Abstract

Density functional theory (DFT) is a powerful tool for quantum-mechanical calculations, but practical calculations suffer systematic errors like incorrect charge densities and total energies in molecular dissociation, underestimated band gaps in bulk materials, and poor energy level alignment at interfaces. These problems are due to delocalization error. The localized orbital scaling correction (LOSC) removes delocalization error in molecules effectively, but screening of the Hartree-exchange-correlation response is necessary to correct it in materials. We introduce LOSC with systemdependent linear-response screening (lrLOSC), which effectively corrects delocalization error in semiconductors and insulators. After correcting for electron-phonon effects, the band gaps of eleven test systems are predicted with a mean absolute error of 0.28 eV, comparable to self-consistent GW. This method represents a significant step forward in correcting densities and total energies across system sizes and solving the band gap and energy level alignment problems entirely within the DFT framework.

TOC Graphic

Density functional theory (DFT)¹⁻⁵ is rightly regarded as the default method for quantummechanical calculations in both chemistry and materials science. It features a combination of reasonably accurate density functional approximations (DFAs) and efficient computational implementations that remains unparalleled decades later. But DFAs suffer systematic errors, including a characteristic and enduring underestimation of the fundamental (band) gap.⁶ Accurately computing this gap—and the orbital energies (energy bands) from which it is obtained⁷⁻⁹—is critical for calculations involving semiconductors;^{10,11} solar cells;¹² photocatalysts;¹³ and interfaces,^{14,15} across which energy bands are renormalized. Behind the band gap problem lies delocalization error.^{16–19}

Delocalization error in DFAs is a significantly and systematically incorrect behavior of the energy E viewed as a function of the number N of electrons, but it looks different depending on the size of the system.¹⁶ The exact E(N) curve is piecewise linear, with derivative discontinuities at integer N; the magnitude of the discontinuity gives the band gap.^{7,20} When calculated with typical DFAs, E(N) is convex for small finite systems, underestimating the derivative discontinuity and thus the gap. In periodic boundary conditions, piecewise linearity of E(N) is restored automatically, but deceptively: the electron delocalizes into the infinite lattice, the derivative discontinuity is underestimated just like for finite N, and the total energy of charged bulk systems is incorrect.¹⁶ Correcting delocalization error in both molecules and materials, then, requires that both the orbital energies and the total energy be corrected, all within the same framework of approximations.

Two ingredients, orbital localization and screening, are key to delocalization error corrections. The localized orbital scaling correction (LOSC) initially featured localization without screening,^{21,22} which is good enough to cure delocalization error in the valence orbitals of atoms and small molecules.²³ LOSC orbital energies have accuracy comparable to GWmethods in molecules,²⁴ and the LOSC orbital energies can replace GW quasiparticle energies as the starting point for Bethe–Salpeter calculations of neutral excitations.²⁵ Screening without localization is realized by the global scaling correction (GSC).^{26,27} GSC with screening, which treats delocalization error in atoms and molecules, is based on the exact second derivatives of the total energy with respect to the orbital occupation number.²⁸ It improves calculated photoemission spectra,²⁹ similar to prior work on valence orbital energies, when orbital relaxation is included.^{27,30,31} Although screening plays a smaller role in the valence orbital ionization of molecules,²⁹ both localization and screening are necessary to describe core-electron quasiparticle energies accurately.³²

Both localization and screening are also necessary to correct delocalization error in bulk materials. GSC, lacking localization, offers no correction at all to the total energy of bulk semiconductors and insulators. On the other hand, the initial version of LOSC significantly overestimates the correction to the orbital energies because screening of the Coulomb repulsion by other electrons is ignored. Mahler et al.³³ proposed screened LOSC (sLOSC), which included an empirically screened Hartree repulsion and substantially improved the band gaps of semiconductors and insulators. But sLOSC's screening is identical for all systems, fundamentally limiting its accuracy. In this work, paralleling similar development for finite systems,³² we extend LOSC to include the linear-response screening of GSC: we call the resulting method lrLOSC. We note the similarity of lrLOSC to Koopmans-compliant spectral functionals, ^{34–36} the Wannier–Koopmans method, ^{37–41} and Wannier optimally-tuned screened range-separated hybrid functionals,^{42,43} all of which correct orbital energies using localized orbitals (in materials, Wannier functions) and screening of the electron-electron interaction. Unlike LOSC, however, these functionals do not correct the total energy of systems with integer orbital occupations, such as physical systems with a finite band gap.³⁴ Thus, their correction cannot be size-consistent for molecular dissociation.²¹

lrLOSC modifies the DFA total energy by

$$\Delta E = \frac{1}{2} \sum_{\sigma} \sum_{ij\mathbf{R}} \lambda_{\mathbf{R}ij\sigma}^* \left(\delta_{\mathbf{R}ij} - \lambda_{\mathbf{R}ij\sigma} \right) \kappa_{\mathbf{R}ij\sigma}, \tag{1}$$

where i, j, σ are respectively the band-like and spin indices of localized orbitals $|w_{\mathbf{R}i\sigma}\rangle$ and

R indexes the primitive cell translation vectors (see below). The local occupations $\lambda_{\mathbf{R}ij\sigma} = \langle w_{\mathbf{0}i\sigma} | \rho | w_{\mathbf{R}j\sigma} \rangle$ are elements of the density matrix ρ in the local orbital basis, and the curvature $\kappa_{\mathbf{R}ij\sigma}$ measures the delocalization error between $|w_{\mathbf{0}i\sigma}\rangle$ and $|w_{\mathbf{R}j\sigma}\rangle$. $\delta_{\mathbf{R}ij}$ is the Kronecker delta, and λ^* is the complex conjugate of λ . Note that lrLOSC assumes a spin-polarized, collinear DFA calculation, with orthogonal Bloch spin orbitals: $\langle \psi_{\mathbf{k}m\sigma} | \psi_{\mathbf{q}n\tau} \rangle \propto \delta_{\mathbf{kq}} \delta_{mn} \delta_{\sigma\tau}$.

LOSC's localized orbitals are called orbitalets in finite systems²² and dually localized Wannier functions (DLWFs) in periodic boundary conditions.⁴⁴ DLWFs are generalized Wannier functions⁴⁵ constructed from the Kohn–Sham Bloch orbitals $|\psi_{\mathbf{k}n\sigma}\rangle$, where **k** indexes the N_k points sampled from the irreducible Brillouin zone, *n* the electronic bands, and σ the spin, as

$$|w_{\mathbf{R}i\sigma}\rangle = \frac{1}{N_k} \sum_{\mathbf{k}} e^{-i\mathbf{k}\cdot\mathbf{R}} \sum_n U_{ni}^{\mathbf{k}} |\psi_{\mathbf{k}n\sigma}\rangle.$$
(2)

The DLWFs are periodic on a supercell N_k times larger than the primitive unit cell and are indexed by a band-like index *i* and a primitive cell translation vector **R**. At each **k**-point, the unitary operator $U^{\mathbf{k}}$ is chosen to minimize the cost function

$$F = \sum_{i} \left[(1 - \gamma) \Delta r_{\mathbf{0}i\sigma}^2 + \gamma \Delta h_{\mathbf{0}i\sigma}^2 \right], \qquad (3)$$

where $\Delta r_{0i\sigma}^2$ is the spatial variance $\langle w_{0i\sigma} | \mathbf{r} | w_{0i\sigma} \rangle^2 - \langle w_{0i\sigma} | r^2 | w_{0i\sigma} \rangle$ and $\Delta h_{0i\sigma}^2$ is the energy variance. The numerical value of γ depends on the units chosen, but all LOSC results to date have used the same value; when Δr^2 is computed in a_0^2 and Δh^2 in eV², $\gamma = 0.47714$. (Setting $\gamma = 0$ recovers maximally localized Wannier functions.⁴⁶) Despite being spatially localized, DLWFs retain information about the energy spectrum, necessary for describing chemical reactivity.⁴⁷ DLWFs can be constructed for both metals and semiconductors because they do not require separation of the valence and conduction manifolds.^{21,22,44}

In finite systems, the curvature is $\kappa_{nn\sigma} = \partial^2 E / \partial f_{n\sigma}^2$, where $f_{n\sigma}$ is the occupation of the Kohn–Sham orbital $|\psi_{n\sigma}\rangle$. When $|\psi_{n\sigma}\rangle$ is a frontier orbital, $\partial^2 E / \partial f_{n\sigma}^2$ describes the deviation of E(N), computed by a DFA, from the correct linear behavior, including the effect of screening by all other electrons (also called orbital relaxation).²⁸ The original GSC method approximated $\kappa_{nn\sigma}$, treating only the Coulomb interaction, and used Kohn–Sham orbital densities instead of the Fukui function $\partial \rho_{\sigma} / \partial f_{n\sigma}$.^{26,27} Yang et al.²⁸ extended the result to include the exchange-correlation interaction, finding the exact second-order derivatives to be

$$\kappa_{nn\sigma} = \langle \rho_{n\sigma} | \sum_{\tau} (\epsilon^{\tau})^{-1} f_{\text{Hxc}}^{\tau\sigma} | \rho_{n\sigma} \rangle = \langle \rho_{n\sigma} | f_{\text{Hxc}}^{\sigma\sigma} + \sum_{\nu\tau} f_{\text{Hxc}}^{\sigma\nu} \chi^{\nu\tau} f_{\text{Hxc}}^{\tau\sigma} | \rho_{n\sigma} \rangle.$$
(4)

Here, $\rho_{n\sigma}(\mathbf{r}) = |\psi_{n\sigma}(\mathbf{r})|^2$ is the density of the Kohn–Sham orbital $|\psi_{n\sigma}\rangle$; $(\epsilon^{\tau})^{-1}(\mathbf{r}, \mathbf{r}')$ is the inverse static microscopic dielectric function;

$$f_{\rm Hxc}^{\sigma\nu}(\mathbf{r},\mathbf{r}') = \frac{\delta^2 E_{\rm Hxc}}{\delta\rho^{\sigma}(\mathbf{r})\delta\rho^{\nu}(\mathbf{r}')} = \frac{1}{|\mathbf{r}-\mathbf{r}'|} + \frac{\delta^2 E_{\rm xc}}{\delta\rho^{\sigma}(\mathbf{r})\delta\rho^{\nu}(\mathbf{r}')}$$
(5)

is the Hartree-exchange-correlation kernel; and

$$\chi^{\nu\tau}(\mathbf{r},\mathbf{r}') = \frac{\delta\rho^{\nu}(\mathbf{r})}{\delta\upsilon^{\tau}(\mathbf{r}')} = \frac{\delta^2 E}{\delta\upsilon^{\nu}(\mathbf{r})\delta\upsilon^{\tau}(\mathbf{r}')}$$
(6)

is the response of the density to an external perturbing potential δv , to linear order. Observe that the curvature is given by a bare kernel f_{Hxc} screened by the inverse dielectric function ϵ^{-1} , or equivalently by the sum of the bare kernel and a relaxed kernel modulated by χ . This curvature was implemented in the most recent iteration of GSC, known as GSC2.²⁹ Compared to the initial implementation, including orbital relaxation modestly improves the performance of GSC, reducing the error in ionization energy and electron affinity for small molecules by an average of about 0.2 eV. GSC2 still gives no correction to the total energy for materials; its screened interaction must be combined with the localized DLWFs. In molecules, including both the screening of Equation (4) and localization greatly improves the energies of core-orbital quasiparticles.³²

In LOSC, the GSC2 curvature is transformed to the DLWF basis; its matrix elements

are

$$\kappa_{\mathbf{R}ij\sigma} = \langle \rho_{\mathbf{0}i\sigma} | f_{\mathrm{Hxc}}^{\sigma\sigma} + \sum_{\nu\tau} f_{\mathrm{Hxc}}^{\sigma\nu} \chi^{\nu\tau} f_{\mathrm{Hxc}}^{\tau\sigma} | \rho_{\mathbf{R}j\sigma} \rangle, \tag{7}$$

where $\rho_{\mathbf{R}j\sigma}(\mathbf{r}) = |w_{\mathbf{R}j\sigma}(\mathbf{r})|^2$ is a DLWF density. Note that κ in LOSC is not diagonal because the DLWFs are not Kohn–Sham eigenfunctions. These off-diagonal elements allow interactions between pairs of orbitals to affect the total energy, even at long range. The analogous elements for canonical orbitals were derived as cross-terms $\partial^2 E/\partial f_{n\sigma} \partial f_{m\sigma}$ in the GSC2 method (see the Supporting Information of Mei et al.²⁹). In lrLOSC, we compute $\kappa_{\mathbf{R}ij\sigma}$ using density functional perturbation theory;⁴⁸ this reduces the computational cost by a factor of N_k , the number of **k**-points, because both curvature elements linear in DLWF densities⁴⁹ and the densities themselves³⁶ decompose monochromatically. Thus

$$\kappa_{\mathbf{R}ij\sigma} = \frac{1}{N_k} \sum_{\mathbf{q}} e^{-i\mathbf{q}\cdot\mathbf{R}} \left[\langle \rho_{\mathbf{0}i\sigma}^{\mathbf{q}} | V_{\mathbf{0}j\sigma}^{\mathbf{q}} \rangle + \sum_{\tau} \langle \delta \rho_{\mathbf{0}i\tau}^{\mathbf{q}} | V_{\mathbf{0}j\tau}^{\mathbf{q}} \rangle \right], \tag{8}$$

where \mathbf{q} samples the Brillouin zone uniformly including its origin, and

$$V_{\mathbf{0}j\tau}^{\mathbf{q}}(\mathbf{r}) = \int d\mathbf{r}' f_{\mathrm{Hxc}}^{\tau\sigma}(\mathbf{r}, \mathbf{r}') \rho_{\mathbf{0}j\sigma}^{\mathbf{q}}(\mathbf{r}'), \qquad (9)$$

$$\delta \rho_{\mathbf{0}i\tau}^{\mathbf{q}}(\mathbf{r}') = \sum_{\nu} \int d\mathbf{r}' \, \chi^{\tau\nu}(\mathbf{r}, \mathbf{r}') V_{\mathbf{0}i\nu}^{\mathbf{q}}(\mathbf{r}').$$
(10)

See the Supporting Information for the details of this derivation.

We compute lrLOSC total and band energy corrections on a set of eleven semiconductors and insulators. DFA calculations are performed with Quantum ESPRESSO,^{50–52} version 7.1. We use the PBE functional,⁵³ optimized norm-conserving Vanderbilt pseudopotentials⁵⁴ built under PBE with scalar relativistic corrections, a wavefunction kinetic energy cutoff of 75 Ry, and a $6 \times 6 \times 6$ Monkhorst–Pack sampling of the irreducible Brillouin zone.

Computing $|\delta \rho_{0i\tau}^{\mathbf{q}}\rangle$ occupies the vast majority of lrLOSC's computational time. For each $|\rho_{0i\tau}^{\mathbf{q}}\rangle$, there are N_{occ} coupled equations that must be solved at each **k**-point, for a total runtime scaling as $\mathcal{O}(N_{\text{DLWF}}N_{\mathbf{k}}^2N_{\text{occ}}^3)$ (since $N_{\mathbf{q}} = N_{\mathbf{k}}$).

The Hartree kernel is computed in reciprocal space, where the Coulomb repulsion is diagonal; its divergence is corrected after integration by the method of Gygi and Baldereschi⁵⁵. The divergence correction to $\langle \delta \rho_{0i\sigma}^{\mathbf{q}} | V_{0j\sigma}^{\mathbf{q}} \rangle$ must be scaled by the macroscopic dielectric constant ϵ_{∞} , which is computed in Quantum ESPRESSO's PHonon module, with the same computational parameters. The energy cutoff and Brillouin zone sampling were chosen to converge ϵ_{∞} to 0.01, and the valence band maximum and conduction band minimum to 0.01 eV.

DLWFs are obtained with a locally maintained fork⁴⁴ of wannier90,⁵⁶⁻⁵⁸ and lrLOSC is implemented in a local fork of Quantum ESPRESSO's development version. It adapts the KCW module,³⁶ leveraging its implementation of the monochromatic decomposition and its linear-response routines.

lrLOSC greatly improves fundamental gaps relative to PBE. Because LOSC is a purely electronic (Born–Oppenheimer) theory, its fundamental gap is not directly comparable to the experimental band gap. Even at zero temperature, coupling of the electrons to the lattice changes the gap, an effect called zero-point renormalization (ZPR).^{59–61} ZPR usually narrows the gap slightly, but in some cases its effect can exceed 1 eV. We thus compare lrLOSC against the *electronic* gap, obtained by subtracting ZPR from the experimental gap, and it performs extremely well: the mean absolute error (MAE) on our test set is only 0.28 eV. This compares well with quasiparticle self-consistent GW, which yielded a MAE of about 0.46 eV on a similar set of materials.⁶²

Note that γ , which describes the balance between spatial and energy localization of the DLWFs in Equation (3), is the only free parameter in lrLOSC. The value we use, $\gamma = 0.47714$, was originally optimized for LOSC in finite systems;²² it is also used for sLOSC in materials.³³ It is interesting that our calculations show that it is also appropriate for lrLOSC.

Figure 2 shows the band structure of lithium fluoride calculated with PBE (left) and lr-LOSC (right). The DFA gap is only $9.19 \,\text{eV}$, much smaller than the electronic gap ($15.43 \,\text{eV}$, including a ZPR of $-1.231 \,\text{eV}$). lrLOSC shifts occupied bands down and virtual bands up relative to the DFA and predicts a gap of $15.24 \,\text{eV}$, within $0.2 \,\text{eV}$ of the electronic gap. lr-

Figure 1: DFA, lrLOSC, and experimental gaps vs. electronic gap.

LOSC also improves the core-level energies, especially the lithium 1s state, compared to the parent DFA. Its performance is very similar in this system to the Koopmans-compliant Wannier functional;³⁶ it slightly outperforms G_0W_0 in the electronic gap, but is outperformed in turn for the core-level energies.

Table 1: Core-level quasiparticle energies and electronic gap of LiF by theory and experiment. The G_0W_0 results are from LDA rather than PBE.

E (eV)	PBE	$G_0 W_0^{63}$	KI^{36}	lrLOSC	$Exp.^{64}$
$\langle \varepsilon \rangle_{{\rm Li} 1s}$	-40.8	-47.2	-46.6	-47.8	-49.8
$\langle \varepsilon \rangle_{\mathrm{F}2s}$	-19.5	-24.8	-19.5	-19.7	-23.9
Gap	9.19	14.3	15.28	15.24	15.43

lrLOSC provides a particularly accurate correction for silicon carbide (Figure 3). The qualitative features of the DFA band gap are virtually unchanged, but the electronic gap is adjusted to within 0.04 eV of the correct value. A modest increase in conduction band energies—coupled with a large downward shift in core-level energies, leaving valence energies mostly unchanged relative to the Fermi level—is typical behavior for lrLOSC on the systems tested. In the systems tested, however, the lrLOSC Fermi level is always observed to be

Figure 2: LiF band structure. Purple dashed lines (top to bottom): ZPR-corrected experimental gap, experimental energies for F 2s, Li 1s states.

lower than E_F^{PBE} .

Figure 3: SiC band structure. Purple dashed line: ZPR-corrected experimental gap.

Because it includes both localization and accurate, system-dependent screening, lrLOSC corrects delocalization error effectively in both molecules and materials. It provides accurate, size-consistent orbital and band energy corrections in semiconductors and insulators, matching the performance of many-body perturbation theory without requiring any many-

body observables. Currently, it is limited to gapped systems, as the density response χ is not well-defined for metals. Future work will provide curvature applicable to metals that still includes system-dependent screening and implement the self-consistent correction to the density⁶⁵ in periodic boundary conditions. With these updates, LOSC will be applicable to interfaces, including molecules on a solid surface. Modeling the energy level alignment of such systems is a major challenge for electronic structure methods,^{66–68} and lrLOSC promises a nearly parameter-free solution entirely within the ubiquitous DFT paradigm.
