#### Abstract

We study uniqueness of best approximation in Orlicz spaces $L^{\Phi}$, for different types of convex functions $\Phi$ and for some finite dimensional approximation classes of functions, where Tchebycheff spaces, and more general approximation ones, are involved.

## 1. Introduction and notations

Let $\Im$ be the class of all non decreasing functions $\varphi$ defined for all real numbers $t \geq 0$, such that $\varphi(t)>0$ if $t>0$, and consider $\Psi$ the class of all convex functions $\Phi$ defined by $\Phi(x)=\int_{0}^{x} \varphi(t) d t$, for $x \geq 0$, with $\varphi \in \Im$. We assume a $\Delta_{2}$ condition for the functions $\Phi$, which means that there exists a constant $\Lambda>0$ such that $\Phi(2 x) \leq \Lambda \Phi(x)$, for $x \geq 0$. We also denote by $\varphi^{-}$and $\varphi^{+}$the left and right derivatives of $\Phi$ respectively.

Let $\Phi \in \Psi$ and let $(\Omega, \mathcal{A}, m)$ be the Lebesgue measure space where $\Omega \subset \mathbb{R}$ is a bounded set. We denote by $L^{\Phi}=L^{\Phi}(\Omega, \mathcal{A}, m)$ the Orlicz space given by the class of all $\mathcal{A}$-measurable functions $f$ defined on $\Omega$ such that $\int_{\Omega} \Phi(|f|) d x<\infty$.

Given a set $S \subset L^{\Phi}$, an element $P \in S$ is called a best $\Phi$-approximation of $f \in L^{\Phi}$ from the approximation class $S$ if and only if

$$
\int_{\Omega} \Phi(|f-P|) d x=\inf _{Q \in S} \int_{\Omega} \Phi(|f-Q|) d x
$$

and, in this case, we write $P \in \mu_{\Phi}(f / S)$. The mapping $\mu_{\Phi}: L^{\Phi} \rightarrow S$ is called the best $\Phi$-approximation operator given $S$.

Given a $n$-dimensional linear space $S_{n} \subseteq C([a, b])$, the existence of a best approximation is assured by Theorem 2.3 in [3]. Recall that $S_{n}$ is called a Tchebycheff space if any non zero element in $S_{n}$ has at most $n-1$ zeros in $[a, b]$.

Uniqueness of best approximation was studied since 1924, for example in [7], and this problem was extensively developed in $L^{1}$ in the $70^{\prime}$ s. Conditions which assure uniqueness of best $L^{1}$ approximation have been studied, for instance for Galkin in [6] and Strauss [14] showed uniqueness in $L^{1}$ by polynomial splines. In [9] Micchelli considered best approximation by weak Tchebychev subspaces. For a very mentioned reference of this problem we also have to cite to DeVore [5], Kroo [8], Pinkus [10] and Strauss [14].

We point out that for Orlicz spaces $L^{\Phi}([a, b])$ it is easy to obtain uniqueness of best $\Phi$ - approximation for a given strictly convex function $\Phi$. In this paper we present first a characterization theorem of best $\Phi$ - approximation which will be used in the sequel. Next, we get uniqueness of the best $\Phi$ - approximation, for a continuous function defined in a real interval $[a, b]$, where we consider a general function $\Phi$ and where the approximation class is a Tchebycheff space which generalizes the classical result in $L^{1}$, setted for example in [12]. Next we get uniqueness of the best $\Phi$ - approximation for more general approximation classes, considering suitable classes of functions $\Phi$. We set also a sufficient and necessary condition to assure that the best approximation of a continuous function is unique, which is an extension, in some way, to Theorem 22 of [4], stablished in the $L^{1}$ space.

## 2. Characterization and properties of the best $\Phi$-approximations.

In this section, we will set a characterization property of the best $\Phi$ - approximations, when the approximation class is a finite dimensional vector space $S_{n}$, which will be useful to get uniqueness of best $\Phi$ - approximation for continuous functions. On the other hand, it is well known that uniqueness results follows straight forward if $\Phi$ is a strictly convex function. We deal with a more general convex functions $\Phi$, where the strictly convexity is not required.

At the end of this section, we will present a property for the not strictly convex functions that will be used in the study of the uniqueness for a suitable class of approximation functions.

The following characterization is a generalization of Theorem 2.2 in [1] for the case $\varphi^{+}(0)>$ 0 and Theorem 2.2 in [2] for the non derivative case of $\Phi$.

Theorem 2.1. Let $\Phi \in \Psi$ and $f \in L^{\Phi}(\Omega)$. Then $P \in \mu_{\Phi}\left(f / S_{n}\right)$ if and only if

$$
\begin{aligned}
\int_{\{Q>0, f>P\} \cup\{Q<0, f<P\}} \varphi^{-}(|f-P|)|Q| d x & -\int_{\{Q<0, f>P\} \cup\{Q>0, f<P\}} \varphi^{+}(|f-P|)|Q| d x \\
\leq & \varphi^{+}(0) \int_{\{f=P\}}|Q| d x
\end{aligned}
$$

for any $Q \in S_{n}$.

Proof. For $P \in \mu_{\Phi}\left(f / S_{n}\right), Q \in S_{n}$ with $Q \neq P$ and $\epsilon \geq 0$, we define

$$
F_{Q}(\epsilon)=\int_{\Omega} \Phi(|f-(P+\epsilon Q)|) d x
$$

Using the convexity of $\Phi$, we have that $F_{Q}$ is also a convex function on $[0, \infty)$, then

$$
\begin{aligned}
F_{Q}\left(a \epsilon_{1}+b \epsilon_{2}\right) & =\int_{\Omega} \Phi\left(\left|(a+b) f-\left((a+b) P+\left(a \epsilon_{1}+b \epsilon_{2}\right) Q\right)\right|\right) d x \\
& \leq \int_{\Omega} \Phi\left(a\left|f-\left(P+\epsilon_{1} Q\right)\right|+b\left|f-\left(P+\epsilon_{2} Q\right)\right|\right) d x \\
& \leq a \int_{\Omega} \Phi\left(\left|f-\left(P+\epsilon_{1} Q\right)\right|\right) d x+b \int_{\Omega} \Phi\left(\left|f-\left(P+\epsilon_{2} Q\right)\right|\right) d x \\
& =a F_{Q}\left(\epsilon_{1}\right)+b F_{Q}\left(\epsilon_{2}\right)
\end{aligned}
$$

for $\epsilon_{1}, \epsilon_{2} \geq 0$, and $a+b=1$. It follows that $F_{Q}(0)=\min _{[0, \infty)} F_{Q}(\epsilon)$, and the equality holds if, and only if, $0 \leqslant F_{Q}^{+}(0)$, where $F_{Q}^{+}(0)$ is the right derivative of $F_{Q}$ in $\epsilon=0$. Now we compute the derivative.

$$
\begin{aligned}
F_{Q}^{+}(0) & =\lim _{\epsilon \rightarrow 0^{+}} \frac{F_{Q}(0+\epsilon)-F_{Q}(0)}{\epsilon} \\
& =\lim _{\epsilon \rightarrow 0^{+}} \frac{1}{\epsilon}\left\{\int_{\Omega} \Phi(|f-(P+\epsilon Q)|) d x-\int_{\Omega} \Phi(|f-P|) d x\right\} \\
& =\lim _{\epsilon \rightarrow 0^{+}} \int_{\Omega \cap\{Q \neq 0\}}\left[\frac{\Phi(|f-(P+\epsilon Q)|)-\Phi(|f-P|)}{\epsilon Q}\right] Q d x .
\end{aligned}
$$

To analyze each absolute value in the argument of $\Phi$, we split the set $\Omega \cap\{Q \neq 0\}$ in seven cases, which will yield the following seven integrals:

$$
\begin{align*}
F_{Q}^{+}(0)=\lim _{\epsilon \rightarrow 0^{+}} & \left\{\int_{\{Q>0, P<P+\epsilon Q<f\}}\left[\frac{\Phi(f-P-\epsilon Q)-\Phi(f-P)}{\epsilon Q}\right] Q d x\right. \\
& +\int_{\{Q<0, P+\epsilon Q<P<f\}}\left[\frac{\Phi(f-P-\epsilon Q)-\Phi(f-P)}{\epsilon Q}\right] Q d x \\
& +\int_{\{Q<0, P+\epsilon Q<f<P\}}\left[\frac{\Phi(f-P-\epsilon Q)-\Phi(P-f)}{\epsilon Q}\right] Q d x \\
& +\int_{\{Q<0, P+\epsilon Q<f=P\}}\left[\frac{\Phi(f-P-\epsilon Q)-\Phi(P-f)}{\epsilon Q}\right] Q d x  \tag{1}\\
& +\int_{\{Q>0, f \leqslant P<P+\epsilon Q\}}\left[\frac{\Phi(P+\epsilon Q-f)-\Phi(P-f)}{\epsilon Q}\right] Q d x \\
& +\int_{\{Q>0, P<f \leqslant P+\epsilon Q\}}\left[\frac{\Phi(P+\epsilon Q-f)-\Phi(f-P)}{\epsilon Q}\right] Q d x \\
& \left.+\int_{\{Q<0, f \leqslant P+\epsilon Q<P\}}\left[\frac{\Phi(P+\epsilon Q-f)-\Phi(P-f)}{\epsilon Q}\right] Q d x\right\},
\end{align*}
$$

that is, $F_{Q}^{+}(0)=\lim _{\epsilon \rightarrow 0^{+}}\left\{I_{1}+I_{2}+I_{3}+I_{4}+I_{5}+I_{6}+I_{7}\right\}$.
By the convexity of $\Phi$, for $0<\epsilon \leqslant 1$ we have:

$$
\begin{equation*}
\frac{|Q||\Phi(|f-(P+\epsilon Q)|)-\Phi(|f-P|)|}{\epsilon|Q|} \leqslant|Q|\left(\varphi^{+}(|f-P|+|Q|)+\varphi^{+}(|f-P|)\right) . \tag{2}
\end{equation*}
$$

The function to the right of the inequality (2), is integrable in $\Omega$ because $\varphi^{+} \in \Delta_{2},|P| \leqslant$ $\|P\|_{\infty},|Q| \leq\|Q\|_{\infty}$ and $|\Omega|<\infty$. By the Dominated Convergence theorem we conclude that:

$$
\begin{aligned}
& \lim _{\epsilon \rightarrow 0^{+}} I_{1}=-\int_{\{Q>0, f>P\}} \varphi^{-}(|f-P|) Q d x, \\
& \lim _{\epsilon \rightarrow 0^{+}} I_{2}=-\int_{\{Q<0, f>P\}} \varphi^{+}(|f-P|) Q d x,
\end{aligned}
$$

$$
\begin{aligned}
\lim _{\epsilon \rightarrow 0^{+}} I_{4} & =\lim _{\epsilon \rightarrow 0^{+}} \int_{\{Q<0, P+\epsilon Q<f=P\}}\left[\frac{\Phi(0)-\Phi(0+\epsilon|Q|)}{\epsilon|Q|}\right] Q d x \\
& =\varphi^{+}(0) \int_{\{Q<0, f=P\}}|Q| d x, \\
\lim _{\epsilon \rightarrow 0^{+}} I_{5}= & \int_{\{Q>0, f \leqslant P\}} \varphi^{+}(|f-P|) Q d x \\
= & \int_{\{Q>0, f<P\}} \varphi^{+}(|f-P|) Q d x+\varphi^{+}(0) \int_{\{Q>0, f=P\}}|Q| d x
\end{aligned}
$$

and

$$
\lim _{\epsilon \rightarrow 0^{+}} I_{7}=\int_{\{Q<0, f<P\}} \varphi^{-}(|f-P|) Q d x .
$$

For the remaining integrals, let us consider a decreasing and convergent sequence $\left\{\epsilon_{n}\right\} \searrow 0$, and the decreasing sets: $A_{n}:=\left\{Q<0, P+\epsilon_{n} Q<f<P\right\}$, then $\bigcap_{n=1}^{\infty} A_{n}=\emptyset$ and:

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \int_{A_{n}}\left[\frac{\Phi\left(f-P-\epsilon_{n} Q\right)-\Phi(P-f)}{\epsilon_{n} Q}\right] Q d x & \leq \lim _{n \rightarrow \infty} \int_{A_{n}} \varphi^{+}(|f-P|+|Q|)+\varphi^{+}(|f-P|) d x \\
& =\lim _{n \rightarrow \infty} \mu\left(A_{n}\right),
\end{aligned}
$$

and $\lim _{n \rightarrow \infty} \mu\left(A_{n}\right)=\mu\left(\bigcap_{n=1}^{\infty} A_{n}\right)=\mu(\emptyset)=0$. Then $\lim _{\epsilon \rightarrow 0^{+}} I_{3}=0$.
Now, let us consider the sets $B_{n}=\left\{Q>0, P<f \leqslant P+\epsilon_{n} Q\right\}$, then $\bigcap_{n=1}^{\infty} B_{n}=\emptyset$ and again, by the Dominated Convergence Theorem we have $\lim _{\epsilon \rightarrow 0^{+}} I_{6}=0$.
Finally, replacing all the results in (1), we obtain

$$
\begin{aligned}
F_{Q}^{+}(0)= & -\int_{\{Q>0, f>P\}} \varphi^{-}(|f-P|) Q d x-\int_{\{Q<0, f>P\}} \varphi^{+}(|f-P|) Q d x \\
& +\int_{\{Q>0, f<P\}} \varphi^{+}(|f-P|) Q d x+\varphi^{+}(0) \int_{\{f=P\}}|Q| d x \\
& +\int_{\{Q<0, f<P\}} \varphi^{-}(|f-P|) Q d x
\end{aligned}
$$

As $F_{Q}^{+}(0) \geqslant 0$, we conclude the statement of the theorem.

For the next result we use the following notations. For a real number $x$ we set $\operatorname{sgn}(x)=$ $\frac{x}{|x|}, x \neq 0$, and $\operatorname{sign}(0)=0$.

Remark 2.2. If $\Phi(x)=\int_{0}^{x} \varphi(t) d t$ is a derivable function then $\varphi^{+}=\varphi^{-}=\varphi$, thus the last result becomes: $P \in \mu_{\Phi}\left(f / S_{n}\right)$ if and only if

$$
\left|\int_{\Omega} \varphi(|f-P|) \operatorname{sgn}(f-P) Q d x\right| \leq \varphi\left(0^{+}\right) \int_{\{f=P\}}|Q| d x
$$

for each $Q \in S_{n}$.

The following result generalizes the Haar's $L_{1}$-version theorem in [7].

Lemma 2.3. Let $\Phi \in \Psi$ and $S_{n}$ be an $n$-dimensional linear space of continuous functions in almost every point in the interval $[a, b]$. If $P_{1}, P_{2} \in \mu_{\Phi}\left(f / S_{n}\right)$ for $f \in L^{\Phi}$, then

$$
\left[f(x)-P_{1}(x)\right]\left[f(x)-P_{2}(x)\right] \geq 0
$$

for almost every $x \in[a, b]$.

Proof. Let's define the functions $g_{1}(x):=f(x)-P_{1}(x), g_{2}(x):=f(x)-P_{2}(x)$ and the number $\rho:=\inf _{Q \in S_{n}} \int_{a}^{b} \Phi(|f-Q|) d x$. We observe that $\rho=\int_{a}^{b} \Phi\left(\left|g_{1}\right|\right) d x=\int_{a}^{b} \Phi\left(\left|g_{2}\right|\right) d x$. Using that $\Phi$ is a non decreasing and convex function, we have:

$$
\int_{a}^{b} \Phi\left(\left|f-\frac{P_{1}+P_{2}}{2}\right| d x \leq \frac{1}{2} \int_{a}^{b} \Phi\left(\left|g_{1}\right|\right) d x+\frac{1}{2} \int_{a}^{b} \Phi\left(\left|g_{2}\right|\right) d x=\rho .\right.
$$

Then $\frac{P_{1}+P_{2}}{2}$ is also a best $\Phi$-approximation for $f$ and

$$
\int_{a}^{b} \Phi\left(\frac{\left|g_{1}+g_{2}\right|}{2}\right) d x=\int_{a}^{b} \frac{\Phi\left(\left|g_{1}\right|\right)}{2} d x+\int_{a}^{b} \frac{\Phi\left(\left|g_{2}\right|\right)}{2} d x .
$$

Which means that

$$
\begin{equation*}
\Phi\left(\frac{\left|g_{1}(x)+g_{2}(x)\right|}{2}\right)=\frac{\Phi\left(\left|g_{1}(x)\right|\right)}{2}+\frac{\Phi\left(\left|g_{2}(x)\right|\right)}{2} \tag{3}
\end{equation*}
$$

in almost every $x \in[a, b]$.

That is because $\Phi$ is continuous and $\frac{\Phi\left(\left|g_{1}(x)\right|\right)}{2}+\frac{\Phi\left(\left|g_{2}(x)\right|\right)}{2}-\Phi\left(\frac{\left|g_{1}(x)+g_{2}(x)\right|}{2}\right) \geq 0$ in $[a, b]$. If for some set $A$ with positive measure, $g_{1}(x)$ and $g_{2}(x)$ have different signs, then $\mid g_{1}(x)+$ $g_{2}(x)\left|<\left|g_{1}(x)\right|+\left|g_{2}(x)\right|\right.$ in $A$, and since $\Phi$ is a increasing and convex function, it satisfies $\Phi\left(\frac{\left|g_{1}(x)+g_{2}(x)\right|}{2}\right)<\Phi\left(\frac{\left|g_{1}(x)\right|+\left|g_{2}(x)\right|}{2}\right) \leq \frac{\Phi\left(\left|g_{1}(x)\right|+\Phi\left(\left|g_{2}(x)\right|\right)\right.}{2}$. But this last inequality contradicts (3), and the proof is then complete.

Recall that a function $\Phi:[0, \infty) \rightarrow \mathbb{R}$ is convex in an interval $I$ if for all $x, y \in I$ and $0 \leq \lambda \leq 1$, then $\Phi(\lambda x+(1-\lambda) y) \leq \lambda \Phi(x)+(1-\lambda) \Phi(y)$. And $\Phi$ is a strictly convex function in $I$ if for all $x \neq y \in I$ and $0<\lambda<1$, then $\Phi(\lambda x+(1-\lambda) y)<\lambda \Phi(x)+(1-\lambda) \Phi(y)$. We observe that linear functions are convex, but not strictly convex. On the other hand, the following lemma shows that a convex, but not strictly convex function, is linear in some sub interval.

Lemma 2.4. Let $\Phi \in \Psi$. If $\Phi$ is not strictly convex in an interval $I$, then there exists an interval $J \subset I$ such that $\Phi$ is a straight line in $J$.

Proof. If $\Phi$ is not strictly convex, then there exists an interval $J=\left(x_{1}, x_{3}\right) \subset I$ and a convex combination of $x_{1}$ and $x_{3}$ called $x_{2}$, such that the point $\left(x_{2}, \Phi\left(x_{2}\right)\right)$ is in the line between the points $\left(x_{1}, \Phi\left(x_{1}\right)\right)$ and $\left(x_{3}, \Phi\left(x_{3}\right)\right)$, where the equation for this line is

$$
\begin{equation*}
\Phi(x)=\frac{\Phi\left(x_{3}\right)-\Phi\left(x_{2}\right)}{x_{3}-x_{2}}\left(x-x_{3}\right)+\Phi\left(x_{3}\right) . \tag{4}
\end{equation*}
$$

If there is an $a \in\left(x_{1}, x_{2}\right)$ such that $\Phi(a)<\frac{\Phi\left(x_{3}\right)-\Phi\left(x_{2}\right)}{x_{3}-x_{2}}\left(a-x_{3}\right)+\Phi\left(x_{3}\right)$, then $\frac{\Phi\left(x_{3}\right)-\Phi(a)}{x_{3}-a}>$ $\frac{\Phi\left(x_{3}\right)-\Phi\left(x_{2}\right)}{x_{3}-x_{2}}$, and we have that $\Phi\left(x_{2}\right)>\frac{\Phi\left(x_{3}\right)-\Phi(a)}{x_{3}-a}\left(x_{2}-x_{3}\right)+\Phi\left(x_{3}\right)$. This inequality means that $x_{2}$ is a convex combination between $a$ and $x_{3}$ such that $\Phi\left(x_{2}\right)$ is not in the segment between the points $(a, \Phi(a))$ and $\left(x_{3}, \Phi\left(x_{3}\right)\right)$; which contradicts the convexity of $\Phi$. A similar argument is used if $a \in\left(x_{2}, x_{3}\right)$. So (4) is satisfied for all $x$ in $J$.

## 3. Uniqueness Results

Next we give uniqueness results of best $\Phi$ - approximation, for a suitable convex function $\Phi$, which is non strictly convex and, according to Lemma 2.4 , it is a straight line in some interval. In each case a convenient approximation class is considered.

Theorem 3.1. Let $\Phi \in \Psi, S_{n} \subseteq C([a, b])$ be a Tchebycheff space in $[a, b]$ and $f$ be a continuous function in $[a, b]$. Then there exists a unique best $\Phi$-approximation of $f$ in $[a, b]$ from the class $S_{n}$.

Proof. Since the approximation class is finite dimensional, the existence of a best approximation, say $P_{1}$, is assured by theorem 2.3 in [3]. It remains to prove the uniqueness of the best $\Phi$ - approximation function. Suppose that $f \notin S_{n}$ and for each $Q \in S_{n}$, consider the set $Z(f-Q):=\{x \in[a, b]: f(x)-Q(x)=0\}$.

Suppose that $Z\left(f-P_{1}\right)$ has measure zero, then by Theorem 2.1 we conclude

$$
\begin{aligned}
& \int_{\left\{Q>0, f>P_{1}\right\}} \varphi^{-}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) Q d x+\int_{\left\{Q<0, f<P_{1}\right\}} \varphi^{-}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) Q d x \\
&+ \int_{\left\{Q<0, f>P_{1}\right\}} \varphi^{+}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) Q d x+\int_{\left\{Q>0, f<P_{1}\right\}} \varphi^{+}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) Q d x \\
& \leq 0
\end{aligned}
$$

for every $Q \in S_{n}$.
Note that $S_{n}$ has a basis $\left\{\delta_{i}\right\}_{i=1}^{n}$ such that for $m<n$, the set $\left\{\delta_{i}\right\}_{i=1}^{m}$ generate also a Tchebycheff space (see Theorem 2.29 in [13]).

We get that the function $\operatorname{sign}\left[f(x)-P_{1}(x)\right]$ has at least $n$ sign changes. In fact, suppose it has only $m<n$ sign changes at the $n$ points $x_{1}<\ldots<x_{m}$ in $(a, b)$. Then there exists a function $P_{m} \in S_{n}, P_{m} \neq 0$ that changes sign only in $x_{i}$, for $i=1, \ldots, m$ (see Proposition 2, page 195, in [11]). It follows that the function $P_{m} \operatorname{sign}\left[f-P_{1}\right] \geq 0$ in $[a, b]$.

Since $\varphi^{+}$and $\varphi^{-}$are positive for $x>0$, we have

$$
\begin{aligned}
0 & =\int_{\left\{P_{m}>0, f>P_{1}\right\}} \varphi^{-}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) P_{m} d x \\
& =\int_{\left\{P_{m}<0, f<P_{1}\right\}} \varphi^{-}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) P_{m} d x \\
& =\int_{\left\{P_{m}<0, f>P_{1}\right\}} \varphi^{+}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) P_{m} d x \\
& =\int_{\left\{P_{m}>0, f<P_{1}\right\}} \varphi^{+}\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) P_{m} d x
\end{aligned}
$$

Thus we conclude $f=P_{1}$ almost everywhere in $[a, b]$, we get a contradiction.
Then, the function $\operatorname{sgn}\left[f(x)-P_{1}(x)\right]$, has at least $n$ sign changes. Now, suppose that there exists $P_{2}$, another best $\Phi$-approximation for $f$ in $[a, b]$. By Lemma 2.3, $f(x)-P_{2}(x)$ is zero at the $n$-points where $f(x)-P_{1}(x)$ changes signs. Then $P_{1}(x)-P_{2}(x)$ has $n$-zeros, so $P_{1}=P_{2}$.

Now, suppose that for any $P_{1} \in \mu_{\Phi}\left(f / S_{n}\right)$ we have $m\left(Z\left(f-P_{1}\right)\right)>0$ and consider another $P_{2} \in \mu_{\Phi}\left(f / S_{n}\right)$. By the convexity of $\Phi$, we have for $\lambda \in[0,1]$ :

$$
\int_{[a, b]} \Phi\left(\left|f-\lambda P_{1}-(1-\lambda) P_{2}\right|\right) d x \leq \lambda \int_{[a, b]} \Phi\left(\left|f-P_{1}\right|\right) d x+(1-\lambda) \int_{[a, b]} \Phi\left(\left|f-P_{2}\right|\right) d x
$$

then $\lambda P_{1}+(1-\lambda) P_{2} \in \mu_{\Phi}\left(f / S_{n}\right)$. Suppose that for each $\lambda \in[0,1]: m\left(Z\left(f-\lambda P_{1}-(1-\lambda) P_{2}\right)\right)>$ 0 . Then there exists $\lambda_{1}, \lambda_{2} \in[0,1]$ such that the sets of zeros $Z\left(f-\lambda_{1} P_{1}-\left(1-\lambda_{1}\right) P_{2}\right)$ and $Z\left(f-\lambda_{2} P_{1}-\left(1-\lambda_{2}\right) P_{2}\right)$ have intersection with positive measure (see Lemma 4-7, page 109 in [12]). In particular, the intersection has $n$-points. Then $P_{1}=P_{2}$ and this concludes the proof.

Next we consider wider approximation classes: the 1 -space and the 0 -space.

Definition 3.2. We say that the $n$-dimensional set $S_{n} \subset C([a, b])$ is a 1-space if there exists $h \in S_{n}$ such that $h(x)>0$ for every $x \in[a, b]$, and if $P_{1}, P_{2} \in S_{n}$ with $P_{1} \neq P_{2}$ then $\left|\left\{P_{1}=P_{2}\right\}\right|=0$. If $S_{n}$ satisfies only the last condition, we say that $S_{n}$ is a 0 -space.

Lemma 3.3. Let $S_{n}$ a 1-space and $P \in \mu_{\Phi}\left(f / S_{n}\right)$. Then there exits $x \in[a, b]$ such that $f(x)=P(x)$.

Proof. We assume $P(x)-f(x)>0$, for every $x \in[a, b]$ and consider $h \in S_{n}, h(x)>0$ for $x \in[a, b]$. Then, for $\varepsilon>0$ such that $\varepsilon<\frac{\min _{x \in[a, b]} P(x)-f(x)}{\max _{x \in[a, b]} h(x)}$, we have

$$
\varepsilon h(x)<P(x)-f(x), x \in[a, b] .
$$

Then

$$
0<\int_{[a, b]} \Phi(P-\varepsilon h-f) d x<\int_{[a, b]} \Phi(P-f) d x
$$

which is a contradiction since $P-\varepsilon h \in S_{n}$

Now we get the following uniqueness result when $S_{n}$ is a 1 -space.

Theorem 3.4. Let $\varphi \in \Im$ which is also a strictly increasing function in $[0, b], b>0$, and $\Phi(x)=\int_{0}^{x} \varphi(t) d t$. If $S_{n}$ is a 1-space, then for every $f \in C([a, b])$ the best approximation set $\mu_{\Phi}\left(f / S_{n}\right)$ is a singleton.

Proof. Suppose $P_{1}, P_{2} \in \mu_{\Phi}\left(f / S_{n}\right)$, with $P_{1} \neq P_{2}$. Now by Lemma 3.3 there exists an interval $I$ such that $\left|f-P_{1}\right|(x) \leq b$, for every $x \in I$, and then the set $J=I \cap\left\{x \in[a, b]: P_{1}(x) \neq\right.$ $\left.P_{2}(x)\right\}$ has positive measure. Then, from the strictly convexity of $\Phi$ in $[0, b]$ and taking into account Lemma 2.3 we get

$$
\int_{J} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x<\frac{1}{2} \int_{J} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{J} \Phi\left(\left|f-P_{2}\right|\right) d x
$$

and then, since the convexity of $\Phi$, we obtain

$$
\int_{[a, b]} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x<\frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{2}\right|\right) d x
$$

which is a contradiction since $\frac{P_{1}+P_{2}}{2} \in S_{n}$.

For the next result we consider a n-dimensional 0 -space $S_{n} \subseteq C([a, b])$ and we give a necessary and sufficient condition on the approximation class $S_{n}$ which assures the uniqueness of $\mu_{\Phi}\left(f / S_{n}\right)$ for convex function $\Phi$, which is a strictly convex function just for $x$ grater than some positive real number. This result follows the same lines considered in [4] for $L^{1}$ and it is a generalization to Orlicz spaces.

Definition 3.5. The set $Z(f):=\{x \in[a, b]: f(x)=0\}$ is called a $\gamma-$ set if $0 \in \mu_{\Phi}\left(f / S_{n}\right)$.

Theorem 3.6. Consider the function $\Phi$ such that for $k, c>0$ and $x \in[0, c], \Phi(x)=k x$, and $\Phi$ is a strictly convex function for $x \in(c, \infty)$. Let $S_{n}$ be a n-dimensional 0-space. Then, for every $f \in C([a, b]) \cap L^{\Phi}([a, b])$ the set $\mu_{\Phi}\left(f / S_{n}\right)$ has an unique element $P_{1}$, if and only if
a) The constant function 0 is the unique element of $S_{n}$ which is 0 on a $\gamma$ - set or
b) For $P_{1} \in \mu_{\Phi}\left(f / S_{n}\right)$, the set $\left\{x \in[a, b]:\left|f(x)-P_{1}(x)\right|>c\right\}$ has positive measure for every $f \in C([a, b]) \cap L^{\Phi}([a, b])$.

Proof. Suppose $P_{1}, P_{2}$ are two different elements in $\mu_{\Phi}\left(f / S_{n}\right)$. Due to the convexity of $\Phi$, we have

$$
\int_{[a, b]} \Phi\left(\left|f-\frac{P_{1}+P_{2}}{2}\right|\right) d x=\frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{2}\right|\right) d x .
$$

Then we get

$$
\Phi\left(\left|f(x)-\frac{P_{1}+P_{2}}{2}(x)\right|\right)=\frac{1}{2} \Phi\left(\left|f(x)-P_{1}(x)\right|\right)+\frac{1}{2} \Phi\left(\left|f(x)-P_{2}(x)\right|\right), \quad x \in[a, b] .
$$

Thus for any $x \in Z\left(f-\frac{P_{1}+P_{2}}{2}\right)$ we have $f(x)-P_{1}(x)=f(x)-P_{2}(x)$, and then $P_{1}(x)-P_{2}(x)=$ 0 , and this is a contradiction of a).

Now assuming condition b) and suppose $P_{1}, P_{2} \in \mu_{\Phi}\left(f / S_{n}\right), P_{2} \neq P_{1}$, then we have $m(I)>0$, for

$$
I=\left\{x \in[a, b]:\left|f(x)-P_{1}(x)\right|>c\right\} \cap\left\{x \in[a, b]: P_{1}(x) \neq P_{2}(x)\right\}
$$

thus

$$
\int_{I} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x<\frac{1}{2} \int_{I} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{I} \Phi\left(\left|f-P_{2}\right|\right) d x
$$

and then we have a contradiction.
On the other hand, suppose there exists $P_{3} \in S_{n}, P_{3} \neq 0$ and $0 \leq\left|P_{3}\right| \leq \frac{c}{2}$, such that $Z\left(f-P_{1}\right) \subseteq Z\left(P_{3}\right), P_{1} \in \mu_{\Phi}\left(f / S_{n}\right)$ and assume $0 \leq\left|f-P_{1}\right|(x) \leq c$, a. e. $x$.

Now, for $h(x)=\left|P_{3}(x)\right| \operatorname{sgn}\left(f-P_{1}\right)(x)$, we have

$$
\int_{[a, b] \cap\left\{f \neq P_{1}\right\}} \varphi(|h|) \operatorname{sgn}(h) Q d x=\int_{[a, b] \cap\left\{f \neq P_{1}\right\}} \varphi(|h|) \operatorname{sgn}\left(f-P_{1}\right) Q d x
$$

and since $\varphi(|h|)=\varphi\left(\left|f-P_{1}\right|\right)=k$, we have

$$
\int_{[a, b] \cap\left\{f \neq P_{1}\right\}} \varphi(|h|) \operatorname{sgn}(h) Q d x=\int_{[a, b] \cap\left\{f \neq P_{1}\right\}} \varphi\left(\left|f-P_{1}\right|\right) \operatorname{sgn}\left(f-P_{1}\right) Q d x
$$

and since $P_{1} \in \mu_{\Phi}\left(f / S_{n}\right)$ and $Z\left(f-P_{1}\right) \subseteq Z(h)$, we get

$$
\int_{[a, b] \cap\{h \neq 0\}} \varphi(|h|) \operatorname{sgn}(h) Q d x \leq \varphi(0) \int_{Z(h)}|Q| d x
$$

which implies, since 2.2 that $0 \in \mu_{\Phi}\left(h / S_{n}\right)$.
Now

$$
\int_{[a, b]} \Phi\left(\left|h-\varepsilon P_{3}\right|\right) d x=\int_{[a, b]} \Phi\left(\left(h-\varepsilon P_{3}\right) \operatorname{sgn}\left(h-\varepsilon P_{3}\right) d x,\right.
$$

and taking into account $\Phi(x)=k x$, for $x \leq c$ we get

$$
\int_{[a, b]} \Phi\left(\left|h-\varepsilon P_{3}\right|\right) d x=\int_{[a, b]} k h \operatorname{sgn}\left(h-\varepsilon P_{3}\right) d x-\varepsilon \int_{[a, b]} k P_{3} \operatorname{sgn}\left(h-\varepsilon P_{3}\right) d x
$$

and then, for $x \in[a, b], h(x)-\varepsilon P_{3}(x) \neq 0$, it holds $\operatorname{sgn}\left(h-\varepsilon P_{3}\right)(x)=\operatorname{sgn}\left(f-P_{1}\right)(x)$, thus

$$
\int_{[a, b]} \Phi\left(\left|h-\varepsilon P_{3}\right|\right) d x=\int_{[a, b]} k h \operatorname{sgn}\left(f-P_{1}\right) d x-\varepsilon \int_{[a, b]} k P_{3} \operatorname{sgn}\left(f-P_{1}\right) d x .
$$

Now, we use remark 2.2 to obtain

$$
-\varepsilon \int_{[a, b]} k P_{3} \operatorname{sgn}\left(f-P_{1}\right) d x \leq \varepsilon \varphi(0) \int_{Z\left(f-P_{1}\right)} k\left|P_{3}\right| d x,
$$

and then

$$
\int_{[a, b]} \Phi\left(\left|h-\varepsilon P_{3}\right|\right) d x \leq \int_{[a, b]} k h \operatorname{sgn}\left(f-P_{1}\right) d x+\varepsilon \varphi(0) \int_{Z\left(f-P_{1}\right)} k\left|P_{3}\right| d x .
$$

Thus, since $Z\left(f-P_{1}\right) \subseteq Z\left(P_{3}\right)$, we have $\int_{Z\left(f-P_{1}\right)}\left|P_{3}\right| d x=0$, then

$$
\int_{[a, b]} \Phi\left(\left|h-\varepsilon P_{3}\right|\right) d x \leq \int_{[a, b]} k h \operatorname{sgn}\left(f-P_{1}\right) d x=\int_{[a, b]} k h \operatorname{sgn}(h) d x=\int_{[a, b]} \Phi(|h|) d x,
$$

which implies that $\varepsilon P_{3} \in \mu_{\Phi}\left(h / S_{n}\right)$, for every $\varepsilon, 0<\varepsilon<1$.

Finally, we set an uniqueness result of $\mu_{\Phi}\left(f / S_{n}\right)$, where a specific convex function $\Phi$ and a suitable 1-space $S_{n}$ are considered.

Theorem 3.7. Let $\Phi \in \Psi, \Phi(x)=\int_{0}^{x} \varphi(t) d t$, where $\varphi \in \Im$ is non continuous in a decreasing positive sequence $a_{n}$, which converges to 0 . Let $S_{n}$ be a 1-space such that every nonzero $P \in S_{n}$ has only a finite amount of zeros on $[a, b]$. Then for every $f \in C([a, b])$ the best approximation set $\mu_{\Phi}\left(f / S_{n}\right)$ is a singleton.

Proof. Suppose that $P_{1}, P_{2} \in \mu_{\Phi}\left(f / S_{n}\right)$ with $P_{1} \neq P_{2}$. Since $\int_{a}^{b} \Phi\left(\left|f-P_{1}\right|\right)-\Phi\left(\left|f-P_{2}\right|\right) d x=0$, the function $\Phi\left(\left|f-P_{1}\right|\right)-\Phi\left(\left|f-P_{2}\right|\right)$ cannot be positive in $[a, b]$. Then, since $\Phi(0)=0$ and Lemma 2.3, there exists $x_{0} \in[a, b]$ such that $f(x)-P_{1}\left(x_{0}\right)=f(x)-P_{2}\left(x_{0}\right)$.

Actually, $x_{0}$ is a zero of $P_{1}-P_{2}$, which is a nonzero element of $S_{n}$. Therefore, $x_{0}$ is an isolated point in $[a, b]$ and there exists a positive real number $\delta_{0}>0$ such that for every $x \in\left(x_{0}, x_{0}+\delta_{0}\right]$, we assume without loss of generality that $f(x)-P_{1}(x)>f(x)-P_{2}(x)>0$.

Also there exists a real number $x_{1} \in\left[x_{0}, x_{0}+\delta_{0}\right]$ such that

$$
\left(f-P_{1}\right)\left(x_{1}\right)=\max _{x \in\left[x_{0}, x_{0}+\delta_{0}\right]}\left(f-P_{1}\right)(x)
$$

Considering that $a_{n} \rightarrow 0$, there must be some $n$ such that $a_{n}<\left(f-P_{1}\right)\left(x_{1}\right)$. Due to $f-P_{1}$ continuity, there is a real number $x_{2} \in\left[x_{0}, x_{0}+\delta_{0}\right]$ such that $\left(f-P_{1}\right)\left(x_{2}\right)=a_{n}$.

For this $x_{2}$ we can find some $\delta_{1}>0$ such that $\left(f-P_{2}\right)(x)<a_{n}<\left(f-P_{1}\right)(x)$ for every $x \in\left(x_{2}, x_{2}+\delta_{1}\right) \subset\left[x_{0}, x_{0}+\delta_{0}\right]$. If there were no such $\delta_{1}>0$, then $f-P_{1}$ would not reach up to its maximum at $\left(f-P_{1}\right)\left(x_{1}\right)$.

Finally, if we set $I:=\left(x_{2}, x_{2}+\delta_{1}\right)$, we can see that

$$
\begin{aligned}
\int_{[a, b]} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x= & \int_{I} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x+\int_{[a, b]-I} \Phi\left(\left|f-\left(\frac{P_{1}+P_{2}}{2}\right)\right|\right) d x \\
< & \frac{1}{2} \int_{I} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{I} \Phi\left(\left|f-P_{2}\right|\right) d x+ \\
& +\frac{1}{2} \int_{[a, b]-I} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{[a, b]-I} \Phi\left(\left|f-P_{2}\right|\right) d x \\
= & \frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{1}\right|\right) d x+\frac{1}{2} \int_{[a, b]} \Phi\left(\left|f-P_{2}\right|\right) d x .
\end{aligned}
$$

This is a contradiction since $\frac{P_{1}+P_{2}}{2} \in S_{n}$.
