#### Abstract

In this paper, we utilize the De Giorgi iteration to quantitatively analyze the upper bound of solutions for Keller-Segel type systems. The refined upper bound estimate presented here has broad applications in determining large time behaviours of weak solutions and improving the regularity for models involving the $p$-Laplace operator. To demonstrate the applicability of our findings, we investigate the asymptotic stability of a chemotaxis model with nonlinear signal production and a chemotaxis-Navier-Stokes model with a logistic source. Additionally, within the context of $p$-Laplacian diffusion, we establish Hölder continuity for a chemotaxis-haptotaxis model and a chemotaxis-Stokes model.

Keywords: Keller-Segel systems; De Giorgi iteration; Boundedness; Asymptotic stability

## 1 Introduction

Chemotaxis is the phenomenon in which cells, organisms, or entities move in response to chemical stimulus. Specially, the movements of single-cell or multicellular organisms are directed by the concentration gradient of certain chemicals in their environment. The pioneering modeling works, describing this biochemotactic phenomenon, are introduced by Keller-Segel [23] and [24]. Afterwards, given the crucial role of chemotaxis in the fields of medicine and biology, an abundance of mathematical research on classical Keller-Segel systems and plenty of related variants have been carried out extensively, see [2, 14, 29] for review literature.

In this work, we consider the following chemotaxis system of a general form:

$$
\begin{cases}n_{t}+\tau \mathbf{u} \cdot \nabla n=\nabla \cdot(a(\nabla n, n, x, t) \nabla n-b(n, x, t) \nabla c)+f(n, x, t), & x \in \Omega, t>0  \tag{1.1}\\ c_{t}+\tau \mathbf{u} \cdot \nabla c=\Delta c-c+g(n, x, t), & x \in \Omega, t>0 \\ a(\nabla n, n, x, t) \frac{\partial n}{\partial \nu}=\frac{\partial c}{\partial \nu}=0, & x \in \partial \Omega, t>0 \\ \left.(n, c)\right|_{t=0}=\left(n_{0}, c_{0}\right), & x \in \Omega\end{cases}
$$

[^0]where $\tau \in\{0,1\}, \Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ is a bounded domain with smooth boundary and $\partial / \partial \nu$ denotes the derivative with respect to the outer normal of $\partial \Omega$. The density of organisms such as cells and bacteria is represented by $n$; the concentration of chemical signal is represented by $c$. In the present work, we also consider scenarios where the environmental fluid, denoted by $\mathbf{u}$, needs to be included in the model. The component $\mathbf{u}$ with the property $\nabla \cdot \mathbf{u}=0$ in the distributional sense, satisfies (Navier-) Stokes equations involving an external gravitational forces generated by the aggregation of organisms. Here, we suppose that $\mathbf{u}$ is a given vector function admitting a certain regularity property. The terms $\nabla \cdot(a(\nabla n, n, x, t) \nabla n)$ and $\nabla \cdot(b(n, x, t) \nabla c)$ exhibit the (nonlinear) self-diffusion and chemotactic cross-diffusion mechanisms, respectively. The cells-kinetics mechanism is characterized by the logistic function $f(n, x, t)$. The production or consumption mechanism of $n$ with respect to $c$ is exhibited by the function $g(n, x, t)$.

Since there are various biological mechanisms in experimental environments or real-world implementations, the nonlinear terms included in the modeled chemotaxis systems will be presented in diverse forms. We first introduce the possible choices of $a$ and $b$. The approach in [16] captures one prominent situation that finite volumes of individuals cannot be neglected. In a particular framework developed in [16], the nonlinear terms $a$ and $b$ are connected through the relationship

$$
\begin{equation*}
a(\xi, s, x, t)=Q(s)-s Q^{\prime}(s) \quad \text { and } \quad b(s, x, t)=s Q(s), \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0 \tag{1.2}
\end{equation*}
$$

where $Q(s)$ with $s=n(x, t)$ represents the density-dependent probability for a cell to find space somewhere in its current neighborhood. The above expressions also imply that $a$ and $b$ can be widely selected through kinds of ways and a very prototypical choice is determined as follows,

$$
\begin{equation*}
a(\xi, s, x, t)=(s+1)^{\alpha} \quad \text { and } \quad b(s, x, t)=s(s+1)^{\beta-1}, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0 \tag{1.3}
\end{equation*}
$$

The solvability results concerning the chemotaxis model with nonlinear terms like (1.3) can be found in $[26,33,28]$. Apart from the above volume filling effects, the $p$-Laplacian as a regularity operator originating from non-Newtonian mechanics [6], nonlinear flow laws [9] and other physical phenomena, also plays an important role in system modeling. When it comes to the $p$-Laplacian, the nonlinear diffusion function $a$ reads as

$$
a(\xi, s, x, t)=|\xi|^{p-2}, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0
$$

and under this setting, the existence of weak solutions to systems has been discussed in [25].
Finally, let us turn to review some typical choices of $f$ and $g$. Taking into account disciplines like population dynamics, it is necessary to incorporate a proper logistic function into the chemotaxis model to characterize the proliferation and death of organisms. The specific form of $f$ depends on practical factors such as environmental capacity and growth rate. The logistic damping effects generated by $f$ under the most prototypical choice $f(s)=r s-\mu s^{2}(r \in \mathbb{R}$ and $\mu>0)$ have been investigated by [35, 32]. For the findings concerned with source functions of generalized types, we refer the readers to e.g., [41, 40].

When the chemical signal is produced by cells, the most common selection of the function $g$ is given by

$$
g(s, x, t)=s, \quad s \geq 0, x \in \bar{\Omega}, t>0
$$

which indicates that the rate of production of the signal is directly proportional to the quantity of substance. Accounting for saturation effects at large densities, the process of signal production through cells no longer needs to depend on the population density in a linear manner, and then the prototype in this case is determined by the choice

$$
g(s, x, t)=s^{\sigma}, \quad s \geq 0, x \in \bar{\Omega}, t>0
$$

An another important selection of $g$ was originally exhibited in [24], where the chemotaxis model was built on the phenomenon that the chemical signal is a kind of nutrient consumed by the organisms. Under this mechanism, a typical choice of $g$ takes the form that

$$
g(s, x, t)=-s^{\sigma} c(x, t)+c(x, t), \quad s \geq 0, x \in \bar{\Omega}, t>0,
$$

where $\sigma$ measures the consumption rate between the signal and cells. In the field of PDE research, the vast majority of studies on the chemotaxis model of type (1.1) focus on addressing solvability or demonstrating the existence of blow-up phenomena. The solvability results, along with the regularity inferred from the space related to solution concepts, are achieved by investigating the energy development of local solutions in the most existing literature, see more details in e.g. [2, 14].

Motivation and ideas of the present work. Different from the approach taken in manuscripts addressing solvability, here we mainly adopt the De Giorgi-Nash theory instead of energy methods to analyze the properties of solutions. In other words, our emphasis is on estimating the size of the level set rather than studying the development of $\int_{\Omega} n^{q}(\cdot, t) d x$. An advantage of employing the De Giorgi iteration is its ability to intuitively exhibit a delicate quantitative estimate on the upper bound of solutions.

As demonstrated above, the diverse mechanisms in the real world lead to varied choices of nonlinear terms in the model. To encompass a wider range of scenarios, we only impose the mild assumptions (1.4)-(1.7) on each nonlinear term appearing in (1.1). Therefore, our boundedness results, as shown in Theorems $1 \& 2$, can provide quantitative analysis on upper bounds for global solutions obtained in many existing literature. This idea also can be found in $[37,38]$, where the authors captured the properties for parabolic equations of a general form and further utilized them to investigate the chemotaxis models.

Hypotheses. In this study, we investigate the properties of solutions defined on $\bar{\Omega} \times[0, T)$, where $T \in(0, \infty)$ or $T=\infty$. We suppose that

$$
\begin{equation*}
a(\xi, s, x, t) \geq a_{0}(s+1)^{\alpha}|\xi|^{p-2}, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0 \tag{1.4}
\end{equation*}
$$

and

$$
\begin{equation*}
b(s, x, t) \leq b_{0}(s+1)^{\beta} \quad \text { as well as } \quad b(0, x, t)=0, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0 \tag{1.5}
\end{equation*}
$$

with $a_{0}>0, b_{0} \geq 0, \alpha, \beta \in \mathbb{R}$ and $p>1$. For any fixed $(x, t) \in \bar{\Omega} \times(0, T)$, one-variable functions $f(\cdot, x, t)$ and $g(\cdot, x, t)$ belong to $C^{1}([0, \infty))$. Moreover, $f$ also satisfies that

$$
\begin{equation*}
f(0, x, t) \geq 0 \quad \text { for all } \quad(x, t) \in \bar{\Omega} \times(0, T) \tag{1.6}
\end{equation*}
$$

and

$$
\begin{equation*}
f(s, x, t) \rightarrow-\infty \quad \text { as } s \rightarrow \infty \tag{1.7}
\end{equation*}
$$

uniformly in $\bar{\Omega} \times(0, T)$. The condition (1.7) guarantees the existence of $K_{f}>1$ such that

$$
\begin{equation*}
f(s, x, t) \leq 0 \quad \text { for any }(x, t) \in \bar{\Omega} \times(0, T) \tag{1.8}
\end{equation*}
$$

as long as $s \geq K_{f}$. The velocity $\mathbf{u}$ is assumed to satisfy that

$$
\begin{equation*}
\mathbf{u} \in L_{l o c}^{\infty}(\bar{\Omega} \times[0, T)) \quad \text { for } \tau=1 \tag{1.9}
\end{equation*}
$$

Notations. To simplify presentations, we need to keep the coming notations in mind. For any $\alpha \in \mathbb{R}$, the symbols $\alpha_{-}$and $\alpha_{+}$denote

$$
\alpha_{-}:=\max \{-\alpha, 0\}, \quad \alpha_{+}:=\max \{\alpha, 0\}
$$

As usual, we employ the domain notation $Q_{T}:=\bar{\Omega} \times(0, T)$. In the following, the symbol $\frac{1}{\alpha_{+}}$will appear several times, which means

$$
\frac{1}{\alpha_{+}}:= \begin{cases}+\infty & \text { if } \alpha \leq 0  \tag{1.10}\\ \frac{1}{\alpha} & \text { if } \alpha>0\end{cases}
$$

For any $k \in \mathbb{R}$ and $\tau \in(0, T)$, we define the level set

$$
\begin{equation*}
A^{+}(k, \tau):=\{x \in \Omega \mid n(x, \tau)>k\} \tag{1.11}
\end{equation*}
$$

For $h \in L^{1}(V)$, the mean average of $h$ is given by

$$
(h)_{V}:=f_{V} h(x) d x=\frac{1}{|V|} \int_{V} h(x) d x
$$

The presence of the fluid term $\mathbf{u}$ necessitates the introduction of the solenoidal subspace of $L^{2}\left(\Omega ; \mathbb{R}^{2}\right)$ as follows,

$$
L_{\sigma}^{2}(\Omega):=\left\{\mathbf{v} \in L^{2}\left(\Omega ; \mathbb{R}^{2}\right) \mid \nabla \cdot \mathbf{v}=0 \text { in the distributional sense }\right\}
$$

Throughout this paper, we adopt the shorthand notation

$$
\text { data }:=\left(p, \alpha, \beta, a_{0}, b_{0}, N, \Omega\right)
$$

Hereafter, $C \equiv C$ (data) represents a pure constant depending only on a subset of $\left\{p, \alpha, \beta, a_{0}, b_{0}, N, \Omega\right\}$, unless otherwise specified.

Before stating our main contributions, we introduce the concept of solutions in this paper.
Definition 1.1. Let $T \in(0, \infty]$ and $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with smooth boundary. Assume $a, b, f, g$ satisfy (1.4)-(1.7) and $\mathbf{u}$ belongs to $L_{l o c}^{\infty}(\bar{\Omega} \times[0, T))$ with the property that $\nabla \cdot \mathbf{u}=0$ in the distributional sense. We call a pair $(n, c)$ with $n \geq 0$ in $Q_{T}$ a global weak solution of (1.1) if

$$
\left\{\begin{array}{l}
n \in L_{l o c}^{p}\left((0, T) ; W^{1, p}(\Omega)\right) \cap C^{0}\left((0, T) ; L^{2+\alpha_{-}}(\Omega)\right)  \tag{1.12}\\
c \in L_{l o c}^{2}\left((0, T) ; W^{1,2}(\Omega)\right)
\end{array}\right.
$$

such that

$$
\begin{gather*}
a(\nabla n(x, t), n(x, t), x, t)(1+n(x, t))^{\alpha_{-}}|\nabla n(x, t)| \in L_{l o c}^{\frac{p}{p-1}}(\bar{\Omega} \times(0, T))  \tag{1.13}\\
b(n(x, t), x, t)(1+n(x, t))^{\alpha_{-}}|\nabla c(x, t)| \in L_{l o c}^{\frac{p}{p-1}}(\bar{\Omega} \times(0, T)) \tag{1.14}
\end{gather*}
$$

as well as

$$
\begin{equation*}
g(n(x, t), x, t) \in L_{l o c}^{1}(\bar{\Omega} \times(0, T)), \quad f(n(x, t), x, t)(1+n(x, t))^{1-\alpha_{-}} \in L_{l o c}^{1}(\bar{\Omega} \times(0, T)) \tag{1.15}
\end{equation*}
$$

and that

$$
\begin{align*}
-\int_{0}^{\infty} \int_{\Omega} n \varphi_{t} d x d t= & \int_{0}^{\infty} \int_{\Omega} n \mathbf{u} \cdot \nabla \varphi d x d t-\int_{0}^{\infty} \int_{\Omega} a(\nabla n, n, x, t) \nabla n \cdot \nabla \varphi d x d t  \tag{1.16}\\
& +\int_{0}^{\infty} \int_{\Omega} b(n, x, t) \nabla c \cdot \nabla \varphi d x d t+\int_{0}^{\infty} \int_{\Omega} f(n, x, t) \varphi d x d t
\end{align*}
$$

and
$-\int_{0}^{\infty} \int_{\Omega} c \psi_{t} d x d t=-\int_{0}^{\infty} \int_{\Omega} \nabla c \cdot \nabla \psi-\int_{0}^{\infty} \int_{\Omega} c \psi d x d t+\int_{0}^{\infty} \int_{\Omega} c \mathbf{u} \cdot \nabla \psi d x d t+\int_{0}^{\infty} \int_{\Omega} g(n, x, t) \psi d x d t$
hold for any $\varphi \in C_{0}^{\infty}(\bar{\Omega} \times(0, T))$ and $\psi \in C_{0}^{\infty}(\bar{\Omega} \times(0, T))$.
As stated in [5, page 76], when considering a regularity operator of the type

$$
a(n, \nabla n) \simeq n^{\alpha}|\nabla n|^{p-2}
$$

it is crucial to emphasize the solution $n$ admits a property like (1.13) so that the integral term involving $a$ in (1.16) makes sense, and subsequent choices of testing functions are feasible. Similarly, necessities of the requiring (1.14) and (1.15) arise from the same reason. The concept of weak solutions of this kind is very common in chemotaxis models, see e.g., $[36,25,30]$.

Now we are in a position to state our main results.
Theorem 1 (Boundedness result). Let $T \in(0, \infty]$ and $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with smooth boundary. Let a pair of functions $(n, c)$ with $n \geq 0$ in $Q_{T}$ be a weak solution to (1.1) in the sense of Definition 1.1, where (1.4)-(1.7) are in force with

$$
\begin{equation*}
\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}\right\}<\frac{p\left(N+2+\alpha_{-}\right)}{N} \tag{1.18}
\end{equation*}
$$

Then for all $t_{0} \in(0, T)$ and any $\hat{t} \in\left(0, t_{0}\right)$, if there holds that

$$
\begin{equation*}
\mathfrak{b}:=\max \left\{\|\nabla c\|_{L^{\infty}\left(\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)\right)}, 1\right\}<\infty \tag{1.19}
\end{equation*}
$$

we find that $n$ is bounded in $\Omega \times\left(t_{0}-\hat{t} / 2, t_{0}\right)$. Furthermore, the upper bound of $n$ is given as

$$
\begin{equation*}
\underset{\Omega \times\left(t_{0}-\hat{t} / 2, t_{0}\right)}{\operatorname{ess} \sup ^{2}} n \leq C \mathfrak{b}^{\kappa}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\hat{\kappa}}\left(f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega} n^{\frac{p\left(N+2+\alpha_{-}\right)}{N}} d x d \tau\right)^{\hat{\kappa}}+K_{f} \tag{1.20}
\end{equation*}
$$

where $K_{f}$ is determined in (1.8), the positive pure constants $\kappa$, $\hat{\kappa}$, and $C$ depend only on data.
Remark 1. In the context of equation (1.1) ${ }_{1}$, the upper bound of the solution $n$ should depend on the norm of $\nabla c$ in a certain Lebesgue space, as well as on the logistic function and parameters present in the equation. The display (1.20) illustrates how these factors affect the sup-estimate of solutions in a detailed manner. By controlling these factors, we can achieve a desired $L^{\infty}$-bound of $n$, which can then be utilized to further explore other properties of solutions. This is one of our intentions in providing a delicate estimate of the upper bound.

Remark 2. Since the specific forms of $\kappa$ and $\hat{\kappa}$ are not closely relevant to our subsequent contents, for simplicity, we merely provide a brief explanation of the dependency of $\kappa$ and $\hat{\kappa}$ in the statement of Theorem 1. We remark that $\kappa$ and $\hat{\kappa}$ are precisely defined by

$$
\frac{1}{\kappa}:=\frac{p-1}{p}\left(\frac{p\left(N+2+\alpha_{-}\right)}{N}-\max \left\{\frac{p\left(\beta+\alpha_{-}\right) N}{p-1}, 2+\alpha_{-}, p\right\}\right)
$$

and

$$
\frac{1}{\hat{\kappa}}:=\frac{p+N}{p}\left(\frac{p\left(N+2+\alpha_{-}\right)}{N}-\max \left\{\frac{p\left(\beta+\alpha_{-}\right) N}{p-1}, 2+\alpha_{-}, p\right\}\right)
$$

Unlike the scenario where $\frac{p\left(N+2+\alpha_{-}\right)}{N}>\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}\right\}$, when $p$ locates in the other range, the local boundedness is not implicit into the notion of weak solution and must be obtained by imposing other information.

Theorem 2 (Boundedness result). Let $T \in(0, \infty]$ and $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with smooth boundary. Let a pair of functions $(n, c)$ with $n \geq 0$ in $Q_{T}$ be a weak solution to (1.1) in the sense of Definition 1.1, where (1.4)-(1.7) are in force with

$$
\begin{equation*}
\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}\right\} \geq \frac{p\left(N+2+\alpha_{-}\right)}{N} \tag{1.21}
\end{equation*}
$$

Then for all $t_{0} \in(0, T)$ and any $\hat{t} \in\left(0, t_{0}\right)$, if there holds that $n$ is bounded in $\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)$ and

$$
\begin{equation*}
\mathfrak{b}:=\max \left\{\|\nabla c\|_{L^{\infty}\left(\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)\right)}, 1\right\}<\infty \tag{1.22}
\end{equation*}
$$

then we have the following upper bound of $n$ :

$$
\begin{equation*}
\underset{\Omega \times\left(t_{0}-\hat{t} / 2, t_{0}\right)}{\operatorname{ess} \sup ^{2}} n \leq C \mathfrak{b}^{\kappa}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\hat{\kappa}}\left(f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega} n^{r} d x d t\right)^{\hat{\kappa}}+K_{f} \tag{1.23}
\end{equation*}
$$

where

$$
r>\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}, \frac{N\left(2+\alpha_{-}\right)}{p}-N, \frac{(p+N)\left(\beta+\alpha_{-}\right)}{p(p-1)}-N-2-\alpha_{-}\right\}
$$

and $K_{f}$ is given in (1.8), the positive constants $\kappa, \hat{\kappa}$ and $C$ depend on data.
Remark 3. One may say the Lipschitz continuity assumption on c required in (1.19) and (1.22) is strong. Actually, the regularity of $c$, as an interconnected component to $n$ within a system, can be obtained through utilizing the semigroup estimates and Sobolev estimates for parabolic equation (1.1) $)_{2}$. Here, we give a sufficient condition ensuring (1.19) without proof: assume that

$$
g(x, t)=g(n(x, t), x, t) \in L^{q}\left(Q_{T}\right)
$$

with some $q>N+2$, then for any $t_{0} \in(0, T)$ we have $\|\nabla c\|_{L^{\infty}\left(\Omega \times\left(t_{0}, T\right)\right)}<\infty$.
When considering the Hölder-continuity of solutions, it becomes necessary to additionally impose the following conditions on $a$ and $b$ :

$$
\begin{equation*}
a(\xi, s, x, t)=\bar{a}(s, x, t)|\xi|^{p-2}, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0 \tag{1.24}
\end{equation*}
$$

where $\bar{a}$ as well as $b$ satisfies that for any $(s, x, t) \in \mathbb{R}^{+} \times \bar{\Omega} \times \mathbb{R}^{+}$and $\left(s_{1}, x_{1}, t_{1}\right) \in \mathbb{R}^{+} \times \bar{\Omega} \times \mathbb{R}^{+}$,

$$
\begin{equation*}
\left|\bar{a}(s, x, t)-\bar{a}\left(s_{1}, x_{1}, t_{1}\right)\right| \leq C_{H}\left(\left|s-s_{1}\right|+\left|x-x_{1}\right|+\left|t-t_{1}\right|\right)^{\omega_{a}} \tag{1.25}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|b(s, x, t)-b\left(s_{1}, x_{1}, t_{1}\right)\right| \leq \hat{C}_{H}\left(\left|s-s_{1}\right|+\left|x-x_{1}\right|+\left|t-t_{1}\right|\right)^{\omega_{b}} \tag{1.26}
\end{equation*}
$$

with some $C_{H}, \hat{C}_{H}>0$ and $\omega_{a}, \omega_{b} \in(0,1)$.

Theorem 3 (Hölder continuity). Assume that $T \in(0, \infty]$ and $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ is a bounded domain with smooth boundary. Let a pair of functions $(n, c)$ with $n \geq 0$ in $Q_{T}$ be a weak solution to (1.1) in the sense of Definition 1.1, where (1.4)-(1.7), (1.9) and (1.24)-(1.26) are in force. For any $t_{0} \in(0, T)$ and every $\hat{T} \in\left(t_{0}, T\right)$, if $n$ is bounded in $\bar{\Omega} \times\left[t_{0}, \hat{T}\right]$, then there holds that $n \in C^{\gamma, \frac{\gamma}{p}}\left(\bar{\Omega} \times\left[t_{0}+\varepsilon, \hat{T}\right]\right)$ with each $\varepsilon \in\left(0, \hat{T}-t_{0}\right)$ and some $\gamma \in(0,1)$. Furthermore, we also have the Hölder continuity of gradient as follows:
(i) If $p>2$, then we can find $\omega \in(0,1)$ and $C>1$ depending upon $\varepsilon, p, \alpha, \beta, a_{0}, b_{0}, C_{H}, \hat{C}_{H}, \omega_{a}, \omega_{b}, N, \Omega$, $\|n\|_{L^{\infty}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)},\|n\|_{W^{1, p}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)}$ and $\|\mathbf{u}\|_{L^{\infty}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)}$ such that for any $V \subset \subset \Omega$,

$$
|\nabla n(x, t)-\nabla n(\hat{x}, \hat{t})| \leq C\left(\frac{|x-\hat{x}|+\sqrt{|t-\hat{t}|}}{\operatorname{dist}(V ; \partial \Omega)}\right)^{\omega}, \quad \forall(x, t), \quad(\hat{x}, \hat{t}) \in \bar{V} \times\left[t_{0}+\varepsilon, \hat{T}\right]
$$

(ii) Suppose $p=2$. Then there exist $\omega \in(0,1)$ and $C>1$ depending upon $\varepsilon, p, \alpha, \beta, a_{0}, b_{0}, C_{H}, \hat{C}_{H}, \omega_{a}$, $\omega_{b}, N, \Omega,\|n\|_{L^{\infty}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)}$ and $\|\mathbf{u}\|_{L^{\infty}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)}$ such that

$$
|\nabla n(x, t)-\nabla n(\hat{x}, \hat{t})| \leq C(|x-\hat{x}|+\sqrt{|t-\hat{t}|})^{\omega}, \quad \forall(x, t), \quad(\hat{x}, \hat{t}) \in \bar{\Omega} \times\left[t_{0}+\varepsilon, \hat{T}\right]
$$

As evidenced by findings in, for instance, [32, 34], chemotaxis models can exhibit an infinite-time explosion phenomenon under certain conditions that are satisfied by parameters in systems and initial data. Therefore, if the $L^{\infty}$-norm of the solution remains bounded as the time-variable $t \rightarrow \infty$, then the infinite-time explosion can be ruled out in the systems. In addition, for models involving volume filling effects, determining asymptotic stability also necessitates a well-suited upper bound estimate of the solution beforehand. Hence, in the upcoming theorem, we will conduct a quantitative analysis of such bound of the global solutions for further use.

Theorem 4 (Boundedness result). Let $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with a smooth boundary. Assume that $T=\infty$, and (1.4)-(1.7) as well as (1.9) are in force. Let $m>N$ and
$r>\max \left\{\frac{p\left(\beta+\alpha_{-}\right) N}{p-1}, 2+\alpha_{-}, \frac{N\left(2+\alpha_{-}\right)}{p}-N, \frac{(p+N)\left(\beta+\alpha_{-}\right)}{p(p-1)}-N-2-\alpha_{-}, \frac{p\left(N+2+\alpha_{-}\right)}{N}\right\}$.
be arbitrarily chosen constants. Then we can obtain pure constants $\Lambda>0$ and $\kappa>0$, determined a priori only in terms of data, such that for any globally bounded solution $(n, c)$ with $n \geq 0$ in $Q_{T}$ to (1.1) in the sense of Definition 1.1, if there exist $K>0$ and a time point $\bar{t}_{0}>0$ ensuring

$$
\|\mathbf{u}(\cdot, t)\|_{L^{\infty}(\Omega)}<K, \quad\|n(\cdot, t)\|_{L^{r}(\Omega)} \leq K, \quad \forall t>\bar{t}_{0}
$$

and

$$
\|g(\cdot, t)\|_{L^{m}(\Omega)} \leq K, \quad \forall t>\bar{t}_{0}
$$

where

$$
g(x, t):=g(n(x, t), x, t), \quad x \in \Omega, t>0
$$

then we can find $\bar{T}>\bar{t}_{0}$ satisfying

$$
\begin{equation*}
\|n(\cdot, t)\|_{L^{\infty}(\Omega)} \leq \Lambda(K+1)^{\kappa}+K_{f}, \quad \forall t>\bar{T} \tag{1.27}
\end{equation*}
$$

and $K_{f}$ is given in (1.8).

Structure of the present work. Section 2 in this work is primarily devoted to the proof of Theorems $1 \& 2$ using the De Giorgi iteration method, with a focus on deriving local upper bound estimates for weak solutions. On the basis of Theorems $1 \& 2$, we proceed to present the Hölder continuity of component $n$ through the proof of Theorem 3 in the remaining part of Section 2, and then utilize Section 3 to build an initial-independent $L^{\infty}$-bound of $n$ as exhibited in Theorem 4. The former can help us to improve the regularity of solutions to models involving the $p$-Laplace operator, while the latter can be used to determine asymptotic stability of solutions.

To better illustrate the role of our results in obtaining asymptotic stability and enhancing regularity for chemotaxis systems, Section 4 is devoted to providing four examples that discuss the long-time behaviors or regularity of solutions, respectively. To highlight the broad applicability of our conclusions, we have selected models from different categories in these examples, which concern chemotaxis models with nonlinear signal production, quasilinear chemotaxis-Navier-Stokes models, p-Laplacian chemotaxis-consumption models, and chemotaxis-hypotaxis models. Certainly, the applications of our theorems obtained here are not limited to the aforementioned models, but due to space constraints, only a few examples are provided in detail here.

## 2 Boundedness and Hölder continuity

Lemma 2.1 (Caccioppoli inequality). Let ( $n, c$ ) with $n \geq 0$ in $Q_{T}$ be a weak solution to (1.1) under the conditions (1.4)-(1.7). Then we can find a pure constant $C=C$ (data) $>0$ such that for any cut-off function $\eta \in C_{0}^{\infty}((0, T))$, if there holds that $\nabla c \in L^{\infty}(\Omega \times \operatorname{supp} \eta)$, then the following inequality

$$
\begin{align*}
& \quad \sup _{t \in(0, T)} \int_{\Omega}(n(x, t)-k)_{+}^{2+\alpha_{-}} \eta(t) d x+\int_{0}^{T} \int_{\Omega}\left|\nabla(n-k)_{+}\right|^{p}(n+1)^{-\alpha_{-}}(n-k)_{+}^{\alpha_{-}} \eta d x d \tau \\
& \leq \\
& C \int_{0}^{T} \int_{A^{+}(k, \tau)}(n-k)_{+}^{2+\alpha_{-}} \eta_{t}(\tau) d x d \tau+C\|\nabla c\|_{L^{\infty}(\Omega \times \operatorname{supp} \eta)}^{\frac{p}{p-1}} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n+1)^{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}} \eta d x d \tau  \tag{2.1}\\
& \quad+C \int_{0}^{T} \int_{\Omega} f(n, x, \tau)(n-k)_{+}^{1+\alpha_{-}} \eta d x d \tau
\end{align*}
$$

is valid for every level $k>1$.
Proof. Case $\alpha \geq 0$. In the weak formulation (1.16) take the testing functions,

$$
\varphi(\cdot, t)=\eta(t)\left(n_{h}(\cdot, t)-k\right)_{+}, \quad t \in(0, T)
$$

where $n_{h}$ is the Steklov average of $n$ given by

$$
n_{h}(\cdot, t) \equiv \begin{cases}\frac{1}{h} \int_{t}^{t+h} n(\cdot, \tau) d \tau, & t \in(0, T-h]  \tag{2.2}\\ 0, & t>T-h\end{cases}
$$

Through the arguments as proceeded in [5, Proposition 3.1, Chapter II], we let $h \rightarrow 0$ and hence derive that for any $t \in(0, T)$,

$$
\begin{aligned}
& \sup _{t \in(0, T)} \int_{\Omega}(n(x, t)-k)_{+}^{2} \eta(t) d x+\int_{0}^{T} \int_{\Omega} a(\nabla n, n, x, \tau) \nabla n \cdot \nabla(n-k)_{+} \eta(\tau) d x d \tau \\
\leq & \int_{0}^{T} \int_{\Omega}(n-k)_{+}^{2} \eta_{t}(\tau) d x d \tau+\int_{0}^{T} \int_{\Omega} b(n, x, \tau) \nabla c \cdot \nabla(n-k)_{+} \eta d x d \tau
\end{aligned}
$$

$$
\begin{equation*}
+\int_{0}^{T} \int_{\Omega} f(n, x, \tau)(n-k)_{+} \eta d x d \tau \tag{2.3}
\end{equation*}
$$

where the second integral on the left-hand side can be estimated by (1.4) as below,

$$
\begin{align*}
\int_{0}^{T} \int_{\Omega} a(\nabla n, n, x, \tau) \nabla n \cdot \nabla(n-k)_{+} \eta d x d \tau & \geq a_{0} \int_{0}^{T} \int_{\Omega}\left|\nabla(n-k)_{+}\right|^{p}(n+1)^{\alpha} \eta d x d \tau \\
& \geq a_{0} \int_{0}^{T} \int_{\Omega}\left|\nabla(n-k)_{+}\right|^{p} \eta d x d \tau . \tag{2.4}
\end{align*}
$$

It follows by using (1.5) and Young's inequality that

$$
\begin{align*}
& \int_{0}^{T} \int_{\Omega} b(n, x, \tau) \nabla(n-k)_{+} \cdot \nabla c \eta d x d \tau \\
\leq & b_{0} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n+1)^{\beta}\left|\nabla(n-k)_{+}\right||\nabla c| \eta d x d \tau \\
\leq & \frac{a_{0}}{4} \int_{0}^{T} \int_{A^{+}(k, \tau)}\left|\nabla(n-k)_{+}\right|^{p} \eta d x d \tau \\
& +\left(\frac{4 b_{0}^{p}}{a_{0}}\right)^{\frac{1}{p-1}}\|\nabla c\|_{L^{\infty}(\Omega \times \operatorname{supp} \eta)}^{\frac{p}{p-1}} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n+1)^{\frac{p \beta}{p-1}} \eta d x d \tau . \tag{2.5}
\end{align*}
$$

A combination of (2.3)-(2.5) guarantees our claim.
Case $\alpha<0$. Utilizing reasoning as leading to (2.3), we have via the test function $\eta(t)\left(n_{h}(\cdot, t)-k\right)_{+}^{1-\alpha}$ that

$$
\begin{align*}
& \sup _{t \in(0, T)} \frac{1}{2-\alpha} \int_{\Omega}(n(x, t)-k)_{+}^{2-\alpha} \eta(t) d x+\int_{0}^{T} \int_{\Omega} a(\nabla n, n, x, \tau) \nabla n \cdot \nabla(n-k)_{+}^{1-\alpha} \eta(\tau) d x d \tau \\
\leq & \frac{1}{2-\alpha} \int_{0}^{T} \int_{\Omega}(n-k)_{+}^{2-\alpha} \eta_{t}(\tau) d x d \tau+\int_{0}^{T} \int_{\Omega} b(n, x, \tau) \nabla c \cdot \nabla(n-k)_{+}^{1-\alpha} \eta(\tau) d x d \tau \\
& +\int_{0}^{T} \int_{\Omega} f(n, x, \tau)(n-k)_{+}^{1-\alpha} \eta(\tau) d x d \tau \tag{2.6}
\end{align*}
$$

The conditions (1.4) and (1.5) imply that

$$
\begin{align*}
& \int_{0}^{T} \int_{\Omega} a(\nabla n, n, x, \tau) \nabla n \cdot \nabla(n-k)_{+}^{1-\alpha} \eta d x d \tau \\
\geq & a_{0}(1-\alpha) \int_{0}^{T} \int_{\Omega}\left|\nabla(n-k)_{+}\right|^{p}(n+1)^{\alpha}(n-k)_{+}^{-\alpha} \eta d x d \tau \tag{2.7}
\end{align*}
$$

and

$$
\begin{align*}
& \int_{0}^{T} \int_{\Omega} b(n, x, \tau) \nabla(n-k)_{+}^{1-\alpha} \cdot \nabla c \eta d x d \tau \\
\leq & b_{0}(1-\alpha) \int_{0}^{T} \int_{A^{+}(k, \tau)}(n-k)_{+}^{-\alpha}(n+1)^{\beta}\left|\nabla(n-k)_{+}\right||\nabla c| \eta d x d \tau \\
\leq & \frac{a_{0}(1-\alpha)}{4} \int_{0}^{T} \int_{A^{+}(k, \tau)}\left|\nabla(n-k)_{+}\right|^{p}(n+1)^{\alpha}(n-k)_{+}^{-\alpha} \eta d x d \tau \\
& +\left(\frac{4 b_{0}^{p}}{a_{0}}\right)^{\frac{1}{p-1}}(1-\alpha)\|\nabla c\|_{L^{\infty}(\Omega \times \operatorname{supp} \eta)}^{\frac{p}{p-1}} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n+1)^{\frac{p(\beta-\alpha)}{p-1}} \eta d x d \tau, \tag{2.8}
\end{align*}
$$

where in the last line we utilized Young's inequality. In light of (2.6), (2.7) and (2.8), we conclude that

$$
\begin{align*}
& \frac{1}{2-\alpha} \sup _{t \in(0, T)} \int_{\Omega}(n(x, t)-k)_{+}^{2-\alpha} \eta(t) d x \\
& \quad+\frac{a_{0}(1-\alpha)}{2} \int_{0}^{T} \int_{\Omega}\left|\nabla(n-k)_{+}\right|^{p}(n+1)^{\alpha}(n-k)_{+}^{-\alpha} \eta d x d \tau \\
& \leq(1-\alpha)\left(\frac{4 b_{0}^{p}}{a_{0}}\right)^{\frac{1}{p-1}}\|\nabla c\|_{L^{\infty}(\Omega \times \operatorname{supp} \eta)}^{\frac{p}{p-1}} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n+1)^{\frac{p}{p-1}(\beta-\alpha)} \eta d x d \tau \\
& \quad+\int_{0}^{T} \int_{\Omega} f(n, x, \tau)(n-k)_{+}^{1-\alpha} \eta d x d \tau+\frac{1}{2-\alpha} \int_{0}^{T} \int_{A^{+}(k, \tau)}(n-k)_{+}^{2} \eta_{t}(\tau) d x d \tau \tag{2.9}
\end{align*}
$$

as expected.
With recalling the definition of $K_{f}$ in (1.8), we select $k_{0} \geq K_{f}$ and choose sequences of increasing levels as

$$
\begin{equation*}
k_{j}:=\left(2-2^{-j}\right) k_{0}, \quad \tilde{k}_{j}:=\frac{k_{j+1}+k_{j}}{2}, \quad j=0,1,2, \ldots \tag{2.10}
\end{equation*}
$$

Assume that $t_{0} \in(0, T)$ and $\hat{t} \in(0, T)$ are given as in Theorem 1 or Theorem 2, and let $\hat{\tau} \in(0, \hat{t})$ and $\sigma \in(0,1)$ be specified later. We set the intervals as

$$
\begin{equation*}
\Gamma_{j}:=\left(t_{0}-\sigma \hat{\tau}-2^{-j}(1-\sigma) \hat{\tau}, t_{0}\right), \quad j=0,1,2, \cdots \tag{2.11}
\end{equation*}
$$

The relation $\Gamma_{j+1} \subseteq \Gamma_{j}$ clearly holds for all $j \in \mathbb{N}$. Let $\eta_{j} \in C_{0}^{\infty}((0, T))$ be the cut-off function w.r.t the time interval $\Gamma_{j}$ and satisfy

$$
\operatorname{supp} \eta_{j} \subseteq \Gamma_{j}, \quad\left|\eta_{j}^{\prime}\right| \leq \frac{C 2^{j}}{(1-\sigma) \hat{\tau}} \text { in } \Gamma_{j}, \quad 0 \leq \eta_{j} \leq 1 \text { in } \Gamma_{j} \text { and } \eta_{j}=1 \text { in } \Gamma_{j+1}
$$

Lemma 2.2. Let $(n, c)$ with $n \geq 0$ in $Q_{T}$ be a weak solution of (1.1) under the conditions (1.4)-(1.7). Let $r$ be a number satisfying

$$
r>\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}, p\right\}
$$

Assume that $n \in L^{r}\left(\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)\right)$ and $\nabla c \in L^{\infty}\left(\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)\right)$. Then we can find a pure constant $C=C$ (data) $>0$ such that for every level $k_{j} \geq K_{f}$, the following inequality is valid

$$
\begin{align*}
& \sup _{t \in \Gamma_{j+1}} \int_{\Omega} w_{j+1}^{2+\alpha-\alpha}(\cdot, \tau) d x+\int_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j+1}\right|^{p} d x d \tau+\int_{\Gamma_{j+1}} \int_{\Omega} w_{j+1}^{p} d x d \tau \\
\leq & \frac{C 4^{\left(r+\alpha_{-}\right) j}\|\nabla c\|_{L^{\infty}\left(\Omega \times\left(t_{0}-\hat{t}, t_{0}\right)\right)}^{\frac{p}{p-1}}}{k_{0}^{r-\frac{p(\beta+\alpha-)}{p-1}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau+\frac{C 2^{\left(r+\alpha_{-}\right) j}}{(1-\sigma) \hat{\tau} k_{0}^{r-2-\alpha_{-}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \\
& +\frac{C 2^{\left(r+\alpha_{-}\right) j}}{k_{0}^{r-p}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.12}
\end{align*}
$$

where $\Gamma_{j}$ is defined in (2.11) and $w_{j}=\left(n-k_{j}\right)_{+}$.

Proof. Case $\alpha \geq 0$. It is not hard to verify that for all $\ell \geq m \geq 0$ and $j \in \mathbb{N}^{+}$,

$$
\begin{align*}
w_{j-1}^{\ell} & \geq\left(n-k_{j-1}\right)_{+}^{\ell} \chi_{\left\{n \geq k_{j}\right\}}(x, t) \\
& \geq\left(k_{j}-k_{j-1}\right)^{\ell-m}\left(n-k_{j-1}\right)_{+}^{m} \chi_{\left\{n \geq k_{j}\right\}}(x, t) \\
& \geq k_{0}^{\ell-m} 2^{-(\ell-m)(j+1)}\left(n-k_{j-1}\right)_{+}^{m} \chi_{\left\{n \geq k_{j}\right\}}(x, t)  \tag{2.13}\\
& \geq k_{0}^{\ell-m} 2^{-(\ell-m)(j+1)} w_{j}^{m} \chi_{\left\{n \geq k_{j}\right\}}(x, t) \quad \text { in } Q_{T} . \tag{2.14}
\end{align*}
$$

By invoking Lemma 2.1 and noticing (1.8) and $k_{j} \geq K_{f}$, we have

$$
\begin{align*}
& \sup _{\tau \in \Gamma_{j}} \int_{\Omega} w_{j}^{2} \eta_{j}(\tau) d x+a_{0} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)}\left|\nabla w_{j}\right|^{p} \eta_{j} d x d \tau \\
\leq & \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau+C\|\nabla c\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{p-1} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)}(n+1)^{\frac{p \beta}{p-1}} \eta_{j} d x d \tau \\
\leq & \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau+C\|\nabla c\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{\frac{p}{p-1}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} n^{\frac{p \beta}{p-1}} \eta_{j} d x d \tau \\
& +C\|\nabla C\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{\frac{p}{p-1}} \int_{\Gamma_{j}}\left|A^{+}\left(k_{j}, \tau\right)\right| d \tau, \tag{2.15}
\end{align*}
$$

where the first term on the right-hand side can be estimated by (2.14) as below,

$$
\begin{equation*}
\int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau \leq \frac{C 2^{r j}}{(1-\sigma) \hat{\tau}_{0}^{r-2}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.16}
\end{equation*}
$$

Similarly, we also have

$$
\begin{equation*}
\int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{p} d x d \tau \leq \frac{2^{r(j+1)}}{k_{0}^{r-p}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau . \tag{2.17}
\end{equation*}
$$

By virtue of (2.13), there holds that

$$
\begin{equation*}
\int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \geq \frac{k_{0}^{r}}{2^{r(j+1)}} \int_{\Gamma_{j}}\left|A^{+}\left(k_{j}, \tau\right)\right| d \tau, \tag{2.18}
\end{equation*}
$$

and

$$
\begin{align*}
\int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau & \geq \frac{C k_{0}^{r-\frac{p \beta}{p-1}}}{2^{\left(r-\frac{p \beta}{p-1}\right) j}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j-1}^{\frac{p \beta}{p-1}} d x d \tau \\
& \geq \frac{C k_{0}^{r-\frac{p \beta}{p-1}}}{2^{\left(r-\frac{p \beta}{p-1}\right) j}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} n^{\frac{p \beta}{p-1}}\left(1-\frac{k_{j-1}}{k_{j}}\right)^{\frac{p \beta}{p-1}} d x d \tau \\
& \geq \frac{C k_{0}^{r-\frac{p \beta}{p-1}}}{2^{r(j+1)}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} n^{\frac{p \beta}{p-1}} d x d \tau . \tag{2.19}
\end{align*}
$$

We substitute (2.16)-(2.19) into (2.15) to derive that

$$
\begin{aligned}
& \sup _{t \in \Gamma_{j+1}} \int_{\Omega} w_{j}^{2} d x+\int_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j}\right|^{p} d x d \tau+\int_{\Gamma_{j+1}} \int_{\Omega} w_{j}^{p} d x d \tau \\
\leq & \frac{C 2^{r j}\|\nabla c\|_{L \infty}^{\frac{p}{p-1}\left(\Omega \times\left(t_{0}, T\right)\right)}}{k_{0}^{r-\frac{p \beta}{p-1}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau+\frac{C 2^{r j}}{(1-\sigma) \hat{\tau} k_{0}^{r-2}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau
\end{aligned}
$$

$$
\begin{equation*}
+\frac{C 2^{r j}}{k_{0}^{r-p}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.20}
\end{equation*}
$$

Case $\alpha<0$. By employing Lemma 2.1 again, we have that

$$
\begin{align*}
& \sup _{t \in \Gamma_{j}} \int_{\Omega} w_{j}^{2-\alpha} \eta_{j}(\tau) d x+\int_{\Gamma_{j}} \int_{\Omega}\left|\nabla w_{j}\right|^{p}(n+1)^{\alpha} w_{j}^{-\alpha} \eta_{j} d x d \tau \\
& \leq \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2-\alpha}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau+C\|\nabla c\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{\frac{p}{p-1}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)}(n+1)^{\frac{p(\beta+\alpha-)}{p-1}} \eta_{j} d x d \tau \\
& \leq \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2-\alpha}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau+C\|\nabla c\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{\frac{p}{p-1}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} n^{\frac{p(\beta+\alpha-)}{p-1}} \eta_{j} d x d \tau \\
& \quad+C\|\nabla c\|_{L^{\infty}\left(\Omega \times \Gamma_{0}\right)}^{\frac{p}{p-1}} \int_{\Gamma_{j}}\left|A^{+}\left(k_{j}, \tau\right)\right| d \tau . \tag{2.21}
\end{align*}
$$

Noticing the monotonicity of the function $f_{j}(x):=\left(x-k_{j}\right)^{-\alpha}(x+1)^{\alpha}$ defined on $\left(k_{j}, \infty\right)$, we obtain that

$$
\begin{align*}
\int_{\Gamma_{j}} \int_{\Omega}\left|\nabla w_{j}\right|^{p}(n+1)^{\alpha} w_{j}^{-\alpha} \eta_{j} d x d \tau & \geq \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j+1}, \tau\right)}\left|\nabla w_{j}\right|^{p}\left(k_{j+1}+1\right)^{\alpha}\left(k_{j+1}-k_{j}\right)_{+}^{-\alpha} \eta_{j} d x d \tau \\
& =\frac{k_{0}^{-\alpha}}{\left(k_{0}+2^{j+1}\right)^{-\alpha}} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j+1}, \tau\right)}\left|\nabla w_{j}\right|^{p} \eta_{j} d x d \tau \\
& \geq 2^{(j+2) \alpha} \int_{\Gamma_{j}} \int_{A^{+}\left(k_{j+1}, \tau\right)}\left|\nabla w_{j}\right|^{p} \eta_{j} d x d \tau \\
& \geq 2^{(j+2) \alpha} \int_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j+1}\right|^{p} d x d \tau \tag{2.22}
\end{align*}
$$

By utilizing the similar arguments as leading to (2.16) and (2.19), we obtain

$$
\begin{equation*}
\int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} w_{j}^{2-\alpha}\left|\eta_{j}^{\prime}(\tau)\right| d x d \tau \leq \frac{C 2^{r j}}{(1-\sigma) \hat{\tau} k_{0}^{r-2+\alpha}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.23}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{\Gamma_{j}} \int_{A^{+}\left(k_{j}, \tau\right)} n^{\frac{p(\beta+\alpha-)}{p-1}} d x d \tau \leq \frac{2^{r(j+1)}}{k_{0}^{r-\frac{p(\beta-\alpha)}{p-1}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.24}
\end{equation*}
$$

A combination of (2.21)-(2.24), (2.17) and (2.18) implies that

$$
\begin{align*}
& \sup _{t \in \Gamma_{j+1}} \int_{\Omega} w_{j+1}^{2-\alpha}(\cdot, \tau) d x+\int_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j+1}\right|^{p} d x d \tau+\int_{\Gamma_{j+1}} \int_{\Omega} w_{j+1}^{p} d x d \tau \\
\leq & \frac{C 2^{(r-\alpha) j}\|\nabla c\|_{L^{\infty}\left(\Omega \times\left(t_{0}, T\right)\right)}^{\frac{p}{p-1}}}{k_{0}^{r-\frac{p(\beta+\alpha-)}{p-1}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau+\frac{C 2^{(r-\alpha) j}}{(1-\sigma) \hat{\tau} k_{0}^{r-2-\alpha_{-}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \\
& +\frac{C 2^{(r-\alpha) j}}{k_{0}^{r-p}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \tag{2.25}
\end{align*}
$$

This together with (2.20) allows us to arrive at the claim immediately.
The following inequality can be obtained by an application of the Hölder inequality and Sobolev embedding inequality, as proved in [5, Chapter I, Proposition 3.1] and [18, Lemma 2.1].

Lemma 2.3. Let $T>0, m \geq 1, p \geq 1$ and $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with Lipschitz boundary. There exists a constant $C$ depending only upon $N, p, m$ and the structure of $\partial \Omega$ such that any $\varphi \in L^{\infty}\left(0, T ; L^{m}(\Omega)\right) \cap L^{p}\left(0, T ; W^{1, p}(\Omega)\right)$ satisfies

$$
\int_{Q_{T}}|\varphi(x, t)|^{\frac{p(N+m)}{N}} d x d t \leq C\left(\int_{Q_{T}}|\nabla \varphi(x, t)|^{p}+|\varphi(x, t)|^{p} d x d t\right)\left(\underset{0<t<T}{\operatorname{ess} \sup } \int_{\Omega}|\varphi(x, t)|^{m} d x\right)^{\frac{p}{N}} .
$$

Lemma 2.4 (Lemma 4.1, [5]). Let $\left\{Y_{j}\right\}_{j \in \mathbb{N}}$ be a sequence of positive numbers, satisfying the recursive inequalities

$$
Y_{j+1} \leq K b^{j} Y_{j}^{1+\delta}, \quad j=0,1,2, \ldots
$$

where $K, b>1$ and $\delta>0$ are given numbers. If

$$
Y_{0} \leq K^{-\frac{1}{\delta}} b^{-\frac{1}{\delta^{2}}}
$$

then $Y_{j}$ converges to zero as $j \rightarrow \infty$.
Proof of Theorem 1. Let the assumptions (1.4)-(1.7) be satisfied as well as (1.19) and $(n, c)$ with $n \geq 0$ in $Q_{T}$ be a weak solution to the model (1.1) in the sense of Definition 1.1. Set

$$
r:=\frac{p\left(N+2+\alpha_{-}\right)}{N}
$$

By (1.18), we further define

$$
\hat{\theta}:=r-\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}, p\right\}>0
$$

Invoking Lemma 2.2 with taking $\sigma=1 / 2$ and $\hat{\tau}=\hat{t}$, and recalling the definition of $\mathfrak{b}$, one sees that

$$
\begin{align*}
& \sup _{t \in \Gamma_{j+1}} \int_{\Omega} w_{j+1}^{2+\alpha-}(\cdot, t) d x+\int_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j+1}\right|^{p} d x d \tau+\int_{\Gamma_{j+1}} \int_{\Omega} w_{j+1}^{p} d x d \tau \\
\leq & \frac{C 2^{r j} \mathfrak{b} \frac{p}{p-1}}{k_{0}^{r-\frac{p(\beta+\alpha-)}{p-1}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau+\frac{C 2^{r j}}{\hat{t} k_{0}^{r-2-\alpha_{-}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau+\frac{C 2^{r j}}{k_{0}^{r-p}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau \\
\leq & C\left(1+\frac{1}{\hat{t}}\right) \frac{2^{r j} \mathfrak{b} \frac{p}{p-1}}{k_{0}^{\hat{\theta}}} \int_{\Gamma_{j}} \int_{\Omega} w_{j-1}^{r} d x d \tau, \tag{2.26}
\end{align*}
$$

where the condition $k_{0} \geq 1$ is employed in the last line. According to Lemma 2.3 applied to the function $w_{j+1}$,

$$
f_{\Gamma_{j+1}} \int_{\Omega} w_{j+1}^{\frac{p\left(N+2+\alpha_{-}\right)}{N}} d x d \tau \leq C\left(f_{\Gamma_{j+1}} \int_{\Omega}\left|\nabla w_{j+1}\right|^{p}+w_{i+1}^{p} d x d \tau\right)\left(\underset{t \in \Gamma_{j+1}}{\operatorname{ess} \sup _{\Omega}} \int_{\Omega} w_{j+1}^{2+\alpha_{-}} d x\right)^{\frac{p}{N}}
$$

which combining with (2.26) yields that

$$
\begin{equation*}
f_{\Gamma_{j+1}} \int_{\Omega} w_{j+1}^{\frac{p\left(N+2+\alpha_{-}\right)}{N}} d x d \tau \leq C\left(1+\frac{1}{\hat{t}}\right)^{\frac{p+N}{N}} \hat{t}^{\frac{p}{N}} \frac{2^{\frac{j r(p+N)}{N}} \mathfrak{b}^{\frac{p+N}{N} \cdot \frac{p}{p-1}}}{k_{0}^{\frac{(p+N) \hat{\theta}}{N}}}\left(f_{\Gamma_{j-1}} \int_{\Omega} w_{j-1}^{r} d x d \tau\right)^{\frac{p+N}{N}} \tag{2.27}
\end{equation*}
$$

Now, let us define the quantity $Y_{j}$ as below,

$$
Y_{j}:=f_{\Gamma_{2 j}} \int_{\Omega} w_{2 j}^{\frac{p\left(N+2+\alpha_{-}\right)}{N}} d x d \tau=\int_{\Gamma_{2 j}} \int_{\Omega} w_{2 j}^{r} d x d \tau, \quad j=0,1,2 \ldots
$$

The estimate (2.27) directly gives a pure constant $\bar{C}=\bar{C}$ (data) $>0$ such that

$$
\begin{align*}
Y_{j} & \leq \bar{C}\left(1+\frac{1}{\hat{t}}\right)^{\frac{p+N}{N}} \hat{t}^{\frac{n}{N}} \frac{4^{\frac{j r(p+N)}{N}} \mathfrak{b}^{\frac{p(p+N)}{N(p-1)}}}{k_{0}^{\frac{(p+N) \hat{\theta}}{p}}}\left(f_{\Gamma_{2 j-2}} \int_{\Omega} w_{2 j-2}^{r} d x d \tau\right)^{\frac{p+N}{N}} \\
& \leq \bar{C}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{N}} \frac{4 \frac{j r(p+N)}{N} \mathfrak{b}^{\frac{p p+N)}{N(p-1)}}}{k_{0}^{\frac{(p+N) \hat{\theta}}{N}}} Y_{j-1}^{1+\frac{p}{N}}, \quad j=1,2,3 \ldots \tag{2.28}
\end{align*}
$$

If $Y_{0}$ satisfies the estimate

$$
\begin{equation*}
Y_{0}=f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega}\left(n-k_{0}\right)_{+}^{\frac{p(N+2+\alpha-)}{N}} d x d \tau \leq(2 \bar{C})^{-\frac{N}{p}} 4^{-\frac{r(p+N) N}{p^{2}}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{-1} \mathfrak{b}^{-\frac{N+p}{p-1}} k_{0}^{\frac{\hat{\theta}(p+N)}{p}}, \tag{2.29}
\end{equation*}
$$

then we can derive by invoking Lemma 2.4 that $Y_{j} \rightarrow 0$ as $j \rightarrow \infty$. Hence, we select

$$
k_{0} \geq \max \left\{K_{f},(2 \bar{C})^{\frac{N}{\theta(p+N)}} 4^{\frac{N r}{\theta_{p}}} \mathfrak{b}^{\frac{p}{\theta(p-1)}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\theta(p+N)}}\left(f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega} n^{\frac{p(N+2+\alpha-)}{N}} d x d \tau\right)^{\frac{p}{\theta(p+N)}}\right\}
$$

to ensure that

$$
\operatorname{ess}_{\Omega \times\left(t_{0}-\hat{t} / 2, t_{0}\right)} n(\cdot, t) \leq C \mathfrak{b}^{\frac{p}{\overline{(p-1)}}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\hat{\theta}(p+N)}}\left(f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega} n^{\frac{p(N+2+\alpha-)}{N}} d x d \tau\right)^{\frac{p}{\theta(p+N)}}+K_{f},
$$

as desired.

Proof of Theorem 2. Let the assumptions (1.11)-(1.7) as well as (1.22) be satisfied and ( $n, c$ ) with $n \geq 0$ in $Q_{T}$ be a weak solution of (1.1). With defining $T_{0}=\hat{t} / 2, T_{i}=\hat{t} / 2+\sum_{k=1}^{i} 2^{-k-1} \hat{t}\left(i \in \mathbb{N}^{+}\right)$ and

$$
\hat{\Gamma}_{i}=\left(t_{0}-T_{i}, t_{0}\right), \quad i=1,2,3, \cdots,
$$

we choose $\hat{\tau}=T_{i+1}$ and $\sigma \hat{\tau}=T_{i}$ in (2.11), and thereby find a sequence of time interval $\left\{\Gamma_{j}\right\}_{j=0}^{+\infty}$

$$
\Gamma_{j}:=\Gamma_{j}^{(i)}=\left(t_{0}-T_{i}-2^{-j}\left(T_{i+1}-T_{i}\right), t_{0}\right), \quad j=0,1,2, \cdots .
$$

Clearly, it can be checked that

$$
1-\sigma=\frac{2^{-i-2}}{1 / 2+\sum_{k=1}^{i+1} 2^{-k-1}} \geq 2^{-i-2}
$$

and

$$
\hat{\Gamma}_{i} \subseteq \ldots \Gamma_{j+1} \subseteq \Gamma_{j} \subseteq \ldots \subseteq \Gamma_{1} \subseteq \Gamma_{0}=\hat{\Gamma}_{i+1} \subseteq\left(t_{0}-\hat{t}, t_{0}\right) .
$$

Then, we select some

$$
r>\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}, \frac{N\left(2+\alpha_{-}\right)}{p}-N, \frac{(p+N)\left(\beta+\alpha_{-}\right)}{p(p-1)}-N-2-\alpha_{-}\right\}
$$

and still, let

$$
\hat{\theta}:=r-\max \left\{\frac{p\left(\beta+\alpha_{-}\right)}{p-1}, 2+\alpha_{-}\right\}>0
$$

The choice of $r$ guarantees with (1.21) that

$$
m:=\frac{N r-p\left(N+2+\alpha_{-}\right)}{\hat{\theta}(p+N)} \in(0,1)
$$

Now let us define the quantity $Y_{j}$ as below,

$$
Y_{j}:=f_{\Gamma_{2 j}} \int_{\Omega} w_{2 j}^{r} d x d \tau, \quad j=0,1,2, \cdots
$$

and

$$
M_{i}=\underset{\Omega \times \hat{\Gamma}_{i}}{\operatorname{ess} \sup } n, \quad i=0,1,2, \cdots
$$

Thus, recalling the definition of $\mathfrak{b}$ and utilizing Lemmas 2.2-2.3, there holds that

$$
\begin{align*}
Y_{j} & \leq\left\|w_{2 j}\right\|_{\left.L^{\infty}-\frac{p\left(N+2+\alpha_{-}\right)}{N} \Gamma_{2 j}\right)}^{f} f_{\Gamma_{2 j}} \int_{\Omega} w_{2 j}^{\frac{p\left(N+2+\alpha_{-}\right)}{N}} d x d \tau \\
& \leq C\left\|w_{2 j}\right\|_{L^{\infty}\left(\Omega \times \frac{p\left(N+2+\alpha_{-}\right)}{N}\right.}^{\left.r \Gamma_{i+1}\right)}\left(f_{\Gamma_{2 j}} \int_{\Omega}\left|\nabla w_{2 j}\right|^{p}+w_{2 j}^{p} d x d \tau\right)\left(\sup _{t \in \Gamma_{2 j}} \int_{\Omega} w_{2 j}^{2+\alpha_{-}} d x\right)^{\frac{p}{N}} \\
& \leq C \mathfrak{b}^{\frac{p(p+N)}{N(p-1)}} 2^{\frac{(p+N) i}{N}} 4^{\frac{r(p+N) j}{N}}\left(1+\frac{1}{\hat{t}}\right)^{\frac{p+N}{N}} \hat{t}^{\frac{p}{N}} \frac{M_{i+1}^{r-\frac{p\left(N+2+\alpha_{-}\right)}{N}}}{k_{0}^{\frac{(p+N) \hat{\theta}}{N}}}\left(f_{\Gamma_{2 j-2}} \int_{\Omega} w_{2 j-2}^{r} d x d \tau\right)^{\frac{p+N}{N}} \\
& \leq \bar{C}^{\frac{p(p+N)}{N(p-1)}} 2^{\frac{(p+N) i}{N}} 4^{\frac{r(p+N) j}{N}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{N}} \frac{M_{i+1}^{r-\frac{p(N+2+\alpha-)}{N}}}{k_{0}^{\frac{(p+N) \hat{\theta}}{N}}} Y_{j-1}^{1+\frac{p}{N}} \tag{2.30}
\end{align*}
$$

where the pure constant $\bar{C}>0$ depends only on data. This in conjunction with Lemma 2.4 indicates that $Y_{j} \rightarrow 0$ as $j \rightarrow \infty$, provided that

$$
Y_{0} \leq \bar{C}^{-\frac{N}{p}} 2^{-\frac{(p+N) i}{p}} 4^{-\frac{r(p+N) N}{p^{2}}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{-1} \mathfrak{b}^{-\frac{p+N}{p-1}} k_{0}^{\frac{\hat{\theta}(p+N)}{p}} M_{i+1}^{\frac{p\left(N+2+\alpha_{-}\right)-N r}{p}},
$$

The above inequality can be achieved by taking

$$
k_{0} \geq \max \left\{\bar{C} 2^{\frac{i}{\theta}} 4^{\frac{r N}{p^{\hat{\theta}}}} \mathfrak{b}^{\frac{p}{\theta(p-1)}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\hat{\theta}(p+N)}}\left(f_{\hat{\Gamma}_{i}} \int_{\Omega} n^{r} d x d \tau\right)^{\frac{p}{\theta(p+N)}} M_{i+1}^{\frac{N r-p\left(N+2+\alpha_{-}\right)}{\theta(p+N)}}, K_{f}\right\}
$$

With this choice of $k_{0}$ and recalling the definition of $m$, we by $Y_{j} \rightarrow 0$ have

$$
\begin{equation*}
\underset{\Omega \times \hat{\Gamma}_{i}}{\operatorname{esss} \sup } n \leq C 2^{\frac{i}{\hat{\theta}} \mathfrak{b}^{\frac{p}{\hat{\theta}(p-1)}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\hat{\theta}(p+N)}}\left(f_{\hat{\Gamma}_{i}} \int_{\Omega} n^{r} d x d \tau\right)^{\frac{p}{\hat{\theta}(p+N)}} M_{i+1}^{m}+K_{f} . . . . . .} \tag{2.31}
\end{equation*}
$$

An application of Young's inequality to (2.31) implies that for $i=0,1,2, \cdots$,

$$
M_{i} \leq \eta M_{i+1}+C 2^{\frac{i}{\hat{\theta}(1-m)}} \mathfrak{b} \frac{p}{\hat{\theta}(p-1)(1-m)}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\theta(p+N)(1-m)}} \eta^{-\frac{m}{1-m}}\left(f_{\hat{\Gamma}_{i}} \int_{\Omega} n^{r} d x d \tau\right)^{\frac{p}{\hat{\theta}(p+N)(1-m)}}+K_{f}
$$

By using an iteration argument, we get

$$
\begin{align*}
M_{0} \leq & \eta^{i+1} M_{i+1}+C 6^{\frac{p}{\theta(p-1)(1-m)}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\hat{\theta}(p+N)(1-m)}} \eta^{-\frac{m}{1-m}}\left(f_{\hat{\Gamma}_{0}} \int_{\Omega} n^{r} d x d \tau\right)^{\frac{p}{\hat{\theta}(p+N)(1-m)}} \\
& \times \sum_{k=0}^{i}\left(2^{\frac{1}{\theta(1-m)}} \eta\right)^{k}+K_{f} \sum_{k=0}^{i} \eta^{k}, \quad i=0,1,2, \ldots \tag{2.32}
\end{align*}
$$

We choose $\eta=1 /\left(2^{\frac{1}{\theta(1-m)}}+1\right)$ to deduce that the sum on the right-hand side can be majored by a convergent series, and then take $i \rightarrow \infty$ to obtain

$$
\begin{equation*}
\operatorname{ess}_{\Omega \times\left(t_{0}-\hat{t} / 2, t_{0}\right)} n \leq C \mathfrak{b}^{\frac{p}{\hat{\theta}(p-1)(1-m)}}\left(\hat{t}+\frac{1}{\hat{t}^{\frac{N}{p}}}\right)^{\frac{p}{\hat{\theta}(p+N)(1-m)}}\left(f_{t_{0}-\hat{t}}^{t_{0}} \int_{\Omega} n^{r} d x d \tau\right)^{\frac{p}{\theta(p+N)(1-m)}}+K_{f} . \tag{2.33}
\end{equation*}
$$

This ends the proof.

Proof of Theorem 3. Let us denote

$$
\overline{\mathbf{a}}(\xi, s, x, t):=a(\xi, s, x, t) \xi-b(s, x, t) \nabla c-\tau n \mathbf{u}, \quad \xi \in \mathbb{R}^{N}, s \geq 0, x \in \bar{\Omega}, t>0
$$

and

$$
\bar{f}(x, t):=f(n(x, t), x, t), \quad x \in \Omega, t>0
$$

Under this setting, $(1.1)_{1}$ with the boundary condition $(1.1)_{3}$ turns to be

$$
\begin{cases}n_{t}=\nabla \cdot \overline{\mathbf{a}}(\nabla n, n, x, t)+\bar{f}(x, t), & x \in \Omega, t>0 \\ \overline{\mathbf{a}}(\nabla n, n, x, t) \cdot \nu=0, & x \in \partial \Omega, t>0\end{cases}
$$

Based on the boundedness results established in Theorems $1 \& 2$, it is easy to verify that $\overline{\mathbf{a}}$ satisfies

$$
\begin{array}{cl}
\overline{\mathbf{a}}(\nabla n, n, x, t) \cdot \nabla n \geq a_{1}|\nabla n|^{p}-a_{2}, & x \in \Omega, t>0 \\
|\overline{\mathbf{a}}(\nabla n, n, x, t)| \leq a_{3}|\nabla n|^{p-1}+a_{4}, & x \in \Omega, t>0
\end{array}
$$

and

$$
|\bar{f}(x, t)| \leq a_{5}, \quad x \in \Omega, t>0
$$

with $a_{i}>0(i=1,2,3,4,5)$. According to [5, Theorem 1.3, Chapter IV\& Theorem 1.3, Chapter III] and [18, Lemma 2.3], we can directly claim that $n$ is Hölder continuous in $\bar{\Omega} \times\left(t_{0}, \hat{T}\right]$ for any $t_{0}, \hat{T} \in$ $(0, T)$ satisfying $t_{0}<\hat{T}$. More specifically, for every pair of points $\left(x_{1}, t_{1}\right),\left(x_{2}, t_{2}\right) \in \bar{\Omega} \times\left[t_{0}+\varepsilon, \hat{T}\right]$,

$$
\left|n\left(x_{1}, t_{1}\right)-n\left(x_{2}, t_{2}\right)\right| \leq C\left(\left|x_{1}-x_{2}\right|+\left|t_{1}-t_{2}\right|^{\frac{1}{p}}\right)^{\gamma}
$$

The constants $C>1$ and $\gamma \in(0,1)$ depend only upon $t_{0},\|n\|_{L^{\infty}\left(\Omega \times\left(t_{0}, \hat{T}\right)\right)}, a_{i}(1 \leq i \leq 5)$ and the structure of $\partial \Omega$.

Furthermore, we apply the regularity results established for degenerate parabolic equations, e.g., [5, Theorem 1.1', Chapter IX], [5, Theorem 5.1, Chapter VIII] and [7, Proposition 4.1] to obtain the Hölder continuity of $\nabla n$ for the case of $p>2$. When $p=2$, the global continuity of $\nabla n$ can be found in [18, Theorem 1].

## 3 An upper bound independent of initial data

This section is dedicated to building an upper bound of $n$ independent of initial data. We let $\mathcal{L}_{q}$ denote the operator $-\Delta+1$ under homogenous Neumann boundary condition, that is, the sectorial operator is defined by

$$
\mathcal{L}_{q} \varphi:=-\Delta \varphi+\varphi \quad \text { for } \varphi \in D\left(\mathcal{L}_{q}\right):=\left\{\varphi \in W^{2, q}(\Omega): \partial_{\nu} \varphi=0 \text { on } \partial \Omega\right\} .
$$

Then it is known from [11, 15] that $\mathcal{L}$ possesses closed fractional powers $\mathcal{L}_{q}^{\gamma}(\gamma>0)$, which is a self-joint operator defined on the domain $D\left(\mathcal{L}_{q}^{\gamma}\right)$.

Lemma 3.1. (i) [15, page 56] Let $\gamma \in(0,1)$ and $1 \leq q<\ell \leq \infty$. The analytic semigroup $\left\{e^{-t \mathcal{L}}\right\}_{t \geq 0}$ (which is independent of $q$ in the sense that $e^{-t \mathcal{L}_{q}} \varphi=e^{-t \mathcal{L}_{\ell}} \varphi$ whenever $\varphi \in L^{\ell}(\Omega) \cap L^{q}(\Omega)$ ) satisfies that

$$
\left\|\mathcal{L}^{\gamma} e^{-t \mathcal{L}} \varphi\right\|_{L^{\ell}(\Omega)} \leq C t^{-\gamma-\frac{N}{2}\left(\frac{1}{q}-\frac{1}{\ell}\right)} e^{-\lambda t}\|\varphi\|_{L^{q}(\Omega)}, \quad \forall t>0
$$

for all $\varphi \in L^{q}(\Omega)$, and with some $\lambda>0$.
(ii) [11, Theorem II 14.1] For all $\alpha, \beta, \delta \in \mathbb{R}$ satisfying $\sigma<\gamma<\delta$, there is $C>0$ such that

$$
\left\|\mathcal{L}^{\gamma} \varphi\right\|_{L^{2}(\Omega)} \leq C\left\|\mathcal{L}^{\delta} \varphi\right\|_{L^{2}(\Omega)}^{\frac{\gamma-\sigma}{\delta-\sigma}}\left\|\mathcal{L}^{\sigma} \varphi\right\|_{L^{2}(\Omega)}^{\frac{\delta-\gamma}{\delta-\sigma}} \quad \text { for all } \varphi \in D\left(\mathcal{L}^{\delta}\right)
$$

Lemma 3.2. Let $(n, c)$ be a weak and global solution of (1.1) and $g(x, t):=g(n(x, t), x, t)$ in $\Omega \times$ $(0, \infty)$. There are pure constants $C=C($ data $)>0$ and $\kappa=\kappa$ (data) $>0$ with the property that if there holds that

$$
\begin{equation*}
\|\mathbf{u}(\cdot, t)\|_{L^{\infty}(\Omega)}<K, \quad\|g(\cdot, t)\|_{L^{m}(\Omega)} \leq K, \quad \forall t>t_{1} \tag{3.1}
\end{equation*}
$$

with some $K>1, m>N$ and $t_{1}>0$, then we can find $t_{2}>t_{1}$ such that

$$
\|\nabla c(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C K^{\kappa}+C, \quad \forall t>t_{2}
$$

Proof. Step 1. We arbitrarily select constants $\sigma \in[1 / 2,1), q, \ell>1$ such that

$$
\begin{equation*}
q<\ell, \quad \sigma+\frac{N}{2 q}-\frac{N}{2 \ell}<1, \quad \sigma+\frac{N}{2 m}-\frac{N}{2 \ell}<1 \tag{3.2}
\end{equation*}
$$

This step is used to show that if $M_{q}(\bar{s})=\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{\infty}\left((\bar{s}, \infty) ; L^{q}(\Omega)\right)}<\infty$ with some $\bar{s}>t_{1}$, then there exists a time point $\hat{s}>\bar{s}$ and a constant $C(\ell, q)>0$ depending only on $\ell, q, \sigma$ as well as $\Omega$ ensuring

$$
\begin{equation*}
\left\|\mathcal{L}^{\sigma} c(\cdot, t)\right\|_{L^{\ell}(\Omega)} \leq C(\ell, q) K+C(\ell, q) K M_{q}(\bar{s}), \quad \forall t>\hat{s} \tag{3.3}
\end{equation*}
$$

Rewriting $c$ according to the variation-of-constants formula, it follows that for any $t>\bar{s}$,

$$
\begin{align*}
\left\|\mathcal{L}^{\sigma} c(\cdot, t)\right\|_{L^{\ell}(\Omega)} \leq & \left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-\bar{s})} c(\cdot, \bar{s})\right\|_{L^{\ell}(\Omega)}+\int_{\bar{s}}^{t}\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-s)} \mathbf{u} \cdot \nabla c(\cdot, s)\right\|_{L^{\ell}(\Omega)} d s \\
& +\int_{\bar{s}}^{t}\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-s)} g(\cdot, s)\right\|_{L^{\ell}(\Omega)} d s \tag{3.4}
\end{align*}
$$

We employ Lemma 3.1 (i) to get

$$
\begin{equation*}
\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-\bar{s})} c(\cdot, \bar{s})\right\|_{L^{\ell}(\Omega)} \leq C(t-\bar{s})^{-\sigma-\frac{N}{2}\left(\frac{2}{\ell+1}-\frac{1}{\ell}\right)} e^{-\lambda(t-\bar{s})}\|c(\cdot, \bar{s})\|_{L^{\frac{\ell+1}{2}}(\Omega)}, \quad \forall t>\bar{s} \tag{3.5}
\end{equation*}
$$

This implies the existence of $\hat{s}>\bar{s}$ such that

$$
\begin{equation*}
\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-\bar{s})} c(\cdot, \bar{s})\right\|_{L^{\ell}(\Omega)} \leq K, \quad \forall t>\hat{s} \tag{3.6}
\end{equation*}
$$

Utilizing Lemma 3.1 (i) again and applying Hölder's inequality, we obtain by (3.1) that

$$
\begin{align*}
& \int_{\bar{s}}^{t}\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-s)} \mathbf{u}(\cdot, s) \cdot \nabla c(\cdot, s)\right\|_{L^{\ell}(\Omega)} d s \\
\leq & C \int_{\bar{s}}^{t}(t-s)^{-\sigma-\frac{N}{2}\left(\frac{1}{q}-\frac{1}{\ell}\right)} e^{-\lambda(t-s)}\|\mathbf{u}(\cdot, s) \cdot \nabla c(\cdot, s)\|_{L^{q}(\Omega)} d s \\
\leq & C \int_{\bar{s}}^{t}(t-s)^{-\sigma-\frac{N}{2 q}+\frac{N}{2 \ell}} e^{-\lambda(t-s)}\|\mathbf{u}(\cdot, s)\|_{L^{\infty}(\Omega)}\left\|\mathcal{L}^{\frac{1}{2}} c(\cdot, s)\right\|_{L^{q}(\Omega)} d s \\
\leq & C K M_{q}(\bar{s}) \quad \text { for any } t>\bar{s} \tag{3.7}
\end{align*}
$$

because of (3.1) and (3.2). Similarly, as above, there holds that

$$
\begin{align*}
\int_{\bar{s}}^{t}\left\|\mathcal{L}^{\sigma} e^{-\mathcal{L}(t-s)} g(\cdot, s)\right\|_{L^{\ell}(\Omega)} d s & \leq C \int_{\bar{s}}^{t}(t-s)^{-\sigma-\frac{N}{2}\left(\frac{1}{m}-\frac{1}{\ell}\right)} e^{-\lambda(t-s)}\|g(\cdot, s)\|_{L^{m}(\Omega)} d s \\
& \leq C K \quad \text { for any } t>\bar{s} \tag{3.8}
\end{align*}
$$

A combination of (3.4)-(3.8) directly leads to our desired estimate (3.3).
Step 2. By testing $(1.1)_{2}$ with $c$ and integrating by parts, we have

$$
\begin{equation*}
\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} c^{2} d x+\int_{\Omega}|\nabla c|^{2} d x+\int_{\Omega} c^{2} d x \leq \int_{\Omega} g c d x \leq \frac{1}{2} \int_{\Omega} c^{2} d x+\frac{1}{2} \int_{\Omega} g^{2} d x, \quad \forall t>0 \tag{3.9}
\end{equation*}
$$

where we used $\nabla \cdot \mathbf{u}=0$ in $\Omega \times(0, T)$ and $c_{\nu}=\mathbf{u}=0$ on $\partial \Omega \times(0, T)$. In view of (3.1), we deduce from Hölder's inequality that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} c^{2} d x+\int_{\Omega} c^{2} d x \leq K^{2}, \quad \forall t>t_{1} \tag{3.10}
\end{equation*}
$$

An argument of ODI (ordinary differential inequalities) applied to the above display ensures the existence $s_{0}>t_{1}$ such that

$$
\begin{equation*}
\|c(\cdot, t)\|_{L^{2}(\Omega)}^{2} \leq K^{2}+1, \quad \forall t>s_{0} \tag{3.11}
\end{equation*}
$$

By testing (1.1) 2 with $\mathcal{L} c$, we derive from Young's inequality that

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left|\mathcal{L}^{\frac{1}{2}} c\right|^{2} d x+\int_{\Omega}|\mathcal{L} c|^{2} d x & \leq \int_{\Omega} \mathbf{u} \cdot \nabla c \mathcal{L} c d x+\int_{\Omega} g \mathcal{L} c d x \\
& \leq \frac{1}{2}\|\mathcal{L} c\|_{L^{2}(\Omega)}^{2}+\|\mathbf{u}\|_{L^{\infty}(\Omega)}^{2}\|\nabla c\|_{L^{2}(\Omega)}^{2}+\|g\|_{L^{2}(\Omega)}^{2}, \quad \forall t>s_{0} \tag{3.12}
\end{align*}
$$

where Lemma 3.1 (ii) along with (3.11) tells that

$$
\begin{aligned}
\|\nabla c\|_{L^{2}(\Omega)}^{2} & \leq C\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{2}(\Omega)}^{2} \leq C\|\mathcal{L} c\|_{L^{2}(\Omega)}\|c\|_{L^{2}(\Omega)} \\
& \leq \frac{1}{4 K^{2}}\|\mathcal{L} c\|_{L^{2}(\Omega)}^{2}+C K^{2}\|c\|_{L^{2}(\Omega)}^{2} \leq \frac{1}{4 K^{2}}\|\mathcal{L} c\|_{L^{2}(\Omega)}^{2}+C K^{4}+C K^{2}
\end{aligned}
$$

Summarizing the two above inequalities and referring back to (3.1) result in the following estimate,

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left|\mathcal{L}^{\frac{1}{2}} c\right|^{2} d x+\frac{1}{4} \int_{\Omega}|\mathcal{L} c|^{2} d x \leq C K^{6}+C K^{4}, \quad \forall t>s_{0} \tag{3.13}
\end{equation*}
$$

By using arguments of ODI again, we can find $s_{1}>s_{0}$ fulfilling

$$
\|\nabla c(\cdot, t)\|_{L^{2}(\Omega)} \leq C K^{3}+C K^{2}, \quad \forall t>s_{1} .
$$

Step 3. In this step, we employ results obtained in the above two steps to achieve our final goal via an iterative process. Let us take $\sigma=\frac{1}{2}$ in (3.2), $q_{i}=2\left(\frac{N}{N-1}\right)^{i-1}$ and $\ell_{i}=\frac{N q_{i}}{N-1}$ with $i \in \mathbb{N}^{+}$. By verifying

$$
\frac{1}{2}+\frac{N}{2 q_{i}}-\frac{N}{2 \ell_{i}}<1, \quad \frac{1}{2}+\frac{N}{2 m}-\frac{N}{2 \ell_{i}}<1
$$

thanks to the assumption $m>N$, we can derive from (3.3) that if $M_{q_{i}}\left(s_{i}\right)<\infty$, then there exists $s_{i+1}>s_{i}$ such that

$$
\begin{equation*}
M_{q_{i+1}}\left(s_{i+1}\right)=M_{\ell_{i}}\left(s_{i+1}\right)=\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{\infty}\left(\left(s_{i+1}, \infty\right) ; L^{\ell_{i}}(\Omega)\right)}<\infty . \tag{3.14}
\end{equation*}
$$

The bound for $\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{2}(\Omega)}$ presented in Step 2 serves as the starting point for our intended iteration. This combined with (3.14) guarantees the existence of increasing sequences $\left\{s_{i}\right\}_{i \in \mathbb{N}^{+}},\left\{C_{i}\right\}_{i \in \mathbb{N}^{+}}$and $\left\{\kappa_{i}\right\}_{i \in \mathbb{N}^{+}}$ensuring

$$
\begin{equation*}
M_{q_{i}}\left(s_{i}\right)=\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{\infty}\left(\left(s_{i}, \infty\right) ; L^{q_{i}}(\Omega)\right)} \leq C_{i} K^{\kappa_{i}}+C_{i} \tag{3.15}
\end{equation*}
$$

With arbitrarily fixing $\hat{q}=2\left(\frac{N}{N-1}\right)^{i_{0}-1}>N$, we further select $\hat{\ell}>\max \{\hat{q}, m\}$ and take $\hat{\sigma} \in(0,1)$ satisfying

$$
\frac{N}{2 \hat{\ell}}+\frac{1}{2}<\hat{\sigma}<\frac{N}{2 \hat{\ell}}+1-\frac{N}{2 \min \{\hat{q}, m\}}
$$

These choices ensure that

$$
\hat{\sigma}+\frac{N}{2 \hat{q}}-\frac{N}{2 \hat{\ell}}<1, \quad \hat{\sigma}+\frac{N}{2 m}-\frac{N}{2 \hat{\ell}}<1, \quad(2 \hat{\sigma}-1) \hat{\ell}>N .
$$

Since $M_{\hat{q}}\left(s_{i_{0}}\right)=\left\|\mathcal{L}^{\frac{1}{2}} c\right\|_{L^{\infty}\left(\left(s_{i_{0}}, \infty\right) ; L^{\hat{q}}(\Omega)\right)} \leq C_{i_{0}} K^{\kappa_{i_{0}}}+C_{i_{0}}$ by virtue of (3.15), we can apply (3.3) again to conclude that

$$
\begin{equation*}
\left\|\mathcal{L}^{\sigma} c(\cdot, t)\right\|_{L^{\hat{\ell}}(\Omega)} \leq C K+C K M_{\hat{q}}\left(s_{i_{0}}\right), \quad \forall t>t_{2} \tag{3.16}
\end{equation*}
$$

with some $t_{2}>s_{i_{0}}$. This in conjunction with the embedding $D\left(\mathcal{L}_{\hat{\ell}}^{\sigma}\right) \hookrightarrow W^{1, \infty}(\Omega)$ clearly implies the desired estimate.

Proof of Theorem 4. Based on Lemma 3.2, we can directly arrive at the desired estimates by (1.20) and (1.23).

## 4 Applications

### 4.1 Asymptotic stability in chemotaxis models

Example (A) Our first example elucidates the application of Theorem 4 in investigating the largetime behaviours for a chemotaxis model involving nonlinear signal production, given as follows:

$$
\begin{cases}n_{t}=\nabla \cdot(\nabla n-n \nabla c), & x \in \Omega, t>0  \tag{4.1}\\ c_{t}=\Delta c-c+n^{\sigma}, & x \in \Omega, t>0 \\ \left.(n, c)\right|_{t=0}=\left(n_{0}, c_{0}\right), & x \in \Omega\end{cases}
$$

under the homogenous Neumann boundary condition for both components. The initial data $\left(n_{0}, c_{0}\right)$ fulfills

$$
\left\{\begin{array}{l}
n_{0} \in C^{\omega}(\bar{\Omega})(0<\omega<1), n_{0} \geq 0, n_{0} \not \equiv 0 \quad \text { on } \bar{\Omega},  \tag{4.2}\\
c_{0} \in W^{1, \infty}(\Omega), c_{0} \geq 0 \quad \text { on } \bar{\Omega} .
\end{array}\right.
$$

As a prerequisite for applying Theorem 4, we need to prove that in the model (4.1), the $L^{q_{-}}$ norm of $g(x, t)=n^{\sigma}(x, t)$ becomes independent of the initial data after some time. The proof of this part will be placed in the Appendix, and in the next proposition. We will directly utilize the result established in Lemma 5.3 to illustrate how we use Theorem 4 to achieve our final goal of determining asymptotic stability.

Proposition 4.1. Let $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with smooth boundary and $0<\sigma<2 / N$. Then there is $M_{*}>0$ only depending on $\Omega, N$ and $\sigma$ such that for any initial data $\left(n_{0}, c_{0}\right)$ satisfying (4.2) and $f_{\Omega} n_{0} d x=M<M_{*}$, (4.1) admits a classical and globally bounded solution $(n, c)$, which converges to $\left(M, M^{\sigma}\right)$ in $L^{\infty}(\Omega)$ exponentially.

Proof. We begin the proof by assuming $M_{*} \leq 1$ and observing

$$
\begin{equation*}
f_{\Omega} n(\cdot, t) d x \equiv f_{\Omega} n_{0} d x=M<M_{*}, \quad \forall t>0 \tag{4.3}
\end{equation*}
$$

Invoking Lemma 5.3 with an arbitrarily selected number $q>\frac{N}{2}$, one can find $t_{1}>0$ such that

$$
\begin{equation*}
\|n(\cdot, t)\|_{L^{q}(\Omega)} \leq C_{1}, \quad \forall t>t_{1} \tag{4.4}
\end{equation*}
$$

with $C_{1}=C_{1}(\sigma, N, \Omega)>0$. Lemma 3.1 provides a time point $t_{2}>t_{1}$ ensuring

$$
\begin{equation*}
\|\nabla c(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C_{2}, \quad \forall t>t_{2} \tag{4.5}
\end{equation*}
$$

with $C_{2}=C_{2}(\sigma, N, \Omega)>0$. An application of Theorem 4 immediately gives an upper bound of $n$ only dependent on $\sigma, N$ and $\Omega$. Having this upper bound at hand, we further exploit Theorem 3 to find a pure constant $C_{3}=C_{3}(\sigma, N, \Omega)>0$ fulfilling

$$
\begin{equation*}
\|n(\cdot, t)\|_{W^{1, \infty}(\Omega)} \leq C_{3}, \quad \forall t>t_{2} \tag{4.6}
\end{equation*}
$$

With (4.5) and (4.6) explicitly exhibiting desired estimates, we proceed in the remaining portion to demonstrate how a smallness condition and the mass conservation can ensure the asymptotic stability of the model. Testing $(4.1)_{1}$ by $n^{\hat{q}-1}$ with fixed $\hat{q}>\frac{N(1-\sigma)}{\sigma}$ and integrating by parts show that

$$
\begin{align*}
\frac{1}{\hat{q}} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} n^{\hat{q}} d x+\frac{4(\hat{q}-1)}{\hat{q}^{2}} \int_{\Omega}\left|\nabla n^{\frac{\hat{q}}{2}}\right|^{2} d x & =(\hat{q}-1) \int_{\Omega} n^{\hat{q}-1} \nabla n \cdot \nabla c d x \\
& \leq \frac{\hat{q}-1}{2} \int_{\Omega} n^{\hat{q}-2}|\nabla n|^{2} d x+\frac{\hat{q}-1}{2} \int_{\Omega} n^{\hat{q}}|\nabla c|^{2} d x, \quad \forall t>t_{2} \tag{4.7}
\end{align*}
$$

The last integral can be estimated by (4.5) as follows,

$$
\begin{equation*}
\int_{\Omega} n^{\hat{q}}|\nabla c|^{2} d x \leq C_{2}^{2} \int_{\Omega} n^{\hat{q}} d x=C_{2}^{2}\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{2}(\Omega)}^{2} \tag{4.8}
\end{equation*}
$$

Utilizing Young's inequality as well as the Gagliardo-Nirenberg inequality to govern the above display, we thereby obtain

$$
\begin{align*}
\left(C_{2}^{2}+1\right)\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{2}(\Omega)}^{2} & \leq C_{3}\left(\left\|\nabla n^{\frac{\hat{q}}{2}}\right\|_{L^{2}(\Omega)}^{\theta}\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}^{1-\theta}+\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}\right)^{2} \\
& \leq \frac{2(\hat{q}-1)}{\hat{q}^{2}} \int_{\Omega}\left|\nabla n^{\frac{\hat{q}}{2}}\right|^{2} d x+2\left(\hat{q}^{\frac{2}{\theta}} C_{3}\right)^{\frac{1}{1-\theta}}(\hat{q}-1)^{-\frac{1}{\theta(1-\theta)}}\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}^{2}+2 C_{3}\left\|n^{\frac{\hat{q}}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}^{2} \tag{4.9}
\end{align*}
$$

with $C_{3}=C_{3}(\hat{q}, N, \Omega)>0$ and

$$
\theta:=\frac{\frac{\hat{q}}{2}-\frac{1}{2}}{\frac{\hat{q}}{2}+\frac{1}{N}-\frac{1}{2}} .
$$

Thus, by taking $C_{4}=2\left(\hat{q}^{\frac{2}{\theta}} C_{3}\right)^{\frac{1}{1-\theta}}(\hat{q}-1)^{-\frac{1}{\theta(1-\theta)}}+2 C_{3}$, we have from (4.3) and (4.7)-(4.9) that

$$
\frac{1}{\hat{q}} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} n^{\hat{q}} d x+\int_{\Omega} n^{\hat{q}} d x \leq C_{4} M^{\hat{q}}, \quad \forall t>t_{2}
$$

Applying a result of ODI, we can find $t_{3}>t_{2}$ such that

$$
\int_{\Omega} n^{\hat{q}} d x \leq 2 \hat{q} C_{4} M^{\hat{q}}, \quad \forall t>t_{3}
$$

By invoking the Gagliardo-Nirenberg inequality again and using (4.6) as well as (4.3), it follows that

$$
\begin{equation*}
\|n(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C_{5}\|n(\cdot, t)\|_{W^{1}, \infty}^{\frac{N}{N+\hat{q}}}\|n(\cdot, t)\|_{L^{\hat{q}}(\Omega)}^{\frac{\hat{q}}{N+\hat{q}}}+C_{5}\|n(\cdot, t)\|_{L^{\hat{q}}(\Omega)} \leq C_{6}\left(M^{\frac{\hat{q}}{N+\hat{q}}}+M\right), \quad \forall t>t_{3} \tag{4.10}
\end{equation*}
$$

with $C_{5}=C_{5}(\hat{q}, N, \Omega)>0, C_{6}=C_{6}(\hat{q}, N, \sigma, \Omega)>0$. Multiplying (4.1) $)_{1}$ with $n-M$ and integrating by parts, we get

$$
\begin{align*}
\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega}(n-M)^{2} d x+\int_{\Omega}|\nabla n|^{2} d x & =-\int_{\Omega} n \nabla n \cdot \nabla c d x \\
& \leq \frac{1}{2} \int_{\Omega}|\nabla n|^{2} d x+\frac{1}{2} \int_{\Omega} n^{2}|\nabla c|^{2} d x, \quad \forall t>t_{3} \tag{4.11}
\end{align*}
$$

where the Poincaré inequality indicates

$$
\int_{\Omega}|\nabla n|^{2} d x \geq C_{p} \int_{\Omega}|n-M|^{2} d x
$$

To estimate the last factor in (4.11) we majorise the integrand by (4.10),

$$
\int_{\Omega} n^{2}|\nabla c|^{2} d x \leq\|n(\cdot, t)\|_{L^{\infty}(\Omega)}^{2} \int_{\Omega}|\nabla c|^{2} d x \leq 4 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{\hat{q}+N}}+M^{2}\right) \int_{\Omega}|\nabla c|^{2} d x, \quad \forall t>t_{3}
$$

We combine the above three inequalities and obtain

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}(n-M)^{2} d x+C_{p} \int_{\Omega}(n-M)^{2} d x \leq 4 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{\bar{q}+N}}+M^{2}\right) \int_{\Omega}|\nabla c|^{2} d x, \quad \forall t>t_{3} \tag{4.12}
\end{equation*}
$$

Testing (4.1) $)_{2}$ with $c-M^{\sigma}$, integrating by parts and utilizing Young's inequality, we have

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x+2 \int_{\Omega}|\nabla c|^{2} d x+\int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x \leq \int_{\Omega}\left(n^{\sigma}-M^{\sigma}\right)^{2} d x, \quad \forall t>t_{3} \tag{4.13}
\end{equation*}
$$

For the point $(\bar{x}, \bar{t}) \in \Omega \times(0, \infty)$ with $n(\bar{x}, \bar{t}) \leq \frac{M}{2}$, it can be verified that

$$
\left|n^{\sigma}-M^{\sigma}\right| \leq|n-M|^{\sigma}=|n-M|^{\sigma-1}|n-M| \leq\left(\frac{M}{2}\right)^{\sigma-1}|n-M|
$$

For the point $(\bar{x}, \bar{t}) \in \Omega \times(0, \infty)$ satisfying $n(\bar{x}, \bar{t})>\frac{M}{2}$, it follows by the mean value theorem that

$$
\left|n^{\sigma}-M^{\sigma}\right|=|\tilde{h}(n)-\tilde{h}(M)| \leq \tilde{h}^{\prime}(n-\chi n+\chi M)|n-M|
$$

for some $\theta \in(0,1)$ with $\tilde{h}(s):=s^{\sigma}$ on $\left(\frac{M}{4}, \infty\right)$. Notice the monotonic decreasing property of $\tilde{h}^{\prime}(s)=$ $\sigma s^{\sigma-1}$ and the fact $n-\theta n+\theta M>\frac{M}{2}$ ensured by $n(\bar{x}, \bar{t})>\frac{M}{2}$. We have

$$
\left|n^{\sigma}-M^{\sigma}\right| \leq \sigma\left(\frac{M}{2}\right)^{\sigma-1}|n-M| .
$$

Thus, by (4.11), there holds that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x+2 \int_{\Omega}|\nabla c|^{2} \mathrm{~d} x+\int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x \leq\left(\frac{M}{2}\right)^{2 \sigma-2} \int_{\Omega}(n-M)^{2} d x, \quad \forall t>t_{3} \tag{4.14}
\end{equation*}
$$

We derive from (4.12) and (4.14) that

$$
\begin{aligned}
& \frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\Omega}(n-M)^{2} d x+2 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{q+N}}+M^{2}\right) \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x\right) \\
& \quad+C_{p} \int_{\Omega}(n-M)^{2} d x+2 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{q+N}}+M^{2}\right) \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x \\
& \leq 2 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{q+N}}+M^{2}\right)\left(\frac{M}{2}\right)^{2 \sigma-2} \int_{\Omega}(n-M)^{2} d x, \quad \forall t>t_{3} .
\end{aligned}
$$

Since the choice $\hat{q}>\frac{N(1-\sigma)}{\sigma}$ ensures $\frac{2 \hat{q}}{\hat{q}+N}>2-2 \sigma$, we can find a positive number $M_{*} \leq 1$ such that

$$
4 C_{6}^{2}\left(M_{*}^{\frac{2 \hat{q}}{q+N}}+M_{*}^{2}\right)\left(\frac{M_{*}}{2}\right)^{2 \sigma-2} \leq \frac{C_{p}}{2}
$$

Then for any $t>t_{3}$,

$$
\begin{aligned}
& \frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\Omega}(n-M)^{2} d x+2 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{q}+N}+M\right) \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x\right) \\
& \quad+\frac{C_{p}}{4} \int_{\Omega}(n-M)^{2} d x+2 C_{6}^{2}\left(M^{\frac{2 \hat{q}}{q}+N}+M\right) \int_{\Omega}\left(c-M^{\sigma}\right)^{2} d x \leq 0
\end{aligned}
$$

provided $M \leq M_{*}$. An application of the Grönwall inequality infers

$$
\|n(\cdot, t)-M\|_{L^{2}(\Omega)}^{2}+\left\|c(\cdot, t)-M^{\sigma}\right\|_{L^{2}(\Omega)}^{2} \leq C_{6} e^{-C_{7}\left(t-t_{3}\right)}, \quad t>t_{3}
$$

with $C_{6}, C_{7}>0$ depending on $M, \sigma, \Omega, N$. Combine this with the Gagliardo-Nirenberg inequality to get

$$
\begin{align*}
\|n(\cdot, t)-M\|_{L^{\infty}(\Omega)} & \leq C_{8}\|\nabla n(\cdot, t)\|_{L^{\infty}(\Omega)}^{\frac{N}{N+2}}\|n(\cdot, t)-M\|_{L^{2}(\Omega)}^{\frac{2}{N+2}}+C_{8}\|n(\cdot, t)-M\|_{L^{2}(\Omega)} \\
& \leq C_{9}\left(e^{-\frac{C_{7}\left(t-t_{3}\right)}{N+2}}+e^{-\frac{C_{7}\left(t-t_{3}\right)}{2}}\right), \quad t>t_{3}+2 \tag{4.15}
\end{align*}
$$

with $C_{8}=C_{8}(\Omega, N), C_{9}=C_{9}(M, \sigma, \Omega, N)>0$. Carrying out the same arguments as resulting in (4.15), we also can derive

$$
\left\|c(\cdot, t)-M^{\sigma}\right\|_{L^{\infty}(\Omega)} \leq C_{10} e^{-\frac{C_{7}\left(t-t_{3}\right)}{N+2}}, \quad t>t_{3}+2
$$

for some $C_{10}=C_{10}(M, \sigma, \Omega, N)>0$. This along with (4.15) completes the proof.
Example (B) The second example is concerned with the constant equilibrium for a chemotaxis-Navier-Stokes model under the two-dimensional setting:

$$
\begin{cases}n_{t}+\mathbf{u} \cdot \nabla n=\nabla \cdot(D(n) \nabla n-S(n) \nabla c)+r n-\mu n^{1+\gamma}, & x \in \Omega, t>0  \tag{4.16}\\ c_{t}+\mathbf{u} \cdot \nabla c=\Delta c-c+n, & x \in \Omega, t>0 \\ \mathbf{u}_{t}+\mathbf{u} \cdot \nabla \mathbf{u}=\Delta \mathbf{u}+\nabla P+n \nabla \Phi, & x \in \Omega, t>0, \\ \nabla \mathbf{u}=0, & x \in \partial \Omega, t>0 \\ \left.(n, c, \mathbf{u})\right|_{t=0}=\left(n_{0}, c_{0}, \mathbf{u}_{0}\right), & x \in \Omega,\end{cases}
$$

where species density $n$ as well as nutrient concentration $c$ has no-flux boundary conditions on $\partial \Omega$, and the fluid $\mathbf{u}$ fulfills the homogenous Dirichlet condition. The initial data ( $n_{0}, c_{0}, \mathbf{u}_{0}$ ) satisfies

$$
\left\{\begin{array}{l}
n_{0} \in C^{\omega}(\bar{\Omega})(0<\omega<1), n_{0} \geq 0, n_{0} \not \equiv 0 \quad \text { on } \bar{\Omega}  \tag{4.17}\\
c_{0} \in W^{1, \infty}(\Omega), c_{0} \geq 0 \quad \text { on } \bar{\Omega} \\
\mathbf{u}_{0} \in L^{\infty}\left(\Omega ; \mathbb{R}^{2}\right) \text { and } \nabla \cdot \mathbf{u}_{0}=0 \quad \text { in } \mathcal{D}^{\prime}(\Omega)
\end{array}\right.
$$

The nonlinearities $D, S \in C^{2}([0, \infty))$ satisfy

$$
\begin{equation*}
D(n) \geq a_{0}(n+1)^{\alpha}, \quad 0 \leq S(n) \leq b_{0} n(n+1)^{\beta-1} \tag{4.18}
\end{equation*}
$$

with $\alpha, \gamma \geq 0, \beta \in \mathbb{R}$ and $a_{0}, b_{0}>0$. On basis of the energy development of $(n, c, \mathbf{u})$ as exhibited in Lemma 5.4, we use the following proposition to establish the large-time behaviours of solutions.

Proposition 4.2. Let $\Omega \subseteq \mathbb{R}^{2}$ be a bounded domain with smooth boundary and $\gamma>1$. Assume that $D$ and $S$ satisfy (4.18) with $\alpha \geq 0$ and $\beta \leq \gamma$. Then there is $\mu^{*}=\mu^{*}\left(a_{0}, b_{0}, \alpha, \beta, r, N, \Omega\right)>0$ such that whenever $\mu>\mu^{*}$, for any initial data $\left(n_{0}, c_{0}, \mathbf{u}_{0}\right)$ with (4.17) the system (4.16) possesses a globally bounded and classical solution $(n, c, \mathbf{u})$ converging to $\left(\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}},\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}, 0\right)$ in $L^{\infty}(\Omega)$ exponentially.
Proof. According to Lemma 5.4, we identify a number $\mu_{*}>0$ such that the condition $\mu>\mu_{*}$ guarantees the global classical solvability to (4.17) and ensures the existence of a time point $t_{1}>0$ fulfilling

$$
\begin{equation*}
\|n(\cdot, t)\|_{L^{2}(\Omega)} \leq C_{1}, \quad \forall t>t_{1} \tag{4.19}
\end{equation*}
$$

with $C_{1}>0$ depending only on $a_{0}, b_{0}, \alpha, \beta, \gamma, r, N$ and $\Omega$. Furthermore, Theorem 4 provides such $C_{2}>0$ and $t_{2}>t_{1}$ that

$$
\begin{equation*}
\|n(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C_{2}+C_{2}\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}, \quad \forall t>t_{2} \tag{4.20}
\end{equation*}
$$

as long as $\mu>\mu_{*}$. Let us define $\chi:=\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}$ and

$$
H(s):=s-\chi-\chi \ln \left(\chi^{-1} s\right) \quad \text { for } s>0
$$

By the Taylor expansion, there exists $\theta=\theta(s, \chi) \in(0,1)$ such that

$$
H(s)=H(\chi)+H^{\prime}(\chi)(s-\chi)+\frac{H^{\prime \prime}(\theta s+(1-\theta) \chi)}{2}(s-\chi)^{2}=\frac{\chi}{2(\theta s+(1-\theta) \chi)^{2}}(s-\chi)^{2}
$$

for all $s>0$. Thus, it clearly holds that $H(s) \geq 0$ and

$$
\begin{equation*}
\lim _{s \rightarrow \chi} \frac{H(s)}{(s-\chi)^{2}}=\lim _{s \rightarrow \chi} \frac{\chi}{2(\theta s+(1-\theta) \chi)^{2}}=\frac{1}{2 \chi} \tag{4.21}
\end{equation*}
$$

We have by (4.16) ${ }_{1}$ and (4.18) that

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} H(n(x, t)) d x= & -\chi \int_{\Omega} \frac{D(n)|\nabla n|^{2}}{n^{2}} d x+\chi \int_{\Omega} \frac{S(n) \nabla c \cdot \nabla n}{n^{2}} d x-\mu \int_{\Omega}(n-\chi)\left(n^{\gamma}-\frac{r}{\mu}\right) d x \\
\leq & -\frac{\chi a_{0}}{2} \int_{\Omega} \frac{|\nabla n|^{2}}{n^{2}} d x+\frac{\chi b_{0}^{2}}{2 a_{0}} \int_{\Omega}(n+1)^{2 \beta-\alpha-2}|\nabla c|^{2} d x \\
& -\mu \int_{\Omega}(n-\chi)\left(n^{\gamma}-\frac{r}{\mu}\right) d x, \quad \forall t>t_{2} \tag{4.22}
\end{align*}
$$

It can be checked by simple calculations that

$$
(n-\chi)\left(n^{\gamma}-\frac{r}{\mu}\right)=(n-\chi)\left(n^{\gamma}-\chi^{\gamma}\right) \geq \chi^{\gamma-1}(n-\chi)^{2}
$$

and hence

$$
-\mu \int_{\Omega}(n-\chi)\left(n^{\gamma}-\frac{r}{\mu}\right) d x \leq-\mu \chi^{\gamma-1} \int_{\Omega}(n-\chi)^{2} d x=-\frac{r}{\chi} \int_{\Omega}(n-\chi)^{2} d x
$$

Substituting this to (4.22) yields

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} H(n(x, t)) d x \leq \chi C_{3} \int_{\Omega}|\nabla c|^{2} d x-\frac{r}{\chi} \int_{\Omega}(n-\chi)^{2} d x, \quad \forall t>t_{2} \tag{4.23}
\end{equation*}
$$

with $C_{3}:=\frac{b_{0}^{2}}{2 a_{0}}\left(\left(C_{2}+C_{2} \chi+1\right)^{2 \beta-\alpha-2}+1\right)$. By $(4.16)_{2}$,

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}(c-\chi)^{2} d x \leq-2 \int_{\Omega}|\nabla c|^{2} d x-\int_{\Omega}(c-\chi)^{2} d x+\int_{\Omega}(n-\chi)^{2} d x, \quad \forall t>t_{2} \tag{4.24}
\end{equation*}
$$

By virtue of (4.23) and (4.24), one sees that

$$
\begin{align*}
& \frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\Omega} H(n(x, t)) d x+\chi C_{3} \int_{\Omega}(c-\chi)^{2} d x\right)+\chi C_{3} \int_{\Omega}(c-\chi)^{2} d x \\
\leq & \chi C_{3} \int_{\Omega}(n-\chi)^{2} d x-\frac{r}{\chi} \int_{\Omega}(n-\chi)^{2} d x, \quad \forall t>t_{2} \tag{4.25}
\end{align*}
$$

Clearly, there is $\mu^{*}>\mu_{*}$ such that

$$
\frac{r}{\chi} \geq \frac{r}{\left(\frac{r}{\mu^{*}}\right)^{\frac{1}{\gamma}}}>\left(\frac{r}{\mu^{*}}\right)^{\frac{1}{\gamma}} C_{3} \geq \chi C_{3}
$$

whenever $\mu \geq \mu^{*}$. An integration of (4.25) w.r.t. the time variable gives

$$
\int_{t_{2}+1}^{\infty} \int_{\Omega}(n-\chi)^{2} d x d t<\infty
$$

which combined with the Schauder estimate of $n$ displayed in Theorem 3 guarantees that

$$
n(\cdot, t) \longrightarrow \chi \quad \text { in } L^{\infty}(\Omega) \text { as } t \longrightarrow \infty
$$

Thus by recalling (4.21), we can find $t_{3}>t_{2}+1$ ensuring

$$
\frac{1}{4 \chi}(n(\cdot, t)-\chi)^{2} \leq H(n(\cdot, t)) \leq \frac{1}{\chi}(n(\cdot, t)-\chi)^{2}, \quad \forall t>t_{3}
$$

We let $C_{4}=\min \left\{1, r-\chi^{2} C_{3}\right\}$ and infer from (4.25) that
$\frac{\mathrm{d}}{\mathrm{d} t}\left(\int_{\Omega} H(n(x, t)) d x+\chi C_{3} \int_{\Omega}(c-\chi)^{2} d x\right)+C_{4}\left(\int_{\Omega} H(n(x, t)) d x+\chi C_{3} \int_{\Omega}(c-\chi)^{2} d x\right) \leq 0, \quad \forall t>t_{3}$.
The Grönwall inequality yields

$$
\begin{aligned}
& \int_{\Omega} H(n(x, t)) d x+\chi C_{3} \int_{\Omega}(c(x, t)-\chi)^{2} d x \\
\leq & \left(\int_{\Omega} H\left(n\left(x, t_{3}\right)\right) d x+\chi C_{3} \int_{\Omega}\left(c\left(x, t_{3}\right)-\chi\right)^{2} d x\right) e^{-C_{4}\left(t-t_{3}\right)}, \quad \forall t>t_{3}
\end{aligned}
$$

In view of this and (4.21), we obtain the decaying estimate of $n(\cdot, t)-\chi$ in $L^{2}(\Omega)$ as below,

$$
\left\|n(\cdot, t)-\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}\right\|_{L^{2}(\Omega)}^{2}+\left\|c(\cdot, t)-\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}\right\|_{L^{2}(\Omega)}^{2} \leq C_{5} e^{-C_{4}\left(t-t_{3}\right)}, \quad \forall t>t_{3}
$$

with $C_{5}>0$. Using the arguments as leading to (4.15), we finally conclude

$$
(n, c, \mathbf{u}) \rightarrow\left(\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}},\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}, 0\right) \quad \text { in } L^{\infty}(\Omega)
$$

exponentially as $t \rightarrow \infty$, as intended.

### 4.2 Higher regularity of solutions

The Hölder continuity of solutions, typically serving as the beginning in the investigation of smooth regularities, stands as one of the most important directions for the study of PDEs. It not only aids in improving the regularity of solutions but also offers compactness for certain problems.

In the context of chemotaxis models, the Hölder continuity w.r.t the spatial variable can be utilized to pursue the asymptotic behaviors of solutions pointwise. Specifically, by verifying the validity of the embedding $C^{\gamma^{\prime}}(\bar{\Omega}) \hookrightarrow W^{\gamma, \ell}(\Omega)$ for all $\ell \in(1, \infty)$ and every pair of $\gamma, \gamma^{\prime} \in(0,1)$ with $\gamma^{\prime}>\gamma$, we then employ the Gagliardo-Nirenberg inequality to show that for any $\ell>\frac{N}{\gamma}$ and $q>1$,

$$
\begin{aligned}
& \|n(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C_{1}\left(\|n(\cdot, t)\|_{W^{\gamma, \ell}(\Omega)}^{\frac{\frac{1}{q}}{\frac{1}{q}+\frac{\gamma}{\ell}}}\|n(\cdot, t)\|_{L^{q}(\Omega)}^{\frac{\frac{\gamma}{q}-\frac{1}{q}}{\frac{1}{q}-\frac{\gamma}{\ell}}}+\|n(\cdot, t)\|_{L^{q}(\Omega)}\right) \\
& \leq C_{2}\left(\|n(\cdot, t)\|_{C^{\gamma}(\bar{\Omega})}^{\frac{\frac{1}{q}}{\frac{1}{q}+\frac{\gamma}{N}-\frac{1}{\ell}}}\|n(\cdot, t)\|_{L^{q}(\Omega)}^{\frac{\frac{\gamma}{q}-\frac{1}{\ell}}{\frac{1}{q}+\frac{\gamma}{\ell}}}+\|n(\cdot, t)\|_{L^{q}(\Omega)}\right)
\end{aligned}
$$

with $C_{1}=C_{1}(\ell, q, \gamma, N, \Omega)>0$ and $C_{2}=C_{2}\left(\ell, q, \gamma, \gamma^{\prime}, N, \Omega\right)>0$. An application of this inequality readily transforms the convergence in the $L^{q}$-norm into that in the $L^{\infty}$-norm.

Example (C) Our third example, derived from modeling the invasion movements of cancer cells, describes the phenomena of chemotaxis and haptotaxis:

$$
\begin{cases}n_{t}=\nabla \cdot\left(|\nabla n|^{p-2} \nabla n\right)-\nabla \cdot(\chi n \nabla c)-\nabla \cdot(\xi n \nabla w)+\mu n(1-n-w), & x \in \Omega, t>0  \tag{4.26}\\ c_{t}=\Delta c-c+n, & x \in \Omega, t>0 \\ w_{t}=-c w, & x \in \Omega, t>0\end{cases}
$$

endowed on the boundary condition $\left(|\nabla n|^{p-2} \nabla n-\chi n \nabla c-\xi n \nabla w\right) \cdot \nu=\partial_{\nu} c=0$ on $\partial \Omega \times(0, \infty)$. The non-negative initial data $\left(n_{0}, c_{0}, w_{0}\right)$ fulfill

$$
\left\{\begin{array}{l}
n_{0} \in L^{\infty}(\Omega),\left|\nabla n_{0}\right|^{p-2} \nabla n_{0} \in L^{2}(\Omega), c_{0}, w_{0} \in W^{2, \infty}(\Omega)  \tag{4.27}\\
\left.\partial_{\nu}\left(\left|\nabla n_{0}\right|^{p-2} \nabla n_{0}\right)\right|_{\partial \Omega}=\left.\partial_{\nu} c_{0}\right|_{\partial \Omega}=\left.\partial_{\nu} w_{0}\right|_{\partial \Omega}=0
\end{array}\right.
$$

The next proposition states that the system (4.26) admits a global Hölder-continuous solution.
Proposition 4.3. Let $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with a smooth boundary. Suppose $\chi>0, \xi>0$ and $\mu>0$. Assume that

$$
p>1+\frac{N(2 N+3 \lambda)}{(N+1)(N+2 \lambda)} \quad \text { with } \lambda=\frac{2 N}{(N-2)_{+}} .
$$

Then for any non-negative initial data $\left(n_{0}, c_{0}, w_{0}\right)$ satisfying (4.27), there exist functions

$$
\left\{\begin{array}{l}
n \in L^{\infty}(\Omega \times(0, \infty)) \cap C^{\gamma, \frac{\gamma}{p}}(\bar{\Omega} \times(0, \infty)) \text { with some } \gamma \in(0,1) \\
c \in C^{0}\left([0, \infty) ; W^{1, \infty}(\Omega)\right) \cap C^{0}(\bar{\Omega} \times[0, \infty)) \cap C^{2+\sigma, 1+\frac{\sigma}{2}}(\bar{\Omega} \times(0, \infty)) \\
w \in C^{0}\left([0, \infty) ; W^{1, \infty}(\Omega)\right)
\end{array}\right.
$$

such that the triple $(n, c, w)$ forms a global solution of (4.26) in the sense that $n$ weakly satisfies $(4.26)_{1}$, and $c$ as well as $w$ classically satisfies $(4.26)_{2}$ and $(4.26)_{3}$.

Proof. The weak and globally bounded solutions have been found in [39, Theorem 1]. Additionally, to determine the solvability by compactness arguments, the authors [39] replaced $\nabla \cdot\left(|\nabla n|^{p-2} \nabla n\right)$ with $\nabla \cdot\left((|\nabla n|+\varepsilon)^{p-2} \nabla n\right)$ in $(4.26)_{1}$, and then introduced a regularized system

$$
\begin{cases}n_{t}=\nabla \cdot\left((|\nabla n|+\varepsilon)^{p-2} \nabla n\right)-\nabla \cdot(\chi n \nabla c)-\nabla \cdot(\xi n \nabla w)+\mu n(1-n-w), & x \in \Omega, t>0  \tag{4.28}\\ c_{t}=\Delta c-c+n, & x \in \Omega, t>0 \\ w_{t}=-c w, & x \in \Omega, t>0\end{cases}
$$

which possesses a global and classical solution $\left(n_{\varepsilon}, c_{\varepsilon}, w_{\varepsilon}\right)$ for every $\varepsilon \in(0,1)$. According to [39, Lemmas $8 \& 11$ ], for any $T>0$, there exists an $\varepsilon$-independent constant $C_{1}$ such that

$$
\begin{equation*}
\left\|n_{\varepsilon}\right\|_{L^{\infty}(\Omega)}+\left\|c_{\varepsilon}\right\|_{W^{1, \infty}(\Omega)}+\left\|w_{\varepsilon}\right\|_{W^{1, \infty}(\Omega)} \leq C_{1}, \quad \forall t>0 \tag{4.29}
\end{equation*}
$$

In light of Theorem 3, we have that for any $t_{0} \in(0, T)$,

$$
\begin{equation*}
\left|n_{\varepsilon}(x, t)-n_{\varepsilon}(\hat{x}, \hat{t})\right| \leq C_{2}\left(|x-\hat{x}|+|t-\hat{t}|^{\frac{1}{p}}\right)^{\gamma}, \quad \forall(x, t), \quad(\hat{x}, \hat{t}) \in \bar{\Omega} \times\left[t_{0}, T\right) \tag{4.30}
\end{equation*}
$$

where $C_{2}>0$ and $\gamma \in(0,1)$ are unform-in- $\varepsilon$ due to (4.29). With the aid of the Arzelà-Ascoli theorem, we thus conclude the limit function $n$ of a subsequence of $\left\{n_{\varepsilon}\right\}_{\varepsilon \in(0,1)}$, as specified in [39, page 16], belongs to the space $C^{0}\left(\left[t_{0}, T\right] ; L^{2}(\Omega)\right)$.

Finally, let us set $f(s, x, t)=\mu s(1-s-w(x, t)), \hat{c}(x, t)=\chi c-\xi w$ for $(x, t) \in \bar{\Omega} \times(0, \infty)$. Under this transformation, [39, Theorem 1] tells us that $n$ weakly satisfies

$$
n_{t}=\nabla \cdot\left(|\nabla n|^{p-2} \nabla n\right)-\nabla \cdot(n \nabla \hat{c})+f(n, x, t), \quad \forall x \in \Omega, t>0
$$

with $\nabla \hat{c} \in L^{\infty}\left(\Omega \times\left[t_{0}, T\right)\right)$. Hence, the expected Hölder continuity result immediately follows by an application of Theorem 3.

Example (D) Finally, let us consider the following chemotaxis with $p$-Laplacian involved:

$$
\begin{cases}n_{t}+\mathbf{u} \cdot \nabla n=\nabla \cdot\left(|\nabla n|^{p-2} \nabla n\right)-\nabla \cdot(n \nabla c), & x \in \Omega, t>0,  \tag{4.31}\\ c_{t}+\mathbf{u} \cdot \nabla c=\Delta c-n c, & x \in \Omega, t>0, \\ \mathbf{u}_{t}=\Delta \mathbf{u}+\nabla P+n \nabla \Phi, & x \in \Omega, t>0, \\ \nabla \cdot \mathbf{u}=0, & x \in \Omega, t>0,\end{cases}
$$

where $n$ and $c$ satisfy homogeneous boundary conditions of Neumann type, and $\mathbf{u}$ satisfies the homogeneous boundary condition of Dirichlet type. The initial data fulfill

$$
\left\{\begin{array}{l}
n_{0} \in C^{\omega}(\bar{\Omega})(0<\omega<1), n_{0} \geq 0, n_{0} \not \equiv 0 \quad \text { on } \bar{\Omega}, \\
c_{0} \in W^{1, \infty}(\Omega), c_{0} \geq 0, \sqrt{c_{0}} \in W^{1,2}(\Omega) \\
\mathbf{u}_{0} \in D\left(\mathcal{A}_{2}^{\gamma}\right) \quad \text { for some } \gamma \in\left(\frac{3}{4}, 1\right)
\end{array}\right.
$$

Proposition 4.4. Let $\Omega \subseteq \mathbb{R}^{3}$ be a bounded domain with smooth boundary, $\Phi \in W^{2, \infty}(\Omega)$ and $p>\frac{23}{11}$. Then there exist functions

$$
\left\{\begin{array}{l}
n \in L^{\infty}(\Omega \times(0, \infty)) \cap C^{\gamma, \frac{\gamma}{p}}(\bar{\Omega} \times(0, \infty)) \text { with some } \gamma \in(0,1), \\
c \in C^{0}\left([0, \infty) ; W^{1, \infty}(\Omega)\right) \cap C^{0}(\bar{\Omega} \times[0, \infty)) \cap C^{2+\sigma, 1+\frac{\sigma}{2}}(\bar{\Omega} \times(0, \infty)), \\
\mathbf{u} \in L^{\infty}\left(\Omega \times(0, \infty) ; \mathbb{R}^{3}\right) \cap L_{l o c}^{2}\left([0, \infty) ; W_{0}^{1,2}\left(\Omega ; \mathbb{R}^{3}\right) \cap L_{\sigma}^{2}\left(\Omega ; \mathbb{R}^{3}\right)\right) \cap C^{0}\left(\bar{\Omega} \times[0, \infty) ; \mathbb{R}^{3}\right)
\end{array}\right.
$$

such that the triple $(n, c, \mathbf{u})$ forms a global solution of (4.31) in the sense that classically satisfies $(4.31)_{2}$, and $n$ together with $\mathbf{u}$ weakly satisfies $(4.31)_{1}$ and $(4.31)_{3}$.

Proof. The global existence of bounded and weak solutions can be found in [27]. Similar reasonings performed in Proposition 4.3 can also be carried out for the model (4.31), resulting in improved regularities of solutions. To avoid repeated arguments, we omit details here.

## 5 Appendix

We use the coming Lemma 5.1 and Lemma 5.2 to prepare some semigroup estimates, which can be found in [4].

Define $D\left(\mathcal{A}_{q}\right):=W^{2, q}\left(\Omega ; \mathbb{R}^{2}\right) \cap W_{0}^{1, q}\left(\Omega ; \mathbb{R}^{2}\right) \cap L_{\sigma}^{q}(\Omega)$ with $q \geq 1$. We let $\mathcal{A}:=-\mathcal{P} \Delta$ denote the realization of the Stokes operator on $D\left(\mathcal{A}_{q}\right)$. Therein, $\mathcal{P}$ stands for the Helmholtz projection from $L^{q}\left(\Omega ; \mathbb{R}^{2}\right)$ to $L_{\sigma}^{q}(\Omega)$. As a sectorial and positive self-adjoint operator, $\mathcal{A}_{q}$ possesses closed fractional powers $\mathcal{A}_{q}^{\theta}$ defined on $D\left(\mathcal{A}_{q}^{\theta}\right)$ with $\theta \in \mathbb{R}$, where the norm is given by $\|\cdot\|_{D\left(\mathcal{A}_{q}^{\theta}\right)}:=\left\|\mathcal{A}_{q}^{\theta}(\cdot)\right\|_{L^{q}(\Omega)}$.

Lemma 5.1. Let $\Omega \subseteq \mathbb{R}^{2}$ be a bounded domain with smooth boundary, and let $\left\{e^{-\mathcal{A} t}\right\}_{t \geq 0}$ be the semigroup generated by the Stokes-operator $\mathcal{A}$. Then there exists $\lambda_{1}>0$ with the following property: For each $\theta \geq 0$ and any $1<\ell \leq q<\infty$ there is $C>0$ depending only on $\theta, q$, $\ell$ and $\Omega$ such that

$$
\left\|\mathcal{A}^{\theta} e^{-t \mathcal{A}} \varphi\right\|_{L^{q}(\Omega)} \leq C t^{-\theta-\left(\frac{1}{\ell}-\frac{1}{q}\right)} e^{-\lambda_{1} t}\|\varphi\|_{L^{\ell}(\Omega)}, \quad \forall t>0
$$

is valid for all $\varphi \in L_{\sigma}^{\ell}(\Omega)$.

Lemma 5.2. Assume that $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ is a bounded domain with a smooth boundary. Let $\left\{e^{t \Delta}\right\}_{t \geq 0}$ be the Neumann heat semigroup generated by $-\Delta$, and let $\lambda_{2}>0$ denote the first nonzero eigenvalue of $-\Delta$ in $\Omega$ under Neumann boundary conditions. Then there exist constants $C_{1}, C_{2}$ depending only on $\Omega, q$ and $\ell$ which have the following properties:
(i) If $1 \leq \ell \leq q \leq \infty$, then

$$
\left\|e^{t \Delta} \varphi\right\|_{L^{q}(\Omega)} \leq C_{1}(q, \ell)\left(1+t^{-\frac{N}{2}\left(\frac{1}{\ell}-\frac{1}{q}\right)}\right) e^{-\lambda_{2} t}\|\varphi\|_{L^{\ell}(\Omega)}, \quad \forall t>0
$$

is true for each $\varphi \in L^{\ell}(\Omega)$.
(ii) If $1 \leq \ell \leq q \leq \infty$, then

$$
\left\|\nabla e^{t \Delta} \varphi\right\|_{L^{q}(\Omega)} \leq C_{2}(q, \ell)\left(1+t^{-\frac{1}{2}-\frac{N}{2}\left(\frac{1}{\ell}-\frac{1}{q}\right)}\right) e^{-\lambda_{2} t}\|\varphi\|_{L^{\ell}(\Omega)}, \quad \forall t>0
$$

holds for any $\varphi \in L^{\ell}(\Omega)$.
Lemma 5.3. Let $\Omega \subseteq \mathbb{R}^{N}(N \geq 2)$ be a bounded domain with smooth boundary and $0<\sigma<2 / N$. For any $q>1$, there are constants $C=C(q, \sigma, \Omega, N)>0$ and $\kappa=\kappa(q, \sigma, \Omega, N)>0$ such that for any solution $(n, c)$ of (4.1), we can find $\hat{t}>0$ satisfying

$$
\|n(\cdot, t)\|_{L^{q}(\Omega)} \leq C M^{\kappa}+C, \quad \forall t>\hat{t}
$$

where $M:=f_{\Omega} n_{0} d x$.
Proof. The existence of global and classical solutions emanating from initial data satisfying (4.2) can be found in [20]. An integration to $(4.1)_{1}$ over $\Omega$ shows that

$$
\begin{equation*}
f_{\Omega} n(\cdot, t) d x \equiv f_{\Omega} n_{0} d x=M, \quad \forall t>0 \tag{5.1}
\end{equation*}
$$

Since $0<\sigma<2 / N$, then we can fix $s \in\left[1, \frac{N}{(N \sigma-1)_{+}}\right)$such that

$$
\begin{equation*}
\sigma-\frac{1}{N}<\frac{1}{s}<\frac{1}{N} \tag{5.2}
\end{equation*}
$$

Thus, based on the variation-of-constant formula, there holds that

$$
\begin{equation*}
\|\nabla c(\cdot, t)\|_{L^{s}(\Omega)} \leq\left\|\nabla e^{t(\Delta-1)} c_{0}\right\|_{L^{s}(\Omega)}+\int_{0}^{t}\left\|\nabla e^{-(t-s)(\Delta-1)} n^{\sigma}\right\|_{L^{s}(\Omega)} d s, \quad \forall t>0 \tag{5.3}
\end{equation*}
$$

We employ Lemma 5.2 (i) to get

$$
\begin{equation*}
\left\|\nabla e^{t(\Delta-1)} c_{0}\right\|_{L^{s}(\Omega)} \leq C_{1} e^{-\lambda_{2} t}\left(1+t^{-\frac{1}{2}}\right)\left\|\nabla c_{0}\right\|_{L^{s}(\Omega)}, \quad \forall t>0 \tag{5.4}
\end{equation*}
$$

and

$$
\begin{align*}
& \int_{0}^{t}\left\|\nabla e^{-(t-s) \mathcal{A}} n^{\sigma}(\cdot, s)\right\|_{L^{s}(\Omega)} d s \\
\leq & C_{2} \int_{0}^{t}(t-s)^{-\frac{1}{2}-\frac{N}{2}\left(\sigma-\frac{1}{s}\right)} e^{-\lambda_{2}(t-s)}\left\|n^{\sigma}(\cdot, s)\right\|_{L^{\frac{1}{\sigma}(\Omega)}} d s \\
\leq & C_{3} M^{\sigma}, \quad \forall t>0 \tag{5.5}
\end{align*}
$$

with positive constants $C_{1}, C_{2}, C_{3}$ depending only on $\sigma, \Omega, N$. We pick a time point $t_{1}>1$ sufficiently large such that $2 e^{-\lambda_{2} t_{1}}\left\|\nabla c_{0}\right\|_{L^{s}(\Omega)} \leq 1$, and then,

$$
\begin{equation*}
\|\nabla c(\cdot, t)\|_{L^{s}(\Omega)} \leq 2 C_{1}+C_{3} M^{\sigma}=: \Lambda_{M}, \quad \forall t>t_{1} \tag{5.6}
\end{equation*}
$$

Now we let $\ell>\max \left\{\frac{s}{2}+1, \frac{(N-2) s}{N}, \frac{s N}{2}\right\}$ big enough assure

$$
\frac{2 \sigma(N-2)}{\frac{2 \ell}{s} \cdot N}<1-\frac{(N-2)(\ell-1)}{N \ell}
$$

With setting $q:=\frac{2 \ell}{s}$, the selection of $\ell$ ensures that $q>N$ and

$$
\begin{equation*}
\frac{2 \sigma(N-2)}{q \cdot N}<1-\frac{(N-2)(\ell-1)}{N \ell} \tag{5.7}
\end{equation*}
$$

This inequality allows us to find $\chi>1$ such that

$$
\begin{equation*}
\frac{2 \sigma(N-2)}{N q}<\frac{1}{\chi}<\min \left\{2 \sigma, 1-\frac{(N-2)(\ell-1)}{N \ell}\right\} \tag{5.8}
\end{equation*}
$$

We also need to select $\nu>1$ fulfilling

$$
\begin{equation*}
\max \left\{1-\frac{2}{N}, 1-\frac{2}{s}\right\}<\frac{1}{\nu}<1-\frac{N-2}{N \ell} \tag{5.9}
\end{equation*}
$$

Testing (4.1) $)_{1}$ by $n^{q-1}$ and using Young's inequality, one sees that for any $t>0$,

$$
\begin{align*}
\frac{1}{q} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} n^{q} d x+(q-1) \int_{\Omega} n^{q-2}|\nabla n|^{2} d x & =-(q-1) \int_{\Omega} n^{q-1} \nabla n \cdot \nabla c d x \\
& \leq \frac{q-1}{2} \int_{\Omega} n^{q-2}|\nabla n|^{2} d x+\frac{q-1}{2} \int_{\Omega} n^{q}|\nabla c|^{2} d x \tag{5.10}
\end{align*}
$$

which yields that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} n^{q} d x+\frac{2(q-1)}{q} \int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x \leq q(q-1) \int_{\Omega} n^{q}|\nabla c|^{2} d x, \quad \forall t>0 \tag{5.11}
\end{equation*}
$$

By a straightforward computation, we verify that

$$
\Delta|\nabla c|^{2}=2\left|D^{2} c\right|^{2}+2 \nabla c \cdot \nabla \Delta c, \quad \forall x \in \Omega, t>0
$$

It follows by $(4.1)_{2}$ and the pointwise estimate $|\Delta c|^{2} \leq N\left|D^{2} c\right|^{2}$ in $\Omega \times(0, \infty)$ that

$$
\begin{equation*}
\left(|\nabla c|^{2}\right)_{t}+\frac{2}{N}|\Delta c|^{2}+2|\nabla c|^{2} \leq \Delta|\nabla c|^{2}+2 \nabla c \cdot \nabla n^{\sigma}, \quad \forall x \in \Omega, t>0 \tag{5.12}
\end{equation*}
$$

Multiplying (5.12) by $|\nabla c|^{2(\ell-1)}$ and integrating over $\Omega$ imply that

$$
\begin{align*}
& \frac{1}{\ell} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega}|\nabla c|^{2 \ell} d x+\frac{2}{N} \int_{\Omega}|\nabla c|^{2(\ell-1)}|\Delta c|^{2} d x+2 \int_{\Omega}|\nabla c|^{2 \ell} d x \\
= & \int_{\Omega}|\nabla c|^{2(\ell-1)} \Delta|\nabla c|^{2} d x+2 \int_{\Omega}|\nabla c|^{2(\ell-1)} \nabla c \cdot \nabla n^{\sigma} d x, \quad \forall t>0 . \tag{5.13}
\end{align*}
$$

Through the integration by parts and Young's inequality, we have

$$
2 \int_{\Omega}|\nabla c|^{2(\ell-1)} \nabla c \cdot \nabla n^{\sigma} d x=-2(\ell-1) \int_{\Omega}|\nabla c|^{2(\ell-2)} \nabla|\nabla c|^{2} \cdot \nabla c n^{\sigma} d x-2 \int_{\Omega}|\nabla c|^{2(\ell-1)} \Delta c n^{\sigma} d x
$$

$$
\begin{aligned}
\leq & \left.\left.\frac{(\ell-1)}{2} \int_{\Omega}|\nabla c|^{2(\ell-2)}|\nabla| \nabla c\right|^{2}\right|^{2} d x+\frac{2}{N} \int_{\Omega}|\nabla c|^{2(\ell-1)}|\Delta c|^{2} d x \\
& +\left(2(\ell-1)+\frac{N}{2}\right) \int_{\Omega}|\nabla c|^{2(\ell-1)} n^{2 \sigma} d x
\end{aligned}
$$

and

$$
\begin{aligned}
\int_{\Omega}|\nabla c|^{2(\ell-1)} \Delta|\nabla c|^{2} d x & =-\left.\left.(\ell-1) \int_{\Omega}|\nabla c|^{2(\ell-2)}|\nabla| \nabla c\right|^{2}\right|^{2} d x+\int_{\partial \Omega}|\nabla c|^{2(\ell-1)} \frac{\partial|\nabla c|^{2}}{\partial \nu} d S \\
& \leq-\left.\left.\frac{2(\ell-1)}{\ell^{2}} \int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x+C_{4} \int_{\Omega}|\nabla c|^{2 \ell} d x
\end{aligned}
$$

where $C_{4}=C_{4}(\sigma, \Omega, N)>0$, we utilized [21, Lemma 4.2] and the trace inequality to govern $\int_{\partial \Omega}|\nabla c|^{2(\ell-1)} \frac{\partial|\nabla c|^{2}}{\partial \nu} d S$. Thereby, there holds that

$$
\begin{align*}
& \frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}|\nabla c|^{2 \ell} d x+\left.\left.\frac{\ell-1}{2 \ell} \int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x \\
\leq & \left(2(\ell-1)+\frac{N}{2}\right) \ell \int_{\Omega}|\nabla c|^{2(\ell-1)} n^{2 \sigma} d x+C_{4} \ell \int_{\Omega}|\nabla c|^{2 \ell} d x, \quad \forall t>0 \tag{5.14}
\end{align*}
$$

We merge (5.14) with (5.11) and use Hölder's inequality to find $C_{5}>0$ such that the following inequality

$$
\begin{align*}
& \frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(n^{q}+|\nabla c|^{2 \ell}\right) d x+\frac{2(q-1)}{q} \int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x+\left.\left.\frac{\ell-1}{2 \ell} \int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x \\
\leq & C_{5} \int_{\Omega} n^{q}|\nabla c|^{2} d x+C_{5} \int_{\Omega} n^{2 \sigma}|\nabla c|^{2(\ell-1)} d x+C_{5} \int_{\Omega}|\nabla c|^{2 \ell} d x \\
\leq & C_{5}\left(\int_{\Omega} n^{q \nu} d x\right)^{\frac{1}{\nu}}\left(\int_{\Omega}|\nabla c|^{2 \nu^{\prime}} d x\right)^{\frac{1}{\nu^{\prime}}}+C_{5}\left(\int_{\Omega} n^{2 \sigma \chi} d x\right)^{\frac{1}{\chi}}\left(\int_{\Omega}|\nabla c|^{2(\ell-1) \chi^{\prime}} d x\right)^{\frac{1}{\chi^{\prime}}} \\
& +C_{5} \int_{\Omega}|\nabla c|^{2 \ell} d x, \quad \forall t>0 \tag{5.15}
\end{align*}
$$

holds for $\nu$ selected in (5.8) and $\nu^{\prime}=\frac{\nu}{\nu-1}$. The Gagliardo-Nirenberg inequality infers

$$
\begin{align*}
\left\|n^{\frac{q}{2}}\right\|_{L^{2 \nu}(\Omega)}^{2} & \leq C_{6}\left\|\nabla n^{\frac{q}{2}}\right\|_{L^{2}(\Omega)}^{2 \theta}\left\|n^{\frac{q}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}^{2(1-\theta)}+C_{6}\left\|n^{\frac{q}{2}}\right\|_{L^{\frac{2}{q}}(\Omega)}^{2} \\
& \leq C_{6}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x\right)^{\theta} M^{q(1-\theta)}+C_{6} M^{q} \tag{5.16}
\end{align*}
$$

where $C_{6}=C_{6}(\sigma, \Omega, N)>0$ and

$$
\theta=\frac{\frac{q}{2}-\frac{1}{2 \nu}}{\frac{1}{N}-\frac{1}{2}+\frac{q}{2}} \in(0,1)
$$

Given (5.6), we apply the Gagliardo-Nirenberg inequality once again to derive that for all $t>t_{1}$,

$$
\begin{align*}
\left\||\nabla c|^{\ell}\right\|_{L^{\frac{2 \nu^{\prime}}{\ell}(\Omega)}}^{\frac{2}{\ell}} & \leq C_{7}\left\|\nabla|\nabla c|^{\ell}\right\|_{L^{2}(\Omega)}^{\frac{2 \delta}{\ell}}\left\||\nabla c|^{\ell}\right\|_{L^{\frac{t^{\ell}}{\ell}(\Omega)}}^{\frac{2(1-\delta)}{\ell}}+C_{7}\left\||\nabla c|^{\ell}\right\|_{L^{\frac{2}{\ell}}(\Omega)}^{\frac{2}{s}} \\
& \leq C_{7}\left(\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x\right)^{\frac{\delta}{\ell}} \Lambda_{M}^{2(1-\delta)}+C_{7} \Lambda_{M}^{2} \tag{5.17}
\end{align*}
$$

where $C_{7}=C_{7}(\sigma, \Omega, N)>0$ and

$$
\delta=\frac{\frac{\ell}{s}-\frac{\ell}{2 \nu^{\prime}}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}} \in(0,1)
$$

Similarly, there exist $C_{8}>0, C_{9}>0$ depending $\sigma, \Omega$ and $N$ satisfying that for any $t>t_{1}$,

$$
\begin{equation*}
\left\|n^{\frac{q}{2}}\right\|_{L^{\frac{4 \sigma \sigma}{q}}(\Omega)}^{\frac{4 \sigma}{q}} \leq C_{8}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x\right)^{\frac{2 \sigma \bar{\theta}}{q}} M^{2 \sigma(1-\bar{\theta})}+C_{8} M^{2 \sigma} \tag{5.18}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\||\nabla c|^{\ell}\right\|_{L^{\frac{2(\ell-1)}{\ell(\ell-1) \chi^{\prime}}}{ }_{(\Omega)}^{\ell}}^{\frac{2}{\ell}} \leq C_{9}\left(\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x\right)^{\frac{(\ell-1) \bar{\delta}}{\ell}} \Lambda_{M}^{2(1-\ell)(1-\bar{\delta})}+C_{9} \Lambda_{M}^{2(1-\ell)} \tag{5.19}
\end{equation*}
$$

with $\chi$ specified in (5.9), $\chi^{\prime}=\frac{\chi}{\chi-1}$ and

$$
\bar{\theta}=\frac{\frac{q}{2}-\frac{q}{4 \sigma \chi}}{\frac{1}{N}-\frac{1}{2}+\frac{q}{2}} \in(0,1) \quad \text { as well as } \quad \bar{\delta}=\frac{\frac{\ell}{s}-\frac{\ell}{2(\ell-1) \chi^{\prime}}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}} \in(0,1)
$$

Inserting (5.16)-(5.19) into (5.15) and applying Young's inequality result in the estimate

$$
\begin{align*}
& \quad \frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(n^{q}+|\nabla c|^{2 \ell}\right) d x+\frac{2(q-1)}{q} \int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x+\left.\left.\frac{\ell-1}{2 \ell} \int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x \\
& \leq \\
& C_{10} M^{q(1-\theta)} \Lambda_{M}^{2(1-\delta)}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x\right)^{\theta}\left(\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x\right)^{\frac{\delta}{\ell}} \\
& \quad+C_{10} M^{2 \sigma(1-\bar{\theta})} \Lambda_{M}^{2(1-\ell)(1-\bar{\delta})}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x\right)^{\frac{2 \sigma \bar{\theta}}{q}}\left(\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x\right)^{\frac{(\ell-1) \bar{\delta}}{\ell}}  \tag{5.20}\\
& \quad+C_{10} \int_{\Omega}|\nabla c|^{2 \ell} d x+C_{10} M^{\kappa_{1}}+C_{10}, \quad \forall t>t_{1}
\end{align*}
$$

with $\kappa_{1}=\kappa_{1}(\sigma, \Omega, N)>0$ and $C_{10}=C_{10}(\sigma, \Omega, N)>0$, where we can verify that

$$
\begin{equation*}
\theta+\frac{\delta}{\ell}=\frac{\frac{q}{2}-\frac{1}{2 \nu}}{\frac{1}{N}-\frac{1}{2}+\frac{q}{2}}+\frac{\frac{1}{s}-\frac{1}{2 \nu^{\prime}}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}}=\frac{\frac{1}{s}+\frac{q}{2}-\frac{1}{2}}{\frac{1}{N}+\frac{q}{2}-\frac{1}{2}}<1 \tag{5.21}
\end{equation*}
$$

because of $s<\frac{1}{N}$, and

$$
\begin{equation*}
\frac{2 \sigma \bar{\theta}}{q}+\frac{(\ell-1) \bar{\delta}}{\ell}=\frac{\sigma-\frac{1}{2 \chi}}{\frac{1}{N}-\frac{1}{2}+\frac{q}{2}}+\frac{\frac{\ell-1}{s}-\frac{1}{2 \chi^{\prime}}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}}=\frac{\sigma+\frac{\ell-1}{s}-\frac{1}{2}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}}<1 \tag{5.22}
\end{equation*}
$$

due to $s>\sigma-\frac{1}{N}$. Young's inequality applied on (5.20) enables us to find $C_{11}>0$ and $\kappa_{2}=$ $\kappa_{2}(\sigma, \Omega, N)>0$ such that

$$
\begin{align*}
& \quad \frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(n^{q}+|\nabla c|^{2 \ell}\right) d x+\frac{q-1}{q} \int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x+\left.\left.\frac{\ell-1}{4 \ell} \int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x \\
& \leq C_{10} \int_{\Omega}|\nabla c|^{2 \ell} d x+C_{11} M^{\kappa_{2}}+C_{11}, \quad \forall t>t_{1} \tag{5.23}
\end{align*}
$$

The Gagliardo-Nirenberg inequality tells us that

$$
\begin{equation*}
\left\|n^{\frac{q}{2}}\right\|_{L^{2}(\Omega)}^{2} \leq C_{12}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x\right)^{\frac{\frac{q}{2}-\frac{1}{2}}{N}-\frac{1}{2}+\frac{q}{2}} M^{\frac{\frac{q}{N}}{\frac{1}{N}-\frac{1}{2}+\frac{q}{2}}}+C_{12} M^{q} \tag{5.24}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(C_{10}+1\right)\left\||\nabla c|^{\ell}\right\|_{L^{2}(\Omega)}^{2} \leq C_{13}\left(\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} d x\right)^{\frac{\frac{\ell}{5}-\frac{1}{2}}{\frac{1}{N}-\frac{1}{2}+\frac{\ell}{s}}} \Lambda_{M}^{\frac{2 \ell}{\bar{J}-\frac{s}{2}+\ell}}+C_{13} \Lambda_{M}^{\frac{2 \ell}{s}} \tag{5.25}
\end{equation*}
$$

with $C_{12}, C_{13}>0$. It can be deduced from (5.23)-(5.25) that there are $\kappa_{3}, C_{14}$ and $C_{15}$ such that

$$
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}\left(n^{q}+|\nabla c|^{2 \ell}\right) d x+C_{14}\left(\int_{\Omega}\left|\nabla n^{\frac{q}{2}}\right|^{2} d x+\left.\left.\int_{\Omega}|\nabla| \nabla c\right|^{\ell}\right|^{2} \mathrm{~d} x\right) \leq C_{15} M^{\kappa_{3}}+C_{15}, \quad \forall t>t_{1}
$$

An argument of ODI to the above inequality guarantees the existence of $t_{2}>t_{1}$ fulfilling

$$
\int_{\Omega} n^{q}(x, t) d x \leq C_{15} M^{\kappa_{3}}+2 C_{15}, \quad \forall t>t_{2}
$$

The proof is finished.
Lemma 5.4. Let $\Omega \subseteq \mathbb{R}^{2}$ be a bounded domain with smooth boundary and $\gamma>1$. Assume that $D$ and $S$ satisfy (4.18) with $\alpha \geq 0$ and $\beta \leq \gamma$. Then there are constants $C>0$ and $\mu_{*}>0$ depending only on $a_{0}, b_{0}, \alpha, \beta, r$ such that whenever $\mu>\mu_{*}$, then for any classical and globally bounded solutions $(n, c, \mathbf{u})$ to (4.16) there exists a time point $\hat{t} \in(0, \infty)$ fulfilling

$$
\|n(\cdot, t)\|_{L^{2}(\Omega)} \leq C \quad \text { and } \quad\|\mathbf{u}(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C, \quad \forall t>\hat{t}
$$

Proof. The Poincaré inequality and Sobolev estimates tell that

$$
\begin{equation*}
\int_{\Omega}|\nabla \psi|^{2} d x \geq C_{p} \int_{\Omega} \psi^{2} d x \quad \text { for any } \psi \in W_{0}^{1,2}(\Omega) \tag{5.26}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{\Omega}|\Delta \psi|^{2} d x+\int_{\Omega} \psi^{2} d x \geq C_{s} \int_{\Omega}|\nabla \psi|^{2} d x \quad \text { for every } \psi \in W^{2,2}(\Omega) \cap W_{0}^{1,2}(\Omega) \tag{5.27}
\end{equation*}
$$

We thus define a constant $\bar{C}:=\max \left\{\frac{C_{p}}{4}, \frac{C_{s}}{2}, \lambda_{1}\right\}$ with $\lambda_{1}>0$ specified as in Lemma 5.1.
The equation (4.16) $)_{1}$ ensures that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} n d x=r \int_{\Omega} n d x-\mu \int_{\Omega} n^{1+\gamma} d x \leq r \int_{\Omega} n d x-\mu|\Omega|^{-\gamma}\left(\int_{\Omega} n d x\right)^{1+\gamma}, \quad \forall t>0 \tag{5.28}
\end{equation*}
$$

According to the Bernoulli inequality [3, Lemma 1.2.4], there holds that

$$
\begin{equation*}
\limsup _{t \rightarrow \infty} \int_{\Omega} n(\cdot, t) d x \leq|\Omega|\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}} \tag{5.29}
\end{equation*}
$$

This gives a time point $t_{1}>0$ such that $\int_{\Omega} n(\cdot, t) d x<2|\Omega|\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}$ for any $t>t_{1}$. This along with (5.28) shows that

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} t}\left(e^{\bar{C} t} \int_{\Omega} n d x\right) & =(r+\bar{C}) e^{\bar{C} t} \int_{\Omega} n d x-\mu e^{\bar{C} t} \int_{\Omega} n^{1+\gamma} d x \\
& \leq 2|\Omega|(r+\bar{C}) e^{\bar{C} t}\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}-\mu e^{\bar{C} t} \int_{\Omega} n^{1+\gamma} d x, \quad \forall t>t_{1}
\end{aligned}
$$

Upon integration over $\left(t_{1}, t\right)$, the above ODI yields that

$$
\begin{equation*}
\mu \int_{t_{1}}^{t} e^{\bar{C}(s-t)} \int_{\Omega} n^{1+\gamma} d x d s \leq 4|\Omega| \frac{\bar{C}+r}{\bar{C}}\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}, \quad \forall t>t_{1} \tag{5.30}
\end{equation*}
$$

which immediately implies that

$$
\begin{align*}
\int_{t_{1}}^{t} e^{\bar{C}(s-t)} \int_{\Omega} n^{2} d x d s & \leq \int_{t_{1}}^{t} e^{\bar{C}(s-t)} \int_{\Omega} n^{1+\gamma} d x d s+\frac{1}{\bar{C}} \\
& \leq 4|\Omega| \frac{\bar{C}+r}{\bar{C} \mu}\left(\frac{r}{\mu}\right)^{\frac{1}{\gamma}}+\frac{1}{\bar{C}}, \quad \forall t>t_{1} \tag{5.31}
\end{align*}
$$

From (4.16) $)_{3}$ and Young's inequality, we obtain

$$
\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} \mathbf{u}^{2} d x+\int_{\Omega}|\nabla \mathbf{u}|^{2} d x \leq \int_{\Omega} n \mathbf{u} d x \leq \frac{1}{2 C_{p}} \int_{\Omega} n^{2} d x+\frac{C_{p}}{2} \int_{\Omega} \mathbf{u}^{2} d x, \quad \forall t>t_{1}
$$

Thus, it follows by (5.26) that

$$
\frac{\mathrm{d}}{\mathrm{~d} t}\left(e^{\frac{C_{p} t}{4}} \int_{\Omega} \mathbf{u}^{2} d x\right)+\frac{e^{\frac{C_{p} t}{4}}}{4} \int_{\Omega}|\nabla \mathbf{u}|^{2} d x \leq \frac{e^{\frac{C_{p} t}{4}}}{C_{p}} \int_{\Omega} n^{2} d x, \quad \forall t>t_{1}
$$

In view of (5.31), one can find $t_{2}>t_{1}$ such that

$$
\begin{equation*}
\|\mathbf{u}(\cdot, t)\|_{L^{2}(\Omega)}^{2} \leq \frac{C_{1}}{\mu^{\frac{1}{\gamma}+1}}, \quad \int_{t_{1}}^{t} e^{\frac{s-t}{2}} \int_{\Omega}|\nabla \mathbf{u}|^{2} d x d s \leq \frac{C_{1}}{\mu^{\frac{1}{\gamma}+1}}, \quad \forall t>t_{2} \tag{5.32}
\end{equation*}
$$

with $C_{1}=C_{1}(r, \gamma, \Omega)>0$. Now we test the equation (4.16) $)_{3}$ with $\Delta \mathbf{u}$ and integrate by parts to get

$$
\begin{align*}
\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega}|\nabla \mathbf{u}|^{2} d x+\int_{\Omega}|\Delta \mathbf{u}|^{2} d x & \leq \int_{\Omega} n \Delta \mathbf{u} d x+\int_{\Omega} \mathbf{u} \cdot \nabla \mathbf{u} \Delta \mathbf{u} d x \\
& \leq \int_{\Omega} n^{2} d x+\frac{1}{2} \int_{\Omega}|\Delta \mathbf{u}|^{2} d x+\int_{\Omega}|\mathbf{u} \cdot \nabla \mathbf{u}|^{2} d x, \quad \forall t>0 \tag{5.33}
\end{align*}
$$

where Hölder's inequality, the Gagliardo-Nirenberg inequality and Young's inequality entail that

$$
\begin{align*}
\int_{\Omega}|\mathbf{u} \cdot \nabla \mathbf{u}|^{2} d x \leq\|\mathbf{u}\|_{L^{4}(\Omega)}^{2}\|\nabla \mathbf{u}\|_{L^{4}(\Omega)}^{2} & \leq C_{2}\left(\|\nabla \mathbf{u}\|_{L^{2}(\Omega)}^{\frac{1}{2}}\|\mathbf{u}\|_{L^{2}(\Omega)}^{\frac{1}{2}}\right)^{2}\left(\|\Delta \mathbf{u}\|_{L^{2}(\Omega)}^{\frac{1}{2}}\|\nabla \mathbf{u}\|_{L^{2}(\Omega)}^{\frac{1}{2}}\right)^{2} \\
& \leq \frac{1}{4}\|\Delta \mathbf{u}\|_{L^{2}(\Omega)}^{2}+C_{2}^{2}\|\mathbf{u}\|_{L^{2}(\Omega)}^{2}\|\nabla \mathbf{u}\|_{L^{2}(\Omega)}^{4} \tag{5.34}
\end{align*}
$$

and

$$
\begin{equation*}
\|\nabla \mathbf{u}\|_{L^{2}(\Omega)}^{4} \leq C_{3}\left(\|\Delta \mathbf{u}\|_{L^{2}(\Omega)}^{2}\|\mathbf{u}\|_{L^{2}(\Omega)}^{2}+\|\mathbf{u}\|_{L^{2}(\Omega)}^{4}\right) \tag{5.35}
\end{equation*}
$$

with $C_{2}, C_{3}>0$. It can be obtained by a combination of (5.33)-(5.35), Young's inequality as well as (5.32) that

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega}|\nabla \mathbf{u}|^{2} d x+\frac{1}{2} \int_{\Omega}|\Delta \mathbf{u}|^{2} d x & \leq C_{4}\left(\|\Delta \mathbf{u}\|_{L^{2}(\Omega)}^{2}\|\mathbf{u}\|_{L^{2}(\Omega)}^{4}+\|\mathbf{u}\|_{L^{2}(\Omega)}^{6}\right)+2 \int_{\Omega} n^{2} d x \\
& \leq \frac{C_{4} C_{1}^{2}}{\mu^{\frac{2}{\gamma}+2}}\|\Delta \mathbf{u}\|_{L^{2}(\Omega)}^{2}+\frac{C_{4} C_{1}^{3}}{\mu^{\frac{3}{\gamma}+3}}+2 \int_{\Omega} n^{2} d x, \quad \forall t>t_{2}
\end{aligned}
$$

with $C_{4}=2 C_{2}^{2} C_{3}$. We let $\mu_{*}>1$ be taken large enough satisfying

$$
\frac{C_{4} C_{1}^{2}}{\mu_{*}^{\frac{2}{\gamma}}+2} \leq \frac{1}{4}
$$

Therefore, the assumption $\mu>\mu_{*}$ and (5.27) imply that

$$
\frac{\mathrm{d}}{\mathrm{~d} t}\left(e^{\frac{C_{s} t}{2}} \int_{\Omega}|\nabla \mathbf{u}|^{2} d x\right) \leq 2 e^{\frac{C_{s} t}{2}}\left(\int_{\Omega} n^{2} \mathrm{~d} x+\frac{C_{4} C_{1}^{3}}{\mu^{\frac{3}{\gamma}+3}}+\frac{C_{1}}{\mu^{\frac{1}{\gamma}+1}}\right), \quad \forall t>t_{2}
$$

Using an ODI argument, we infer from the above display and (5.31) that there is $t_{3}>t_{2}$ ensuring

$$
\begin{equation*}
\|\nabla \mathbf{u}(\cdot, t)\|_{L^{2}(\Omega)}^{2} \leq 2 C_{4} C_{1}^{3} r^{\frac{3}{\gamma}}+2 C_{1}++8 r^{\frac{1}{\gamma}}|\Omega| \frac{\bar{C}+r}{\bar{C} \mu}+\frac{2}{\bar{C}}, \quad \forall t>t_{3} \tag{5.36}
\end{equation*}
$$

Similar reasonings as leading to (5.32) and (5.36) allow us to derive

$$
\begin{equation*}
\|c(\cdot, t)\|_{W^{1,2}(\Omega)}^{2} \leq C_{5}, \quad \forall t>t_{4} \tag{5.37}
\end{equation*}
$$

with some $t_{4}>t_{3}$ and $C_{5}=C_{5}(r, \gamma, \Omega)>0$.
In view of the variation-of-constants formula according to $(4.16)_{2}$, there holds

$$
\begin{align*}
\left\|\mathcal{A}^{\frac{1}{2}} \mathbf{u}(\cdot, t)\right\|_{L^{1+\gamma}(\Omega)} \leq & \left\|\mathcal{A}^{\frac{1}{2}} e^{-\left(t-t_{2}\right) \mathcal{A}} \mathbf{u}\left(\cdot, t_{3}\right)\right\|_{L^{1+\gamma}(\Omega)}+\int_{t_{3}}^{t}\left\|\mathcal{A}^{\frac{1}{2}} e^{-(t-s) \mathcal{A}} \mathbf{u} \cdot \nabla \mathbf{u}(\cdot, s)\right\|_{L^{1+\gamma}(\Omega)} d s \\
& +\int_{t_{3}}^{t}\left\|\mathcal{A}^{\frac{1}{2}} e^{-(t-s) \mathcal{A}} n\right\|_{L^{1+\gamma}(\Omega)} d s, \quad \forall t>t_{3} \tag{5.38}
\end{align*}
$$

We apply Lemma 3.1 (i), Hölder's inequality and the Sobolev embedding to get

$$
\left\|\mathcal{A}^{\frac{1}{2}} e^{-t \mathcal{A}} \mathbf{u}\left(\cdot, t_{3}\right)\right\|_{L^{1+\gamma}(\Omega)} \leq C_{5} e^{-\lambda_{1}\left(t-t_{2}\right)}\left\|\mathcal{A}^{\frac{1}{2}} \mathbf{u}\left(\cdot, t_{2}\right)\right\|_{L^{1+\gamma}(\Omega)}, \quad \forall t>t_{3}
$$

and

$$
\begin{aligned}
& \int_{t_{3}}^{t}\left\|\mathcal{A}^{\frac{1}{2}} e^{-(t-s) \mathcal{A}} \mathbf{u}(\cdot, s) \cdot \nabla \mathbf{u}(\cdot, s)\right\|_{L^{1+\gamma}(\Omega)} d s \\
\leq & C_{6} \int_{t_{3}}^{t}(t-s)^{-1+\frac{1}{2(1+\gamma)}} e^{-\lambda_{1}(t-s)}\|\mathbf{u}(\cdot, s) \cdot \nabla \mathbf{u}(\cdot, s)\|_{L^{\frac{2+2 \gamma}{2+\gamma}(\Omega)}} d s \\
\leq & C_{7} \int_{t_{3}}^{t}(t-s)^{-1+\frac{1}{2(1+\gamma)}} e^{-\lambda_{1}(t-s)}\|\mathbf{u}(\cdot, s)\|_{L^{2(1+\gamma)}(\Omega)}\|\nabla \mathbf{u}(\cdot, s)\|_{L^{2}(\Omega)} d s \\
\leq & C_{8} \int_{t_{3}}^{t}(t-s)^{-1+\frac{1}{2(1+\gamma)}} e^{-\lambda_{1}(t-s)}\|\nabla \mathbf{u}(\cdot, s)\|_{L^{2}(\Omega)}^{2} d s, \quad \forall t>t_{3}
\end{aligned}
$$

and

$$
\begin{aligned}
& \int_{t_{3}}^{t}\left\|\mathcal{A}^{\frac{1}{2}} e^{-(t-s) \mathcal{A}} n(\cdot, s)\right\|_{L^{1+\gamma}(\Omega)} d s \\
\leq & C_{9} \int_{t_{3}}^{t}(t-s)^{-\frac{1}{2}} e^{-\lambda_{1}(t-s)}\|n(\cdot, s)\|_{L^{1+\gamma}(\Omega)} d s \\
\leq & C_{9} \int_{t_{3}}^{t} e^{-\lambda_{1}(t-s)}\|n(\cdot, s)\|_{L^{1+\gamma}(\Omega)}^{1+\gamma} d s+C_{9} \int_{t_{3}}^{t}(t-s)^{-\frac{1+\gamma}{2 \gamma}} e^{-\lambda_{1}(t-s)} d s, \quad \forall t>t_{3},
\end{aligned}
$$

where the positive constants $C_{5}, C_{6}, C_{7}, C_{8}, C_{9}$ depend only on $\gamma$ and $\Omega$. Summarizing the above estimates and recalling (5.36), (5.30) deduce the existence of $t_{5}>t_{3}$ such that

$$
\left\|\mathcal{A}^{\frac{1}{2}} \mathbf{u}(\cdot, t)\right\|_{L^{1+\gamma}(\Omega)} \leq C_{10}, \quad \forall t>t_{5}
$$

and hence,

$$
\begin{equation*}
\|\mathbf{u}(\cdot, t)\|_{L^{\infty}(\Omega)} \leq C_{11}, \quad \forall t>t_{5} \tag{5.39}
\end{equation*}
$$

due to an application of the Sobolev embedding inequality.
By utilizing (4.16) $)_{1}$ and noticing (4.18), we obtain for any $t>t_{6}:=\max \left\{t_{4}, t_{5}\right\}$,

$$
\begin{aligned}
\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t} \int_{\Omega} n^{2} d x+\int_{\Omega} D(n)|\nabla n|^{2} d x & =-\int_{\Omega} S(n) \nabla n \cdot \nabla c d x+r \int_{\Omega} n^{2} d x-\mu \int_{\Omega} n^{\gamma+2} d x \\
& =\int_{\Omega} H_{s}(n) \cdot \Delta c d x+r \int_{\Omega} n^{2} d x-\mu \int_{\Omega} n^{\gamma+2} d x \\
& \leq \int_{\Omega} H_{s}(n)^{\frac{\gamma+2}{\gamma+1}} d x+\int_{\Omega}|\Delta c|^{\gamma+2} d x+r \int_{\Omega} n^{2} d x-\mu \int_{\Omega} n^{\gamma+2} d x
\end{aligned}
$$

with

$$
\begin{aligned}
H_{s}(n):=\int_{0}^{n} S(\sigma) d \sigma & \leq C_{12} n^{(\beta-1)_{+}+2}+C_{12} \\
& \leq C_{12} n^{\gamma+1}+2 C_{12}
\end{aligned}
$$

where we utilized the assumption $\beta \leq \gamma$ and $C_{12}$ depends only on $b_{0}, r$ and $\Omega$. A simple calculation implies

$$
(2+\gamma+2 r) \int_{\Omega} n^{2} d x \leq \mu \int_{\Omega} n^{\gamma+2} d x+\frac{(2+\gamma+2 r)^{\frac{2}{\gamma}+1}|\Omega|}{\mu^{\frac{2}{\gamma}}}
$$

Combining the above estimates, one has

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\Omega} n^{2} d x+(2+\gamma) \int_{\Omega} n^{2} d x \leq & 2 C_{12}^{\frac{\gamma+2}{\gamma+1}} \int_{\Omega} n^{\gamma+2} d x+\int_{\Omega}|\Delta c|^{\gamma+2} d x-\mu \int_{\Omega} n^{\gamma+2} d x \\
& +\frac{(2+\gamma+2 r)^{\frac{2}{\gamma}+1}|\Omega|}{\mu^{\frac{2}{\gamma}}}+4 C_{12}^{\frac{\gamma+2}{\gamma+1}}, \quad \forall t>t_{6}
\end{aligned}
$$

namely,

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} t}\left(e^{(\gamma+2) s} \int_{\Omega} n^{2} d x\right) \leq & 2 C_{12}^{\frac{\gamma+2}{\gamma+1}} e^{(\gamma+2) s} \int_{\Omega} n^{\gamma+2} d x+e^{(\gamma+2) s} \int_{\Omega}|\Delta c|^{\gamma+2} d x-\mu e^{(\gamma+2) s} \int_{\Omega} n^{\gamma+2} d x \\
& +e^{(\gamma+2) s} \frac{(2+\gamma+2 r)^{\frac{2}{\gamma}+1}|\Omega|}{\mu^{\frac{2}{\gamma}}}+4 C_{12}^{\frac{\gamma+2}{\gamma+1}} e^{(\gamma+2) s}, \quad \forall t>t_{6} \tag{5.40}
\end{align*}
$$

The maximal $L^{p}-L^{q}$ estimates [13] along with the Gagliardo-Nirenberg inequality and the Sobolev estimates indicate that

$$
\begin{aligned}
\int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s}|\Delta c|^{\gamma+2} d x d s \leq & C_{13} \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s}|\mathbf{u} \cdot \nabla c|^{\gamma+2} d x d s+C_{13} \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s \\
& +C_{13} e^{(\gamma+2) t_{6}} \int_{\Omega}|\Delta c|^{\gamma+2}\left(x, t_{6}\right) d x
\end{aligned}
$$

$$
\begin{aligned}
\leq & C_{13}\|\mathbf{u}\|_{L^{\infty}\left(\Omega \times\left(t_{6}, t\right)\right)}^{\gamma+2} \int_{t_{6}}^{t} e^{(\gamma+2) s}\|\nabla c\|_{L^{\gamma+2}(\Omega)}^{\gamma+2} d s+C_{13} \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s \\
& +C_{13} e^{(\gamma+2) t_{6}} \int_{\Omega}|\Delta c|^{\gamma+2}\left(x, t_{6}\right) d x \\
\leq & C_{14}\|\mathbf{u}\|_{L^{\infty}\left(\Omega \times\left(t_{6}, t\right)\right)}^{\gamma+2} \int_{t_{6}}^{t} e^{(\gamma+2) s}\left(\|\Delta c\|_{L^{\gamma+2}(\Omega)}^{\frac{\gamma+2}{2}}\|c\|_{L^{\gamma+2}(\Omega)}^{\frac{\gamma+2}{2}}+\|c\|_{L^{\gamma+2}(\Omega)}^{\gamma+2}\right) d s \\
& +C_{13} \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s+C_{13} e^{(\gamma+2) t_{6}} \int_{\Omega}|\Delta c|^{\gamma+2}\left(x, t_{6}\right) d x, \quad \forall t>t_{6}
\end{aligned}
$$

with $C_{13}=C_{13}(\gamma, \Omega)>0$ and $C_{14}=C_{14}(\gamma, \Omega)>0$. Thus, by virtue of (5.39) and (5.37), we employ Young's inequality to the above display and obtain

$$
\begin{align*}
\int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s}|\Delta c|^{\gamma+2} d x d s \leq & C_{15} \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s+C_{15} e^{(\gamma+2) t_{6}} \int_{\Omega}|\Delta c|^{\gamma+2}\left(x, t_{6}\right) d x \\
& +C_{15} e^{(\gamma+2) t}, \quad \forall t>t_{6} \tag{5.41}
\end{align*}
$$

Integrating (5.40) over $\left(t_{6}, t\right)$ and using (5.41) directly shows that

$$
\begin{align*}
e^{(\gamma+2) t} \int_{\Omega} n^{2}(x, t) d x \leq & \left(2 C_{12}^{\frac{\gamma+2}{\gamma+1}}+C_{15}\right) \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s-\mu \int_{t_{6}}^{t} \int_{\Omega} e^{(\gamma+2) s} n^{\gamma+2} d x d s \\
& +e^{(\gamma+2) t_{6}} \int_{\Omega} n^{2}\left(x, t_{6}\right) d x+C_{15} e^{(\gamma+2) t_{6}} \int_{\Omega}|\Delta c|^{\gamma+2}\left(x, t_{6}\right) d x \\
& +\left(\frac{(2+\gamma+2 r)^{\frac{2}{\gamma}+1}|\Omega|}{\mu^{\frac{2}{\gamma}}}+4 C_{12}^{\frac{\gamma+2}{\gamma+1}}+C_{15}\right) e^{(\gamma+2) t}, \quad \forall t>t_{6} \tag{5.42}
\end{align*}
$$

We further enlarge $\mu_{*}>2 C_{12}^{\frac{\gamma+2}{\gamma+1}}+C_{15}$ (if necessary) and let $\mu \geq \mu_{*}$ to conclude that there is $t_{7}>t_{6}$ fulfilling

$$
\int_{\Omega} n^{2}(x, t) d x \leq \frac{(2+\gamma+2 r)^{\frac{2}{\gamma}+1}|\Omega|}{\mu_{*}^{\frac{2}{\gamma}}}+4 C_{12}^{\frac{\gamma+2}{\gamma+1}}+2 C_{15}+1, \quad \forall t>t_{7}
$$

where all the factors appearing on the right-hand side depend only on $\gamma, \beta, r, b_{0}$ and $\Omega$. This ends our proof.

## Conflict of interest

The authors declare that there is no conflict of interest. We also declare that this manuscript has no associated data.

## Data availability

Data sharing is not applicable to this article as no datasets were generated or analysed during the current study.
