structure and difficulties, that we connect to in parallel to the general results in this section. A more precise overview can be found below in Section 5, more precisely Example 5.9, or in the literature [16, 24, 32, 49]. Take as base field $F = \mathbb{R}$ or $F = \mathbb{C}$ and write $\mathfrak{H}_3(F)$ for the three-dimensional Heisenberg group. That is, the Lie algebra $\mathfrak{h}_2(F)$ of $\mathfrak{H}_3(F)$ is spanned over F by X, Y , and Z with Lie bracket defined from the commutation relation $[X, Y] = Z$. If \mathfrak{X} is a compact Carnot manifold (assumed to be complex if $F = \mathbb{C}$) whose osculating groups are isomorphic to $\mathfrak{H}_3(F)$, we can construct

an associated curved BGG-complex of the form

$$\begin{array}{ccccccc}
& & C^\infty(\mathfrak{X}; L_{\alpha_x}) & \xrightarrow{-D_{XY+Z}} & C^\infty(\mathfrak{X}; L_{2\alpha_x+\alpha_y}) & & \\
& \nearrow^{D_X} & & & & \searrow^{-D_Y} & \\
0 & \longrightarrow & C^\infty(\mathfrak{X}) & & & & C^\infty(\mathfrak{X}; L_{2\alpha_x+2\alpha_y}) \longrightarrow 0 \\
& \searrow^{D_Y} & & & & \nearrow^{D_X} & \\
& & C^\infty(\mathfrak{X}; L_{\alpha_y}) & \xrightarrow{D_{YX-Z}} & C^\infty(\mathfrak{X}; L_{\alpha_x+2\alpha_y}) & &
\end{array}
\tag{2.1}$$

The operators in the complex (2.1) can in each point on \mathfrak{X} up to lower order terms be written as the indicated element of the universal enveloping algebra $\mathcal{U}(\mathfrak{h}_3(F))$, e.g. D_{XY+Z} is $XY + Z$ up to lower order terms. Here the complex line bundles $L_\alpha \rightarrow \mathfrak{X}$ are summands in a subquotient of the exterior bundle $\wedge^* T^* \mathfrak{X}$ derived from taking fibrewise Lie algebra cohomology of $\mathfrak{t}_H \mathfrak{X}$. To make this example more precise, the reader can keep in mind the following two cases: firstly the full flag manifold $\mathfrak{X} = SL(3, F)/B(F)$, where $B(F)$ is the Borel subgroup of upper triangular matrices in $SL(3, F)$, and secondly the nilmanifold $\mathfrak{X} = H_3(F)/\Gamma$ where Γ is a lattice. For $\mathfrak{X} = SL(3, F)/B(F)$, the inclusion $H_3(F) \subseteq SL(3, F)$ as strictly lower triangular matrices produces an embedding of $H_3(F)$ as a Zariski open subset of \mathfrak{X} . The nilmanifold $\mathfrak{X} = H_3(F)/\Gamma$ is locally diffeomorphic as a Carnot manifold to $H_3(F)$. As such, in both cases the operators in the complex (2.1) are well defined up to lower order terms. In both cases, $H^*(\mathfrak{h}_3(F))$ decomposes as indicated in the diagram and the subscripts in L_α indicates an appropriate character that describes L_α as a homogeneous vector bundle, for more details see Subsection 5.1. We can also collect the vertical terms in the diagram above to a complex

$$0 \rightarrow C^\infty(\mathfrak{X}) \xrightarrow{D_1} C^\infty \left(\mathfrak{X}; \begin{array}{c} L_{\alpha_x} \\ \oplus \\ L_{\alpha_y} \end{array} \right) \xrightarrow{D_2} C^\infty \left(\mathfrak{X}; \begin{array}{c} L_{2\alpha_x+\alpha_y} \\ \oplus \\ L_{\alpha_x+2\alpha_y} \end{array} \right) \xrightarrow{D_3} C^\infty(\mathfrak{X}; L_{2\alpha_x+2\alpha_x}) \rightarrow 0.
\tag{2.2}$$

The cohomology of the complex (2.2) coincides with that of the de Rham complex if $F = \mathbb{R}$ and with that of the Dolbeault-de Rham complex if $F = \mathbb{C}$. In this particular case, the curved BGG-complex (2.1) is a Rockland complex. In general, we arrive at a sequence that is a complex only in leading term and is only Rockland in a graded sense, for precise definitions see Section 5.

In Section 6 we study how curved BGG-complexes, or more generally graded Rockland sequences, fit into K -homology. Phrased in terms of Atiyah's initial idea for K -homology [3], we ask for an abstract elliptic operator on \mathfrak{X} that encodes a graded Rockland sequence. The following result can be found in Subsection 6.1.

Theorem 1. *Let \mathfrak{X} be a Carnot manifold with a continuous filtered action by diffeomorphisms of a locally compact group G . Assume that D_\bullet is a G -equivariant graded Rockland sequence admitting G -equivariant Rockland splittings B_\bullet in the sense of Definition 6.2. Then the operator $F_\bullet := D_\bullet + B_\bullet$ defines a K -homology cycle for $C(\mathfrak{X})$ such that $g^{-1}F_\bullet g - F_\bullet$ is a compact operator depending continuously on $g \in G$.*

The fact that graded Rockland sequences admit Heisenberg splittings (in the sense of Definition 6.2) when dropping the group action can be found in Proposition 6.1. Let us return to our three dimensional example (2.1)-(2.2). In this case as in most other in this paper, there is no obvious method to prove existence of G -equivariant Rockland splittings (in the sense of Definition 6.2) beyond the Heisenberg calculus. If $\mathfrak{X} = SL(3, F)/B(F)$ the complex D_\bullet is an $SL(3, F)$ -equivariant graded Rockland sequence but as we shall see below, we do not have any $SL(3, F)$ -equivariant Heisenberg splittings but G -equivariant Heisenberg splittings for $G \subseteq SL(3, F)$ of rank one or less. It is unclear to the author if there is a more relevant method for finding G -equivariant Rockland splittings, but the

example of $SL(3, F)$ shows how a Heisenberg calculus for multifiltered manifolds in the sense of [51] holds potential to solve the problem. For $\mathfrak{X} = \mathbb{H}_3(F)/\Gamma$ the complex D_\bullet is an $\mathbb{H}_3(F)$ -equivariant graded Rockland sequence and by building a Heisenberg split locally, we see that there are equivariant Heisenberg splittings.

Remark 2.1. We note that Theorem 1 is stated in the context of a group action. In most interesting situation, the action of G is not unitary (unless G is compact). Therefore Theorem 1 does not produce a bona fide cycle for equivariant KK -theory. However, for an appropriate length function ℓ , such as that in Proposition 6.4, we can therefore from Theorem 6.6 conclude that F_\bullet forms a well defined class associated with the equivariant graded Rockland sequence in a KK -group $KK_0^{G, \ell}(C(\mathfrak{X}), \mathbb{C})$ defined using exponentially bounded group actions on Hilbert spaces.

Remark 2.2. If \mathfrak{X} is a Carnot manifold with a filtered action by diffeomorphisms of a compact group G , and D_\bullet is a G -equivariant graded Rockland sequence we show that D_\bullet even admits admitting G -equivariant Heisenberg splittings B_\bullet in the sense of Definition 6.2. This is done via an algebraic trick (see Proposition 6.1) and averaging over the group. In particular, for a compact group G a G -equivariant graded Rockland sequence canonically defines a G -equivariant K -homology cycle for $C(X)$ via the operator F_\bullet .

The assumption in Remark 2.2 that the group G is compact can in some cases be relaxed. We do however note that there are rigidity results for the size of the automorphism groups of parabolic geometries, such as Ferrand-Obata's theorem on conformal actions, and Schoen's generalization [45] to CR -manifolds, as well as Bader-Frances-Melnick's work [4] in higher rank that we recall in Theorem 3.11 below. Such rigidity results forces automorphism groups of parabolic geometries to be lower rank than the geometry, and in rank one even to be compact [22] unless $\mathfrak{X} = \mathbb{G}/\mathbb{P}$ is the flat parabolic manifold. However, for many applications the flat parabolic manifold $\mathfrak{X} = \mathbb{G}/\mathbb{P}$ is of primary importance. For this situation we have the following no-go result for constructing equivariant splittings in the Heisenberg calculus found in Subsection 6.2. For notational clarity, we write \mathbb{G} for Lie groups used to define parabolic geometries and G for groups we consider actions of. In the case of flat parabolic geometries, \mathbb{G}/\mathbb{P} we often have $G = \mathbb{G}$.

Theorem 2. *Let $G = \mathbb{G}$ be a connected, semisimple Lie group and $\mathbb{P} \subseteq \mathbb{G}$ a parabolic subgroup. Write $\mathfrak{X} = \mathbb{G}/\mathbb{P}$ for the flat parabolic manifold of type (\mathbb{G}, \mathbb{P}) with \mathbb{G} acting on \mathfrak{X} as filtered diffeomorphisms. We write $D_\bullet^{\text{BGG}(V)}$ for the BGG-complex associated with a finite-dimensional \mathbb{G} -representation V . Then D_\bullet admits \mathbb{G} -equivariant Heisenberg splittings B_\bullet in the sense of Definition 6.2 if \mathbb{G} has rank less than or equal to one but does not if the rank of \mathbb{G}/\mathbb{P} is greater than one.*

This result can be exemplified for our three-dimensional example (2.1)-(2.2) for $G = \mathbb{G} = SL(3, F)$ and $\mathfrak{X} = SL(3, F)/B(F)$ where the rank is 2. Indeed, if we look for the first Heisenberg splitting among Heisenberg operators

$$B_1 : C^\infty \left(\mathfrak{X}; \begin{array}{c} L_{\alpha_x} \\ \oplus \\ L_{\alpha_y} \end{array} \right) \rightarrow C^\infty(X),$$

then the incompatibility of the characters and the homogeneity of the Heisenberg calculus forces any such operator $B_1 = (B_{11}, B_{12})$ in the Heisenberg calculus to be a differential operator, for more details see Corollary 4.6. But $B_1 D_1 = 1$ has no solution B_1 among the space of differential operators. Further discussion on the higher rank situation can be found in [51], where multifiltered geometries pose a potential solution to the issues at hand.

We have by Theorem 1, and the accompanying Remark 2.2, that a graded Rockland sequence defines an equivariant K -cycle for a compact group action. We describe the

associated K -homology class in the case of BGG-complexes on parabolic geometries in Section 7. The results of that section can be summarized in the following theorem.

Theorem 3. *Let \mathfrak{X} be a parabolic manifold with a filtered action by diffeomorphisms of a compact group G . Assume that $\text{BGG}(\nabla_{\mathbf{E}})$ is the G -equivariant curved BGG-sequence associated with a tractor bundle \mathbf{E} with tractor connection $\nabla_{\mathbf{E}}$. Then the class of $\text{BGG}(\nabla_{\mathbf{E}})$ in $K_0^G(\mathfrak{X})$ is explicitly described by the Euler class $\text{Euler}(\mathfrak{X}) \in K_0^G(\mathfrak{X})$ as*

$$[\text{BGG}(\nabla_{\mathbf{E}})] = \text{Euler}(\mathfrak{X}) \cap [\mathbf{E}].$$

If \mathfrak{X} is a complex parabolic manifold, and the G -action as well as the tractor bundle are holomorphic, then the class of $\text{BGG}(\nabla_{\mathbf{E}})$ in $K_0^G(\mathfrak{X})$ is explicitly described by the fundamental class $[\mathfrak{X}] \in K_0^G(\mathfrak{X})$ (associated with the complex structure) as

$$[\text{BGG}(\nabla_{\mathbf{E}})] = [\mathfrak{X}] \cap [\mathbf{E}].$$

Remark 2.3. By a result of Rosenberg [41], the Euler class of \mathfrak{X} in K -homology is “trivial” in the sense that $\text{Euler}(\mathfrak{X}) = \chi(\mathfrak{X})[\text{pt}]$. Here $\chi(\mathfrak{X}) \in \mathbb{Z}$ is the Euler characteristic and $[\text{pt}] \in K_0(\mathfrak{X})$ the class defined from including a point into \mathfrak{X} . In particular, in the case of G being trivial and \mathfrak{X} a real parabolic geometry

$$[\text{BGG}(\nabla_{\mathbf{E}})] = \text{Euler}(\mathfrak{X}) \cap [\mathbf{E}] = \chi(\mathfrak{X})\text{rk}(\mathbf{E})[\text{pt}].$$

3. CARNOT MANIFOLDS

The main source of geometric examples in this paper is that of parabolic geometry, that in turn fits into a larger scheme of Carnot manifolds. We recall the notion of a Carnot manifold and after that we specialize to parabolic manifolds.

Definition 3.1. A Carnot manifold of depth $r \in \mathbb{N}_+$ is a manifold \mathfrak{X} equipped with a filtration

$$T\mathfrak{X} = T^{-r}\mathfrak{X} \subsetneq T^{-r+1}\mathfrak{X} \subsetneq \dots \subsetneq T^{-2}\mathfrak{X} \subsetneq T^{-1}\mathfrak{X} \subsetneq 0,$$

of sub-bundles such that $[T^j\mathfrak{X}, T^k\mathfrak{X}] \subseteq T^{j+k}\mathfrak{X}$ for any j, k . For simplicity, we set $T^j\mathfrak{X} = T\mathfrak{X}$ for $j \leq -r$ and $T^j\mathfrak{X} = 0$, $j \geq 0$.

If \mathfrak{X} is a complex manifold, and each $T^{-j}\mathfrak{X} \subseteq T\mathfrak{X}$ is a holomorphic subbundle, we say that \mathfrak{X} is a complex Carnot manifold.

Associated with a Carnot structure, we have a fibrewise Lie algebra structure on the graded bundle

$$\text{gr}(T\mathfrak{X}) := \bigoplus_j T^{-j}\mathfrak{X}/T^{-j+1}\mathfrak{X}.$$

More precisely, the Lie bracket on vector fields induces a bundle map $(T^{-j}\mathfrak{X}/T^{-j+1}\mathfrak{X}) \times (T^{-k}\mathfrak{X}/T^{-k+1}\mathfrak{X}) \rightarrow T^{-j+k}\mathfrak{X}/T^{-j+k+1}\mathfrak{X}$ for any j, k which in turn induces a graded Lie bracket on $\text{gr}(T\mathfrak{X})$. When equipped with the anchor mapping $0 : \text{gr}(T\mathfrak{X}) \rightarrow T\mathfrak{X}$, $\text{gr}(T\mathfrak{X})$ forms a Lie algebroid that we denote by $\mathfrak{t}_H\mathfrak{X}$. Since the Lie bracket is nilpotent, $\mathfrak{t}_H\mathfrak{X}$ integrates to a Lie groupoid $T_H\mathfrak{X}$ with unit space \mathfrak{X} with source and range map coinciding. The source/range mapping $T_H\mathfrak{X} \rightarrow \mathfrak{X}$ defines a fibre bundle; each fibre is a simply connected nilpotent Lie group.

We call $\mathfrak{t}_H\mathfrak{X}$ the osculating Lie algebroid of \mathfrak{X} and $T_H\mathfrak{X}$ the osculating Lie groupoid of \mathfrak{X} . For a point $x \in \mathfrak{X}$, we call $\mathfrak{t}_H\mathfrak{X}_x$ the osculating Lie algebroid in x and $T_H\mathfrak{X}_x$ the osculating Lie groupoid in x . Let \mathbf{N} be a graded, simply connected, nilpotent Lie group with Lie algebra \mathfrak{n} . We say that \mathfrak{X} is a regular Carnot manifold of type \mathbf{N} (or \mathfrak{n}) if $T_H\mathfrak{X} \rightarrow \mathfrak{X}$ is a locally trivial bundle of graded, nilpotent Lie groups with fibre \mathbf{N} .

Theorem 3.2 (Morimoto, [39, Chapter 3]). *Let \mathfrak{X} be a Carnot manifold and \mathfrak{n} a graded, nilpotent Lie algebra. Then \mathfrak{X} is regular of type \mathfrak{n} if and only if for any point $x \in \mathfrak{X}$, there is a graded Lie algebra isomorphism $\mathfrak{t}_H\mathfrak{X}_x \cong \mathfrak{n}$.*

Definition 3.3. If \mathfrak{X} and \mathfrak{Y} are Carnot manifolds, and $f : \mathfrak{X} \rightarrow \mathfrak{Y}$ is a smooth mapping we say that f is a Carnot morphism if

$$Df(T^j\mathfrak{X}) \subseteq T^j\mathfrak{Y}, \quad \forall j$$

If f additionally is a diffeomorphism, we say that f is a Carnot isomorphism or if $\mathfrak{X} = \mathfrak{Y}$ in which case we say that f is a Carnot automorphism. We write $\text{Aut}_C(\mathfrak{X})$ for the group of Carnot automorphisms of \mathfrak{X} .

A complex Carnot isomorphism (or automorphism) $f : \mathfrak{X} \rightarrow \mathfrak{Y}$ of complex Carnot manifolds is a Carnot isomorphism which is also holomorphic. We write $\text{Aut}_{\mathcal{O}C}(\mathfrak{X})$ for the group of holomorphic Carnot automorphisms of a complex Carnot manifold \mathfrak{X} .

Definition 3.4. Let G be a second countable, locally compact group. A (complex) G -Carnot manifold is a (complex) Carnot manifold \mathfrak{X} equipped with a continuous action of G as (complex) Carnot automorphisms.

3.1. Restricted frame bundles. Let \mathbf{N} be a graded, simply connected, nilpotent Lie group with graded Lie algebra $\mathfrak{n} = \bigoplus_{j=-r}^{-1} \mathfrak{n}_j$. Set $\mathfrak{n}^k := \bigoplus_{j=-r}^k \mathfrak{n}_j$. We introduce the notion of a Carnot principal bundle of type \mathbf{N} on a manifold \mathfrak{X} of dimension $\dim(\mathfrak{n})$ to be a principal $\text{Aut}_{\text{gr}}(\mathbf{N})$ -bundle $P \rightarrow \mathfrak{X}$ such that the frame bundle $P_{\mathfrak{X}} \rightarrow \mathfrak{X}$ reduces to P under the natural map $\text{Aut}_{\text{gr}}(\mathbf{N}) \rightarrow \text{Aut}_{\mathbb{R}}(\mathfrak{n})$ and $T^k\mathfrak{X} := P \times_{\text{Aut}_{\text{gr}}(\mathfrak{n})} \mathfrak{n}^k \subseteq T\mathfrak{X}$, $k = -r, \dots, -1$, defines a Carnot structure. A gradedly G -equivariant Carnot principal bundle of type \mathbf{N} is a Carnot principal bundle $P \rightarrow \mathfrak{X}$ of type \mathbf{N} where P and \mathfrak{X} are equipped with G -actions making $P \rightarrow \mathfrak{X}$ equivariant.

Proposition 3.5. *Consider a graded, simply connected Lie group \mathbf{N} . There is an equivalence of categories between gradedly G -equivariant Carnot principal bundles of type \mathbf{N} and regular G -Carnot manifolds \mathfrak{X} of type \mathbf{N} . The equivalence is defined from*

$$P \mapsto (T^k\mathfrak{X} = P \times_{\text{Aut}_{\text{gr}}(\mathfrak{n})} \mathfrak{n}^k)_{k=-r, \dots, -1},$$

with inverse defined by letting P denote the graded automorphism frame bundle of the Carnot structure

3.2. Parabolic geometry. A parabolic geometry is a Cartan geometry of type (\mathbf{G}, \mathbf{P}) for a semi-simple Lie group \mathbf{G} and a parabolic subgroup \mathbf{P} . This is to say that in a certain infinitesimal sense, a manifold \mathfrak{X} is a parabolic geometry of type (\mathbf{G}, \mathbf{P}) if it in a certain infinitesimal sense looks like \mathbf{G}/\mathbf{P} at each point. A fuller picture of parabolic geometry is found in the textbook [10]. We here recall its salient feature and in the meanwhile set notations. *We use the convention that Lie groups used to define parabolic geometries are denoted by \mathbf{G} , to distinguish from a group G acting on a geometry.*

Consider a connected, semi-simple Lie group \mathbf{G} . Write \mathfrak{g} for its Lie algebra. We often assume that \mathfrak{g} is $|k|$ -graded, i.e. we have fixed a grading

$$\mathfrak{g} = \mathfrak{g}_{-k} \oplus \mathfrak{g}_{-k+1} \oplus \cdots \oplus \mathfrak{g}_{-1} \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_{k-1} \oplus \mathfrak{g}_k,$$

with $[\mathfrak{g}_j, \mathfrak{g}_l] \subseteq \mathfrak{g}_{j+l}$ for any j, l . We let $\mathbf{P} \subseteq \mathbf{G}$ denote a parabolic subgroup that we tacitly assume to relate to the $|k|$ -grading of \mathfrak{g} via its Lie algebra \mathfrak{p} and the identity

$$\mathfrak{p} = \mathfrak{g}_0 \oplus \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_{k-1} \oplus \mathfrak{g}_k.$$

Write $\mathfrak{p}_+ = \mathfrak{g}_+ := \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_{k-1} \oplus \mathfrak{g}_k$ for the nilradical of \mathfrak{p} . Let $\mathbf{G}_0 \subseteq \mathbf{G}$ be the reductive, closed sub-group integrating \mathfrak{g}_0 . The Langlands decomposition $\mathbf{P} = \text{MAP}_+ = \mathbf{G}_0\mathbf{P}_+$, where \mathbf{P}_+ integrates \mathfrak{p}_+ , factors $\mathbf{G}_0 = \mathbf{M}\mathbf{A}$ into its semi-simple and abelian part.

Example 3.6. The prototypical example of a $|k|$ -grading to keep in mind comes about the other way; starting from a standard parabolic subgroup $\mathbf{P} \subseteq \mathbf{G}$ there is an associated $|k|$ -grading of \mathfrak{g} defined from the total degree in the restricted root spaces of \mathbf{P} (see [10], Chapter 3.2.1 for the complex case and Chapter 3.2.9 for the real case), in this $|k|$ -grading $\mathfrak{p} = \mathfrak{g}_0 \oplus \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_{k-1} \oplus \mathfrak{g}_k$ coincides with the Lie algebra of \mathbf{P} .

Let us describe the parabolic subgroups and the associated gradings in some more details, following [36, Chapter VI and VII] for the former and [10, Chapter 3.2] for the latter. The standard parabolic subgroups are standard relative to a choice of Cartan involution θ on \mathfrak{G} , with corresponding maximally abelian subalgebra \mathfrak{a} of the θ -invariant subspace of \mathfrak{g} , restricted roots Σ , a choice of positive roots Σ^+ and simple roots Π . The minimal parabolic subgroup is defined from $\mathfrak{p}_{\min} := \mathfrak{a} \oplus_{\lambda \in \Sigma^+} \mathfrak{g}_\lambda$. The standard parabolic subgroups stand in a one-to-one correspondence with subsets $\Pi' \subseteq \Pi$ via

$$\mathfrak{p} = \mathfrak{p}_{\min} \oplus_{\lambda \in \text{span}(\Pi')} \mathfrak{g}_\lambda.$$

If Π' is the set of simple restricted roots corresponding to \mathfrak{P} , we can define $\text{ht}_{\mathfrak{P}} : \mathfrak{a}^* \rightarrow \mathbb{R}$ following [10, Chapter 3.2.1] by

$$\text{ht}_{\mathfrak{P}}\left(\sum_{\alpha \in \Pi} a_\alpha \alpha\right) = \sum_{\alpha \in \Pi \setminus \Pi'} a_\alpha. \quad (3.1)$$

The $|k|$ -grading is now defined by

$$\mathfrak{g}_j := \bigoplus_{\alpha: \text{ht}_{\mathfrak{P}}(\alpha)=j} \mathfrak{g}_\alpha, \quad j = -k, -k+1, \dots, k-1, k,$$

for k being the largest value of $\text{ht}_{\mathfrak{P}}$ on Σ . We note that for $\mathfrak{a}_{\mathfrak{P}} := \bigcap \text{Ker}_{\beta \in \text{span}(\Pi')} \text{Ker } \beta \subseteq \mathfrak{a}$ having dimension > 1 , i.e. \mathfrak{P} has rank > 1 , the $|k|$ -grading is overlooking a great deal of information pertained by the multifiltering [51] defined from the restricted roots.

We shall make heavy use of the graded nilpotent Lie algebra

$$\mathfrak{n} := \mathfrak{g}_{-k} \oplus \mathfrak{g}_{-k+1} \oplus \dots \oplus \mathfrak{g}_{-1}.$$

Write \mathbf{N} for the simply connected Lie group integrating \mathfrak{n} . The $|k|$ -grading ensures that \mathbf{G}_0 acts as graded Lie algebra automorphisms of \mathfrak{n} . Note that there is an abstract Lie algebra isomorphism $\mathfrak{n} \cong \mathfrak{p}_+$ since \mathfrak{g} is semisimple. The Killing form implements a natural \mathbf{G}_0 -equivariant isomorphism

$$\mathfrak{n} \cong \mathfrak{p}_+^*. \quad (3.2)$$

By an abuse of notation, we shall use this isomorphism as an identity. We also write $\mathfrak{n}^{-j} := \mathfrak{g}_{-j} \oplus \mathfrak{g}_{-j+1} \oplus \dots \oplus \mathfrak{g}_{-1}$.

The flag manifold

$$\mathfrak{X} := \mathbf{G}/\mathfrak{P},$$

carries a natural \mathbf{G} -action and a \mathbf{G} -equivariant filtration

$$0 \subseteq T^{-1}\mathfrak{X} \subseteq T^{-2}\mathfrak{X} \subseteq T^{-k+1}\mathfrak{X} \subseteq T^{-k}\mathfrak{X} = T\mathfrak{X},$$

defined from identifying $\mathfrak{g}/\mathfrak{p} = \mathfrak{n}$ and setting

$$T^{-j}\mathfrak{X} := \mathbf{G} \times_{\mathfrak{P}} \mathfrak{n}^{-j} = \bigoplus_{l=1}^j (\mathbf{G}/\mathfrak{P}_+) \times_{\mathbf{G}_0} \mathfrak{g}_{-l}.$$

Here the P -action is defined from factoring over the quotient map $\mathfrak{P} \rightarrow \mathbf{G}_0$. As such, \mathfrak{X} is a \mathbf{G} -Carnot manifold of type \mathbf{N} . The Carnot frame bundle of \mathfrak{X} naturally identifies with $(\mathbf{G}/\mathfrak{P}_+) \times_{\mathbf{G}_0} \text{Aut}_{\text{gr}}(\mathbf{N})$. More generally, we have the following definition.

Definition 3.7. Let \mathbf{G} be a $|k|$ -graded, semi-simple, connected Lie group with associated parabolic subgroup $\mathfrak{P} \subseteq \mathbf{G}$. A parabolic manifold of type $(\mathbf{G}, \mathfrak{P})$ is a pair (\mathfrak{X}, ω) of a smooth manifold \mathfrak{X} and a Cartan connection $\omega : \mathcal{V} \rightarrow T^*\mathcal{V} \otimes \mathfrak{g}$ on a principal \mathfrak{P} -bundle $\mathcal{V} \rightarrow \mathfrak{X}$ such that

- (1) $\text{Ad}(p)(p^*\omega) = \omega$, for all $p \in \mathfrak{P}$, where in $T^*\mathcal{V} \otimes \mathfrak{g}$ the operation $\text{Ad}(p)$ is on the second factor and the pullback is in the first factor;
- (2) $\omega(X_\xi) = \xi$ for $\xi \in \mathfrak{p}$, where X_ξ is the vectorfield on \mathcal{V} associated with $\xi \in \mathfrak{p}$ and the \mathfrak{P} -action on \mathcal{V} ;
- (3) $\omega_p : T_p\mathcal{V} \rightarrow \mathfrak{g}$ is a linear isomorphism for all points $p \in \mathcal{V}$.

If \mathbf{G} and \mathbf{P} are complex, we tacitly assume all structures to be holomorphic and speak of a complex parabolic manifold of type (\mathbf{G}, \mathbf{P})

For two parabolic manifolds (\mathfrak{X}, ω) and (\mathfrak{X}', ω') of type (\mathbf{G}, \mathbf{P}) we say that a diffeomorphism $f : \mathfrak{X} \rightarrow \mathfrak{X}'$ is parabolic if f lifts to a \mathbf{P} -equivariant diffeomorphism $f_{\mathcal{V}} : \mathcal{V} \rightarrow \mathcal{V}'$ such that $f_{\mathcal{V}}^* \omega' = \omega$. If (\mathfrak{X}, ω) and (\mathfrak{X}', ω') are complex parabolic manifolds of type (\mathbf{G}, \mathbf{P}) , a parabolic diffeomorphism $f : \mathfrak{X} \rightarrow \mathfrak{X}'$ is a parabolic diffeomorphism of the underlying real structure which is holomorphic and lifts to a holomorphic $f_{\mathcal{V}}$. We write $\text{Aut}(\mathfrak{X}, \omega)$ for the group of parabolic self-diffeomorphisms of a parabolic geometry, and if (\mathfrak{X}, ω) is a complex parabolic manifold we write $\text{Aut}(\mathfrak{X}, \omega)$ for the group of complex parabolic self-diffeomorphisms.

Remark 3.8. We can topologize $\text{Aut}(\mathfrak{X}, \omega)$ in many different ways, we shall choose the C^∞ -topology. By work of Frances-Melnick [23] it coincides with the C^0 -topology.

If (\mathfrak{X}, ω) is a parabolic geometry, the Cartan connection induces a restriction of the frame bundle of \mathfrak{X} to the \mathbf{G}_0 -principal bundle $\mathcal{V}/\mathbf{P}_+ \rightarrow \mathfrak{X}$. By the discussion above, there is a group homomorphism $\mathbf{G}_0 \rightarrow \text{Aut}_{\text{gr}}(\mathbf{N})$ so there is an associated filtration $T^{-k}\mathfrak{X} := (\mathcal{V}/\mathbf{P}_+) \times_{\mathbf{G}_0} \mathfrak{n}^k$ of $T\mathfrak{X}$. This filtration together with the information of the \mathbf{G}_0 -principal bundle $\mathcal{V}/\mathbf{P}_+ \rightarrow \mathfrak{X}$ and the \mathbf{G}_0 -invariant forms $\theta_i : T^i(\mathcal{V}/\mathbf{P}_+) \rightarrow \mathfrak{g}_i$ induced from the Cartan connection ω , is called the infinitesimal flag structure of (\mathfrak{X}, ω) , see more in [10, Definition 3.1.6]. The infinitesimal flag structure does not automatically define a Carnot structure, and we make the following definition.

Definition 3.9. We say that (\mathfrak{X}, ω) is a **regular** parabolic geometry of type (\mathbf{G}, \mathbf{P}) if the $\text{Aut}_{\text{gr}}(\mathbf{N})$ -principal bundle

$$(\mathcal{V}/\mathbf{P}_+) \times_{\mathbf{G}_0} \text{Aut}_{\text{gr}}(\mathbf{N}) \rightarrow \mathfrak{X},$$

is a Carnot principal bundle of type \mathbf{N} . Or in other words, (\mathfrak{X}, ω) is a **regular** parabolic geometry if the infinitesimal flag structure induces a Carnot structure.

For parabolic geometries, there is more control of geometric structure than for general Carnot manifolds. For instance, it is shown in [10, Chapters 3.1.14, 3.1.16, and 3.1.16] that there is an equivalence of categories between regular infinitesimal flag structures of type (\mathbf{G}, \mathbf{P}) on \mathfrak{X} and normal, regular parabolic geometries of type (\mathbf{G}, \mathbf{P}) on \mathfrak{X} . Here normal means that the curvature function

$$\kappa : \mathcal{V} \rightarrow \text{Hom}(\wedge^2(\mathfrak{g}/\mathfrak{p}), \mathfrak{g}), \quad [\kappa(p)](X, Y) := [X, Y] - \omega_p([\omega^{-1}(X), \omega^{-1}(Y)]_p),$$

is a cycle for the Kostant boundary map (cf. [10, Chapter 3.1.12]).

Remark 3.10. If (\mathfrak{X}, ω) is a regular parabolic manifold the discussion above shows that there is an induced Carnot structure. It is clear that we have an inclusion of groups $\text{Aut}(\mathfrak{X}, \omega) \hookrightarrow \text{Aut}_C(\mathfrak{X})$. By the same token, if (\mathfrak{X}, ω) is a regular complex parabolic manifold, then $\text{Aut}(\mathfrak{X}, \omega) \hookrightarrow \text{Aut}_{\mathcal{O}C}(\mathfrak{X})$.

The inclusion $\text{Aut}(\mathfrak{X}, \omega) \subseteq \text{Aut}_C(\mathfrak{X})$ is in general strict. For instance, if $\mathfrak{X} = S^{2n-1}$ with ω defined to make (\mathfrak{X}, ω) into the flat parabolic geometry $S^{2n-1} = SU(n, 1)/\mathbf{P}$ for the parabolic subgroup $\mathbf{P} \subseteq SU(n, 1)$. Then ω is a CR-structure and $\text{Aut}(\mathfrak{X}, \omega) = SU(n, 1)$ consists of the CR-automorphisms of \mathfrak{X} . However, \mathfrak{X} viewed as a Carnot manifold is a contact manifold and complex conjugation in $S^{2n-1} \subseteq \mathbb{C}^n$ is a filtered diffeomorphism so we have an inclusion $\text{Aut}(\mathfrak{X}, \omega) \times (\mathbb{Z}/2) \subseteq \text{Aut}_C(\mathfrak{X})$

We can in general expect there to be few parabolic automorphisms as the following generalization of Ferrand-Obata's theorem and Schoen's theorem [45] shows.

Theorem 3.11 (Bader-Frances-Melnick [4]). *Let (\mathfrak{X}, ω) be a regular parabolic manifold of type (\mathbf{G}, \mathbf{P}) but not a discrete quotient of the universal cover of \mathbf{G}/\mathbf{P} . Then $\text{Aut}(\mathfrak{X}, \omega)$ is smaller than \mathbf{G} in the sense that the adjoint representation of any connected Lie subgroup $H \subseteq \text{Aut}(\mathfrak{X}, \omega)$ has rank strictly less than the rank of \mathbf{G} . In particular, if $\text{rk}(\mathbf{G}) = 1$, then $\text{Aut}(\mathfrak{X}, \omega)$ is compact.*

4. HEISENBERG CALCULUS

An important technical tool throughout the paper is the Heisenberg calculus on Carnot manifolds. We shall only recall its overall structure and refer the details to the literature [2, 16, 20, 24, 46]. Recall the Lie algebroid $\mathfrak{t}_H\mathfrak{X} := \oplus_j T^{-j}\mathfrak{X}/T^{-j+1}\mathfrak{X}$ defined from a Carnot structure. Each fibre of the vector bundle $\mathfrak{t}_H\mathfrak{X}$ is a nilpotent Lie algebra, and we can integrate to a Lie groupoid $T_H\mathfrak{X} \rightarrow \mathfrak{X}$. As a fibre bundle, $T_H\mathfrak{X} \rightarrow \mathfrak{X}$ is a vector bundle but the fibrewise Lie group structure is a polynomial operation determined from the Baker-Campbell-Hausdorff formula and may vary in general. There is an $\mathbb{R}_{>0}$ -action on $\mathfrak{t}_H\mathfrak{X}$ defined by $\delta_\lambda(X) := \lambda^{-j}X$ for $X \in T^{-j}\mathfrak{X}/T^{-j+1}\mathfrak{X}$. By construction, δ_λ is a fibrewise Lie algebra automorphism integrating to a smooth $\mathbb{R}_{>0}$ -action on the Lie groupoid $T_H\mathfrak{X}$.

4.1. The parabolic tangent groupoid. To build the Heisenberg calculus, [46] combined Connes' tangent groupoid with Debord-Skandalis' approach to homogeneity. The analogue of Connes' tangent groupoid is the parabolic tangent groupoid $\mathbb{T}_H\mathfrak{X} \rightrightarrows \mathfrak{X} \times [0, \infty)$. Set theoretically, the groupoid $\mathbb{T}_H\mathfrak{X}$ is defined by

$$\mathbb{T}_H\mathfrak{X} := T_H\mathfrak{X} \times \{0\} \dot{\bigcup} \mathfrak{X} \times \mathfrak{X} \times (0, \infty).$$

The groupoid $\mathbb{T}_H\mathfrak{X}$ is endowed with a Lie groupoid structure by choosing a graded connection ∇ on $\mathfrak{t}_H\mathfrak{X}$ and declaring the mapping

$$\psi : T_H\mathfrak{X} \times [0, \infty) \rightarrow \mathbb{T}_H\mathfrak{X}, \quad \psi(x, v, t) := \begin{cases} (x, v, 0), & t = 0, \\ (\exp^\nabla(\delta_t(v)), x, t), & t > 0, \end{cases}$$

to be a local diffeomorphism. The scaling action of $\mathbb{R}_{>0}$ extends to the a smooth $\mathbb{R}_{>0}$ -action on the parabolic tangent groupoid by extending it to $t > 0$ via

$$\delta_\lambda(x, y, t) = (x, y, \lambda^{-1}t).$$

4.2. van Erp-Yuncken's calculus. Following [46], for two vector bundles $E_1, E_2 \rightarrow \mathcal{X}$, we consider the space $\mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2)$ of properly supported r -fibred distributions on the Lie groupoid $\mathbb{T}_H\mathfrak{X} \rightrightarrows \mathfrak{X} \times [0, \infty)$ with coefficients in $r^*E_2 \otimes s^*E_1^*$. Pushing forward along the $\mathbb{R}_{>0}$ -action induces an isomorphism $(\delta_\lambda)_*$ of $\mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2)$. Let $|\Lambda|$ denote the 1-densities on \mathfrak{X} and $|\Lambda_r| := r^*|\Lambda|$. We write $C_p^\infty(\mathbb{T}_H\mathfrak{X}; r^*E_2 \otimes s^*E_1^* \otimes |\Lambda_r|)$ for the space of smooth properly supported sections of $r^*E_2 \otimes s^*E_1^* \otimes |\Lambda_r|$, this is precisely the space of smooth elements of $\mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2)$. Evaluation in $t = 0$ produces a mapping

$$\text{ev}_{t=0} : \mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2) \rightarrow \mathcal{E}'_r(T_H\mathfrak{X}; E_1, E_2),$$

onto the analogous space of distributions on the Lie groupoid of osculating Lie groups. Evaluation in $t \in (0, \infty)$ produces a mapping

$$\text{ev}_t : \mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2) \rightarrow \mathcal{E}'_r(\mathfrak{X} \times \mathfrak{X}; E_1, E_2).$$

We note that by the Schartz kernel theorem,

$$\mathcal{E}'_r(\mathfrak{X} \times \mathfrak{X}; E_1, E_2) = C^\infty(\mathfrak{X}; E_2 \otimes \mathcal{D}'(\mathfrak{X}; E_1^* \otimes |\Lambda|)).$$

Definition 4.1. Let \mathfrak{X} be a compact Carnot manifold, $m \in \mathbb{C}$ and $E_1, E_2 \rightarrow \mathfrak{X}$ two vector bundles. We write $\Psi_H^m(\mathfrak{X}, E_1, E_2)$ for the space of properly supported, r -fibred distribution $\mathbf{A} \in \mathcal{E}'_r(\mathbb{T}_H\mathfrak{X}; E_1, E_2)$ which is almost homogeneous of degree m in the sense that

$$(\delta_\lambda)_*\mathbf{A} - \lambda^m\mathbf{A} \in C_p^\infty(\mathbb{T}_H\mathfrak{X}; r^*E_2 \otimes s^*E_1^* \otimes |\Lambda_r|).$$

We say that an operator $A : C^\infty(\mathfrak{X}, E_1) \rightarrow C^\infty(\mathfrak{X}, E_2)$ is a Heisenberg pseudodifferential operator of order $m \in \mathbb{C}$ if there exists a properly supported, r -fibred distribution $\mathbf{A} \in \Psi_H^m(\mathfrak{X}, E_1, E_2)$ such that the Schwartz kernel $k_A \in C^\infty(\mathfrak{X}; E_2 \otimes \mathcal{D}(\mathfrak{X}; E_1^* \otimes |\Lambda|))$ is given by

$$k_A := \text{ev}_{t=1}(\mathbf{A}).$$

It can be shown [16, 24, 46] that composition, adjoints, addition and so on is well defined and respect homogeneity so we arrive at a filtered $*$ -algebra (under composition of operators) of Heisenberg pseudodifferential operators $\Psi_H^*(\mathfrak{X}, E)$ for any vector bundle $E \rightarrow \mathfrak{X}$. We write $\Psi_H^*(\mathfrak{X}; E_1, E_2)$ for the space of Heisenberg pseudodifferential operator $C^\infty(\mathfrak{X}, E_1) \rightarrow C^\infty(\mathfrak{X}, E_2)$ that viewed as a summand in $\Psi_H^*(\mathfrak{X}, E_1 \oplus E_2)$ inherits the relevant algebraic properties.

4.3. Heisenberg-Sobolev spaces. Turning to analytic properties, we can construct a positive, invertible, even order differential operator $\mathfrak{D} \in \Psi_H^{2m}(\mathfrak{X}, E)$ admitting complex powers $\mathfrak{D}^z \in \Psi_H^{2mz}(\mathfrak{X}; E)$, $z \in \mathbb{C}$, by [17]. From this family we define the scale of Heisenberg-Sobolev spaces

$$W_H^s(\mathfrak{X}; E) := \mathfrak{D}^{-s/2m} L^2(\mathfrak{X}; E).$$

By [16], for $A \in \Psi_H^m(X; E_1, E_2)$ the operator $A : C^\infty(\mathfrak{X}, E_1) \rightarrow C^\infty(\mathfrak{X}, E_2)$ extends by density to a continuous operator

$$A : W_H^s(X; E_1) \rightarrow W_H^t(X; E_2), \quad \text{for } s \geq t + \text{Re}(m), \quad (4.1)$$

which is compact if $s > t + \text{Re}(m)$.

4.4. Symbolic structure. Let us now describe the microlocal structure of a Heisenberg pseudodifferential operator. Take $A \in \Psi_H^*(\mathfrak{X}, E)$ with lift \mathbf{A} as in Definition 4.1. The r -fibered distribution \mathbf{A} admits a Taylor expansion at $t = 0$, that translates into an asymptotic expansion

$$(\psi^{-1})_* \mathbf{A}(x, v, t) \sim \sum_{j=0}^{\infty} t^j k_j(x, v),$$

where $k_j \in \mathcal{E}'_r(T_H \mathfrak{X}) \cap C^\infty(T_H \mathfrak{X} \setminus \mathfrak{X})$ are almost homogeneous in the sense that $(\delta_\lambda)_* k_j - t^{m-j} k_j \in C_c^\infty(T_H \mathfrak{X})$. In particular, we can deduce that for any $k \in \mathbb{N}$ there exists an $N \in \mathbb{N}$ such that

$$k_A(x, \exp_x^\nabla(\delta_t v)) - \sum_{j=0}^N k_j(x, v) \in C^k(T_H \mathfrak{X}; E_2 \otimes E_1^* \otimes |\Lambda|).$$

By construction, we see that \mathbf{A} is determined modulo smooth, properly supported kernels by A . In particular, we can define the principal symbol of A as the homogeneous element

$$\sigma_H^m(A) := \text{ev}_{t=0}(\mathbf{A}) \in \mathcal{E}'_r(T_H \mathfrak{X}) / C_c^\infty(T_H \mathfrak{X}).$$

Clearly, $\sigma_H^m(A)$ can be represented by $k_0 + C_c^\infty(T_H \mathfrak{X})$. The main features of the principal symbol can be captured in the following theorem. We use the notation $\mathcal{P}^m(\mathfrak{X}; E_1, E_2) \subseteq C^\infty(T_H \mathfrak{X}; E_2 \otimes E_1^* \otimes |\Lambda|)$ for the space of fibrewise polynomial densities of total degree m . In particular, $\mathcal{P}^m(\mathfrak{X}; E_1, E_2) = 0$ unless $m \in -\dim_h(\mathfrak{X}) - \mathbb{N}$.

Theorem 4.2. *Let \mathfrak{X} be a compact Carnot manifold and $E \rightarrow \mathfrak{X}$ a vector bundle and write $\Psi_H^*(\mathfrak{X}, E)$ for the filtered algebra of Heisenberg pseudodifferential operators. For any $m \in \mathbb{C}$, $\Psi_H^m(\mathfrak{X}, E)$ fits into a short exact sequence*

$$0 \rightarrow \Psi_H^{m-1}(\mathfrak{X}, E) \rightarrow \Psi_H^m(\mathfrak{X}, E) \rightarrow \Sigma_H^m(\mathfrak{X}, E) \rightarrow 0,$$

where the symbol algebra $\Sigma_H^m(\mathfrak{X}, E) \subseteq \mathcal{D}'_r(T_H \mathfrak{X}) / \mathcal{P}^m(\mathfrak{X}; E)$ consists of elements of the form

$$k_m + p_m \log |\cdot|_H, \quad (4.2)$$

for $k_m \in \mathcal{D}'_r(T_H \mathfrak{X}; E) / \mathcal{P}^m(\mathfrak{X}; E)$ being homogeneous of degree m , $p_m \in \mathcal{P}(\mathfrak{X}; E)$ and $|\cdot|_H$ a fibrewise gauge. The symbol algebra $\Sigma_H^m(\mathfrak{X}, E)$ also fits into the short exact sequence

$$0 \rightarrow C_c^\infty(T_H \mathfrak{X}, \text{Hom}(E) \otimes |\Lambda|) \rightarrow \tilde{\Sigma}_H^m(\mathfrak{X}, E) \rightarrow \Sigma_H^m(\mathfrak{X}, E) \rightarrow 0,$$

where

$$\begin{aligned}\tilde{\Sigma}_H^m(\mathfrak{X}, E) &:= \text{im}(\text{ev}_{t=0} : \Psi_H^m(\mathfrak{X}, E) \rightarrow \mathcal{E}'_r(T_H\mathfrak{X}; \text{Hom}(E) \otimes |\Lambda|)) = \\ &= \{k \in \mathcal{E}'_r(T_H\mathfrak{X}; \text{Hom}(E) \otimes |\Lambda|) : \lambda_*k - \lambda^m k \in C_c^\infty, \lambda > 0\}.\end{aligned}$$

4.5. Represented symbols and the Rockland condition. To better understand the symbol algebra $\Sigma_H^m(\mathfrak{X}, E)$ we study its action as fibrewise convolution operators. We write $\mathcal{S}(T_H\mathfrak{X}; E)$ for the subspace of elements in $C^\infty(T_H\mathfrak{X}; E)$ that together with all of its derivatives decay faster than polynomially. We introduce the notation $\mathcal{S}_0(T_H\mathfrak{X}; E)$ for the subspace of elements $f \in \mathcal{S}(T_H\mathfrak{X}; E)$ such that for any $x \in \mathfrak{X}$ and any polynomial p on $T_H\mathfrak{X}_x$ we have $\int_{T_H\mathfrak{X}_x} p(v)f(x, v)dx = 0$. Convolving elements of $\mathcal{S}_0(T_H\mathfrak{X}; E)$ with $\mathcal{P}^m(X; E)$ is trivial, so any $a \in \Sigma_H^m(\mathfrak{X}; E)$ can be identified with a convolution operator

$$a : \mathcal{S}_0(T_H\mathfrak{X}; E) \rightarrow \mathcal{S}_0(T_H\mathfrak{X}; E).$$

In fact, if $m \notin -\dim_h(\mathfrak{X}) - \mathbb{N}$ then this convolution operator extends to an operator $a : \mathcal{S}(T_H\mathfrak{X}; E) \rightarrow \mathcal{S}(T_H\mathfrak{X}; E)$. The finer analytic structure of this convolution operator is studied in [24, Part 5]. This construction can be localized in representations of the osculating Lie groupoid. For $x \in \mathfrak{X}$ and π a unitary representation of $T_H\mathfrak{X}_x$ on a Hilbert space \mathcal{H}_π , we write $\mathcal{S}_0(\pi) := \pi(\mathcal{S}_0(T_H\mathfrak{X}_x))\mathcal{H}_\pi$. If π is irreducible and not the trivial representation, $\mathcal{S}_0(\pi) \subseteq \mathcal{H}_\pi$ is dense in the norm topology and in fact

$$\mathcal{S}_0(\pi) = \mathcal{S}(\pi) := \pi(\mathcal{S}(T_H\mathfrak{X}_x))\mathcal{H}_\pi.$$

And convolving with a symbol $a \in \Sigma_H^m(\mathfrak{X}; E)$ localizes to an operator

$$\pi(a) : \mathcal{S}(\pi) \otimes E_x \rightarrow \mathcal{S}(\pi) \otimes E_x.$$

The same structures hold also for $a \in \Sigma_H^m(\mathfrak{X}, E_1, E_2)$. An operator $A \in \Psi_H^m(\mathfrak{X}; E_1, E_2)$ is said to satisfy the **Rockland condition** if for any $x \in \mathfrak{X}$ and π any irreducible, unitary, non-trivial representation of $T_H\mathfrak{X}_x$ the represented symbol

$$\pi(\sigma_H^m(A)) : \mathcal{S}(\pi) \otimes (E_1)_x \rightarrow \mathcal{S}(\pi) \otimes (E_2)_x,$$

is injective.

Theorem 4.3. *Let \mathfrak{X} be a compact Carnot manifold and $A \in \Psi_H^m(\mathfrak{X}; E_1, E_2)$. Then the following are equivalent:*

- (1) *A satisfies the Rockland condition.*
- (2) *There is a $B \in \Psi_H^{-m}(\mathfrak{X}; E_2, E_1)$ such that $BA - 1 \in \Psi^{-\infty}(\mathfrak{X}; E_1)$.*
- (3) *There is a $b \in \Sigma_H^{-m}(\mathfrak{X}; E_2, E_1)$ such that $b\sigma_H^m(A) = 1$.*
- (4) *The operator*

$$A : W_H^s(X; E_1) \rightarrow W_H^{s-\text{Re}(m)}(X; E_2),$$

is left-Fredholm for some s .

The proof of this theorem is referred to the literature. It is clear that 2) and 3) are equivalent, that 2) implies 4) and that 3) implies 1). That 1) implies 3) is proven in [16] and that 4) implies 1) follows from [2].

4.6. Graded calculus. In many situations we consider in this paper, graded vector bundles and graded operators with graded analogues of the Rockland condition arise. The setup is close to the ungraded situation, but to see the similarity appropriate conventions are needed. We follow the setup of [5], modelled on the Douglis-Nirenberg calculus [1] as used in the study of boundary value problems [25], see also [30]. We write $\mathbf{E} \rightarrow \mathfrak{X}$ for a graded vector bundle, i.e. $\mathbf{E} = \bigoplus_{\nu \in \mathbb{R}} \mathbf{E}[\nu]$ where $\mathbf{E}[\nu] \rightarrow \mathfrak{X}$ is a vector bundle (said to be of degree ν) and $\mathbf{E}[\nu] = 0$ for all but finitely many ν . For a graded vector bundle $\mathbf{E} \rightarrow \mathfrak{X}$, we define

$$W_{H,\text{gr}}^s(\mathfrak{X}; \mathbf{E}) := \bigoplus_{\nu \in \mathbb{R}} W^{s-\nu}(\mathfrak{X}; \mathbf{E}[\nu]).$$

Given two graded bundles, $\mathbf{E}_1, \mathbf{E}_2 \rightarrow \mathfrak{X}$ we define the graded calculus

$$\Psi_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2) := \{A = (A_{\mu\nu})_{\mu,\nu} : A_{\mu,\nu} \in \Psi_H^{m+\mu-\nu}(\mathfrak{X}; \mathbf{E}_1[\nu], \mathbf{E}_2[\mu])\}.$$

Composition defines a well defined operation $\Psi_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_2, \mathbf{E}_3) \times \Psi_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2) \rightarrow \Psi_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_3)$ and the principal symbol map extends as

$$\sigma_{H,\text{gr}}^m(A) = (\sigma_H^{m+\mu-\nu}(A_{\mu\nu}))_{\mu,\nu}.$$

We also write

$$\Sigma_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2) := \{a = (a_{\mu\nu})_{\mu,\nu} : a_{\mu,\nu} \in \Sigma_H^{m+\mu-\nu}(\mathfrak{X}; \mathbf{E}_1[\nu], \mathbf{E}_2[\mu])\},$$

for the range (as well as codomain) of the graded symbol mapping. We can again view the principal symbol as a convolution operator

$$\sigma_{H,\text{gr}}^m(A) : \mathcal{S}_0(T_H \mathfrak{X}; \mathbf{E}_1) \rightarrow \mathcal{S}_0(T_H \mathfrak{X}; \mathbf{E}_2),$$

that for $x \in \mathfrak{X}$ and an irreducible, nontrivial, unitary representation π of $T_H \mathfrak{X}_x$ localizes to an operator

$$\pi(\sigma_{H,\text{gr}}^m(A)) : \mathcal{S}(\pi) \otimes (\mathbf{E}_1)_x \rightarrow \mathcal{S}(\pi) \otimes (\mathbf{E}_2)_x.$$

If $\pi(\sigma_{H,\text{gr}}^m(A))$ is injective for all irreducible, nontrivial, unitary representation π we say that A satisfies the Rockland condition. In the vein of Theorem 4.3, $A \in \Psi_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2)$ satisfies the Rockland condition if and only if $\sigma_{H,\text{gr}}^m(A)$ admits a left inverse $b \in \Sigma_{H,\text{gr}}^{-m}(\mathfrak{X}; \mathbf{E}_2, \mathbf{E}_1)$ if and only if

$$A : W_{H,\text{gr}}^s(\mathfrak{X}; \mathbf{E}_1) \rightarrow W_{H,\text{gr}}^{s-m}(\mathfrak{X}; \mathbf{E}_2),$$

is left Fredholm.

4.7. The symbol algebra on flat parabolic geometries. We end this section with a description of the symbol algebra of flat parabolic geometries $\mathfrak{X} = \mathbf{G}/\mathbf{P}$ where we later will be interested in the structure of equivariant symbols. We consider a connected, semi-simple Lie group \mathbf{G} and a standard parabolic subgroup $\mathbf{P} \subseteq \mathbf{G}$ with respect to a Cartan involution θ and a maximal compact subgroup \mathbf{K} . We have a Langlands decomposition

$$\mathbf{P} = \mathbf{M}_{\mathbf{P}} \mathbf{A}_{\mathbf{P}} \mathbf{N}_{\mathbf{P}},$$

of \mathbf{P} . Here $\mathbf{M}_{\mathbf{P}}$ is a semi-simple Lie group, $\mathbf{A}_{\mathbf{P}}$ a split tori over \mathbb{R} and $\mathbf{N}_{\mathbf{P}}$ a nilpotent Lie group. We have that $\mathbf{G}/\mathbf{P} = \mathbf{K}/(\mathbf{K} \cap \mathbf{M}_{\mathbf{P}})$ as smooth manifolds, and the conjugate nilpotent group $\overline{\mathbf{N}}_{\mathbf{P}} := \theta(\mathbf{N}_{\mathbf{P}})$ defines a dense open chart $\overline{\mathbf{N}}_{\mathbf{P}} \hookrightarrow \mathbf{G}/\mathbf{P}$ using Bruhat decompositions. Write $\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbf{P}})$ for the polynomial densities of degree m on $\overline{\mathbf{N}}_{\mathbf{P}}$. We introduce the notation $\Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}} \subseteq \mathcal{D}'_r(\overline{\mathbf{N}}_{\mathbf{P}})/\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbf{P}})$ for the set of elements of the form in (4.2) but independent of the base space. Convolution defines a product

$$\Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}} \times \Sigma_H^{m'} \overline{\mathbf{N}}_{\mathbf{P}} \rightarrow \Sigma_H^{m+m'} \overline{\mathbf{N}}_{\mathbf{P}}.$$

Since $\mathbf{M}_{\mathbf{P}} \mathbf{A}_{\mathbf{P}}$ normalizes $\mathbf{N}_{\mathbf{P}}$ and $\overline{\mathbf{N}}_{\mathbf{P}}$, it acts as automorphisms of $\Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}}$ respecting the product. The following is clear from Theorem 4.2.

Proposition 4.4. *Consider the flat parabolic geometry $\mathfrak{X} = \mathbf{G}/\mathbf{P}$. For finite-dimensional $\mathbf{A}_{\mathbf{P}} \mathbf{M}_{\mathbf{P}}$ -representations V_1 and V_2 we define the homogeneous vector bundles $E_j = \mathbf{G} \times_{\mathbf{P}} V_j \rightarrow \mathfrak{X}$. Then $\Sigma_H^m(X; E_1, E_2)$ consists of the smooth sections of a \mathbf{G} -equivariant bundle of algebras whose fibre is*

$$\Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}} \otimes \text{Hom}(V_1, V_2).$$

More precisely, we have a \mathbf{G} -equivariant isomorphism

$$\Sigma_H^m(X; E_1, E_2) \cong C^\infty(\mathbf{G}/\mathbf{N}_{\mathbf{P}}, \Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}} \otimes \text{Hom}(V_1, V_2))^{M_{\mathbf{P}} \mathbf{A}_{\mathbf{P}}},$$

that respects products. Here the $\mathbf{M}_{\mathbf{P}} \mathbf{A}_{\mathbf{P}}$ -action is the diagonal one and from the right on $\mathbf{G}/\mathbf{N}_{\mathbf{P}}$. In particular, the \mathbf{G} -equivariant symbols are described by

$$\Sigma_H^m(X; E_1, E_2)^{\mathbf{G}} \cong (\Sigma_H^m \overline{\mathbf{N}}_{\mathbf{P}} \otimes \text{Hom}(V_1, V_2))^{M_{\mathbf{P}} \mathbf{A}_{\mathbf{P}}}$$

Recall the definition of $\text{ht}_{\mathbb{P}}$ from Equation (3.1) and write $\mathfrak{a}_{\mathbb{C}}^* := \mathfrak{a}^* \otimes_{\mathbb{R}} \mathbb{C}$. We can extend this map to a complex linear map $\text{ht}_{\mathbb{P}} : \mathfrak{a}_{\mathbb{C}}^* \rightarrow \mathbb{C}$ and restrict it to a map $\text{ht}_{\mathbb{P}} : \mathfrak{a}_{\mathbb{P}, \mathbb{C}}^* \rightarrow \mathbb{C}$ which is an isomorphism if $\mathbf{A}_{\mathbb{P}}$ has rank one. A quasicharacter on $\mathbf{A}_{\mathbb{P}}$ is a homomorphism $\mathbf{A}_{\mathbb{P}} \rightarrow \mathbb{C}^{\times}$, and the space of quasicharacters coincides with $\mathfrak{a}_{\mathbb{P}, \mathbb{C}}^*$ under the logarithm. For a quasicharacter χ we define $\text{ht}_{\mathbb{P}}(\chi)$ in this way. We let \mathbb{C}_{χ} denote the $\mathbf{A}_{\mathbb{P}}$ -representation \mathbb{C} with the group acting via χ .

Lemma 4.5. *Let \mathbf{G} be a semi-simple Lie group, $\mathbf{P} = \mathbf{M}_{\mathbb{P}}\mathbf{A}_{\mathbb{P}}\mathbf{N}_{\mathbb{P}}$ a standard parabolic subgroup and χ_1 and χ_2 two quasi-characters of $\mathbf{A}_{\mathbb{P}}$. Then*

$$(\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \text{Hom}(\mathbb{C}_{\chi_1}, \mathbb{C}_{\chi_2}))^{\mathbf{A}_{\mathbb{P}}} = \begin{cases} (\mathcal{U}_m(\overline{\mathbf{n}}_{\mathbb{P}}) \otimes \text{Hom}(\mathbb{C}_{\chi_1}, \mathbb{C}_{\chi_2}))^{\mathbf{A}_{\mathbb{P}}}, & \text{if } \text{rk}(\mathbf{A}_{\mathbb{P}}) > 1 \text{ or} \\ & m \neq \text{ht}_{\mathbb{P}}(\chi_1) - \text{ht}_{\mathbb{P}}(\chi_2), \\ \Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}}, & \text{if } \text{rk}(\mathbf{A}_{\mathbb{P}}) = 1 \text{ and} \\ & m = \text{ht}_{\mathbb{P}}(\chi_1) - \text{ht}_{\mathbb{P}}(\chi_2). \end{cases}$$

The content of this lemma is that either the $\mathbf{A}_{\mathbb{P}}$ -invariant part consists of invariant elements of the universal enveloping algebra or it is the whole symbol algebra.

Proof. We first note that the dilation on $\overline{\mathbf{N}}_{\mathbb{P}}$ factors over the action of $\mathbf{A}_{\mathbb{P}}$ on $\overline{\mathbf{N}}_{\mathbb{P}}$ defined from conjugation. Let $\mathbf{A}_{\mathbb{P}}^0 \subseteq \mathbf{A}_{\mathbb{P}}$ be a complement to the corresponding embedding $\mathbb{R}_{>0} \hookrightarrow \mathbf{A}_{\mathbb{P}}$. And in fact, the basis vector $1 \in \text{Hom}(\mathbb{C}_{\chi_1}, \mathbb{C}_{\chi_2})$ implements an isomorphism

$$(\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \text{Hom}(\mathbb{C}_{\chi_1}, \mathbb{C}_{\chi_2}))^{\mathbf{A}_{\mathbb{P}}} \cong \begin{cases} (\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi})^{\mathbf{A}_{\mathbb{P}}^0}, & m = \text{ht}_{\mathbb{P}}(\chi_1) - \text{ht}_{\mathbb{P}}(\chi_2) \\ 0, & \text{otherwise.} \end{cases}$$

where χ is the restriction of $\chi_2 \chi_1^{-1}$ to $\mathbf{A}_{\mathbb{P}}^0$. We see from this identity that the case $\text{rk}(\mathbf{A}_{\mathbb{P}}) = 1$ holds true. To simplify the remainder of the argument, we can without loss of generality assume that χ_1 is trivial and that $m = -\text{ht}_{\mathbb{P}}(\chi_2)$.

It remains to show that $(\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi})^{\mathbf{A}_{\mathbb{P}}^0} = (\mathcal{U}_m(\overline{\mathbf{n}}_{\mathbb{P}}) \otimes \mathbb{C}_{\chi})^{\mathbf{A}_{\mathbb{P}}^0}$ when $\text{rk}(\mathbf{A}_{\mathbb{P}}) > 1$. In fact, it is sufficient to show that $(\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi})^{\mathbf{A}_{\mathbb{P}}^0}$ is in the kernel of the restriction mapping $\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi} \rightarrow C^{\infty}(\overline{\mathbf{N}}_{\mathbb{P}} \setminus \{0\})/\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbb{P}})$. On both sides we use the $\mathbf{A}_{\mathbb{P}}$ -action $\delta_a^{\mathbb{P}}$ defined by $\delta_a^{\mathbb{P}} k(n) := k(ana^{-1})$ defined for $a \in \mathbf{A}_{\mathbb{P}}$ and k in any of the two spaces. The range of $(\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi})^{\mathbf{A}_{\mathbb{P}}^0}$ under the restriction mapping $\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \mathbb{C}_{\chi} \rightarrow C^{\infty}(\overline{\mathbf{N}}_{\mathbb{P}} \setminus \{0\})/\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbb{P}})$ is contained in the set of elements $k \in C^{\infty}(\overline{\mathbf{N}}_{\mathbb{P}} \setminus \{0\})/\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbb{P}})$ such that $\delta_a^{\mathbb{P}} k = \chi_2(a)k$. However, since $\text{rk}(\mathbf{A}_{\mathbb{P}}) > 1$ the only element $k \in C^{\infty}(\overline{\mathbf{N}}_{\mathbb{P}} \setminus \{0\})/\mathcal{P}^m(\overline{\mathbf{N}}_{\mathbb{P}})$ such that $\delta_a^{\mathbb{P}} k = \chi_2(a)k$ is the zero function as the homogeneity otherwise forces there to be non-trivial singular support. And the lemma follows. \square

For later purposes, we work with graded homogeneous bundles. We say that a finite-dimensional $\mathbf{A}_{\mathbb{P}}\mathbf{M}_{\mathbb{P}}$ -representations V is graded if $V = \bigoplus_{\nu \in \mathbb{R}} V[\nu]$ for finite-dimensional $\mathbf{A}_{\mathbb{P}}\mathbf{M}_{\mathbb{P}}$ -representation $V[\nu]$. If so, the associated homogeneous bundle $\mathbf{E} = \mathbf{G} \times_{\mathbf{P}} V \rightarrow \mathfrak{X}$ is graded by $\mathbf{E}[\nu] = \mathbf{G} \times_{\mathbf{P}} V[\nu]$.

Corollary 4.6. *Consider the flat parabolic geometry $\mathfrak{X} = \mathbf{G}/\mathbf{P}$. For finite-dimensional graded $\mathbf{A}_{\mathbb{P}}\mathbf{M}_{\mathbb{P}}$ -representations V_1 and V_2 we define the homogeneous vector bundles $\mathbf{E}_j = \mathbf{G} \times_{\mathbf{P}} V_j \rightarrow \mathfrak{X}$. Then the invariant algebra $\Sigma_{\mathbb{H}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2)^{\mathbf{G}}$ consists of symbols of differential operators if $\text{rk}(\mathbf{A}_{\mathbb{P}}) > 1$ and if $\text{rk}(\mathbf{A}_{\mathbb{P}}) = 1$ we have that*

$$\Sigma_{\mathbb{H}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2)^{\mathbf{G}} \cong (\Sigma_{\mathbb{H}}^m \overline{\mathbf{N}}_{\mathbb{P}} \otimes \text{Hom}_{\mathbf{A}_{\mathbb{P}}}(V_1^{(m)}, V_2))^{M_{\mathbb{P}}},$$

where $V_1^{(m)} = V_1 \otimes \mathbb{C}_{\chi}$ for the quasicharacter $\chi := \text{ht}_{\mathbb{P}}^{-1}(m)$.

5. BGG-SEQUENCES AND GRADED ROCKLAND SEQUENCES

Throughout this section, we fix a G -Carnot manifold \mathfrak{X} . For simplicity, we assume that \mathfrak{X} is compact and remark that local statements will extend to non-compact \mathfrak{X} .

Definition 5.1. Consider a collection $\mathbf{E}_\bullet = (\mathbf{E}_0, \mathbf{E}_1, \dots, \mathbf{E}_N)$ of graded vector bundles $\mathbf{E}_j \rightarrow \mathfrak{X}$ and numbers $\mathbf{m} = (m_1, \dots, m_N) \in \mathbb{R}^N$. We let

$$D_\bullet : 0 \rightarrow C^\infty(\mathfrak{X}; \mathbf{E}_0) \xrightarrow{D_1} C^\infty(\mathfrak{X}; \mathbf{E}_1) \xrightarrow{D_2} \dots \xrightarrow{D_N} C^\infty(\mathfrak{X}; \mathbf{E}_N) \rightarrow 0, \quad (5.1)$$

be a sequence of maps $D_j \in \Psi_{H, \text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j)$. We say that the sequence D_\bullet in Equation (5.1) is a *graded Rockland sequence* if the symbol sequence $\sigma_H(D_\bullet)$ defined by

$$0 \rightarrow \mathcal{S}_0(T_H \mathfrak{X}; \mathbf{E}_0) \xrightarrow{\sigma_H(D_1)} \mathcal{S}_0(T_H \mathfrak{X}; \mathbf{E}_1) \xrightarrow{\sigma_H(D_2)} \dots \xrightarrow{\sigma_H(D_N)} \mathcal{S}_0(T_H \mathfrak{X}; \mathbf{E}_N) \rightarrow 0,$$

localizing in any non-trivial unitary representation of the osculating Lie groupoid $T_H \mathfrak{X}$ to an exact sequence. We say that \mathbf{m} is the order of D_\bullet .

- In the special case that a Rockland sequence D_\bullet as in Equation (5.1) is a complex, we call D_\bullet a *graded Rockland complex*.
- In the special case that $\mathbf{E}_0, \mathbf{E}_1, \dots, \mathbf{E}_N \rightarrow \mathfrak{X}$ are all trivially graded, a Rockland sequence D_\bullet as in Equation (5.1) is called a *Rockland sequence*.

Remark 5.2. Upon shifting the grading of each \mathbf{E}_j in a graded Rockland sequence, we can achieve that D_\bullet has order $\mathbf{0} = (0, \dots, 0) \in \mathbb{R}^N$.

5.1. BGG-sequences. In the paper [8], Bernstein-Gelfand-Gelfand studied the resolution of a highest weight module of a complex, semi-simple Lie algebra by means of Verma modules. This led Bernstein-Gelfand-Gelfand to the category \mathcal{O} , for an introduction thereto see [31]. The construction of Bernstein-Gelfand-Gelfand was later extended to generalized Verma modules by Lepowsky [37]. The construction is by now understood in larger generality. We restrict to the setting of finite-dimensional representations of complex, semi-simple Lie groups using algebraic tools in this section and return to the general case below in Subsection 5.2.

We start by discussing Bernstein-Gelfand-Gelfand's algebraic setup whereafter we bring it back to the geometric interpretation of relevance to us. Let \mathbf{G} be a connected, complex, semi-simple Lie group with Lie algebra \mathfrak{g} . We fix a maximal compact subgroup $\mathbf{K} \subseteq \mathbf{G}$ and a Cartan subalgebra $\mathfrak{h} \subseteq \mathfrak{g}$ integrating to $\mathbf{H} \subseteq \mathbf{G}$. Set $\mathbf{M} := \mathbf{K} \cap \mathbf{H}$. We can factorize $\mathbf{G} = \mathbf{KAN}_+$ where \mathbf{A} comes from the factorization $\mathbf{H} = \mathbf{MA}$ and \mathbf{N}_+ is a (complex) nilpotent Lie group. Here we use notation mimicking that of parabolic geometry from Subsection 3.2. The Borel subgroup is defined by

$$\mathbf{B} := \mathbf{MAN}_+ = \mathbf{HN}_+,$$

and is solvable with nilpotent radical $[\mathbf{B}, \mathbf{B}] = \mathbf{N}_+$. Let \mathfrak{b} denote the Lie algebra of \mathbf{B} and \mathfrak{n}_+ the Lie algebra of \mathbf{N}_+ . In terms of the roots $\Delta \subseteq \mathfrak{h}^*$, and a suitable choice of positive root system Δ_+ , the description above stems from the root decompositions

$$\mathfrak{g} = \mathfrak{h} + \sum_{\alpha \in \Delta} \mathfrak{g}_\alpha, \quad \mathfrak{b} = \mathfrak{h} + \sum_{\alpha \in \Delta_+} \mathfrak{g}_\alpha \quad \text{and} \quad \mathfrak{n}_+ = \sum_{\alpha \in \Delta_+} \mathfrak{g}_\alpha,$$

where $\mathfrak{g}_\alpha := \{Y \in \mathfrak{g} : [h, Y] = \alpha(h)Y \forall h \in \mathfrak{h}\}$. We shall also make use of the nilpotent Lie algebra

$$\mathfrak{n}_- = \sum_{\alpha \in \Delta_+} \mathfrak{g}_{-\alpha}.$$

In terms of a $|k|$ -grading as in Subsection 3.2, the above description is related via a height of roots as in Example 3.6. For complex Lie groups, the set of restricted roots Σ coincides with the set of all roots Δ . The height with respect to the Borel group is $\text{ht}_{\mathbf{B}}(\sum_{\alpha \in \Pi} a_\alpha \alpha) := \sum_{\alpha \in \Pi} a_\alpha$ for a choice of simple roots Π . The Iwasawa decomposition described above can as in Subsection 3.2 be constructed from the $|k|$ -grading

$$\mathfrak{g}_j := \bigoplus_{\alpha \in \Delta : \text{ht}_{\mathbf{B}}(\alpha) = j} \mathfrak{g}_\alpha.$$

The Verma module associated with a weight $\lambda \in \mathfrak{h}^*$ is the \mathfrak{g} -module defined by

$$\mathcal{M}(\lambda) := \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} \mathbb{C}_\lambda.$$

Here $\mathcal{U}(\mathfrak{g})$ denotes the universal enveloping algebra and \mathbb{C}_λ is the \mathfrak{b} -module defined from the character λ extended to \mathfrak{b} via the quotient map $\mathfrak{b} \rightarrow \mathfrak{h}$. By [18, Proposition 7.1.8], the Verma module is cofinal among all \mathfrak{g} -modules with highest weight λ . The Poincaré-Birkhoff-Witt theorem induces a vector space isomorphism

$$\mathcal{M}(\lambda) \cong \mathcal{U}(\mathfrak{n}_-). \quad (5.2)$$

The idea underlying the construction of the BGG-resolution is the fact that there are very few morphisms between Verma modules. Indeed, to quantify what is mean by “very few” we recall the following result due to Bernstein-Gelfand-Gelfand [8, page 41], see also [18]. First, we recall the standard notation

$$\rho := \frac{1}{2} \sum_{\alpha \in \Delta_+} \alpha.$$

We also let W denote the Weyl group and equip it with its Bruhat order (cf. [10, Chapter 3.2.14]).

Theorem 5.3. *Let λ and μ be weights. Then there is a non-zero morphism of \mathfrak{g} -modules*

$$\mathcal{M}(\mu) \leftarrow \mathcal{M}(\lambda),$$

if and only if λ is an integral weight such that $\lambda + \rho$ and $\mu + \rho$ are in the same orbit of the Weyl group, and more precisely for $w_1 \geq w_2 \in W$ the weight $w_1^{-1}(\lambda + \rho) = w_2^{-1}(\mu + \rho)$ is the unique dominant weight in the orbit of $\lambda + \rho$. If so, the morphism is uniquely determined up to a complex scalar and injective.

Bernstein-Gelfand-Gelfand [8] proved that when assembling these morphisms together according to lengths in the Weyl group, they fit into a resolution. Note that if V is a \mathfrak{g} -module with highest weight λ , there is a natural map $\mathcal{M}(\lambda) \rightarrow V$.

Theorem 5.4 (The Bernstein-Gelfand-Gelfand resolution). *Let V be a finite-dimensional \mathfrak{g} -module with highest weight λ . Write $d + 1$ for the longest length in the Weyl group. Define the \mathfrak{g} -modules*

$$C_k := \bigoplus_{w \in W, |w|=k} \mathcal{M}(w(\lambda + \rho) - \rho), \quad k = 0, \dots, d.$$

Then there are elements $\delta_k \in \text{Hom}_{\mathcal{U}(\mathfrak{g})}(C_k, C_{k-1})$ making the following sequence exact

$$0 \leftarrow V \leftarrow C_0 \xleftarrow{\delta_1} C_1 \xleftarrow{\delta_2} \dots \xleftarrow{\delta_{d-1}} C_{d-1} \xleftarrow{\delta_d} C_d \leftarrow 0.$$

To compute with the BGG-complex, it is useful to better understand the Lie algebra homology bundles $\mathcal{H}_j(V) \rightarrow \mathfrak{X} = \mathbf{G}/\mathbf{P}$. In other words, we wish to describe the \mathbf{G}_0 -module structure on $H_j(\mathfrak{p}_+, V)$. For complex \mathbf{G} and \mathbf{P} its Borel subgroup, the \mathbf{G}_0 -module structure on $H_j(\mathfrak{p}_+, V)$ was described by Kostant [34] and the general case can be found in Cap-Slovak’s monograph [10, Theorem 3.3.5 and Proposition 3.3.6]. We recall it in a form relevant to this work.

Theorem 5.5. *Let \mathfrak{g} be a $|k|$ -graded semisimple Lie algebra and V a complex, finite-dimensional highest weight representation of \mathfrak{g} . Write λ for the highest weight of V , δ for the lowest form on \mathfrak{g} and $W^{\mathfrak{p}} \subseteq W$ for the Hasse diagram of \mathfrak{p} in the Weyl group W of \mathfrak{g} (see [10, Chapter 3.2.15]).*

- Assume that \mathfrak{g} is complex and the representation V is complex linear. Then for a \mathfrak{g}_0 -dominant weight ν , then the G_0 -isotypical component $H^k(\mathfrak{p}_+, V)^\nu$ vanishes unless $\nu = w(\lambda + \delta) - \delta$ for a $w \in W^{\mathfrak{p}}$ with $\ell(w) = k$, in which case $H^{\ell(w)}(\mathfrak{p}_+, V)^{w(\lambda + \delta) - \delta}$ is irreducible. In particular, as G_0 -modules

$$H^k(\mathfrak{p}_+, V) = \bigoplus_{w \in W^{\mathfrak{p}}, \ell(w)=k} \mathcal{V}_{w(\lambda + \delta) - \delta},$$

where $\mathcal{V}_{w(\lambda + \delta) - \delta}$ are irreducible finite-dimensional G_0 -representations with highest weight $w(\lambda + \delta) - \delta$.

- Assume that \mathfrak{g} is real. Then

$$H^k(\mathfrak{p}_+, V) = H^k(\mathfrak{p}_{+, \mathbb{C}}, V),$$

as G_0 -modules where the right hand side is computed from the complex $|k|$ -graded semisimple Lie algebra $\mathfrak{g}_{\mathbb{C}} = \mathfrak{g} \otimes_{\mathbb{R}} \mathbb{C}$ as in the previous item.

The algebraic construction in Theorem 5.4 has a geometric counterpart on the full flag manifold $\mathfrak{X} := G/B$. Making the transition to geometry, we use the following correspondence.

Proposition 5.6. *Let W be a finite-dimensional representation of the Borel group B and let $E(W) := G \times_B W$ denote the corresponding homogeneous vector bundle on $\mathfrak{X} := G/B$. Then we have a G -equivariant isomorphism*

$$\begin{aligned} \mathrm{Hom}_{\mathcal{U}(\mathfrak{g})}(\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W, C^\infty(G)) &\xrightarrow{\sim} C^\infty(\mathfrak{X}, E(W)^*), \\ \varphi &\mapsto [(g, v) \mapsto (g^{-1})^*(\varphi(1 \otimes v))], \end{aligned} \quad (5.3)$$

where we equip $C^\infty(G)$ with the $\mathcal{U}(\mathfrak{g})$ -module structure from the right action and we equip $\mathrm{Hom}_{\mathcal{U}(\mathfrak{g})}(\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W, C^\infty(G))$ with the G -action defined from left translation on G .

Moreover, the isomorphism (5.3) is contravariantly functorial for $\mathcal{U}(\mathfrak{g})$ -module maps in the sense that if W_1 and W_2 are two B -representations and

$$\delta \in \mathrm{Hom}_{\mathcal{U}(\mathfrak{g})}(\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_1, \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_2),$$

there is a G -equivariant differential operator $D \in \mathcal{DO}(\mathfrak{X}; E(W_2)^*, E(W_1)^*)$ making the following diagram commute:

$$\begin{array}{ccc} \mathrm{Hom}_{\mathcal{U}(\mathfrak{g})}(\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_2, C^\infty(G)) & \xrightarrow{\delta^*} & \mathrm{Hom}_{\mathcal{U}(\mathfrak{g})}(\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_1, C^\infty(G)) \\ \cong \downarrow & & \downarrow \cong \\ C^\infty(\mathfrak{X}, E(W_2)^*) & \xrightarrow{D} & C^\infty(\mathfrak{X}, E(W_1)^*) \end{array},$$

where the vertical isomorphisms is that of (5.3). The differential operator is uniquely determined from the pairing with jets at $eB \in \mathfrak{X}$.

Proof. Equation (5.3) follows from Frobenius reciprocity. The second part of the statement follows from an analysis of how \mathfrak{g} -module maps $\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_1 \rightarrow \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{b})} W_2$ pair with jets at $eB \in \mathfrak{X}$, for more details, see [50]. \square

In light of Proposition 5.6, one has the following geometric reformulation of Theorem 5.4. Note that the longest element of the Weyl group has length $d + 1$, where $d = \dim_{\mathbb{C}}(G/B)$ (see [10, Chapter 3]).

Theorem 5.7 (The geometric BGG-sequence). *Let V be a finite-dimensional representation of the complex, semisimple Lie group G . Let λ denote the highest weight of V . Define the homogeneous vector bundles on $\mathfrak{X} := G/B$ from*

$$E_k^V := \bigoplus_{w \in W, |w|=k} G \times_B \mathbb{C}_{-w(\lambda + \rho) + \rho}, \quad k = 0, \dots, d.$$

Then there are differential operators $D_k \in \mathcal{DO}(\mathfrak{X}; E_{k-1}^V, E_k^V)$ making the following sequence into a complex of differential operators

$$0 \rightarrow C^\infty(\mathfrak{X}; E_0^V) \xrightarrow{D_1} C^\infty(\mathfrak{X}; E_1^V) \xrightarrow{D_2} \dots \xrightarrow{D_{d-1}} C^\infty(\mathfrak{X}; E_{d-1}^V) \xrightarrow{D_d} C^\infty(\mathfrak{X}; E_d^V) \rightarrow 0,$$

which is exact except in degree 0 where we have $\text{Ker}(D_1) = V$.

Definition 5.8. The BGG-complex of a finite-dimensional representation V of a complex, semisimple Lie group G is the differential complex on G/B from Theorem 5.7. We denote it by $\text{BGG}_\bullet(V)$.

The BGG-complex of a finite-dimensional representation is a prototypical example of a graded Rockland sequence, as we recall below in Subsection 5.2 from the work of Dave-Haller [16]. The Carnot structure on $\mathfrak{X} = G/B$ in which the BGG-complex is graded Rockland, is defined in terms of the simple root system used to define the order in the Weyl group and the height of roots. Let $\Pi \subseteq \Delta_+$ denote this simple root system.

We note that $T\mathfrak{X}$ is the homogeneous vector bundle

$$T\mathfrak{X} = G \times_B (\mathfrak{g}/\mathfrak{b}) \cong G \times_B \mathfrak{n}_-,$$

where B acts on $\mathfrak{n}_- = \sum_{\alpha \in \Delta_+} \mathfrak{g}_{-\alpha}$ via the isomorphism $\mathfrak{n}_- \cong \mathfrak{g}/\mathfrak{b}$. The nilpotent Lie algebra \mathfrak{n}_- is graded by the height of roots. In particular, $\mathfrak{n}_-^{-1} = \sum_{\alpha \in \Pi} \mathfrak{g}_{-\alpha}$ and we inductively have that

$$\mathfrak{n}_-^{-k-1} := \mathfrak{n}_-^{-k} + [\mathfrak{n}_-^{-1}, \mathfrak{n}_-^{-k}].$$

The action of B on \mathfrak{n}_- respects the filtering (as it increases the order), and

$$G \times_B \mathfrak{n}_-^{-j} \rightarrow \mathfrak{X} = G/B,$$

is a well defined bundle that we identify with a sub-bundle $T^{-j}\mathfrak{X} \subseteq T\mathfrak{X}$. By equivariance, the subbundles $T^{-j}\mathfrak{X} \subseteq T\mathfrak{X}$ form a complex Carnot structure on \mathfrak{X} . We note that we can identify

$$\mathfrak{t}_H\mathfrak{X} = G \times_B \mathfrak{n}_-,$$

as G -equivariant bundles of graded, nilpotent Lie algebras. In particular, $\mathfrak{X} = G/B$ is regular of type \mathfrak{n}_- . We note that we can reduce the structure group to H via the quotient mapping $B \rightarrow B/N_+ = H$ and the graded action

$$H \rightarrow \text{Aut}_{\text{gr}}(\mathfrak{n}_-).$$

Therefore, we have G -equivariant isomorphisms of bundles of graded, nilpotent Lie algebras

$$\mathfrak{t}_H\mathfrak{X} = G \times_B \mathfrak{n}_- \cong (G/N_+) \times_H \mathfrak{n}_-.$$

If we disregard G -actions and use that $G/AN_+ = K$ so $G/B = K/M$, we can also write $\mathfrak{t}_H\mathfrak{X} \cong K \times_M \mathfrak{n}_-$ as bundles of graded, nilpotent Lie algebras.

Example 5.9. Let us compute a longer example of the BGG-complex on $G = SL(3, \mathbb{C})$. For the group $SL(3, \mathbb{C})$, many more details can be found in the work of Yuncken [50], who also computed further examples in [51].

We take the maximal compact subgroup $K = SU(3) \subseteq SL(3, \mathbb{C})$ and $H \cong (\mathbb{C}^\times)^2$ to consist of the diagonal matrices with determinant 1. We choose the isomorphism $(z_1, z_3) \mapsto \text{diag}(z_1, (z_1 z_3)^{-1}, z_3)$. Similarly, $A \cong \mathbb{R}_+^2$ consists of the positive diagonal matrices with determinant 1. Now $M = K \cap H \cong U(1)^2$ consists of the unitary diagonal matrices with determinant 1. The Weyl group of $SL(3, \mathbb{C})$ is $W = S_3$.

The nilpotent Lie groups N_\pm consists of unipotent, lower (+)/upper (-) triangular matrices. There are isomorphisms $N_\pm \cong H_{3, \mathbb{C}}$ to the three-dimensional complex Heisenberg group. That is, \mathfrak{n}_\pm is the complex span of elements $e_X^\pm, e_Y^\pm, e_Z^\pm$ subject to the commutation relation

$$[e_X^\pm, e_Y^\pm] = e_Z^\pm.$$

In terms of the matrix units $(e_{jk})_{j,k=1}^3$ spanning $\mathfrak{gl}(3, \mathbb{C})$, $e_X^\pm = e_{21}, e_Y^\pm = e_{32}$, and $e_Z^\pm = e_{31}$ and e_X^-, e_Y^-, e_Z^- are given by their transposes.

The corresponding roots α_x, α_y and $\alpha_z = \alpha_x + \alpha_y$ are under our chosen isomorphism $\mathfrak{h} \cong \mathbb{C}^2$ computed as

$$\begin{cases} \alpha_x(z_1, z_3) = -2z_1 - z_3 \\ \alpha_y(z_1, z_3) = z_1 + 2z_3. \end{cases}$$

The more standard notation for the Chevalley-Serre basis defined from $e_X^\pm, e_Y^\pm, e_Z^\pm$ is $e_j = e_j^+$ and $f_j = e_j^-$ (for $j \in \{X, Y, Z\}$). In particular, as an \mathfrak{h} -module,

$$\mathfrak{n}_- \cong \mathbb{C}_{\alpha_x} \oplus \mathbb{C}_{\alpha_y} \oplus \mathbb{C}_{\alpha_z}.$$

The Borel group $\mathbf{B} \cong (\mathbb{C}^\times)^2 \rtimes \mathbf{N}_+$ consists of the lower triangular matrices with determinant 1. The full flag manifold takes the form

$$\mathfrak{X} = SL(3, \mathbb{C})/\mathbf{B} = SU(3)/\mathbf{M}.$$

The complex G -equivariant Carnot structure is depth two and comes from the decomposition into homogeneous line bundles

$$T\mathfrak{X} = SL(3, \mathbb{C}) \times_{\mathbf{B}} \mathbb{C}_{\alpha_x} \oplus SL(3, \mathbb{C}) \times_{\mathbf{B}} \mathbb{C}_{\alpha_y} \oplus SL(3, \mathbb{C}) \times_{\mathbf{B}} \mathbb{C}_{\alpha_z},$$

as

$$T^{-1}\mathfrak{X} = SL(3, \mathbb{C}) \times_{\mathbf{B}} (\mathbb{C}_{\alpha_x} \oplus \mathbb{C}_{\alpha_y}).$$

Let us construct the BGG-complex of the G -module $V = \mathbb{C}$ algebraically. We follow the ideas of [50]. The highest weight of \mathbb{C} is $\lambda = 0$ and

$$\mathcal{M}(0) = \mathcal{U}(\mathfrak{sl}_3) \otimes_{\mathcal{U}(\mathfrak{b})} \mathbb{C}_0 \cong \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}),$$

where $\mathfrak{h}_{3, \mathbb{C}} = \mathfrak{n}_-$ denotes the complex Heisenberg Lie algebra. For notational simplicity, we write X, Y, Z for the standard generators of $\mathfrak{h}_{3, \mathbb{C}}$. The natural map

$$\epsilon : \mathcal{M}(0) \rightarrow \mathbb{C},$$

is in terms of $\mathcal{U}(\mathfrak{h}_{3, \mathbb{C}})$ given by the trivial character $\mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \rightarrow \mathbb{C}$. The kernel of the natural map $\epsilon : \mathcal{M}(0) \rightarrow \mathbb{C}$ is therefore

$$\text{Ker}(\epsilon) \cong \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}})X + \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}})Y,$$

because $[X, Y] = Z \in \text{Ker}(\epsilon)$. We therefore define the \mathfrak{g} -linear map

$$\delta_1 : \mathcal{M}(-\alpha_x) \oplus \mathcal{M}(-\alpha_y) \rightarrow \mathcal{M}(0),$$

from the PBW-isomorphism (5.2) $\mathcal{M}(-\alpha_x) \oplus \mathcal{M}(-\alpha_y) \cong \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \oplus \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}})$ and the map

$$\mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \oplus \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \rightarrow \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}), \quad (w_1, w_2) \mapsto w_1X + w_2Y.$$

By construction, δ_1 surjects onto $\text{Ker}(\epsilon)$. After some algebra, we see that $\text{Ker}(\delta_1)$ under the PBW-isomorphism is generated by the vectors

$$v_1 = \begin{pmatrix} -XY - Z \\ X^2 \end{pmatrix}, \quad \text{and} \quad v_2 = \begin{pmatrix} -Y^2 \\ YX - Z \end{pmatrix}.$$

We therefore define the \mathfrak{g} -linear map

$$\delta_2 : \mathcal{M}(-2\alpha_x - \alpha_y) \oplus \mathcal{M}(-\alpha_x - 2\alpha_y) \rightarrow \mathcal{M}(-\alpha_x) \oplus \mathcal{M}(-\alpha_y),$$

from the PBW-isomorphism (5.2) and the map

$$\mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \oplus \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \rightarrow \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}) \oplus \mathcal{U}(\mathfrak{h}_{3, \mathbb{C}}), \quad (w_1, w_2) \mapsto w_1v_1 + w_2v_2.$$

By construction δ_2 surjects onto $\text{Ker}(\delta_1)$. Continuing in this fashion we arrive at the algebraic BGG-resolution for $V = \mathbb{C}$, that we write as

$$\begin{array}{ccccccc}
& & \mathcal{M}(-\alpha_X) & \xleftarrow{-XY-Z} & \mathcal{M}(-2\alpha_X - \alpha_Y) & & \\
& \swarrow X & & \searrow -Y^2 & & \swarrow -Y & \\
0 & \longleftarrow \mathbb{C} & \xleftarrow{\epsilon} \mathcal{M}(0) & & & & \mathcal{M}(-2\alpha_X - 2\alpha_Y) \longleftarrow 0 \\
& \searrow Y & & \swarrow X^2 & & \swarrow X & \\
& & \mathcal{M}(-\alpha_Y) & \xleftarrow{YX-Z} & \mathcal{M}(-\alpha_X - 2\alpha_Y) & &
\end{array}$$

For a weight λ , write $L_\lambda := \mathbf{G} \times_{\mathbf{B}} \mathbb{C}_\lambda$. Dualizing this as in Proposition 5.6, we arrive at the geometric BGG-complex:

$$\begin{array}{ccccccc}
& & C^\infty(\mathfrak{X}; L_{\alpha_X}) & \xrightarrow{-D_{XY+Z}} & C^\infty(\mathfrak{X}; L_{2\alpha_X+\alpha_Y}) & & \\
& \swarrow D_X & & \searrow -D_{Y^2} & & \swarrow -D_Y & \\
0 & \longrightarrow C^\infty(\mathfrak{X}) & & \swarrow D_{X^2} & & \swarrow D_X & C^\infty(\mathfrak{X}; L_{2\alpha_X+2\alpha_Y}) \longrightarrow 0 \\
& \searrow D_Y & & \swarrow D_{YX-Z} & & \swarrow D_X & \\
& & C^\infty(\mathfrak{X}; L_{\alpha_Y}) & \xrightarrow{D_{YX-Z}} & C^\infty(\mathfrak{X}; L_{\alpha_X+2\alpha_Y}) & &
\end{array}$$

This complex $\text{BGG}_\bullet(\mathbb{C})$ is a graded $SL(3, \mathbb{C})$ -equivariant complex of differential operators by Theorem 5.7. Its principal symbol complex in the point $e\mathbf{B} \in \mathbf{G}/\mathbf{B}$ is given by

$$\begin{array}{ccccccc}
& & \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) & \xrightarrow{-XY-Z} & \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) & & \\
& \swarrow X & & \searrow -Y^2 & & \swarrow -Y & \\
0 & \longrightarrow \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) & & \swarrow X^2 & & \swarrow X & \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) \longrightarrow 0 \\
& \searrow Y & & \swarrow YX-Z & & \swarrow X & \\
& & \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) & \xrightarrow{YX-Z} & \mathcal{S}_0(\mathbf{H}_3, \mathbb{C}) & &
\end{array}$$

Here X, Y, Z denote the generators of \mathfrak{n}_- acting on $\mathcal{S}_0(\mathbf{H}_3, \mathbb{C})$ by right invariant vector fields. For the special case of $\mathbf{G} = SL(3, \mathbb{C})$, there is an ingenious construction involving Kasparov's technical theorem due to Yuncken [50], that produces a class in $KK_0^{SL(3, \mathbb{C})}(C(SL(3, \mathbb{C})/\mathbf{B}), \mathbb{C})$ from the BGG-complex. Our methods above does not quite even produce classes with exponential bounds in $KK_0^{SL(3, \mathbb{C}), \ell}(C(SL(3, \mathbb{C})/\mathbf{B}), \mathbb{C})$

5.2. Curved Bernstein-Gelfand-Gelfand complexes. The BGG-complex for complex Lie groups was extended much further to parabolic geometries by Cap-Slovak-Soucek [11]. The more recent work of Dave-Haller [16] provides an explicit construction of the BGG-complex from Kostant codifferentials that we briefly recall. We restrict the global aspects of our discussion to the flag manifolds $\mathfrak{X} = \mathbf{G}/\mathbf{P}$ for \mathbf{G} a connected, semisimple Lie group and \mathbf{P} a parabolic subgroup. Our discussion provides the local foundation for describing curved BGG-complexes for general parabolic geometries and pinpointing their symbol complex.

Fix a complex finite-dimensional representation V of \mathbf{G} , for instance the trivial representation. Let $C_*(\mathfrak{n}, V) := \wedge^* \mathfrak{g} \otimes V$ and $C^*(\mathfrak{n}, V) = \wedge^* \mathfrak{g}^* \otimes V$ denote the Lie algebra homology and cohomology complex, respectively, with coefficients in V . We filter these spaces using the grading of \mathfrak{n} . The \mathbf{G}_0 -equivariant identification (3.2) allow us to identify the \mathbf{G}_0 -spaces

$$C^*(\mathfrak{n}, V) = C_*(\mathfrak{p}_+, V).$$

The right hand side is equipped with the differential $\delta : C_*(\mathfrak{p}_+, V) \rightarrow C_{*-1}(\mathfrak{p}_+, V)$ defining Lie algebra homology

$$\begin{aligned} \delta(X_1 \wedge \cdots \wedge X_k \otimes v) &= \sum_{j=1}^n (-1)^{j+1} X_1 \wedge \cdots \wedge \widehat{X}_j \wedge \cdots \wedge X_k \otimes X_j(v) + \\ &\quad + \sum_{i < j} (-1)^{i+j} [X_i, X_j] \wedge X_1 \wedge \cdots \wedge \widehat{X}_i \wedge \cdots \wedge \widehat{X}_j \wedge \cdots \wedge X_k \otimes v \end{aligned}$$

We can identify δ with a differential $\partial : C^*(\mathfrak{n}, V) \rightarrow C^{*-1}(\mathfrak{n}, V)$ called Kostant's codifferential. By construction, ∂ is of filtered degree 0 and \mathfrak{G}_0 -equivariant.

Write $E_V := \mathfrak{G} \times_{\mathfrak{P}} V \rightarrow \mathfrak{X}$. Using

$$\wedge^* T^* \mathfrak{X} \otimes E_V = \mathfrak{G} \times_{\mathfrak{P}} (C^j(\mathfrak{n}, V)) = (\mathfrak{G}/\mathfrak{P}_+) \times_{\mathfrak{G}_0} (C^j(\mathfrak{n}, V)),$$

Kostant's codifferential ∂ induces a vector bundle morphism

$$\partial_{\mathfrak{X}} : \wedge^* T^* \mathfrak{X} \otimes E_V \rightarrow \wedge^{*-1} T^* \mathfrak{X} \otimes E_V,$$

which is \mathfrak{G} -equivariant and of filtered degree 0. Here we use the filtering of $T^* \mathfrak{X}$ dual to the filtering of $T \mathfrak{X}$.

Let ∇_V denote the tractor connection on E_V and extend it to a differential operator

$$\nabla_V : C^\infty(\mathfrak{X}; \wedge^* T^* \mathfrak{X} \otimes E_V) \rightarrow C^\infty(\mathfrak{X}; \wedge^{*+1} T^* \mathfrak{X} \otimes E_V),$$

using the Leibniz rule. The differential operator ∇_V is \mathfrak{G} -equivariant, of graded Heisenberg degree 0 and its curvature ∇_V^2 is of filtered degree -1 .

We now proceed as in [16] to construct BGG-sequences. The method produces the same result as in [8, 11, 37] due to the arguments of [11, 16]. We note that there is a \mathfrak{G} -equivariant identity $T^{-j} \mathfrak{X} = \bigoplus_{l=1}^j T_{-l} \mathfrak{X}$ where $T_{-l} \mathfrak{X} := (\mathfrak{G}/\mathfrak{P}_+) \times_{\mathfrak{G}_0} \mathfrak{g}_{-l}$. Therefore, there is a canonical \mathfrak{G} -equivariant identification $T \mathfrak{X} \cong \text{gr}(T \mathfrak{X})$. Note that under this identification and (3.2), $T^* \mathfrak{X}$ is graded by $T^* \mathfrak{X} = \bigoplus_{l=1}^k T_l^* \mathfrak{X}$ for $T_l^* \mathfrak{X} := (\mathfrak{G}/\mathfrak{P}_+) \times_{\mathfrak{G}_0} \mathfrak{g}_l$. Write $[\wedge^l T^* \mathfrak{X} \otimes E_V]_j$ for the space of elements of homogeneous degree j . Note the following consequence of [16, Lemma 4.4].

Lemma 5.10. *Let V be a complex \mathfrak{G} -representation, and $\partial_{\mathfrak{X}}$ the Kostant codifferential and ∇_V the tractor connection as above. For $j = 0, \dots, d = \dim(\mathfrak{X})$, consider the graded Heisenberg degree 0 differential operator*

$$\square_j := \nabla_V \partial_{\mathfrak{X}} + \partial_{\mathfrak{X}} \nabla_V : C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V) \rightarrow C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V),$$

and its diagonal piece

$$\tilde{\square}_j := \bigoplus_l \square_j|_{C^\infty(\mathfrak{X}; [\wedge^j T^* \mathfrak{X} \otimes E_V]_l)} : C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V) \rightarrow C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V).$$

Then $\tilde{\square}_j$ is a bundle endomorphism whose generalized eigenprojection \tilde{P}_j for the eigenvalue 0 is also a bundle endomorphism.

Moreover, there exists a unique graded Heisenberg order 0, differential projector

$$P_j : C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V) \rightarrow C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V),$$

such that

- (1) $P_j \square_j = \square_j P_j$
- (2) $\bigoplus_l P_j|_{C^\infty(\mathfrak{X}; [\wedge^j T^* \mathfrak{X} \otimes E_V]_l)} = \tilde{P}_j$
- (3) *The decomposition*

$$C^\infty(\mathfrak{X}; \wedge^j T^* \mathfrak{X} \otimes E_V) = \text{Ker}(P_j) \oplus \text{im}(P_j),$$

is preserved by \square_j which acts nilpotently on the first summand and invertibly on the second.

Consider the operators

$$L_j := P_j \tilde{P}_j + (1 - P_j)(1 - \tilde{P}_j). \quad (5.4)$$

A degree argument shows that L_j is invertible with inverse being a graded Heisenberg order 0, differential operator. These graded Heisenberg order 0, differential operators restrict to isomorphisms

$$\begin{aligned} L_j| : C^\infty(\mathfrak{X}; \tilde{P}_j(\wedge^j T^* \mathfrak{X} \otimes E_V)) &\xrightarrow{\sim} \text{im}(P_j), \\ L_j| : C^\infty(\mathfrak{X}; (1 - \tilde{P}_j)(\wedge^j T^* \mathfrak{X} \otimes E_V)) &\xrightarrow{\sim} \text{Ker}(P_j). \end{aligned}$$

It follows from Hodge theory that \tilde{P}_j projects onto the bundle

$$\mathcal{H}_j(V) := (\mathbb{G}/\mathbb{P}_+) \times_{\mathbb{G}_0} H^j(\mathfrak{p}_+, V) \rightarrow \mathfrak{X}$$

viewed as a sub-bundle of $\wedge^j T^* \mathfrak{X} \otimes E_V$ in terms of harmonic forms. Note that the \mathbb{G}_0 -representation $H^j(\mathfrak{p}_+, V)$ can be computed from Theorem 5.5 and the highest weight λ of V , the lowest form δ on \mathfrak{g} and the Hasse diagram $W^{\mathfrak{p}} \subseteq W$ of \mathfrak{p} , as

$$\bigoplus_{w \in W^{\mathfrak{p}}, \ell(w)=j} \mathcal{V}_{w(\lambda+\delta)-\delta},$$

where $\mathcal{V}_{w(\lambda+\delta)-\delta}$ are irreducible finite-dimensional \mathbb{G}_0 -representations with highest weight $w(\lambda + \delta) - \delta$.

Definition 5.11. Let V be a complex \mathbb{G} -representation. Form the graded Heisenberg order 0, differential operator

$$D_j^{\text{BGG}} := \tilde{P}_j L_j^{-1} \nabla_V L_j : C^\infty(\mathfrak{X}; \mathcal{H}_{j-1}(V)) \rightarrow C^\infty(\mathfrak{X}; \mathcal{H}_j(V)).$$

The BGG-complex of V is the \mathbb{G} -equivariant sequence of differential operators

$$\begin{aligned} \text{BGG}_\bullet(V) : \quad 0 \rightarrow C^\infty(\mathfrak{X}; \mathcal{H}_0(V)) &\xrightarrow{D_1^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_1(V)) \xrightarrow{D_2^{\text{BGG}}} \dots \\ &\xrightarrow{D_{d-1}^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_{d-1}(V)) \xrightarrow{D_d^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_d(V)) \rightarrow 0, \end{aligned}$$

where $d = \dim(\mathfrak{X})$.

From [16, Proposition 4.5] we conclude the following.

Proposition 5.12. *The sequence $\text{BGG}_\bullet(V)$ is a graded Rockland complex (cf. Definition 5.1) and its \mathbb{K} -equivariant index class $\text{ind}_{\mathbb{K}}[\text{BGG}_\bullet(V)] \in R(\mathbb{K})$ coincides with the index class of the de Rham complex*

$$\begin{aligned} 0 \rightarrow C^\infty(\mathfrak{X}; E_V) &\xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; T^* \mathfrak{X} \otimes E_V) \xrightarrow{\nabla_V} \dots \\ &\xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; \wedge^{d-1} T^* \mathfrak{X} \otimes E_V) \xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; \wedge^d T^* \mathfrak{X} \otimes E_V) \rightarrow 0. \end{aligned}$$

Proof. By construction, $\nabla_V = L_j(D_j^{\text{BGG}} \oplus \mathfrak{B}_j)L_{j-1}^{-1}$ and \mathfrak{B}_j fits into an acyclic complex by item (3) of Lemma 5.10. Since \mathbb{K} is compact, all structures can be assumed to be \mathbb{K} -equivariant so $\text{ind}_{\mathbb{K}}[\nabla_V] = \text{ind}_{\mathbb{K}}[\text{BGG}_\bullet(V)] + \text{ind}_{\mathbb{K}}[\mathfrak{B}_\bullet] = \text{ind}_{\mathbb{K}}[\text{BGG}_\bullet(V)]$. \square

Remark 5.13. Since the Euler characteristic of S^k vanishes for odd k , it is clear that for $\mathbb{G} = Sp(n, 1), SU(n, 1), SO(2n, 1)$ the associated BGG-complexes will have a \mathbb{K} -equivariant index of vanishing formal dimension. In particular, since $\text{Res}_{\mathbb{K}}^{\mathbb{G}} \gamma = 1$ the γ -element can in these cases not be represented by a BGG-complex. See [32, 33] for more creative approaches.

We can now turn to the case of the general parabolic geometries. The ideas of Lemma 5.10 and the discussion after it holds for general parabolic geometries, so for any \mathbb{G} -representation W and regular parabolic geometry (\mathfrak{X}, ω) of type (\mathbb{G}, \mathbb{P}) we can define a tractor bundle $E(W) := V \times_{\mathbb{P}} W \rightarrow \mathfrak{X}$ with induced connection ∇_W . Proceeding as above,

we arrive at a BGG-sequence $\text{BGG}_\bullet(\mathfrak{X}, W)$ which is the $\text{Aut}(\mathfrak{X}, \omega)$ -equivariant sequence of differential operators of the form

$$\begin{aligned} \text{BGG}_\bullet(\mathfrak{X}, W) : \quad 0 \rightarrow C^\infty(\mathfrak{X}; \mathcal{H}_0(W)) \xrightarrow{D_1^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_1(W)) \xrightarrow{D_2^{\text{BGG}}} \dots \\ \xrightarrow{D_{d-1}^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_{d-1}(W)) \xrightarrow{D_d^{\text{BGG}}} C^\infty(\mathfrak{X}; \mathcal{H}_d(W)) \rightarrow 0, \end{aligned}$$

where $d = \dim(\mathfrak{X})$ and $\mathcal{H}_j(W) = V \times_{\mathbb{P}} H^j(\mathfrak{p}_+, V)$. We again have that the complex $\text{BGG}_\bullet(\mathfrak{X}, V)$ is a graded Rockland sequence (cf. Definition 5.1). Moreover, for any compact subgroup $K \subseteq \text{Aut}(\mathfrak{X}, \omega)$ its K -equivariant index class $\text{ind}_K[\text{BGG}_\bullet(\mathfrak{X}, V)] \in R(K)$ coincides with the index class of the de Rham sequence

$$\begin{aligned} 0 \rightarrow C^\infty(\mathfrak{X}; E(W)) \xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; T^*\mathfrak{X} \otimes E(W)) \xrightarrow{\nabla_V} \dots \\ \xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; \wedge^{d-1} T^*\mathfrak{X} \otimes E(W)) \xrightarrow{\nabla_V} C^\infty(\mathfrak{X}; \wedge^d T^*\mathfrak{X} \otimes E(W)) \rightarrow 0. \end{aligned}$$

We sometimes write $\text{BGG}_\bullet(\mathfrak{X}, W) = \text{BGG}_\bullet(\nabla_E)$ when we want to emphasize the dependence on the tractor connection.

6. K -HOMOLOGY CLASSES AND GRADED ROCKLAND SEQUENCES

6.1. Constructing K -cycles from graded Rockland sequences.

Proposition 6.1. *Let $\mathbf{m} = (m_1, \dots, m_N) \in \mathbb{R}^N$. Consider a sequence*

$$D_\bullet : \quad 0 \rightarrow C^\infty(\mathfrak{X}; \mathbf{E}_0) \xrightarrow{D_1} C^\infty(\mathfrak{X}; \mathbf{E}_1) \xrightarrow{D_2} \dots \xrightarrow{D_N} C^\infty(\mathfrak{X}; \mathbf{E}_N) \rightarrow 0,$$

where $D_j \in \Psi_{H, \text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j)$. Then the following are equivalent

- (1) D_\bullet is a graded Rockland sequence.
- (2) There is a graded Rockland sequence of order $-\mathbf{m}$

$$B_\bullet : \quad 0 \leftarrow C^\infty(\mathfrak{X}; \mathbf{E}_0) \xleftarrow{B_1} C^\infty(\mathfrak{X}; \mathbf{E}_1) \xleftarrow{B_2} \dots \xleftarrow{B_N} C^\infty(\mathfrak{X}; \mathbf{E}_N) \leftarrow 0,$$

such that

$$B_j D_j + D_{j-1} B_{j-1} - 1 \in \Psi_{H, \text{gr}}^{-1}(\mathfrak{X}; \mathbf{E}_j).$$

- (3) There is a graded Rockland sequence of order $-\mathbf{m}$

$$B_\bullet : \quad 0 \leftarrow C^\infty(\mathfrak{X}; \mathbf{E}_0) \xleftarrow{B_1} C^\infty(\mathfrak{X}; \mathbf{E}_1) \xleftarrow{B_2} \dots \xleftarrow{B_N} C^\infty(\mathfrak{X}; \mathbf{E}_N) \leftarrow 0,$$

such that

$$B_j D_j + D_{j-1} B_{j-1} - 1 \in \Psi^{-\infty}(\mathfrak{X}; \mathbf{E}_j).$$

We call B_\bullet a Heisenberg splitting. We note that the principal symbol of a Heisenberg splitting is the same as a chain homotopy from the identity map to the zero map on the principal symbol complex.

Proof. It is clear that 3) implies 2), and by asymptotic completeness (and an argument as in [30, Chapter XVIII]) 2) implies 3). It is also clear that 2) implies 1). It remains to prove that a Rockland sequence admits a Heisenberg splitting.

To construct splitting operators $B_j \in \Psi_{H, \text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_{j+1}, \mathbf{E}_j)$ of a Rockland sequence D_\bullet , it suffices to construct its principal symbols $b_j := \sigma_H^{-m_j}(B_j) \in \Sigma_{H, \text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_{j-1})$ such that

$$b_j d_j + d_{j-1} b_{j-1} = 1.$$

Here we write $d_j := \sigma_H^{m_j}(D_j) \in \Sigma_{H, \text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_{j+1})$.

Since D_\bullet is a Rockland sequence, d_1 satisfies the Rockland condition and admits a left inverse $b_1 \in \Sigma_{H, \text{gr}}^{-m_1}(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_0)$ by Theorem 4.3. We form $e_1 := d_1 b_1$ which is a range projection for d_1 . To construct b_j , for $j > 1$, we proceed by induction. Assume that we constructed $b_k \in \Sigma_{H, \text{gr}}^{-m_k}(\mathfrak{X}; \mathbf{E}_k, \mathbf{E}_{k-1})$, $k = 1, \dots, j-1$, such that $b_k d_k + d_{k-1} b_{k-1} = 1$,

$b_{k-1}b_k = 0$ and that $d_k b_k$ is a range projection of d_k , for $k = 1, \dots, j-1$. Consider the symbol

$$\hat{d}_j := \begin{pmatrix} d_j \\ b_{j-1} \end{pmatrix} \in \Sigma_H^{m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j \oplus \mathbf{E}_{j-2}\langle m_j - m_{j-1} \rangle),$$

where we write $\mathbf{E}_{j-2}\langle m_j - m_{j-1} \rangle$ for \mathbf{E}_{j-2} with degree shifted by $m_j - m_{j-1}$. By the induction assumption, \hat{d}_j satisfies the Rockland condition and admits a left inverse $\hat{b}_j \in \Sigma_{H, \text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_j \oplus \mathbf{E}_{j-2}\langle m_j - m_{j-1} \rangle, \mathbf{E}_{j-1})$ by Theorem 4.3. We write

$$\hat{b}_j = (b_j, \tilde{b}_j).$$

Here $b_j \in \Sigma_{H, \text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_{j-1})$ and unravelling the degree shifts we see that

$$\tilde{b}_j \in \Sigma_{H, \text{gr}}^{m_{j-1}}(\mathfrak{X}; \mathbf{E}_{j-2}, \mathbf{E}_{j-1}).$$

Our defining property of \hat{b}_j is that

$$b_j d_j + \tilde{b}_j b_{j-1} = 1. \quad (6.1)$$

However, the property (6.1) is unaltered if we replace \tilde{b}_j with $\tilde{b}_j(1 - d_{j-2}b_{j-2})$. Since $1 - d_{j-2}b_{j-2}$ is idempotent by assumption, we therefore have imposed that

$$\tilde{b}_j = \tilde{b}_j(1 - d_{j-2}b_{j-2}) = \tilde{b}_j b_{j-1} d_{j-1},$$

where we use the induction assumption in the last equality. Multiplying the identity (6.1) with d_{j-1} from the right we see that $\tilde{b}_j = d_{j-1}$ and the induction step is complete. \square

Definition 6.2. Consider a graded Rockland sequence D_\bullet of order $\mathbf{m} = (m_1, \dots, m_N) \in \mathbb{R}^N$ on a collection of graded vector bundles $\mathbf{E}_j \rightarrow \mathfrak{X}$ with graded G -actions making the symbol complex $\sigma_H(D_\bullet)$ G -equivariant.

- If the splitting operators $B_\bullet \in \Psi_{H, \text{gr}}^{m_\bullet}(\mathfrak{X}; \mathbf{E}_\bullet, \mathbf{E}_{\bullet-1})$ from item 3) in Proposition 6.1 can be chosen so that $\sigma_H(B_\bullet)$ is G -equivariant, we say that B_\bullet is a G -equivariant Heisenberg splitting and we say that D_\bullet is G -equivariantly Heisenberg split.
- We say that D_\bullet has a G -equivariant Rockland splitting of order $\mathbf{s} \in \mathbb{R}^{N+1}$, solving $s_j - s_{j-1} = m_j$ for $j = 1, \dots, N$, if there are bounded operators

$$B_j : W_H^{s_j}(\mathfrak{X}; \mathbf{E}_j) \rightarrow W_H^{s_{j-1}}(\mathfrak{X}; \mathbf{E}_{j-1}),$$

commuting with the G -actions and $C^\infty(\mathfrak{X})$ up to compact operators, and

$$B_j D_j + D_{j-1} B_{j-1} - 1 \in \mathbb{K}(W^{s_j}(\mathfrak{X}; \mathbf{E}_j)).$$

A G -equivariant Heisenberg splitting is clearly a G -equivariant Rockland splitting. We note the following fact that follows from averaging over the group action.

Proposition 6.3. *Let G be a compact group. Consider a graded Rockland sequence D_\bullet on a collection of graded vector bundles $\mathbf{E}_j \rightarrow \mathfrak{X}$ with graded G -actions. If the symbol complex $\sigma_H(D_\bullet)$ is G -equivariant, then D_\bullet is G -equivariantly Heisenberg split. In fact, we can choose the splitting operators $B_\bullet \in \Psi_{H, \text{gr}}^{m_\bullet}(\mathfrak{X}; \mathbf{E}_\bullet, \mathbf{E}_{\bullet-1})$ from Proposition 6.1 to be G -equivariant.*

We are interested in making more precise the way a group acts on the Heisenberg-Sobolev spaces, so we shall make the topology of the latter more precise. Fix a volume density $d\mu$ on \mathfrak{X} . For a graded hermitean vector bundle $\mathbf{E} \rightarrow \mathfrak{X}$ with a graded hermitean connection $\nabla_{\mathbf{E}} = \oplus_k \nabla_{\mathbf{E}[k]}$, write $W_{H, \text{gr}}^s(\mathfrak{X}; \mathbf{E}) := \oplus_k W_H^{s-k}(\mathfrak{X}; \mathbf{E}[k])$ for $s \in \mathbb{R}$ where $W_H^{s-k}(\mathfrak{X}; \mathbf{E}[k])$ is equipped with a Hilbert space structure from the connection $\nabla_{\mathbf{E}[k]}$, and duality and interpolation.

Proposition 6.4. *Assume that ℓ_0, ℓ_1, ℓ_2 are length functions on G such that*

$$(1) \quad \frac{dg_* \mu}{d\mu} \leq e^{2\ell_0(g)} \text{ for any } g \in G;$$

(2) For any $x \in \mathfrak{X}$ and $j = 0, \dots, N$, and $g \in G$

$$\|g : \mathbf{E}_{j,x} \rightarrow \mathbf{E}_{j,gx}\| \leq e^{\ell_1(g)}.$$

(3) For any $j = 0, \dots, N$, $f \in C^\infty(\mathfrak{X}; \mathbf{E}_j)$ and $g \in G$

$$\int_{\mathfrak{X}} \|\nabla_{\mathbf{E}_j}(g^* f)\|_{T\mathfrak{X} \otimes \mathbf{E}_j}^2 d\mu \leq e^{2\ell_2(g)} \left(\int_{\mathfrak{X}} \|g^*(\nabla_{\mathbf{E}_j} f)\|_{T\mathfrak{X} \otimes \mathbf{E}_j}^2 d\mu + \int_{\mathfrak{X}} \|f\|_{\mathbf{E}_j}^2 d\mu \right).$$

Then there is a $C > 0$ such that the length function defined by

$$\ell = \ell_0 + \ell_1 + |\mathbf{s}|_{L^\infty} \ell_2 + C.$$

satisfies that for $g \in G$ acting on $W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)$, we have that

$$\|g\|_{W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)} \leq e^{\ell(g)}.$$

There exists length functions ℓ_0, ℓ_1, ℓ_2 on G satisfying the conditions of Proposition 6.4, as one can reverse engineer the conditions into definitions. For instance, we can define $\ell_0(g) := \frac{1}{2} \left\| \log \left(\frac{dg_* \mu}{d\mu} \right) \right\|_{L^\infty}$.

Proof. The proof is by a long computation for \mathbf{s} integer; commuting the group action through connections and changes of variables. The case of a general \mathbf{s} follows from interpolation. \square

Write \mathbf{E}_j^{tr} for \mathbf{E}_j equipped with the trivial grading. We fix order reducing operators $\Lambda_{j,s} \in \Psi_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_j^{\text{tr}})$, i.e. $\Lambda_{j,s}$ is invertible and H -elliptic. From the order reducing operators we define an invertible operator

$$U : L^2(\mathfrak{X}; \mathbf{E}_\bullet^{\text{tr}}) \rightarrow W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet), \quad (6.2)$$

that we can assume to be unitary.

Proposition 6.5. *Consider the C^* -algebra*

$$A := C(\mathfrak{X}) + \mathbb{K}(L^2(\mathfrak{X}; \mathbf{E}_\bullet^{\text{tr}})) \subseteq \mathbb{B}(L^2(\mathfrak{X}; \mathbf{E}_\bullet^{\text{tr}})).$$

The unitary isomorphism (6.2) induces a faithful representation

$$\pi : A \rightarrow \mathbb{B}(W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)), \quad a \mapsto UaU^*,$$

satisfies that

$$\pi(a) - a \in \mathbb{K}(W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)), \quad a \in A.$$

The action of G on $W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)$ satisfies that

$$g^{-1}\pi(a)g - \pi(g^* a) \in \mathbb{K}(W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet)), \quad a \in C(\mathfrak{X}),$$

and the inclusion of the compact operators defines a G -equivariant split short exact sequence

$$0 \rightarrow \mathbb{K}(L^2(\mathfrak{X}; \mathbf{E}_\bullet)) \rightarrow A \rightarrow C(\mathfrak{X}) \rightarrow 0.$$

Proof. The first statement is clear from construction and the fact that the calculus commute up to lower order terms with smooth functions. The second statement follows from the first. \square

Theorem 6.6. *Let D_\bullet be a G -equivariant graded Rockland sequence of order $\mathbf{m} = (m_1, \dots, m_N)$ on $\mathbf{E}_\bullet = (\mathbf{E}_0, \dots, \mathbf{E}_N)$. Assume that the G -action on \mathbf{E} is by conformal unitaries. Take $\mathbf{s} = (s_0, \dots, s_N) \in \mathbb{R}^{N+1}$ such that*

$$s_{j-1} - s_j = m_j, \quad j = 1, \dots, N.$$

Assume that we have a G -equivariant Rockland splitting B_\bullet of order \mathbf{s} . If we set

$$F_0 := D_\bullet + B_\bullet : W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet) \rightarrow W_{H,\text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_\bullet),$$

and $F := F_0|F_0|^{-1}$, then the collection

$$(\pi, W_{H, \text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_{\bullet}), F),$$

forms a Fredholm module for $C(\mathfrak{X})$ with $g(F) - F \in \mathbb{K}(W_{H, \text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_{\bullet}))$ for any $g \in G$.

Proof. By assumption, $F_0^2 - 1$ is compact and F_0 almost commutes with A and the G -action. Since the G -action on \mathbf{E} is by conformal unitaries, the contragradient representation $\pi^*(g) := \pi(g^{-1})^*$ takes the form $\pi^*(g) = a_g \pi(g)$ for an A -valued G -cocycle $g \mapsto a_g$. Therefore, F_0 also almost commutes with the contragradient representation. We conclude that both F_0 and F_0^* almost commutes with A and the G -action, so F almost commutes with A and the G -action. \square

Proposition 6.7. *Let D_{\bullet} be a G -equivariant graded Rockland sequence. The Fredholm module $(\pi, W_{H, \text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_{\bullet}), F)$ from Theorem 6.6 is up to operator homotopy independent of the choice of B_{\bullet} and \mathbf{s} . In fact, as soon as D'_{\bullet} is another G -equivariant graded Rockland sequence with $\sigma_H(D_{\bullet}) = \sigma_H(D'_{\bullet})$ then the associated Fredholm modules are operator homotopic.*

Proof. For fixed D_{\bullet} , the class for two different B_{\bullet} and B'_{\bullet} coincides as seen from the operator homotopy defined from $B_{\bullet, t} = tB_{\bullet} + (1-t)B'_{\bullet}$. The statement that the class only depends on the symbol $\sigma_H(D_{\bullet})$ follows by considering the operator homotopy defined from $D_{\bullet, t} = tD_{\bullet} + (1-t)D'_{\bullet}$. \square

Definition 6.8. When G is compact, we arrive at a class in $KK_0^G(C(\mathfrak{X}), \mathbb{C})$ of the cycle $(\pi, W_{H, \text{gr}}^{\mathbf{s}}(\mathfrak{X}; \mathbf{E}_{\bullet}), F)$ constructed in Theorem 6.6. We denote it by $[D_{\bullet}] \in K_0^G(\mathfrak{X})$.

The class $[D_{\bullet}]$ was previously defined, using somewhat different yet equivalent methods, in [24, Section 27].

6.2. On existence of equivariant splittings for G/P . In the previous subsection we saw that if there are equivariant Rockland splittings we can define Fredholm modules with good equivariance properties. We also saw that for a compact group there is a constructive method of finding equivariant Heisenberg splittings, or in other words equivariant Rockland splittings in the Heisenberg calculus. We now study the existence question of equivariant Heisenberg splittings for BGG-sequences on the flat parabolic geometry $\mathfrak{X} = G/P$.

Theorem 6.9. *Let G be a connected semisimple Lie group, P a parabolic subgroup of G and V a finite-dimensional G -representation. If G/P has rank > 1 then the G -equivariant Rockland sequence $\text{BGG}_{\bullet}(V)$ on G/P does not admit a G -equivariant Heisenberg splitting.*

Proof. If B_{\bullet} is a G -equivariant Heisenberg splitting then Corollary 4.6 shows that B_{\bullet} in the leading term is a differential operator. This is clearly a contradiction, as for instance D_1 is a differential operator of positive order. \square

Theorem 6.10. *Let G be a connected semisimple Lie group, P a parabolic subgroup of G and V a finite-dimensional G -representation. If G has rank 1 then the G -equivariant Rockland sequence $\text{BGG}_{\bullet}(V)$ on G/P admits a G -equivariant Heisenberg splitting.*

Proof. It suffices to find G -equivariant $b_{\bullet} \in \Sigma_{H, \text{gr}}^{-m_{\bullet}}(G/P; \mathcal{H}_{\bullet}(V), \mathcal{H}_{\bullet-1}(V))$ such that for any j

$$b_j d_j + d_{j-1} b_{j-1} = 1.$$

However, Corollary 4.6 shows that

$$\Sigma_H^m(G/P; \mathcal{H}_{\bullet}(V), \mathcal{H}_{\bullet-1}(V))^G \cong (\Sigma_H^m \bar{N}_P \otimes \text{Hom}_{A_P}(H^{\bullet}(\mathfrak{p}_+, V)^{(m)}, H^{\bullet-1}(\mathfrak{p}_+, V)))^{M_P},$$

this isomorphism is implemented by evaluating in $eP \in G/P$. Since G is rank one, $M_P = P \cap K$ is compact. For degree reasons, we have a Heisenberg splitting whose value in eP belongs to $\Sigma_H^m \bar{N}_P \otimes \text{Hom}_{A_P}(H^{\bullet}(\mathfrak{p}_+, V)^{(m)}, H^{\bullet-1}(\mathfrak{p}_+, V))$ that we by averaging can assume is M_P -invariant. Therefore there is a G -equivariant Heisenberg splitting. \square

Remark 6.11. The reader can note that non-existence of equivariant Heisenberg splittings is proved using that \mathbf{A}_P has rank > 1 , which is a property of G/P . However, existence of equivariant Heisenberg splittings is proved requiring not only that \mathbf{A}_P has rank $= 1$ but that M_P is compact so that P must be minimal, and as such we are imposing a rank condition on G .

7. THE INDEX PROBLEM FOR CURVED BGG-SEQUENCES

We are now going to study the K -theoretical invariants associated with a graded Rockland sequence. To do so, we set up the relevant equivariant Hilbert C^* -modules, after which we relate the K -theoretical invariants back to the K -homological invariants and prove Theorem 3. *Throughout this section, we consider a compact group G and a compact G -Carnot manifold \mathfrak{X} .*

7.1. An intermezzo on Hilbert C^* -modules and K -theory. First, we need some equivariant Hilbert C^* -modules fitting together with the symbol complex. Consider a G -equivariant graded Rockland sequence D_\bullet acting on the collection of graded hermitean vector bundles $\mathbf{E}_0, \mathbf{E}_1, \dots, \mathbf{E}_N$ with unitary G -actions. We define the spaces

$$\mathcal{E}_{j,c}^\infty := C_c^\infty(\mathbb{T}_H \mathfrak{X}; r^* \mathbf{E}_j).$$

The space $\mathcal{E}_{j,c}^\infty$ has a right $C_c^\infty(\mathbb{T}_H \mathfrak{X})$ -action with a compatible G -action that we denote by $\pi_{\mathbf{E}_j}$. The inner product on each bundle, induces an inner product

$$\mathcal{E}_{j,c}^\infty \times \mathcal{E}_{j,c}^\infty \rightarrow C_c^\infty(\mathbb{T}_H \mathfrak{X}).$$

Proposition 7.1. *The completion \mathcal{E}_j of $\mathcal{E}_{j,c}^\infty$ in the inner product to a $C^*(\mathbb{T}_H \mathfrak{X})$ -Hilbert C^* -module is well defined. Moreover, the action of G extends to a unitary continuous action of G that we also denote by $\pi_{\mathbf{E}_j}$.*

Write \mathbf{E}_j^{tr} for \mathbf{E}_j equipped with the trivial grading. We fix G -invariant order reducing operators $\mathbf{\Lambda}_{j,s} \in \Psi_{H,\text{gr}}^s(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_j^{\text{tr}})$, i.e. $\mathbf{\Lambda}_{j,s}$ is invertible and $\mathbf{\Lambda}_{j,s} = \text{ev}_{t=1} \mathbf{\Lambda}_{j,s}$ is H -elliptic. We define the right $C^*(\mathbb{T}_H \mathfrak{X})$ -Hilbert C^* -module

$$\mathcal{E}_j^s := \mathbf{\Lambda}_{j,s}^{-1} \mathcal{E}_j.$$

We equip \mathcal{E}_j^s with the G -action defined from the G -action on $\mathcal{E}_{j,c}^\infty$ and density of $\mathcal{E}_{j,c}^\infty \subseteq \mathcal{E}_j^s$. For $t > 0$, using the isomorphism $C^*(\mathbb{T}_H \mathfrak{X}|_{\{t\} \times \mathfrak{X}}) \cong \mathbb{K}(L^2(\mathfrak{X}))$, we have that

$$\mathcal{E}_j^s \otimes_{\text{ev}_t} \mathbb{K}(L^2(\mathfrak{X})) \cong \mathbb{K}(W_{H,\text{gr}}^{-s}(\mathfrak{X}; \mathbf{E}_j), L^2(\mathfrak{X})),$$

and $\mathcal{E}_j^s \otimes_{\text{ev}_{t=0}} C^*(\mathbb{T}_H \mathfrak{X})$ is a completion of $C_c^\infty(\mathbb{T}_H \mathfrak{X}; r^* \mathbf{E}_j)$ for a suitable Sobolev inner product. For more details, see [24, Section 22].

We also need some further notions in K -theory. These ideas can be found in the non-equivariant setting in [24, Section 27], see also [29].

Definition 7.2. Consider a $G - C^*$ -algebra B and two sequences of G -equivariant B -Hilbert C^* -modules

$$\begin{aligned} 0 \rightarrow \mathcal{E}_1 \xrightarrow{d_1} \mathcal{E}_2 \xrightarrow{d_2} \dots \rightarrow \mathcal{E}_N \xrightarrow{d_N} \mathcal{E}_{N+1} \rightarrow 0, \\ 0 \leftarrow \mathcal{E}_1 \xleftarrow{b_1} \mathcal{E}_2 \xleftarrow{b_2} \dots \leftarrow \mathcal{E}_N \xleftarrow{b_N} \mathcal{E}_{N+1} \leftarrow 0, \end{aligned}$$

where all maps are adjointable. The data $(\mathcal{E}_\bullet, d_\bullet, b_\bullet)$ is said to form a G -equivariant B -Fredholm sequence of length $N + 1$ if

$$\begin{cases} b_j d_j + d_{j-1} b_{j-1} - 1 \in \mathbb{K}_B(\mathcal{E}_j), \\ \pi(g) d_j \pi(g)^{-1} - d_j \in \mathbb{K}_B(\mathcal{E}_{j-1}, \mathcal{E}_j), \\ \pi(g) b_j \pi(g)^{-1} - b_j \in \mathbb{K}_B(\mathcal{E}_j, \mathcal{E}_{j-1}), \end{cases}$$

for all j and $g \in G$. We use the convention that $b_j = 0$ and $d_j = 0$ for $j \notin \{1, \dots, N+1\}$. To simplify notations, we sometimes write

$$0 \rightarrow \mathcal{E}_{1d_1} \xleftarrow{b_1} \mathcal{E}_{2d_2} \xleftarrow{b_2} \dots \xleftarrow{b_N} \mathcal{E}_{Nd_N} \xleftarrow{b_N} \mathcal{E}_{N+1} \rightarrow 0,$$

instead of $(\mathcal{E}_\bullet, d_\bullet, b_\bullet)$.

An acyclic B -Fredholm sequence is one where

$$\begin{cases} b_j d_j + d_{j-1} b_{j-1} = 1, \\ \pi(g) d_j \pi(g)^{-1} = d_j, \\ \pi(g) b_j \pi(g)^{-1} = b_j, \end{cases}$$

for all j and $g \in G$.

As in [24, Section 27], we can define isomorphism and homotopies of G -equivariant B -Fredholm sequences. We make the following definition.

Definition 7.3. For a $G - C^*$ -algebra B , let $\tilde{K}_0^G(B)$ denote the set of equivalence classes of G -equivariant B -Fredholm sequence under the equivalence relation generated by homotopy and declaring acyclic G -equivariant B -Fredholm sequences equivalent to the zero complex.

With the same ideas as in [24, Section 27], we have the following result.

Theorem 7.4. For a $G - C^*$ -algebra B , there is a natural isomorphism

$$KK_0^G(\mathbb{C}, B) \xrightarrow{\sim} \tilde{K}_0^G(B),$$

defined on cycles by

$$\left[\left(\begin{array}{c} \mathcal{E}_+ \\ \oplus \\ \mathcal{E}_- \end{array}, \begin{pmatrix} 0 & F_+ \\ F_- & 0 \end{pmatrix} \right) \right] \mapsto [(0 \rightarrow \mathcal{E}_{-F_+} \xleftarrow{F_-} \mathcal{E}_+ \rightarrow 0)].$$

7.2. The index class in K -theory. The index class of a G -equivariant graded Rockland sequence will be defined in terms of G -equivariant B -Fredholm sequences. Write

$$\mathcal{E}_{j,t=0}^s := \mathcal{E}_j^s \otimes_{\text{ev}_{t=0}} C^*(T_H \mathfrak{X}).$$

Recall the notation $\Psi_H^m(\mathfrak{X}; E_1, E_2)$ from Definition 4.1, with its obvious graded generalization denoted by $\Psi_{H,\text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2)$.

Lemma 7.5. Consider a G -equivariant graded Rockland sequence

$$D_\bullet : 0 \rightarrow C^\infty(\mathfrak{X}; \mathbf{E}_0) \xrightarrow{D_1} C^\infty(\mathfrak{X}; \mathbf{E}_1) \xrightarrow{D_2} \dots \xrightarrow{D_N} C^\infty(\mathfrak{X}; \mathbf{E}_N) \rightarrow 0,$$

of order $\mathbf{m} = (m_1, \dots, m_N)$ and take $\mathbf{s} = (s_0, \dots, s_N) \in \mathbb{R}^{N+1}$ such that

$$s_{j-1} - s_j = m_j, \quad j = 1, \dots, N.$$

Choose a G -equivariant Heisenberg splitting $B_\bullet \in \Psi_{H,\text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_{j-1})$ as well as lifts $D_\bullet \in \Psi_{H,\text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j)$ of D_\bullet and $B_\bullet \in \Psi_{H,\text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j)$ of B_\bullet . Then the sequence

$$D_\bullet : 0 \rightarrow \mathcal{E}_0^{s_0} D_N \xleftarrow{B_1} \mathcal{E}_1^{s_1} D_2 \xleftarrow{B_2} \dots D_N \xleftarrow{B_N} \mathcal{E}_N^{s_N} \rightarrow 0,$$

is a G -equivariant $C^*(\mathbb{T}_H \mathfrak{X}|_{[0,1] \times \mathfrak{X}})$ -Fredholm complex that we denote by D_\bullet . Up to homotopy, the Fredholm complex D_\bullet depends only on the graded principal symbol $\sigma_{H,\text{gr}}(D_\bullet)$ and is independent of the choice of \mathbf{s} , D_\bullet and B_\bullet .

Proof. By assumption $D_{j-1} B_{j-1} + B_j D_j - 1$ is smoothing. Therefore the homogeneity modulo C_c^∞ implies that $D_{j-1} B_{j-1} + B_j D_j - 1$ acts on \mathcal{E}_j as an element from $C_c^\infty(\mathbb{T}_H \mathfrak{X}|_{[0,1] \times \mathfrak{X}}; r^* \mathbf{E}_j \otimes s^* \mathbf{E}_j \otimes |\Lambda_r|)$. The latter space acts by compact operators on \mathcal{E}_j – it is even dense in the space of compact operators. The lemma follows. \square

Remark 7.6. The reader can recall the notation $\tilde{\Sigma}_H^m(\mathfrak{X}; E_1, E_2)$ from Theorem 4.2. We also write $\tilde{\Sigma}_{H,\text{gr}}^m(\mathfrak{X}; \mathbf{E}_1, \mathbf{E}_2)$ for its analogously defined graded version. In the setting of Lemma 7.5, the choice of \mathbf{D}_\bullet fixes lifts

$$\tilde{d}_j := \text{ev}_{t=0} \mathbf{D}_j \in \tilde{\Sigma}_{H,\text{gr}}^{m_j}(\mathfrak{X}; \mathbf{E}_{j-1}, \mathbf{E}_j),$$

of the symbols $d_\bullet = \sigma_{H,\text{gr}}(\mathbf{D}_\bullet)$, and the choice of \mathbf{B}_\bullet fixes lifts

$$\tilde{b}_j := \text{ev}_{t=0} \mathbf{B}_j \in \tilde{\Sigma}_{H,\text{gr}}^{-m_j}(\mathfrak{X}; \mathbf{E}_j, \mathbf{E}_{j-1}),$$

of the symbols $b_\bullet = \sigma_{H,\text{gr}}(\mathbf{B}_\bullet)$. Lemma 7.5 implies that the sequence

$$0 \rightarrow \mathcal{E}_{j,t=0\tilde{d}_1}^{s_0} \xleftrightarrow{\tilde{b}_1} \mathcal{E}_{j,t=0\tilde{d}_2}^{s_1} \xleftrightarrow{\tilde{b}_2} \cdots \xleftrightarrow{\tilde{b}_N} \mathcal{E}_{j,t=0}^{s_N} \rightarrow 0,$$

is a G -equivariant $C^*(T_H\mathfrak{X})$ -Fredholm complex that we denote by $\sigma_{H,\text{gr}}(\mathbf{D}_\bullet)$.

Definition 7.7. We write $[\sigma_H(\mathbf{D}_\bullet)] \in K_0^G(C^*(T_H\mathfrak{X}))$ for the class of the $C^*(T_H\mathfrak{X})$ -Fredholm complex $\sigma_{H,\text{gr}}(\mathbf{D}_\bullet)$ for some \mathbf{s} .

From Remark 7.6, we conclude that

$$\sigma_{H,\text{gr}}(\mathbf{D}_\bullet) = \mathbf{D}_\bullet \otimes \text{ev}_{t=0} C^*(T_H\mathfrak{X}).$$

The last identity leads us to the next lemma.

Proposition 7.8. *The class $[\mathbf{D}_\bullet] \in \tilde{K}_0^G(C^*(\mathbb{T}_H\mathfrak{X}|_{[0,1] \times \mathfrak{X}}))$ satisfies*

$$\tilde{K}_0(\text{ev}_{t=0})[\mathbf{D}_\bullet] = [\sigma_{H,\text{gr}}(\mathbf{D}_\bullet)],$$

and therefore $[\mathbf{D}_\bullet]$ lifts the class $[\sigma_{H,\text{gr}}(\mathbf{D}_\bullet)] \in \tilde{K}_0^G(C^*(T_H\mathfrak{X}))$ under the natural map

$$\tilde{K}_0(\text{ev}_{t=0}) : \tilde{K}_0^G(C^*(\mathbb{T}_H\mathfrak{X}|_{[0,1] \times \mathfrak{X}})) \rightarrow \tilde{K}_0^G(C^*(T_H\mathfrak{X})).$$

7.3. Poincaré duality map. To relate the symbol classes back to operators, we make use of an analytic Poincaré duality. This duality was first introduced for contact manifolds in [7] and utilized on Carnot manifolds in [24, 38]. Let $\partial_H \in KK^G(C^*(T_H\mathfrak{X}), \mathbb{C})$ denote the class of the boundary map associated with

$$0 \rightarrow S\mathbb{K} \rightarrow C^*(\mathbb{T}_H\mathfrak{X}|_{[0,1]}) \xrightarrow{\text{ev}_{t=0}} C^*(T_H\mathfrak{X}) \rightarrow 0,$$

that uses the identification $S\mathbb{K} \rightarrow C^*(\mathbb{T}_H\mathfrak{X}|_{(0,1)}) = C^*(\mathfrak{X} \times \mathfrak{X} \times (0, 1) \rightrightarrows \mathfrak{X} \times (0, 1))$.

Definition 7.9. The analytic Poncaré duality map

$$\text{PD}_H^{\text{an}} : K_0^G(C^*(T_H\mathfrak{X})) \rightarrow K_0^G(\mathfrak{X}),$$

is defined as the composition

$$\begin{aligned} K_0^G(C^*(T_H\mathfrak{X})) &= KK_0^G(\mathbb{C}, C^*(T_H\mathfrak{X})) \xrightarrow{\alpha_{\mathfrak{X}}} KK_0^G(C(\mathfrak{X}), C^*(T_H\mathfrak{X})) \\ &\xrightarrow{\partial_H} KK_0^G(C(\mathfrak{X}), \mathbb{C}) = K_0^G(\mathfrak{X}). \end{aligned}$$

Here $\alpha_{\mathfrak{X}}$ denotes inflation by $C(\mathfrak{X})$ using that $C(\mathfrak{X})$ acts as central multipliers of $C^*(T_H\mathfrak{X})$. For the trivial Carnot structure, we use the notation

$$\text{PD}^{\text{an}} : K_0^G(C^*(T\mathfrak{X})) = K_G^0(T^*\mathfrak{X}) \rightarrow K_0^G(\mathfrak{X}),$$

Proposition 7.10. *Let \mathfrak{X} be a compact G -Carnot manifold and \mathbf{D}_\bullet a G -equivariant graded Rockland sequence on \mathfrak{X} . Then it holds that*

$$\text{PD}_H^{\text{an}}[\sigma_H(\mathbf{D}_\bullet)] = [\mathbf{D}_\bullet] \in K_0^G(\mathfrak{X}).$$

The proposition follows from Proposition 7.8 and the observation that the boundary map ∂_H has as its defining property that $\tilde{K}_0(\text{ev}_{t=0}) \otimes_{C^*(T_H\mathfrak{X})} \partial_H = \tilde{K}_0(\text{ev}_{t=1})$.

To relate the index theory in the Heisenberg calculus to ordinary K -theory, we use Nistor's Connes-Thom isomorphism [40]. We define the adiabatic groupoid

$$A_H\mathfrak{X} := TX \times \{0\} \dot{\bigcup} T_H\mathfrak{X} \times (0, \infty) \rightrightarrows \mathfrak{X} \times [0, \infty),$$

with smooth structure defined from declaring the map

$$T\mathfrak{X} \times [0, \infty) \rightarrow A_H\mathfrak{X}, \quad (x, v, t) \mapsto \begin{cases} (x, v, 0), & t = 0, \\ (x, \delta_t(\exp(v)), t), & t > 0, \end{cases}$$

to be a diffeomorphism. Here we are implicitly using a choice of isomorphism $T\mathfrak{X} \cong \mathfrak{t}_H\mathfrak{X}$. We can define $\psi \in KK_0^G(C_0(T^*\mathfrak{X}), C^*(T_H\mathfrak{X}))$ from the isomorphisms $C_0(T^*\mathfrak{X}) \cong C^*(T\mathfrak{X})$, $SC^*(T_H\mathfrak{X}) \cong C^*(A_H\mathfrak{X}|_{(0, \infty)})$ and the short exact sequence

$$0 \rightarrow SC^*(T_H\mathfrak{X}) \rightarrow C^*(A_H\mathfrak{X}) \xrightarrow{\text{ev}_{t=0}} C_0(T^*\mathfrak{X}) \rightarrow 0.$$

The latter defines an extension class in $KK_1^G(C_0(T^*\mathfrak{X}), SC^*(T_H\mathfrak{X}))$. The next theorem can be found in [7, 24, 38]. In these references, the result is stated for the trivial group but extends readily to compact group actions.

Theorem 7.11. *Let \mathfrak{X} be a compact G -Carnot manifold. Then the following diagram commutes*

$$\begin{array}{ccc} & K_*^G(C^*(T_H\mathfrak{X})) & \\ \psi \nearrow & & \searrow \text{PD}_H^{\text{an}} \\ K_G^*(T^*\mathfrak{X}) & \xrightarrow{\text{PD}^{\text{an}}} & K_*^G(\mathfrak{X}) \end{array}$$

7.4. The index class and BGG-compression. Above in Subsection 6 we saw how equivariant Rockland sequences gave rise to elements of K -homology and in Subsection 5.2 how filtered connections can be compressed into a curved BGG-sequence. We shall see that the K -homology class is not altered by BGG-compression. As explained in [16], the procedure of compressing to a BGG-sequence requires only the existence of a Kostant differential on the Lie algebroid $\mathfrak{t}_H\mathfrak{X}$, but for simplicity we restrict to parabolic geometries with an action of a compact group G . We summarize the context of this subsection into an assumption that will stand for the remainder of the subsection.

Assumption 1. We let \mathfrak{X} denote a compact parabolic geometry \mathfrak{X} with an action of a compact group $G \rightarrow \text{Aut}(\mathfrak{X}, \omega)$, and $\mathbf{E} \rightarrow \mathfrak{X}$ a graded G -equivariant tractor bundle equipped with a G -invariant filtered connection $\nabla_{\mathbf{E}}$ of degree 0 with curvature in degree 1. If \mathfrak{X} is a complex parabolic geometry, we also assume that $\nabla_{\mathbf{E}}$ is a filtered complex connection.

An example satisfying Assumption 1 is the flat parabolic geometry $\mathfrak{X} = \mathbf{G}/\mathbf{P}$ and $G \subseteq \mathbf{G}$ a compact subgroup, and $\mathbf{E} \rightarrow \mathfrak{X}$ a homogeneous bundle graded by the weights of its generic fibres.

It follows from Assumption 1 that the classical symbol complex

$$\begin{aligned} \sigma(\nabla_{\mathbf{E}, \bullet}) : \quad 0 \rightarrow \mathcal{S}(T^*\mathfrak{X}; \mathbf{E}) &\xrightarrow{\sigma(\nabla_{\mathbf{E}})} \mathcal{S}(T^*\mathfrak{X}; T^*\mathfrak{X} \otimes \mathbf{E}) \xrightarrow{\sigma(\nabla_{\mathbf{E}})} \dots \\ &\dots \xrightarrow{\sigma(\nabla_{\mathbf{E}})} \mathcal{S}(T^*\mathfrak{X}; \wedge^n T^*\mathfrak{X} \otimes \mathbf{E}) \rightarrow 0, \end{aligned}$$

defines a G -equivariant elliptic complex on $T^*\mathfrak{X}$ and defines a class

$$[\sigma(\nabla_{\mathbf{E}})] \in K_G^0(T^*\mathfrak{X}).$$

Moreover, if \mathfrak{X} is a complex G -Carnot manifold and $\nabla_{\mathbf{E}}$ is a filtered complex connection of degree 0, the classical symbol complex of the associated $\bar{\partial}$ -sequence

$$\begin{aligned} \sigma(\bar{\partial}_{\mathbf{E}, \bullet}) : \quad 0 \rightarrow \mathcal{S}(T^*\mathfrak{X}; \mathbf{E}) &\xrightarrow{\sigma(\bar{\partial}_{\mathbf{E}})} \mathcal{S}(T^*\mathfrak{X}; \wedge^{0,1} T^*\mathfrak{X} \otimes \mathbf{E}) \xrightarrow{\sigma(\bar{\partial}_{\mathbf{E}})} \dots \\ &\dots \xrightarrow{\sigma(\bar{\partial}_{\mathbf{E}})} \mathcal{S}(T^*\mathfrak{X}; \wedge^{0,n} T^*\mathfrak{X} \otimes \mathbf{E}) \rightarrow 0, \end{aligned}$$

defines a G -equivariant elliptic complex on $T^*\mathfrak{X}$ and defines a class that we denote by

$$[\sigma(\bar{\partial}_{\mathbf{E},\bullet})] \in K_G^0(T^*\mathfrak{X}).$$

In both the real and complex case, the symbol does not depend on the choice of connection $\nabla_{\mathbf{E}}$ so neither does the cycles $\sigma(\nabla_{\mathbf{E},\bullet})$ or $\sigma(\bar{\partial}_{\mathbf{E},\bullet})$ nor the associated classes in $K_G^0(T^*\mathfrak{X})$.

We can also form the graded Heisenberg symbol complex

$$\begin{aligned} \sigma_{H,\text{gr}}(\nabla_{\mathbf{E},\bullet}) : \quad 0 \rightarrow \mathcal{S}(T_H\mathfrak{X}; \mathbf{E}) \xrightarrow{\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})} \mathcal{S}(T_H\mathfrak{X}; T^*\mathfrak{X} \otimes \mathbf{E}) \xrightarrow{\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})} \dots \\ \dots \xrightarrow{\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})} \mathcal{S}(T_H\mathfrak{X}; \wedge^n T^*\mathfrak{X} \otimes \mathbf{E}) \rightarrow 0, \end{aligned}$$

completes to a G -equivariant Fredholm complex over $C^*(T_H\mathfrak{X})$ and defines a class

$$[\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})] \in K_0^G(C^*(T_H\mathfrak{X})).$$

Moreover, if \mathfrak{X} is a complex G -Carnot manifold and $\nabla_{\mathbf{E}}$ is a filtered complex connection of degree 0, the classical symbol complex of the associated $\bar{\partial}$ -sequence

$$\begin{aligned} \sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E},\bullet}) : \quad 0 \rightarrow \mathcal{S}(T_H\mathfrak{X}; \mathbf{E}) \xrightarrow{\sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E}})} \mathcal{S}(T_H\mathfrak{X}; \wedge^{0,1} T^*\mathfrak{X} \otimes \mathbf{E}) \xrightarrow{\sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E}})} \dots \\ \dots \xrightarrow{\sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E}})} \mathcal{S}(T_H\mathfrak{X}; \wedge^{0,n} T^*\mathfrak{X} \otimes \mathbf{E}) \rightarrow 0, \end{aligned}$$

completes to a G -equivariant Fredholm complex over $C^*(T_H\mathfrak{X})$ and defines a class

$$[\sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E},\bullet})] \in K_0^G(C^*(T_H\mathfrak{X})).$$

In both the real and complex case, the graded Heisenberg symbol does not depend on the choice of connection $\nabla_{\mathbf{E}}$ so neither does the cycles $\sigma_{H,\text{gr}}(\nabla_{\mathbf{E},\bullet})$ or $\sigma_{H,\text{gr}}(\bar{\partial}_{\mathbf{E},\bullet})$ nor the associated classes in $K_G^0(T^*\mathfrak{X})$.

Lemma 7.12. *Under Assumption 1, we have the equality*

$$[\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})] = [\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}}))] \in K_0^G(C^*(T_H\mathfrak{X})).$$

Proof. By the definition of the BGG-sequence (see Definition 5.11) we can split the symbol complex $\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})$ as

$$\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}}) = \sigma_{H,\text{gr}}(L_{\bullet})(\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}})) \oplus \mathfrak{b}_{\bullet})\sigma_{H,\text{gr}}(L_{\bullet}^{-1})$$

for the operators L_{\bullet} from (5.4) and a symbol complex \mathfrak{b}_{\bullet} which lifts to a nullhomotopic complex over $\tilde{\Sigma}_H^*$ by item (3) of Lemma 5.10. We conclude that the class of \mathfrak{b}_{\bullet} in $\tilde{K}_0^G(C^*(T_H\mathfrak{X}))$ vanishes and the lemma follows. \square

The next result is the main technical result of this section and key in computing the K -homology class of curved BGG-sequences.

Lemma 7.13. *Under Assumption 1 we have the equality*

$$[\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}}))] = \psi[\sigma(\nabla_{\mathbf{E}})] \in K_0^G(C^*(T_H\mathfrak{X})),$$

and in the complex case

$$[\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}}))] = \psi[\sigma(\bar{\partial}_{\mathbf{E}})] \in K_0^G(C^*(T_H\mathfrak{X})),$$

Proof. We give the proof in the real case, the complex case goes analogously. We note that we can extend $\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})$ by homogeneity to a complex defined from $\mathcal{S}(A_H\mathfrak{X}, \wedge^{\bullet} T^*\mathfrak{X} \otimes \mathbf{E})$ with differentials being unbounded multipliers $\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})$ with $\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})|_{t=0} = \sigma(\nabla_{\mathbf{E}})$. Arguing as above, we form the adiabatic graded Heisenberg symbol complex

$$\begin{aligned} \sigma_{A,\text{gr}}(\nabla_{\mathbf{E},\bullet}) : \quad 0 \rightarrow \mathcal{S}(A_H\mathfrak{X}; \mathbf{E}) \xrightarrow{\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})} \mathcal{S}(A_H\mathfrak{X}; T^*\mathfrak{X} \otimes \mathbf{E}) \xrightarrow{\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})} \dots \\ \dots \xrightarrow{\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})} \mathcal{S}(A_H\mathfrak{X}; \wedge^n T^*\mathfrak{X} \otimes \mathbf{E}) \rightarrow 0. \end{aligned}$$

This complex localizes at $t = 0$ to the symbol complex defined from $\sigma(\nabla_{\mathbf{E}})$ and at $t = 1$ to the symbol complex defined from $\sigma_{H,\text{gr}}(\nabla_{\mathbf{E}})$. If we take a Heisenberg splitting $b_{\bullet,0}$

at $t = 0$ to $\sigma(\nabla_{\mathbf{E}})$ (using the trivial Carnot structure), then by openness we can extend $b_{\bullet,0}$ to a Heisenberg splitting b_{\bullet} of $\sigma_{A,\text{gr}}(\nabla_{\mathbf{E},\bullet})$ on a small neighborhood of $t = 0$. By a gluing argument, we arrive at a Heisenberg splitting b_{\bullet} of $\sigma_{A,\text{gr}}(\nabla_{\mathbf{E},\bullet})$ over the unit interval. Therefore, $\sigma_{A,\text{gr}}(\nabla_{\mathbf{E},\bullet})$ completes to a G -equivariant Fredholm complex over $C^*(A_H\mathfrak{X}|_{\mathfrak{X}\times[0,1]})$ and defines a class

$$[\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})] \in K_0^G(C^*(A_H\mathfrak{X}|_{\mathfrak{X}\times[0,1]})).$$

By construction,

$$\begin{aligned} \text{ev}_{t=0}[\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})] &= [\sigma(\nabla_{\mathbf{E}})] \in K_0^G(C_0(T^*\mathfrak{X})) \quad \text{and} \\ \text{ev}_{t=1}[\sigma_{A,\text{gr}}(\nabla_{\mathbf{E}})] &= \sigma_{H,\text{gr}}(\nabla_{\mathbf{E}}) = [\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}}))] \in K_0^G(C^*(T_H\mathfrak{X})), \end{aligned}$$

where we in the last equality used Lemma 7.12. The defining property of ψ is that

$$K_0(\text{ev}_{t=0}) \otimes_{C^*(T_H\mathfrak{X})} \psi = K_0(\text{ev}_{t=1}),$$

and the lemma follows. \square

We will now start comparing K -theory classes to K -homology classes. Write $\text{Euler}(\mathfrak{X}) \in K_0^G(\mathfrak{X})$ for the class of the Euler-de Rham operator, i.e. the Dirac operator $d+d^*$ on $C^\infty(\mathfrak{X}, \wedge^*T^*\mathfrak{X})$ graded by form degree modulo 2. If \mathfrak{X} is a complex manifold with a holomorphic G -action, we write $[\mathfrak{X}] \in K_0^G(\mathfrak{X})$ for the fundamental class of the spin^c -structure. The latter is defined from the Dolbeault-Dirac operator $\bar{\partial}+\bar{\partial}^*$ on $C^\infty(\mathfrak{X}, \wedge^{0,*}T^*\mathfrak{X})$ graded by form degree modulo 2, where $\wedge^{0,q}T^*\mathfrak{X}$ denotes the bundle of $(0,q)$ -forms. The following result is well known.

Proposition 7.14. *Let \mathfrak{X} , \mathbf{E} and $\nabla_{\mathbf{E}}$ be as in Assumption 1. Then*

$$\text{PD}^{\text{an}}[\sigma(\nabla_{\mathbf{E}})] = \text{Euler}(\mathfrak{X}) \cap [\mathbf{E}].$$

and if \mathfrak{X} is complex, then

$$\text{PD}^{\text{an}}[\sigma(\bar{\partial}_{\mathbf{E},\bullet})] = [\mathfrak{X}] \cap [\mathbf{E}].$$

The proposition follows from for instance Proposition 7.10 applied to the trivial Carnot structure, or if one prefers it also follows from Kasparov's index theorem.

Theorem 7.15. *Let \mathfrak{X} be a G -Carnot manifold and $\nabla_{\mathbf{E}}$ be a connection satisfying Assumption 1. Then in the real case, we have the equality*

$$[\text{BGG}_{\bullet}(\nabla_{\mathbf{E}})] = \text{Euler}(\mathfrak{X}) \cap [\mathbf{E}].$$

and if \mathfrak{X} is complex, the following identity holds

$$[\text{BGG}_{\bullet}(\nabla_{\mathbf{E}})] = [\mathfrak{X}] \cap [\mathbf{E}].$$

Proof. We consider the real case and compute that

$$\begin{aligned} \text{Euler}(\mathfrak{X}) \cap [\mathbf{E}] &= \text{PD}^{\text{an}}[\sigma(\nabla_{\mathbf{E}})] = \text{PD}_H^{\text{an}} \circ \psi[\sigma(\nabla_{\mathbf{E}})] = \\ &= \text{PD}_H^{\text{an}}[\sigma_{H,\text{gr}}(\text{BGG}_{\bullet}(\nabla_{\mathbf{E}}))] = [\text{BGG}_{\bullet}(\nabla_{\mathbf{E}})]. \end{aligned}$$

where the first equality uses Proposition 7.14, the second equality uses Theorem 7.11, the third equality uses Lemma 7.13, and the final equality uses Proposition 7.10. The proof in the complex goes ad verbatim to the real case. \square

Remark 7.16. We can apply Theorem 7.15 to the K -equivariant geometry of the full flag manifold G/B of a connected, complex, semisimple Lie group G (with maximal compact subgroup K and Borel subgroup B). In this case, for any finite-dimensional G -representation V we have that

$$[\text{BGG}_{\bullet}(V)] = [G/B] \cap [G \times_B V] \in K_0^K(G/B).$$
