Abstract

In mathematical proof education, there remains a need for interventions that help students learn to write mathematical proofs. Research has shown that timely feedback can be very helpful to students learning new skills. While for many years natural language processing models have struggled to perform well on tasks related to mathematical texts, recent developments in natural language processing have created the opportunity to complete the task of giving students instant feedback on their mathematical proofs. In this paper, we present a set of training methods and models capable of autograding freeform mathematical proofs by leveraging existing large language models and other machine learning techniques. The models are trained using proof data collected from four different proof by induction problems. We use four different robust large language models to compare their performances, and all achieve satisfactory performances to various degrees. Additionally, we recruit human graders to grade the same proofs as the training data, and find that the best grading model is also more accurate than most human graders. With the development of these grading models, we create and deploy an autograder for proof by induction problems and perform a user study with students. Results from the study shows that students are able to make significant improvements to their proofs using the feedback from the autograder, but students still do not trust the AI autograders as much as they trust human graders. Future work can improve on the autograder feedback and figure out ways to help students trust AI autograders.

Keywords: Automated short answer grading, Mathematical proofs, Natural language processing

1 Introduction

Writing mathematical proofs has been identified as an important [1-3] and yet challenging topic [4] in computing education and mathematics education. A large body of research has shown that timely feedback is crucial to student learning [5, 6]. However, students are largely unable to receive timely feedback on written proofs due to the need to have proofs collected and hand-graded by instructors or teaching assistants. The ability to grade student proofs fully automatically with natural language processing (NLP) alleviates this need by allowing us to give students instant feedback on their proofs to let students iteratively enhance the quality of their proofs.

In this paper, we propose a novel set of training methods and models capable of autograding freeform mathematical proofs, a problem at the intersection of mathematical proof education and Automatic Short Answer Grading (ASAG), by using existing NLP models and other machine learning techniques. Our proof autograder enables the development of grading systems that provide instant feedback to students without needing attention from instructors. It can also be deployed in large-scale educational platforms, allowing for more access for students.

The main contributions of this paper are:

- Introducing the first pipeline of machine learning models capable of autograding mathematical proofs with similar accuracy to human graders
- Quantifying the amount of training data needed to achieve a satisfactory performance from the grading models
- Publishing an anonymized and labeled mathematical proof dataset that can be used in future model developments [7]
- Creating a set of autograded problems using the grading pipeline, and performing a user study that answers the following research questions:
 - Are students able to write better proofs by interacting with the autograder and the feedback it generates?
 - Are students satisfied with the autograder and the feedback it provides?
 - Does using the autograder make students more willing to use similar AI autograders in the future?

The rest of the paper is organized as follows: we first introduce the related work in Section 2, and then present the source and preprocessing of the training data for our model in 3.1. We then introduce the large language models used in the grading process and our own model for grade calculation in Sections 3.2 and 3.3. Section 3.4 gives the methods for the comparison to human graders. In Section 4, we show the performances from each large language model on the data, and compare the model grading against human grader performances. In Sections 5 and 6, we provide detail about a user study where we recruited students to write and improve their proofs using the developed autograders, and collected their progress and feedback with the autograder.

2 Related Work

2.1 Research on Mathematical Proof Education

While there has been extensive work both on software tooling and its evaluation for helping students learn school geometry proofs [5], there is still a need for tools to provide students with interventions and scaffolding on learning to write college-level mathematical proofs. Stylianides and Stylianides' review of the literature on teaching and learning proofs concluded that "more intervention-oriented studies in the area of proof are sorely needed" [8]. Several tools have been created which provide a visual method for students to construct simple mathematical proofs [9–11]. While these tools can act as scaffolding for students in the early stages of learning to write proofs, there are currently no existing software tools that can provide help to students working on the authentic task of writing proofs on their own from scratch. The grading models contributed by this paper enables to the creation of software tools which can give students automated feedback on their work as they practice writing natural language mathematical proofs on their own.

2.2 Natural Language Processing (NLP)

As a subfield of artificial intelligence, NLP primarily focuses on training and using models focusing on interpreting and generating natural languages used by humans. In 2017, NLP researchers invented the Transformer architecture, utilizing attention as its only mechanism and achieving good performance in learning the dependencies in inputs and outputs [12]. It also enabled easier training and inference by lowering the need of advanced training equipments or extended training time [12]. Further developments have led to the introduction of various pretrained large language models accessible such as BERT, Llama and Llama2, and OpenAI's GPT family of models [13–15]. In addition to being able to generate text, these models can take texts as inputs and return vectors representing the words or sentences in the texts. These vectors are called embeddings.

The word embedding method is a major part of the current field of NLP aiming to map words and phrases into a multi-dimensional continuous vector space. Each vector captures the semantic meaning of each word and phrase, and researchers can use the vectors to perform downstream tasks such as word prediction and sentence classification [16]. Multiple Word embeddings of a sentence can also be combined into one sentence embedding through the use of an extra network to capture the meaning of the whole sentence [17]. In essence, sentence embeddings capture the semantic meaning of the whole sentence.

2.3 Automatic Short Answer Grading (ASAG)

Researchers have attempted to use sentence embeddings to perform ASAG. Various NLP models have been tested on their performance, with attention-based models performing relatively well in terms of accuracy, latency, reproducibility, and ease in fine-tuning [18]. Existing training data sets cover topics in data structures, introductory statistics, and a few other topics, with no coverage of mathematical proof problems [18]. Previous work has also produced systems able to grade student's descriptions of short snippets of Python code, achieving over 85% accuracy with a dataset of less then 600 samples [19]. These models have successfully been deployed in the classroom to help students receive timely feedback and reduce instructor grading load [20].

The focus on ASAG has been put into mathematical contexts as well, with limited success so far. Researchers have developed Mathematical Language Processing to perform mathematical ASAG, and achieved an absolute mean error of 0.04 out of a full grade of 3 [21]. However, the approach taken by Mathematical Language Processing only allows a small set of mathematical vocabulary, and relies heavily on symbolic manipulation on the answers. As a result, it will not be able to autograde mathematical proofs, which usually involves reasoning using natural language, such as proof by induction or proof on graphs. MathBERT was created by fine-tuning BERT, aimed at dealing with a larger mathematical vocabulary and more complex mathematical contexts [22]. It achieved over 90% accuracy on autograding tasks, but the problems used were one-sentence Q&A problems that did not require much reasoning or formula manipulation, and were much shorter than the full inductive proofs that we treat in this work. To deal with verifying longer proofs, researchers have also attempted autoformalization [23], translating natural language into formal logic. This should make checking the correctness of the steps in a proof easier. However, even with several years of research, none of the existing work is able to translate even half of the proofs to formal logic [23]. The low success rate makes autoformalization not suited for grading mathematical proofs at the moment.

To our knowledge, no tools have successfully dealt with grading mathematical proofs using natural language processing. More emphasis needs to be put on verifying the natural language reasoning part of the proofs in addition to the arithmatic formulae.

Utilizing ASAG in practice poses a few difficulties. First of all, it is hard for the ASAG systems to be perfect: mistakes will likely happens during the grading process. In the context of potentially inaccurate feedback from the graders, helping students navigate through the feedback can be crucial in achieving the full potentials from ASAG systems [24]. Another challenge facing the wider use of ASAG is students' trust in AI. Previous research around AI trust has shown that people are more likely to trust human decisions than algorithmic decisions, especially when the tasks are more subjective [25, 26]. Some previous work has observed that students underestimated the accuracy of some ASAG systems, believing they were graded incorrectly when the grades were accurate [27]. The lack of trust in the technology behind the ASAG systems could hinder the effectiveness of the ASAG systems.

3 Model Development

We propose an automated grading process with two steps. First, we run studentwritten proofs through a pretrained large language model to get the embeddings. We then apply our custom grading model to the embeddings to calculate accuracy on

various rubric points. We also recruited human graders to re-grade proofs in our data set, which are used for baseline comparison.

3.1 Data

The proofs used in this study were collected from the pretest and posttest of a series of studies designed to measure the learning gains of students using Proof Blocks [28–30]. The study participants were students recruited from a Discrete Mathematics course at the University of Illinois Urbana-Champaign. The proofs were originally collected in the form of markdown files, and later graded by members of the research team. The proofs were graded in a multi-step process which involved multiple members of the research team grading the proofs independently, and then meeting together to discuss disagreements. The graders were able to reach an inter-rater reliability rating of Cronbach's α at 0.82, 0.88, and 0.92 for each of the three studies respectively [28–30].

These measurements show very high consistency among the agreement between researchers, and so we use these labels as ground truth for our training and further analysis. Since the grading of informally written mathematical proofs can be subjective, we recognize that our AI autograders and the human baseline comparison must not only agree with fundamental truths but also align with the grading standards set by the research team that created the original labels. However, we note that this is the same task that an ASAG system or a teaching assistant must accomplish when grading student work for a course—not only verifying underlying truth but also adhering to the grading criteria set by the instructor, who acts as the ground truth in this context. We also believe that our use of only technical, and not stylistic rubric points, as well as the rigorous process we used to have multiple researchers agree on a grading scheme (rather than have them decided by a single instructor), make our grading system as objective as possible in this context.

The proofs were graded using seven rubric points, each identifying a step of the induction proof:

- **R1** Identifying the base case(s)
- **R2** Proving the base case(s)
- **R3** Stating the inductive hypothesis
- **R4** Setting the bound of the inductive hypothesis
- **R5** Stating the goal of the inductive step
- **R6** Breaking down the inductive step
- **R7** Applying the inductive hypothesis

We selected four different proof by induction problems, and labeled them as P1, P2, P3, P4. P1 focuses on induction with a recursively defined function, and has 1623 non-empty proofs collected; P2 and P3 are induction proving the closed form solution to a summation formula, and have 1288 and 342 proofs respectively; P4 proves the divisibility of a function over the natural numbers, and has 333 proofs. The problems statements are shown in Table 1. The proofs were initially graded as 0, 1, 2 for each rubric point. A grade of 0 is given if the required rubric point is not present, 1 if the rubric point is partially correct, and 2 if it is completely correct. In our work, we collapse the grades into two categories, correct and incorrect. Original labels of 0 and 1 are combined into 0, standing for incorrect proofs; original labels of 2 are changed

P1	Suppose that $g: \mathbb{N} \to \mathbb{R}$ is defined by $g(0) = 0$, $g(1) = \frac{4}{3}$, and $g(n) = \frac{4}{3}g(n-1) - \frac{1}{3}g(n-2)$ for $n \ge 2$. Use induction to prove that $g(n) = 2 - \frac{2}{3^n}$ for any natural number n .
P2	Prove the following statement by induction. $\forall n \in \mathbb{N}, \sum_{i=0}^{n} i = \frac{n(n+1)}{2}$.
P3	Use (strong) induction to prove the following claim: $\sum_{p=0}^{n} (p \cdot p!) = (n+1)! - 1 \text{ for any natural number } n.$
P4	Use (strong) induction to prove the following claim: for any natural number n , $2n^3 + 3n^2 + n$ is divisible by 6.

Table 1: Problem statements for P1-P4.

FOr all natural numbers n; let the proposition P(n) be $\sum_{i=0}^{i}$ (from 0 to n) = to n(n+1)/2P(1) is $\sum_{i=0}^{i}$ (sigma from 0 to 1) = to 1(1+1)/2 Left hand side =1; right hand side = 1 So P(1) is true Therefore let P(x) be, P(x) = $\sum_{i=0}^{i}$ (sigma from 0 to x) = x(x+1)/2Therefore assume P(x+1) = $\sum_{i=0}^{i}$ (sigma from 0 to x+1) = (x+1)(x+2)/2the difference of sums between sigma to x and sigma to x+1 is the term x +1 only if we subtract P(x) from P(x+1) the reamaing number sould be x+1 $(x+1)(x+2)/2 - x(x+1)/2 = \frac{x^2+x}{2} - \frac{x^2+3x+2}{2} = \frac{2x+2}{2} = x + 1$ Therefore its proved by mathematical induction

Fig. 1: An example proof for P2. In the original labeling by previous researchers, this proof was labeled correct on rubric points R1: Identifying the base case, R2: Proving the base case, and R6: Breaking down the inductive step, and incorrect on all other rubric points.

to 1 to represent fully correct proofs. This allows us to give students individualized feedback on the correctness of each of the seven rubric points. Future work may use more complex labels for even more granular feedback. One sample proof and its R1-R7 labels are shown in Figure 1. We have published our data set in a public data repository so that future researchers may replicate our work and make further improvements in autograding mathematical proofs [7].

3.2 Model selection for Embeddings

Several pretrained large language models are capable of calculating embeddings such as BERT and its mathematically fine-tuned version MathBERT [22], Llama2 and its mathematically fine-tuned version Llemma [31], and GPT-3 [32]. Base BERT and base Llama2 are excluded because MathBERT and Llemma have been observed to perform better than their corresponding base models when dealing with mathematical contexts [22, 31]. MathBERT is among the best pretrained language models at mathematical language, and runs on a CPU. The memory requirement is typically less

than 600MB. Because of the low memory requirement, MathBERT allows for cheap deployment. It is worthwhile trying MathBERT despite having fewer parameters than most large language models, because if MathBERT can achieve similar performances as the other large language models, it would also be cheaper to deploy. This can be a determining factor of the grading models if they need to be scaled in the future to serve more students. GPT-3 is the best accessible language model at the moment for embeddings. We use the latest embedding endpoint text-embedding-3-large for analysis, as it outperforms the old endpoint text-embedding-ada-002 by 0.3% in accuracy in our grading tasks. GPT-3 requires API calls for embeddings, and each API call costs a small amount of money. This additional cost should be taken into consideration when scaling this grading model for larger number of students. We did not use GPT-4 as it does not yet support embeddings, which are preferred to text completion for classification tasks such as ours [32]. Llemma has two versions, Llemma7b with 7 billion parameters, and Llemma34b with 34 billion parameters. Both can be run locally, but take a significant amount of RAM and require a GPU even for inference. In our study, we utilize MathBERT, GPT-3, Llemma34b, and Llemma7b for embeddings and then compare the performances of the models.

One extra step of data manipulation was performed only for the MathBERT model. Currently, MathBERT is unable to recognize certain mathematical or mathematical LaTeX notation such as "f(x)" or "\sum_{i=1}^n". These symbols would be recognized as individual characters in MathBERT, lowering its ability to fully understand the contents. We modified the tokens from MathBERT so that it would recognize function calls and some latex expressions in the same token, enhancing the model's ability to understand the words and phrases accurately, increasing the accuracy of the model by a few percent. The modification also made sure that every proof in the dataset fit within the input token limit. The embeddings are calculated based on the modified MathBERT tokens.

3.3 Model fitting

The downstream task is to grade the proofs using the embeddings as inputs. Because the LLM we use for embedding handles the difficult task of extracting the relevant features in the text, we were able to use a relatively simple model for classification afterwards. We tried both linear regression and SVMs, with similar results, and so we chose to use linear regression for its simplicity. More complexity can be added if needed in the future. We trained one grading model for each rubric point of each problem, as the exact expectations of the rubric points might not be generalizable across different problems.

The input dimension of the grading model is the same as the returned sentence embedding dimension of the pretrained model. By default, MathBERT embeddings have length 768, GPT-3 embeddings have length 1536, and Llemma embeddings have 4096 and 8192 entries respectively for the two versions. The output dimension is set to 2 to match the two distinct categories for grading: "incorrect" (0) and "correct" (1). The model produces a probability score from the input embeddings, and normalizes using the softmax function to yield the probability distribution over the two classes. We will use this probability distribution to test the model and to autograde future submissions.

The dataset is broken down into training, testing, and validation sets, with 15% for testing and another 15% for validation. The remaining 70% are used for training. Performance on the test set will be used to compare the performances of models. The 15% data for validation is reserved for use in future work when the model complexity is increased.

In training our grading model, we chose a batch size of 128 as it is a common choice for training networks. Number of epochs for training range from 100 to 1000, with a step size of 100 epochs. Initially, the learning rate is set to 0 and linearly increased to a peak value of 0.001 over the first 60% of the training epochs. This linear increase provides a warm-up period for the model to gradually adapt to the task. Subsequently, during the second half of the training, the learning rate is exponentially decreased to $\frac{1}{10}$ of the peak value, allowing the model to fine-tune its parameters and converge towards a stable solution.

To save computational resources, we generate all embeddings by running the pretrained models once on the entire proof dataset. Then we save the mapping between each proof and its corresponding embedding to a pickle file. The two Llemma models were run on our University's supercomputing cluster, using eight NVIDIA A100 GPUs simultaneously, taking about one second on average to turn one proof into embeddings; GPT-3 embeddings were retrieved from an OpenAI API call; MathBERT was run on a single NVIDIA RTX4090 GPU. The customized grading models are built and trained using PyTorch [33] on the same NVIDIA GPU. For each model, trainings completed at a rate of about 2 seconds per 100 training epochs and 10 batchs.

3.4 Comparison to human graders

Theoretically, it is hard for machine learning models to perfectly grade the freeform mathematical proofs. However, it can also be hard for humans to agree on the grading of mathematical proofs both due to ambiguity in language and honest mistakes. In the case that there is any subjectivity in the grading, human graders also need to match the specification set by the course instructor. To our knowledge, no prior study exists that quantifies the accuracy of humans grading mathematical proofs to match an instructor specification. We are also interested in how well human graders can match the grading specification compared with our NLP grading models.

Using the last author's professional network, we recruited graduate students from several universities who had been teaching assistants in discrete mathematics courses. These graduate students all had experience grading mathematical induction proofs. 9 graduate students from 4 different institutions participated in the grading tasks. For each human grader, we sent 15 student proofs from each of the 4 proof problems (for a total of 60 problems each), and asked them to grade these proofs using the same rubric. Along with the proofs to grade, we also provided 15 examples of graded proofs for each of the problems, the original problem statements, and detailed notes with explanations of the rubrics created by previous researchers. This combination of example labeled proofs and detailed rubric explanations were designed to set the graders up to be as successful as possible on their grading task. In fact, we provided

the graders with more training materials for grading than many instructors do for grading for actual courses (in our experience). The graders were also free to ask us any questions regarding problems encountered during the grading process, as they would be when grading student work for an actual course. Each grader received a \$100 gift card as compensation for their grading efforts. This human subjects data collection procedure was approved by the institutional review board at Utah State University.

4 Model Performance Results

In this section, we will provide an overview on the performance of the grading models, the accuracy of the human graders, and an analysis of how much training data we need to get satisfactory performance.

4.1 Grading Model Performance

For each model and each training epoch, we calculate the performance using the validation set, comparing the model predictions to ground truth labels that previous researchers created. We compute the confusion matrix to obtain the number of true positive, true negative, false positive, false negative cases, and to calculate the accuracies and F1 scores. Among the models using different training epochs, we select the one with the highest accuracy. Model results for each problem and each pretrained model are summarized by averaging the accuracies from the testing set for all rubric points. The results are shown in Table 2.

All four pretrained models achieve over 80% average accuracy. MathBERT is the lowest performing one with an average of 84.1% accuracy across all problems, as it is the model with the fewest parameters, thus capturing fewer details accurately. The best grading models are Llemma-based, both Llemma34b and Llemma7b, with 90.0% and 90.2% average accuracy, even beating GPT-3-based models. This is likely because Llemma is more specifically trained to handle mathematical language. Moreover, the large number of parameters gives Llemma the ability to capture almost the same amount of information as GPT-3. The accuracies and F1 scores of Llemma34b graders on a by-rubric-point basis appears in Table 3.

Based on these results, there seems to be no pattern of which rubric points are more easily gradable than others. Currently, Llemma and Llemma-based grading models perform well enough for use by students as practice for writing mathematical proofs. In future work, we want to investigate how to provide more accurate and detailed feedback to students, as the correctness of the models is not guaranteed.

4.2 Comparison to human graders

After the human graders finish the grading process, we calculate the accuracies and F1 scores of human grader results and compare them with those of the grading models. The overall performance is also shown in Table 2, with the detailed accuracy and F1 score for each rubric point shown in Table 4. On average, human graders achieve 86.6% agreement with the research team labels, which is higher than MathBERT but

Problem	Data Size	Grading Method	Accuracy
P1		MathBERT & linear	83.6%
	1623	GPT-3 & linear	87.9%
11	1020	Llemma7b & linear	90.7%
		Llemma34b & linear	90.2%
		Human Graders	84.1%
		MathBERT&linear	83.7%
P2	1288	GPT-3 & linear	88.3%
12	1200	Llemma7b & linear	90.9%
		Llemma34b & linear	90.7%
		Human Graders	91.3%
		MathBERT&linear	85.7%
P3	342	GPT-3 & linear	89.2%
10	012	Llemma7b & linear	85.7%
		Llemma34b & linear	86.6%
		Human Graders	85.1%
		MathBERT&linear	86.3%
P4	333	GPT-3 & linear	85.4%
	000	Llemma7b & linear	89.9%
		Llemma34b & linear	90.2%
		Human Graders	85.8%

Table 2: Overall grading accuracy for grading models and human graders. Llemma-based grading models have the highest accuracy on average, and slightly higher than human graders.

lower than GPT-3. The comparison provides a solid ground for further developing and utilizing our grading models in real courses.

Accuracies for all grading models and individual human graders are plotted in Figure 2. Human graders are separated into two groups based on whether they have been a grader at the same university where the data was collected. Group A graders are from the same university that the proof data was originally collected at, and thus have more experience using the same rubric that was used for the study. Group B graders are from other universities, but still have experience in grading proof by induction problems (perhaps with different rubrics). The figure shows that in general, group A graders are more accurate than group B graders, and are also more accurate than the grading models. We conclude that our grading models are able to regularly outperform minimally trained human graders at matching a grading specification, but human graders with more extensive training will be able to outperform our grading models. This difference is similar to the comparison between graders with different amounts of training in a prior work [34].

	R	21	R	2	R	3	R	4	R	15	R	86	R	.7

P4	.881	.921	.874	.912	.859	.882	.815	.834	.807	.750	.867	.640	.904	.698

Table 4: Human grading accuracy and F1 scores, broken down by rubric point. The data size is different from the model accuracy testing, as each human grader graded 60 proofs in total.

4.3 How large of a dataset do we need?

We are also interested in learning how much data is needed to achieve an acceptable performance. We did another set of training and testing to compare the effect of training data size on model performance. To ensure consistency, the same 30% of the data is used as the testing set. The training set sizes range from 50 to the max available size, with a step size of 50 (before size 200) or 100 (after size 200). The model performance on each training data size is shown in Figure 3.

For all four models, the performance is still increasing even with 1100 training data points, so there is space for improvement by collecting more data. Model performance might also be better by making the grading models more complex, such as adding extra layers. However, most of the improvement seems to be complete before the 400 training size threshold. For Llemma34b, the performance at 400 training data already achieves 98.8% of the full data size accuracy. Based on these results, we conclude that training a model with 400 proofs is sufficient for adequate results.

5 User Study Methods

Using the trained grading pipelines, we implemented an autograder for proof by induction problems using the online assessment system PrairieLearn [35]. Due to computational resource restrictions and the fact that GPT-3 performed nearly as well as Llemma on the 3 proofs we used for the user study, we chose to use GPT-3 as the embedding model for our user study. For each submitted student proof on a problem, the grading pipeline reports seven correct/incorrect results using the rubrics R1-R7 introduced in 3.1. The final score for the proof is the sum of the 7 rubric point results, ranged between 0 and 7, and the rescaled to 0-100. The grader then provides feedback

Fig. 2: Accuracy for each grading model and human grader. A_i are the graders from the same university and are more familiar with the used grading rubrics, and B_i are from other universities. Graders with more experience with the grading rubrics achieve higher accuracy than unexperienced graders and all grading models.

on the rubric point results based on various strategies we defined. Figure 4 shows an example page from PrairieLearn where students can submit their proofs and receive automatic feedback.

5.1 Study Setup

To investigate the accuracy of our grading models in a real class and better understand if they can help students write better proofs without the support of human graders, we conducted a study in Spring 2024 with students registered in the Discrete Mathematics course (CS173) at the University of Illinois Urbana-Champaign. We address the following research questions:

- RQ1 Are students able to write better proofs by interacting with the autograder and the feedback it generates?
- RQ2 Are students satisfied with the autograder and the feedback it provides?
- RQ3 Does using the autograder make students more willing to use similar AI autograders in the future?

The study was conducted earlier in the semester before students had been introduced to systematic instructions on proof by induction or had practiced any induction problems at the college level. As part of the study, students were asked to complete a learning activity and were offered extra credit points for its completion, equivalent to the completion of one homework (about 0.36% of the course grade). The students had one week to complete the learning activity at a time of their choice.

The learning activity consisted of three parts. In the first part, students were expected to read a 6-page textbook section about induction, including information on

Fig. 3: Training Size vs. Accuracy. With 400 training data, all grading models are achieving near convergent accuracy, and this accuracy is about 1.2% away from the maximum accuracy for the grading models.

the theoretical ground for induction, the steps of an induction proof, and an example problem with solution. The second part asked students to complete 3 induction problems (P1-P3 as defined in 3.1). We only consider 3 problems out of the 4 used in the model training process for two reasons: first, we wanted to limit the length of the learning activity to 1 hour, which would not be reasonable if we expected students to read the text and complete all 4 problems; second, we removed P4 due to its low accuracy compared to P1-P3, as this could potentially hinder the students' learning experiences. The third part of the learning activity was a feedback survey. The questions are listed below:

- S01 In CS173, I usually receive accurate grading from human graders for my proofs.
- S02 Feedback from human graders has helped me improve my proofs.
- S03 Overall, I am satisfied with my experience with human graders in CS173.
- **S04** I would prefer to wait for a week to get human grading feedback for the proofs I write for my homework than use the autograder for instant feedback.
- **S05** Even if a well-developed AI autograder has about the same accuracy as human graders, I still trust the grading results from human graders more.

Suppose that $g: \mathbb{N} \to \mathbb{R}$ is defined by • $g(0) = 0$ • $g(1) = \frac{4}{3}$ • $g(n) = \frac{4}{3}g(n-1) - \frac{1}{3}g(n-2)$, for $n \ge 2$. Use induction to prove that $g(n) = 2 - \frac{2}{3^n}$ for any natural number n . answer.md 1 Base cases: 2 n=0, $g(0)=2-2=0;$ 4 n=1, $g(1)=2-2/3=4/3$. 5 suppose $g(n)=2-\frac{1}{3^n}$ for all $n \ge 2$	\$

(b) Graded results and feedback from the autograder

Fig. 4: An example of an autograded problem in PrairieLearn. Students type in their proof in the markdown editor box, and are able to see the markdown preview in real time. Once they click "Save & Grade", they receive immediate feedback form the autograder, indicating if the submission is correct or not.

- **S06** I am comfortable using a well-developed AI autograder in my course to give me feedback as I prepare for my quizzes.
- **S07** Given that I can still regrade my work with human graders, I am comfortable having a well-developed AI autograder in my course to grade my quizzes.
- S08 I received accurate grading from the autograder.
- S09 Feedback from the autograder helped me improve my proofs.
- **S10** Overall, I am satisfied with my experience of using the autograder.

The first subsection of the survey includes questions S01-S03, which asks the students about their prior experience with human graders in the course. The second subsection includes questions S04-S07, focusing on students' perceptions of using AI for autograding. The last questions ask students to share their experiences with the AI autograder during the learning activity. The survey questions are presented on a five-point Likert scale using the following options and corresponding numeric values: "Strongly disagree" (-2), "Disagree" (1), "Neutral" (0), "Agree" (1), "Strongly agree" (2). Negatively worded questions (e.g., "I would prefer to wait for a week to get human grading feedback for the proofs I write for my homework than use the autograder for instant feedback") are reverse coded in the statistical analysis.

To help us get a more full picture of student perceptions about the graders, we also asked the following open-ended survey questions:

- S11 In your opinion, how can the autograder be useful in your learning experiences?
- ${\bf S12}\,$ Can you share a positive experience you had with the autograder?
- $\mathbf{S13}$ Can you share a negative experience you had with the autograder?

 ${\bf S14}\,$ Do you have other comments on the autograder?

We do not use S11-S14 to directly answer any of the research questions, but we will use them in the discussion as we seek to understand the student's reasoning behind why they answered the way they did on the Likert items.

5.2 Experimental Conditions

The students were randomly assigned to 3 groups. We refer to the groups as *Self-eval*, *First*, and *Random*. The *Self-eval* group was the control group. In the *Self-eval* group, students did not have access to the AI autograders during the learning activity. Instead, upon proof submission, students in this group could see the 7 rubric points for the problem and were asked to self-assess and make improvements to their proof until they were satisfied with the solution. This is our baseline group, as it mimics a student completing a proof on their own.

Both the *First* and Random groups had access to the AI autograders, forming our treatment groups. Students in the *First* group received feedback on the first rubric point out of the seven that the autograder identified them having done incorrectly. The order is defined by the sequence of rubrics R1-R7, which corresponds to the logical flow of a proof. For an induction proof, it is common to state and prove the base cases first, then state the goal for the induction steps before actually completing the steps. The strategy of reporting the first incorrect rubric point is based on some students' preference to work incrementally, fixing the earlier parts of their work before moving

on to the next part. When we designed the experiment, we expected this strategy to be the most helpful to students.

Students in the *Random* group received feedback for one of rubric points, randomly selected from all those that the autograder assessed as incorrect. This group is included in our study to test if different strategies for reporting have different effects.

6 User Study Results

After the learning activity deadline, we manually screened all students' submissions and excluded students who showed no effort during the study. These excluded students either submitted blank proofs to all 3 problems or only typed something trivial such as "hello" or a question mark in their proofs. After applying this exclusion criteria, we had 68 students in the *Self-eval* group, 59 students in the *First* group, and 42 students in the *Random* group. Due to constraints imposed by the online assessment platform PrairieLearn, it was easier to pre-assign all eligible students to one of the experimental conditions before they elected to participate. Students agreed to participate upon opening the assessment in PrairieLearn. These two exclusion criteria combined resulted in the small variation in the population of sizes for each treatment. This small variation has no effect on the conclusions of the study because the assignment of students to experimental groups was still random.

6.1 Proof Problem Performance

For each student, we collected the number of submissions for each problem and the score for each submission. We are interested in investigating the difference between students' initial submissions and best submissions for all three problems. Figure 5 shows the distribution of the initial scores and best scores for each student group, and figure 6 shows the number of submissions for all the proof problems combined.

For each of the three proof problems (P1-P3), we performed a Kruskal-Wallis test across all groups to find the difference between students' earned scores on their initial submission. The results are p = 0.26, 0.14, 0.27 respectively. These indicate that students are starting their proof-writing with similar quality across all groups, which makes sense as the students are randomly assigned to the three groups.

On the other hand, a Kruskal-Wallis test on students' earned scores on their best submission shows statistically significant differences for all three problems, as shown in Table 5. Post-hoc pairwise tests reveal that the best submission scores are significantly higher for students in *First* and *Random* than *Self-eval*, while there is no significant difference between *First* and *Random*.

To better understand the effect of using the AI autograder to support the writing of proofs while controlling for initial student knowledge, we propose a regression model to determine the score gain for students in the three groups, using the students' initial and best submission scores. We fit an ordinary least squares (OLS) model of the form

$$BEST_{ij} = \mu_j + \alpha I_{ij} + \beta_1 G I_i + \beta_2 G 2_i \tag{1}$$

Fig. 5: Distribution of initial and best scores in all problems, separated by the group. Distributions of initial and best submissions for the *Self-eval* group are similar, while *Random* and *First* have different distributions.

		Mean(SD)			
Problem	Self-eval	Random	First	H	p
P1	75.8(38.8)	90.1(24.1)	92.1(22.9)	10.95	0.004
P2	60.1(32.4)	79.1(24.6)	76.8(25.6)	13.62	0.001
P3	51.1(40.4)	68.8(37.8)	75.9(34.6)	13.68	0.001

Table 5: Kruskal-Wallis, mean, and standard deviation for the best submission scores of each problem. Students in *Random* and *First* have a significantly higher score in their best submissions.

where BEST_{ij} is the predicted best submission score for student *i* on problem *j*, and I_{ij} is the initial score for student *i* on problem *j*. Both scores range between 0 and 100. $G1_i$ and $G2_i$ are indicators of the students being in *Random* or *First*, respectively. For any student in *Self-eval*, both values are 0; for students in *Random* $G1_i$ is 1 and $G2_i$ is 0, and for students in *First* $G1_i$ is 0 and $G2_i$ is 1. We want to estimate the parameters μ_j , α , β_1 , and β_2 , which can be interpreted as follows:

- μ_j : Control for the difficulty of problem j
- α : Control for the initial score of the proof
- β_1 : The effect of feedback for students in the *Random* group

Fig. 6: Histogram for the number of submissions per student for each of the three groups. Students in the *Self-eval* group have slightly fewer submissions for all proof problems combined.

• β_2 : The effect of feedback for students in the *First* group

Table 6 summarizes the results from the regression analysis using Equation 1. The baseline students are students in *Self-eval*, who do not receive the results or feedback from the autograder. Compared with *Self-eval* students, students in the *First* and *Random* groups are able to gain respectively 11.6 and 11.3 more points from the proofs they write after controlling for their initial submission performances. This shows that students can improve and write more accurate proofs using the feedback from the autograder compared with students who are just self-evaluating using the rubric. In future work, we will seek to also measure knowledge retention by having students complete additional proofs without the autograder in a delayed posttest.

6.2 Survey Results

The survey results are shown in Figure 7 and Figure 8. The three subsections of the surveys address different aspect of student perceptions: S01-S03 address student perceptions of human graders, S04-S07 address students willingness to have AI graders integrated into various parts of their course, and S08-S10 address student perceptions of the AI graders. We calculated a Cronbach's α for each of the three subsections. The calculated Cronbach's α are 0.81, 0.72, 0.82 respectively, indicating good internal

Coefficient	Description	Value	stderr	t	p
α	Control for initial score	0.693	0.03	27.9	< 0.001
β_1	Effect of the Random group	11.3	2.32	4.86	< 0.001
β_2	Effect of the <i>First</i> group	11.6	2.10	5.51	< 0.001
μ_1	Control for difficulty of P1	26.5	2.56	10.36	< 0.001
μ_2	Control for difficulty of P2	20.2	2.37	8.52	< 0.001
μ_3	Control for difficulty of P3	20.0	2.25	8.92	< 0.001

Table 6: Coefficients from Equation 1. The R^2 metric of this regression is 0.665, indicating a strong relationship between variables. Students in the experimental groups using the AI autograder are able to achieve 11 more points in the proofs than students using the rubrics for selfevaluation.

reliability. The *Self-eval* group were not asked questions S08-S14 as these students did not interact with the autograder during the learning activity.

6.2.1 *RQ2:* Are students satisfied with the autograder and feedback?

We use responses to survey questions S01-S03 and S08-S10, as shown in Table 7, to address RQ2. S01-S03 capture students' perceptions of human graders, while S08-S10 assess their perceptions of the AI autograder. Specifically, S01 and S08 measure the perceived accuracy of the graders, S02 and S09 evaluate their helpfulness, and S03 and S10 measure overall satisfaction with the graders. On average, human graders are perceived to be more accurate and helpful than the AI autograder, with statistically significant differences (p < 0.05). However, although the mean satisfaction rating is higher for human graders, the differences are not statistically significant for either the First or Random groups. We hypothesize that this is due to the known benefits of the AI autograder, such as timely feedback and the ability to submit an unlimited number of times.

	Accuracy				Helpfulness				Satisfaction			
Group	S01	S08	t	p	S02	S09	t	p	S03	S10	t	p
Self-eval	0.84	_	_		0.76	_	_		0.74			_
First	1.14	0.41	4.37	< 0.001	0.86	0.22	3.61	< 0.001	0.75	0.44	1.69	0.094
Random	1.02	0.48	2.81	0.006	0.69	0.24	2.14	0.035	0.74	0.52	0.97	0.336

Table 7: S01-S03 and S08-S10 statistics for three groups, and the pairwise t-test for independence. *Self-eval* students did not have access to S08-S10 as these students did not interact with the autograder during the learning activity. All scores range between -2 and 2.

6.2.2 RQ3: Does using the autograder make students more willing to use AI autograders?

We want to understand students' perception and trust on using an autograder for their coursework during various settings. We want to know whether interactions with the

Fig. 7: Responses from survey questions given to all 3 groups. The percentages shown on each distribution represent the percentage of negative responses (disagree & strongly disagree), the percentage of netural responses, and the percentage of positive responses (agree & strongly agree).

autograder can lead to more positive perceptions. These are reflected through S04-S07 (see Table 8). S04 examines students' preferences between receiving instant feedback from AI autograders and obtaining more reliable feedback from human graders. S05 assesses the level of trust students have in AI autograders in general. S06 and S07 explore potential applications of AI autograders.

On average, students in *First* and *Random* are slightly more comfortable using a well-developed autograding system in the future. However, one-way ANOVA tests among the groups show the differences are not statistically significant.

Fig. 8: Responses from survey questions given to only *First* and *Random*. The percentages shown on each distribution represent the percentage of negative responses (disagree & strongly disagree), the percentage of netural responses, and the percentage of positive responses (agree & strongly agree).

Survey	Self-eval	Random	First	F	p
S04	-0.06	-0.29	0.10	1.20	0.31
S05	-0.51	-0.36	-0.22	1.06	0.35
S06	0.72	0.95	0.92	1.01	0.37
S07	0.63	0.98	0.76	1.17	0.31

Table 8: S04-S07 mean numeric scores about perceptions using AI autograders, with one-way ANOVA test statistics. All scores range between -2 and 2.

7 Discussion

7.1 Model Accuracy

In terms of student-perceived accuracy, the results mostly agree with the accuracy measures in 4.2. Although GPT-3 models are observed to perform relatively well, they are still less accurate than experienced human graders. This difference in accuracy can be amplified even more in practice. Repetition of similar proofs might skew the accuracy measures because similar proofs tend to be graded the same way due to the stable nature of the large language models. Students can potentially encounter multiple incorrect gradings in a row by submitting similar proofs, which increases their sense of mistrust on the graders.

Currently, the large language models are used as black boxes for embedding. There are cases where the models do not precisely interpret the input sentences, but it is hard to predict why, when, or how the misinterpretation happens. This can lead to the autograder giving wrong grades in mysterious ways. This has happened to some of the users. Some open-ended feedback from the users are listed below:

• "Additionally, when I added 'Suppose that' in front of my Inductive Hypothesis, it deemed it incorrect."

- "It was not always accurate especial [sic] when I didnt us LateX perfectly."
- "My grade also improved by changing some, but not all, of my '\times' to '\cdot' for no apparent reason, either. When I changed all of them, my grade remained unchanged."
- "Spacing my sentences out into separate paragraphs improved my grade by 15%, also for no apparent reason."

One possible improvement for this situation is to break down a proof problem into sub-problems, where students submit portions of the proof into different input boxes. This can help decrease the complexity of the proofs being submitted and provide more accurate embeddings. This also makes the task slightly different due to the added scaffolding, which may be appropriate for formative settings, but less so for exams.

7.2 Feedback Helpfulness

Despite our findings showing that students are able to make improvements using the feedback from the autograder, some students felt that the feedback was not detailed enough. The outputs from the grading models are always booleans representing correctness: they can tell if a student proof is incorrect, but not why the proof is incorrect. This form of feedback roughly aligns with knowledge of results defined by Shute [6], which was shown to be less effective than elaborated feedback in several studies [36]. The lack of useful feedback that can help students improve their proofs is also reported.

- "Some of the feedback was basic. didn't say anything specific."
- "I also think that the autograder was not specific enough to identify what exactly was wrong with my proofs. I was stuck on the 2nd problem for a while, and the feedback that I was getting was not exactly enough to pinpoint what exactly was wrong."

Providing such automated and elaborated feedback should be possible with the help of generative models. Using few-shot training techniques such as Retrieval-Augmented Generation [37], we can fine-tune chatbots such as ChatGPT to provide suggestions or hints that can help students make improvements and are better aligned with the learning requirements for individual courses. This enhancement to our system can be treated in future work.

On the other hand, some students acknowledged that having the instant feedback was already very helpful in their proof-writing process.

- "The autograder tells me where exactly I am lacking information, which helps me more because I can pinpoint where I need to work on."
- "The autograder allows for quick and efficient feedback of on proofs versus waiting to hear back days after on issues with ones proof. This quick turn around time allows for a easy/fast way to get better at proof writing."
- "I got absolutely stuck with the last proof! However, when I used the autograder, it gave me around a 75%. This gave me confidence that I was on the right track, and I was able to not get discouraged. I was slowly able to incorporate more parts of the solution into my proof"

7.3 Perceptions on AI grading

Proof grading is a subjective task, which can lead to low levels of trust from students. In our initial designing of the learning activities, we had hoped that students could have more trust or willingness in using AI autograders in the future as a result of interacting with our grader. However, results in 6.2 do not confirm our initial hypothesis. Students in *First* and *Random* are slightly more willing to use an AI autograder in various settings, but the difference is not statistically significant. Simply using the autograder does not sufficiently increase students' willingness to use AI autograders in general. One possible action to enhance trust in AI autograding is to provide more feedback and explanation during the grading process, as Ha and Kim suggests that providing additional information about AI models can be effective in mitigating cognitive bias [38].

8 Conclusions and Future Work

In this study, we have developed a set of machine learning models to autograde freeform mathematical proofs. These models allow for fast training, and they achieve similar accuracy in autograding freeform mathematical proofs compared with most human graders recruited in the study. These models can be used to develop NLP graders and deployed on large-scale educational platforms in the future, enabling more students to receive the necessary support when learning to write mathematical proofs.

After creating and deploying autograded proof by induction problems using the grading models, we conducted a user study to find the impact of the autograder. Our results show that students who use the autograder for getting feedback and making improvements were able to score more than 10% higher on the proof problems than students who did not use the autograder. This is an encouraging sign for creating more autograded problems in the future. Despite being helped by the autograder, many students still preferred feedback from human graders, even if it was delayed.

In the future, it can be helpful to put effort in enabling more student trust in AI autograders. Efforts can be put on improving the grading models as well. As we only trained the grading models on mathematical induction problems, the abilities for similar models to grade other types of proof such as proof of bijection or geometry is still unknown. We will start to collect proof data for various types of mathematical proof problems, and check if our designed grading models can perform as well on these problems. The cost of training and running the models can also be lowered, as currently the best performing models require good GPUs to run, and the CPU-based models do not achieve performances that are as good.

Acknowledgments

This work used the Delta system at the National Center for Supercomputing Applications through allocation CIS230355 from the Advanced Cyberinfrastructure Coordination Ecosystem: Services & Support (ACCESS) program, which is supported by National Science Foundation grants #2138259, #2138286, #2138307, #2137603, and #2138296.

The work is also made possible by members of previous research projects collecting and labeling the proof data, and graders from multiple institutes providing grading data for comparison.
