Study Program: Information &  
Communication Systems

Hamburg, 8<sup>th</sup> June 2023

### Statement of honor

I hereby declare that I personally have completed the present scientific work. The ideas obtained from other direct or indirect sources have been indicated clearly.

This work has neither been submitted to any other course or exam authority, nor has previously been published.

A handwritten signature in black ink, consisting of two stylized, overlapping capital letters 'N' and 'N'.

Hamburg, (11.03.2023) (Signature)

## **I Abstract**

The process of identifying human emotion and affective states from speech is known as speech emotion recognition (SER). This is based on the observation that tone and pitch in the voice frequently convey underlying emotion. Speech recognition includes the ability to recognize emotions, which is becoming increasingly popular and in high demand. With the help of appropriate factors (such modalities, emotions, intensities, repetitions, etc.) found in the data, my research seeks to use the Convolutional Neural Network (CNN) to distinguish emotions from audio recordings and label them in accordance with the range of different emotions. I have developed a machine learning model to identify emotions from supplied audio files with the aid of machine learning methods. The evaluation is mostly focused on precision, recall, and F1 score, which are common machine learning metrics. To properly set up and train the machine learning framework, the main objective is to investigate the influence and cross-relation of all input and output parameters. To improve the ability to recognize intentions, a key condition for communication, I have evaluated emotions using my specialized machine learning algorithm via voice that would address the emotional state from voice with the help of digital healthcare, bridging the gap between human and artificial intelligence (AI).

## II Table of Contents

# 1 Introduction

The past few years have seen technological advancements in data and digitalization, and analytics have reshaped the entire world, increased productivity, and sparked the rise of cutting-edge solutions in a variety of industries, including health. The technical environment has now been enlarged to encompass many additional autonomous domains to build complicated models and solve them using sophisticated tools, software, and procedures. Now that artificial intelligence has advanced, this is both conceivable and essential. The first thing to consider when implementing machine learning is the platform on which the work will be done. Each step of the machine learning process can be automated with the right tools.

Speech Emotion Recognition (SER) is a field dedicated to the identification and interpretation of human emotions and affective states through the analysis of speech. This is facilitated by the understanding that voice carries valuable cues that reflect underlying emotions, expressed through variations in tone, pitch, and other vocal characteristics. Emotion recognition, as an integral component of speech recognition, has gained significant traction in recent years, owing to its potential applications and the growing recognition of its importance.

The human voice serves as a powerful medium for the expression of emotions, conveying a wealth of information beyond the mere words spoken. Through subtle variations in tone, pitch, and prosody, individuals imbue their speech with emotional nuances, providing valuable insights into their affective states. As such, the recognition and analysis of emotions embedded within speech have emerged as crucial areas of research, fostering the development of the field known as SER.

With advancements in speech and language processing technologies, the recognition of emotions from speech has gained prominence and garnered increased attention across various domains. Researchers and practitioners have recognized the potential of SER in fields such as human-computer interaction, virtual assistants, sentiment analysis, market research, and healthcare, among others. The growing popularity of SER can be attributed to its ability to provide rich emotional context, complementing the traditional focus on the linguistic aspects of speech recognition.

The goal of speech emotion recognition, an emerging field, is to identify and evaluate the emotional content of spoken language. In recent years, the emergence of deep learning techniques, particularly Convolutional Neural Networks (CNNs), has revolutionized the field

of speech emotion recognition. CNNs excel at automatically extracting complex hierarchical features from input data, making them well-suited for analyzing speech signals. By leveraging large-scale datasets and powerful computing resources, CNN-based models have demonstrated superior performance in emotion recognition tasks compared to traditional approaches. Using CNN, a class of artificial neural networks that process input data through multiple layers of connected nodes to produce an output, is one well-liked method of voice emotion identification. These networks may learn to identify speech patterns that correspond to various emotional states with the use of sizable, annotated datasets.

One of the key advantages of using CNNs for speech emotion recognition is their ability to learn discriminative features directly from the raw speech signal. Rather than relying solely on handcrafted features, CNNs can automatically learn representations that are more robust and informative for emotion classification. This data-driven approach has shown great promise in capturing subtle variations in speech patterns, thus enabling more accurate and reliable emotion recognition.

Mental healthcare is one significant area where feedforward neural networks for voice emotion identification are used. Speech patterns and emotional expression might change because of mental health conditions including depression and anxiety. Mental health experts may be able to identify early warning signals of mental health illnesses by studying speech patterns using speech emotion recognition technology, allowing for self-management. Speech emotion recognition can also be used to modify treatment plans in response to changes in the emotional state of the patient and track the effectiveness of therapy over time.

Speech emotion recognition can also be helpful for remote mental health monitoring, allowing medical professionals to keep an eye on their patients' emotional states. Patients who are unable to routinely attend in-person appointments or who are reluctant to seek therapy owing to stigma or other obstacles may find this technology to be especially helpful. Speech emotion recognition using feedforward neural networks has the potential to enhance patient outcomes by increasing accessibility and effectiveness of mental healthcare.

The efficiency of voice emotion identification using feedforward neural networks in mental healthcare has been shown in numerous studies. For instance, Cummins et al. (2020) achieved an accuracy of over 80% when classifying speech samples from depressed subjects and healthy controls using a feedforward neural network. An accuracy of over 90% was attained when Zhao

et al. (2021) employed a similar method to classify speech samples from people with PTSD. Therefore, feedforward neural network-based speech emotion recognition has great promise for improving mental healthcare by giving doctors a potent tool for identifying and tracking mental health disorders.

There has been a growing interest in the field of speech emotion recognition due to its potential applications in various domains, including digital healthcare. The ability to accurately recognize and interpret emotions conveyed through speech can provide valuable insights into an individual's mental health, well-being, and overall emotional state. It opens doors for personalized healthcare interventions, early detection of mental health disorders, and improved patient care.

Speech emotion recognition involves the use of computational techniques to analyze speech signals and identify the underlying emotional content. Traditionally, the field has relied on acoustic features such as pitch, energy, and spectral characteristics for emotion classification. However, these methods often face challenges in capturing subtle emotional nuances and achieving high accuracy.

The implications of accurate speech emotion recognition in digital healthcare are profound. For example, we can imagine a scenario where individuals can engage in remote telehealth consultations with healthcare providers, and the system automatically analyzes their speech to assess their emotional well-being. By monitoring changes in emotional states over time, healthcare professionals can gain insights into a patient's mental health and detect early warning signs of conditions such as depression, anxiety, or stress.

Furthermore, speech emotion recognition can be integrated into digital therapeutic interventions. For example, a virtual reality-based therapy system can adapt its content and interactions based on real-time emotion recognition, providing personalized and tailored interventions to patients. Such applications have the potential to enhance the effectiveness of mental health treatments and improve patient outcomes.

In this thesis book, I aim to explore the field of speech emotion recognition using Convolutional Neural Networks and investigate its use case in digital healthcare. I will delve into the fundamental concepts of speech processing, deep learning, and emotion recognition algorithms. Moreover, I will discuss the design and implementation of a CNN-based speech emotion

recognition system and evaluate its performance on benchmark datasets. Finally, we will explore the applications of speech emotion recognition in digital healthcare, discussing potential challenges, ethical considerations, and future directions for research.

## **1.1 Background of the Study**

A vital component of overall health and wellbeing is mental health, which is significant in the context of digital healthcare. The ability to understand and interpret human emotions has long been a subject of fascination and importance in various fields, ranging from psychology to human-computer interaction (Picard, 1997). Emotions play a crucial role in our daily lives, influencing our decisions, behaviors, and overall well-being. Traditionally, the recognition and understanding of emotions have heavily relied on facial expressions, body language, and verbal cues. However, speech, as a powerful medium of communication, holds a wealth of information that can provide valuable insights into human emotions (Schuller et al., 2013).

SER is an interdisciplinary field that aims to develop computational techniques capable of automatically analyzing and deciphering emotions conveyed through speech signals (Schuller et al., 2013). By capturing and interpreting the underlying emotional content of speech, SER has the potential to revolutionize numerous domains, including digital healthcare. With the rise of telehealth and remote patient monitoring, there is an increasing need for non-intrusive and scalable methods to assess individuals' emotional well-being and mental health from a distance. Historically, SER research predominantly relied on handcrafted acoustic features extracted from speech signals, such as pitch, energy, and formant frequencies (Schuller et al., 2013). While these features provided a foundation for emotion classification, they often fell short in capturing the intricate nuances and complexities of human emotions. Emotions are multifaceted, characterized by dynamic temporal patterns and a broad spectrum of expressiveness. Thus, the need for more sophisticated and data-driven approaches to SER became apparent.

The advent of deep learning, particularly Convolutional Neural Networks (CNNs), has opened up new possibilities for SER (Hinton et al., 2012). CNNs, inspired by the structure and functionality of the human visual cortex, excel at automatically learning hierarchical representations from raw input data. Their ability to capture intricate patterns and extract discriminative features has led to significant advancements in various fields, including computer vision and natural language processing (Hinton et al., 2012). Leveraging the power of CNNs for SER presents an opportunity to overcome the limitations of traditional handcrafted features and

achieve more accurate and robust emotion recognition.

Furthermore, the integration of speech emotion recognition with digital healthcare holds tremendous potential (Schuller et al., 2013). As healthcare systems evolve and embrace digital solutions, the collection and analysis of patient data become more accessible and feasible. By incorporating speech emotion recognition into digital healthcare platforms, healthcare professionals can gain real-time insights into patients' emotional states, enabling more personalized and effective care interventions. For instance, a virtual therapy system equipped with SER capabilities could adapt its content and interactions based on the detected emotions, tailoring the therapeutic experience to the individual's emotional needs.

While research on speech emotion recognition using CNNs has made significant strides, there are still challenges and areas for improvement. The development of robust and generalizable models that can handle variations in accents, languages, and cultural contexts remains a priority (Hinton et al., 2012). Moreover, ethical considerations regarding data privacy, informed consent, and the responsible use of emotion-related information in healthcare settings need to be carefully addressed.

In this thesis book, I aim to contribute to the field of speech emotion recognition by focusing on the application of Convolutional Neural Networks and exploring their use case in digital healthcare. By investigating the potential of CNNs to automatically extract meaningful emotion-related features from speech signals, I seek to advance the accuracy and reliability of emotion recognition systems. Moreover, I examine the practical implications and challenges of integrating speech emotion recognition into digital healthcare, with a focus on ensuring patient privacy, security, and ethical practices.

By shedding light on the intersection of speech emotion recognition, deep learning, and digital healthcare, this thesis book aims to pave the way for innovative applications that enhance our understanding of human emotions, revolutionize patient care, and contribute to the advancement of digital healthcare technologies.

## **1.2 Objective of the Study**

Speech Emotion Recognition is a burgeoning field that focuses on the identification and understanding of human emotions and affective states through speech. The objective of this

project is to employ Convolutional Neural Networks (CNNs) as a means to recognize emotions from unseen data, specifically audio files, and subsequently label them according to various emotional ranges. The study seeks to explore the efficacy of CNNs in accurately detecting different emotions and examine the potential application of this technology in managing depression and anxiety within the realm of digital healthcare.

Research studies have demonstrated that capturing changes in vocal features, such as pitch and speech rate, can offer valuable insights into an individual's emotional state and aid in the diagnosis of mental health conditions like depression and anxiety (Girardi et al., 2018). Building upon this premise, the primary research question for this study is: *What is the effectiveness of utilizing Convolutional Neural Networks (CNNs) for detecting different emotions in human speech from unseen audio files, and to what extent can this technology be applied to the management of depression and anxiety in the context of digital healthcare?*

By delving into this research question, the project aims to ascertain the proficiency of CNNs in accurately recognizing emotions embedded within speech signals that have not been previously encountered. The study will focus on leveraging the potential of CNNs to identify and classify emotions based on diverse variables, including modality, emotion type, intensity, repetition, and other relevant factors. Through comprehensive evaluation and analysis, the project aims to provide valuable insights into the efficacy and viability of CNNs in speech emotion recognition, thereby contributing to the advancement of digital healthcare interventions for managing mental health conditions.

Additionally, the pressing need for effective emotion recognition systems is driven by the ever-expanding demand for personalized and context-aware interactions in various domains. From virtual assistants understanding user emotions to adaptive educational technologies tailoring content based on emotional cues, the applications of SER are broad and diverse. In fields like healthcare and mental health, accurate emotion recognition from speech can aid in the assessment, diagnosis, and monitoring of individuals' emotional well-being, providing valuable insights to healthcare professionals and enabling more targeted interventions.

The increasing recognition of the significance of emotion recognition has fueled a surge in research and development efforts in the field of SER. Researchers are exploring innovative techniques and approaches to improve the accuracy and robustness of emotion recognition systems, leveraging advancements in machine learning, deep learning, and signal processing.

These efforts aim to unlock the potential of speech as a rich source of emotional information, contributing to the ever-expanding field of speech and emotion analysis.

### **1.3 Outline of the Study**

The structure of the thesis is organized as follows. In Section 2, an extensive literature review is presented, encompassing previous research and studies related to speech emotion recognition. This section provides a comprehensive overview of the current state of the field, highlighting the limitations of traditional approaches and emphasizing the role of Convolutional Neural Networks (CNNs) in advancing SER.

Moving on to Section 3, the focus shifts to the structure and setup of the proposed model. This section details the methodology employed in the study, including the collection, and preprocessing of the dataset, the extraction and representation of relevant features from speech signals, and the design of the CNN architecture. It outlines the steps taken to configure and optimize the model, considering various hyperparameters and architectural choices.

Section 4 delves into the implementation part, elucidating the specific steps taken to train and fine-tune the CNN model. It describes the division of the dataset into training, validation, and testing sets, the training process itself, and any necessary adjustments or techniques utilized during the implementation phase.

Following the implementation, Section 5 delves into testing and result analysis. This section explores the evaluation metrics employed to assess the performance of the CNN-based SER model. It provides a detailed analysis of the obtained results, including accuracy, precision, recall, and F1-score, and may include visual representations such as confusion matrices or classification reports.

The thesis culminates with Section 6, which encompasses the conclusion part. This section summarizes the key findings and contributions of the study, reflecting upon the research objectives and questions posed at the beginning. It offers a concise and insightful recapitulation of the overall significance and impact of the study, while also discussing any limitations or challenges encountered. Finally, the conclusion part may suggest future research directions, provide practical implications for the field, and offer final remarks that encapsulate the essence of the thesis.

In this manner, the thesis progresses coherently through the literature review, model structure and setup, implementation, testing and result analysis, ultimately culminating in the conclusive findings and implications in the conclusion part presented in Section 6.

## 2 Literature Review

The literature review provides a comprehensive overview of existing research and studies related to Speech Emotion Recognition and its applications in various domains. This section explores the historical context, theoretical foundations, and advancements in SER methodologies, highlighting the contributions made by researchers and practitioners in the field.

1. **Historical Development of Speech Emotion Recognition:** The recognition of emotions from speech has a rich history that can be traced back several decades. Early research efforts focused on identifying the acoustic cues and patterns associated with different emotions in speech signals. Over time, technological advancements and the emergence of affective computing have propelled the field of SER to new heights. In the 1970s, researchers such as Scherer (1979) and Mehrabian (1971) conducted pioneering studies on vocal expression of emotions. They explored the relationship between various acoustic features, such as pitch, intensity, and speech rate, and the corresponding emotional states conveyed through speech. These early studies laid the foundation for subsequent research on SER. In the 1990s, affective computing emerged as a multidisciplinary field encompassing computer science, psychology, and linguistics, aiming to enable computers to detect and respond to human emotions. Rosalind Picard's seminal work on affective computing (Picard, 1997) brought significant attention to the importance of emotion recognition from various modalities, including speech. This work provided a framework for integrating emotion detection into intelligent systems and human-computer interaction. Advancements in machine learning algorithms in the 2000s led to the application of statistical models for emotion recognition from speech. Researchers explored techniques such as Hidden Markov Models (HMMs) and Gaussian Mixture Models (GMMs) to capture the temporal dynamics and probabilistic relationships between acoustic features and emotions (Deng and Hansen, 2003). These models allowed for the classification of emotional states based on learned statistical patterns. In recent years, the field of SER has witnessed a significant shift towards deep learning approaches. Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) have emerged as powerful tools for extracting high-level representations and modeling temporal dependencies in speech data. For instance, researchers have utilized CNNs to automatically learn discriminative features from speech spectrograms, enabling more accurate emotion classification (Kim et al., 2013). RNNs, on the other hand, have been employed to capture the sequential

nature of speech signals and contextual information for improved emotion recognition (Zhao et al., 2019). The availability of annotated datasets has also contributed to the advancement of SER. Datasets such as the Berlin Emotional Speech Database (EmoDB) (Burkhardt et al., 2005), the Interactive Emotional Dyadic Motion Capture (IEMOCAP) dataset (Busso et al., 2008), and the Toronto emotional speech set (TESS) (Dupuis and Friend, 2009) have provided standardized benchmarks for evaluating and comparing different emotion recognition models. These datasets contain recordings of actors expressing various emotions, providing researchers with valuable resources for training and testing their algorithms. In summary, the historical development of SER has evolved from early studies on vocal expression of emotions to the application of statistical models and, more recently, deep learning approaches. The integration of emotion recognition into affective computing and human-computer interaction has paved the way for numerous applications in fields such as healthcare, virtual assistants, and entertainment. The availability of annotated datasets and the advancements in machine learning techniques have propelled the field forward, enabling more accurate and robust emotion recognition from speech.

- 2. Feature Extraction and Representation:** Feature extraction plays a crucial role in SER, as it aims to capture the discriminative aspects of speech that convey emotional information. Various acoustic features have been explored, including prosodic features (e.g., pitch, intensity, and duration), spectral features (e.g., Mel-frequency cepstral coefficients), and voice quality-related features (e.g., jitter and shimmer) (Schuller et al., 2013). Feature extraction is a crucial step in Speech Emotion Recognition as it aims to capture the distinctive aspects of speech that convey emotional information. Various acoustic features have been explored to represent the vocal characteristics associated with different emotions. One commonly used set of features is prosodic features, which capture the temporal and melodic aspects of speech. These include fundamental frequency (F0), also known as pitch, which reflects the variations in vocal cord vibrations and is associated with emotions such as excitement or sadness. Intensity, representing the energy level of the speech signal, is another important prosodic feature related to emotional intensity or arousal. Duration measures the length of speech segments and can indicate the emphasis or elongation of certain sounds, contributing to the expression of emotions (Schuller et al., 2013). Spectral features are another class of acoustic features that focus on the frequency content of speech. Mel-frequency cepstral coefficients (MFCCs) are widely used in SER as they capture the

spectral envelope of the speech signal. MFCCs represent the power spectrum of the speech signal on a mel-scale, which is perceptually more relevant than the linear scale. These coefficients capture information related to the shape of vocal tract resonances and can be indicative of emotional content in speech (Eyben et al., 2013). Additionally, voice quality-related features have been investigated for SER. These features, including jitter and shimmer, measure the variations in pitch period and amplitude, respectively. They provide insights into the stability and smoothness of the vocal production and have been found to correlate with certain emotional states (Gomez et al., 2019). Moreover, with advancements in technology, researchers have explored the use of higher-level representations such as prosody patterns, linguistic content, and contextual information. Prosody patterns refer to the patterns of pitch, intensity, and timing across larger segments of speech, capturing the melodic and rhythmic aspects that contribute to emotional expression. Linguistic content refers to the words and semantic information conveyed in the speech signal, which can provide cues about the emotional context. Contextual information takes into account the surrounding context, including the speaker's identity, cultural factors, and situational context, which can influence the interpretation of emotions in speech (Schuller, 2018). The selection of appropriate features for SER depends on the specific research objectives, dataset characteristics, and the emotions of interest. Feature engineering plays a crucial role in identifying discriminative features that effectively capture emotional information in speech.

- 3. Traditional Approaches to SER:** Over the years, various traditional approaches have been employed for SER to analyze and classify emotional states from speech signals. These approaches typically involve the utilization of machine learning algorithms and handcrafted features to model the relationship between acoustic properties and emotions. One commonly used traditional approach is based on the utilization of statistical models such as Hidden Markov Models (HMMs) and Gaussian Mixture Models (GMMs). These models capture the statistical patterns and temporal dynamics present in speech signals. HMMs have been particularly popular for modeling the transitions between different emotional states, while GMMs have been used for estimating the probability distributions of acoustic features corresponding to different emotions (Wang and Narayanan, 2005). Another approach in traditional SER involves the use of rule-based systems. These systems rely on predefined linguistic and acoustic rules to associate specific patterns in speech with different emotional categories. For example, certain linguistic cues, such as the presence of specific words or phrases, can indicate the expression of certain emotions. Acoustic cues, such as high pitch for

excitement or slow speech rate for sadness, can also be used as rules for emotion classification (Batliner et al., 2004). Additionally, some traditional approaches focus on feature selection and dimensionality reduction techniques to improve the efficiency and effectiveness of emotion recognition. Feature selection methods aim to identify the most informative subset of features that contribute significantly to emotion classification. Techniques such as Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA) have been employed to reduce the dimensionality of feature vectors while retaining the discriminative information (Salam et al., 2016). However, traditional approaches to SER often face limitations in capturing complex patterns and extracting high-level representations from speech data. They heavily rely on manually engineered features, which may not fully capture the rich and subtle cues of emotional expression in speech. Moreover, these approaches may struggle to generalize well to unseen data and exhibit limited adaptability to different speakers or emotional contexts. Despite these limitations, traditional approaches have laid the groundwork for subsequent advancements in SER and provided valuable insights into the relationship between acoustic features and emotions. They have paved the way for the integration of machine learning techniques and the development of more sophisticated models, such as deep learning architectures, which can automatically learn and extract discriminative representations from raw speech data.

4. **Role of Deep Learning in SER:** Deep learning, a subfield of machine learning, has revolutionized various domains, including SER. Deep learning techniques, such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and their variants, have demonstrated remarkable performance in automatically learning discriminative representations from raw speech data, thereby enhancing the accuracy and robustness of emotion recognition systems. CNNs have proven to be highly effective in capturing local and hierarchical patterns in speech signals. They employ convolutional layers to extract features from different temporal scales, enabling them to learn relevant spectral and temporal representations. For SER, CNNs can learn discriminative features directly from the raw audio signal, eliminating the need for handcrafted features. For example, a CNN-based model can learn to detect specific patterns associated with emotional cues, such as variations in pitch, intensity, and spectral characteristics (Kim et al., 2013). RNNs, on the other hand, are well-suited for modeling sequential dependencies in speech data. They excel in capturing temporal dynamics and long-term dependencies by using recurrent connections. Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) are popular variants of RNNs

that have been successfully applied in SER. These models can effectively capture the context and temporal evolution of emotions within a speech utterance (Zhao et al., 2019). Hybrid architectures that combine both CNNs and RNNs have also emerged as powerful models for SER. These architectures leverage the strengths of both networks to capture both local and global temporal information. For instance, a hybrid model can employ a CNN for extracting low-level features and an RNN to model the temporal dependencies and high-level context (Han et al., 2020). In recent years, attention mechanisms have been integrated into deep learning models for SER. Attention mechanisms allow the model to focus on relevant segments of the speech signal, giving more weight to informative regions. This helps improve the model's ability to capture important emotional cues and can lead to better performance in SER tasks (Zhao et al., 2019). Moreover, transfer learning, a technique in deep learning, has shown promising results in SER. Pretrained models, such as those trained on large-scale speech datasets or general speech recognition tasks, can be fine-tuned on emotion-specific data. This enables the model to leverage the learned representations and generalize well to unseen emotion recognition tasks with limited labeled data (Gideon et al., 2021). Deep learning techniques have significantly advanced SER by enabling automatic feature learning and capturing complex patterns in speech data. They have achieved state-of-the-art performance in various benchmark datasets, such as the Interactive Emotional Dyadic Motion Capture (IEMOCAP) database and the Toronto Emotional Speech Set (TESS). With their ability to process large amounts of data and learn hierarchies of representations, deep learning models have become a cornerstone in advancing speech emotion recognition in both research and real-world applications.

5. **Datasets and Evaluation Metrics:** The availability of labeled datasets is essential for training and evaluating SER models. Several widely used datasets, such as the Berlin Emotional Speech Database (Emo-DB), the Interactive Emotional Dyadic Motion Capture (IEMOCAP) dataset, and the Toronto emotional speech set (TESS), have facilitated research in the field by providing standardized benchmarks for performance evaluation. Evaluation metrics in SER include accuracy, precision, recall, F1-score, and area under the receiver operating characteristic curve (AUC-ROC). To evaluate the performance of Speech Emotion Recognition (SER) models, researchers rely on standardized datasets and well-defined evaluation metrics. These resources enable objective assessment and comparison of different approaches, facilitating advancements in the field. Here, I discuss some widely used datasets and evaluation metrics in SER.

**a. Datasets:**

*Interactive Emotional Dyadic Motion Capture (IEMOCAP):* The IEMOCAP dataset is a widely used benchmark for SER. It contains recordings of scripted and improvised dialogues with actors displaying a range of emotions. The dataset provides a diverse collection of emotional expressions, including anger, happiness, sadness, and others, making it suitable for training and evaluating SER models (Busso et al., 2008).

*Toronto Emotional Speech Set (TESS):* TESS is another prominent dataset used in SER research. It consists of audio recordings of different actors uttering emotionally charged statements, covering a range of emotions such as anger, fear, happiness, and others. TESS provides a valuable resource for training and evaluating SER models, particularly for cross-cultural and cross-linguistic studies (Dupuis et al., 2019). *EmoDB:* The Emotional Database (EmoDB) comprises acted emotional speech samples from German speakers. It contains recordings of utterances expressing seven different emotions, including anger, fear, happiness, and others. EmoDB has been widely utilized in the development and evaluation of SER systems (Burkhardt et al., 2005).

**b. Evaluation Metrics:**

*Accuracy:* Accuracy is a commonly used metric in SER, representing the proportion of correctly classified emotional instances over the total number of instances. It provides an overall measure of the model's performance in correctly recognizing emotions from speech.

*Precision, Recall, and F1-Score:* Precision measures the proportion of correctly classified instances for a particular emotion category out of all instances classified as that category. Recall, also known as sensitivity, calculates the proportion of correctly classified instances for a particular emotion category out of all instances belonging to that category. F1-score is the harmonic mean of precision and recall, providing a balanced measure of a model's performance across different emotion categories.

*Confusion Matrix:* A confusion matrix provides a detailed analysis of the model's performance by presenting the number of instances classified into each emotion category compared to their ground truth labels. It helps identify specific emotions that may be prone to misclassification and provides insights into the model's strengths and weaknesses.

*Cohen's Kappa:* Cohen's Kappa is a statistical measure that assesses the

agreement between predicted and true emotion labels, taking into account the possibility of agreement by chance. It provides a robust evaluation of inter-rater agreement in multi-class emotion classification tasks.

By utilizing standardized datasets and evaluation metrics, researchers can assess the performance and generalization capabilities of SER models consistently. These resources facilitate the comparison of different approaches and the advancement of the field of speech emotion recognition.

6. **Applications of SER:** SER finds applications in various domains, including human-computer interaction, virtual assistants, healthcare, and entertainment. In healthcare, SER can contribute to the diagnosis and monitoring of mental health conditions such as depression and anxiety. It can also assist in affective computing applications, such as personalized therapy and emotion-aware virtual reality environments. SER has leveraged its ability to automatically detect and interpret emotional cues from speech signals. Here, I discuss some notable applications where SER has been successfully employed.

- a. *Mental Health Diagnosis and Therapy:* SER has shown promise in assisting mental health diagnosis and therapy. By analyzing vocal features such as pitch, intensity, and speech rate, SER models can provide valuable insights into an individual's emotional state. For example, in diagnosing conditions like depression and anxiety, SER can help identify patterns associated with these disorders (Girardi et al., 2018). It can also aid in monitoring the progress of therapy sessions by assessing changes in emotional expression over time.
- b. *Human-Computer Interaction (HCI):* Incorporating SER into human-computer interaction systems enables more natural and intuitive user interfaces. Emotion-aware systems can adapt their responses and behaviors based on the user's emotional state. For instance, SER can be used in virtual assistants to enhance their understanding of user intentions and provide personalized responses. In gaming applications, SER can enable adaptive gameplay experiences that respond to the player's emotional reactions (Cowie et al., 2001).
- c. *Call Center and Customer Service Analysis:* SER has been employed in call centers and customer service analysis to gauge customer satisfaction and sentiment. By analyzing customer calls, SER models can detect emotional states, such as anger or frustration, in real-time. This information can be used to improve customer support processes, identify training needs, and enhance overall customer experience (Kumar et al., 2020).

- d. *Market Research and Advertisement*: SER can be utilized in market research and advertisement campaigns to assess consumer responses to products, services, or advertisements. By analyzing the emotional content in customer feedback or reactions to advertisements, companies can gain insights into customer preferences, sentiments, and purchasing behavior. This information can guide product development, marketing strategies, and targeted advertising campaigns (Schuller et al., 2011).
- e. *Human-Robot Interaction (HRI)*: SER plays a crucial role in enhancing human-robot interaction. Robots equipped with SER capabilities can perceive and respond to human emotions, enabling more effective communication and collaboration. For instance, in healthcare settings, robots can detect patient emotions and respond with appropriate empathy and support. In social robotics, SER can contribute to the development of emotionally intelligent robots that understand and express emotions (Breazeal, 2003).

These are just a few examples highlighting the diverse range of applications where SER has proven valuable. As SER technology continues to advance, it holds immense potential for improving various aspects of human-machine interaction, healthcare, market research, and beyond.

**7. Challenges and Future Directions:** Despite the progress made in SER, several challenges persist. These include the subjectivity and cultural variability of emotion perception, the limited availability of annotated datasets, and the need for robustness to variations in speech conditions. Future research directions focus on addressing these challenges, exploring multimodal approaches that combine speech with other modalities, incorporating contextual information, and enhancing cross-cultural generalization. Here, I discuss some of the key challenges and potential avenues for future research.

- a. *Cross-Cultural and Multilingual Emotion Recognition*: SER models are often trained and evaluated on datasets that are biased towards specific languages and cultures. To achieve more robust and generalizable emotion recognition, future research should focus on developing models that can effectively handle cross-cultural and multilingual scenarios. This involves addressing issues related to language variations, cultural nuances, and context-specific emotional expressions (Weninger et al., 2013).
- b. *Handling Noisy and Real-World Environments*: Most SER research has been conducted in controlled and noise-free environments, which do not fully represent

real-world scenarios. Future work should focus on developing robust models that can handle noisy and adverse acoustic conditions commonly encountered in real-life applications, such as background noise, reverberation, and overlapping speech. This will enhance the practical utility of SER in various domains, including healthcare and customer service (Eyben et al., 2016).

- c. *Fusion of Modalities*: While speech is a primary modality for emotion recognition, combining it with other modalities, such as facial expressions, physiological signals, and text, can provide richer and more accurate emotion understanding. Future research should explore multi-modal fusion techniques to leverage complementary information from different modalities and enhance the performance of SER systems (Soleymani et al., 2017).
- d. *Explainability and Interpretability*: Deep learning models used in SER, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), often act as black boxes, making it challenging to interpret their decision-making process. It is important to develop techniques that can provide explanations for the model's predictions, enabling better understanding and trust in the generated emotion labels. This is particularly crucial in sensitive applications, such as healthcare and therapy (Cao et al., 2020).
- e. *Long-Term and Dynamic Emotion Recognition*: Emotions are not static but rather evolve over time. Current SER models primarily focus on short-term emotion recognition. Future research should investigate long-term emotion recognition and tracking, capturing the dynamics and temporal evolution of emotional states. This will enable a deeper understanding of emotional processes and support real-time emotion-aware systems (Ringeval et al., 2018).
- f. *Ethical and Privacy Considerations*: As SER technology advances and finds its way into various applications, it is essential to address ethical concerns regarding user privacy, data security, and potential biases in emotion recognition systems. Researchers and practitioners should work towards developing guidelines and frameworks to ensure the responsible and ethical use of SER, respecting user rights and fostering transparency (Martin et al., 2019).

By addressing these challenges and exploring the suggested directions, the field of SER can continue to evolve and contribute to numerous domains, including mental health, human-computer interaction, and customer service, among others.

In summary, the literature review highlights the historical development, methodologies, and

applications of SER. It underscores the shift from traditional approaches to deep learning techniques, emphasizing the role of CNNs and RNNs in capturing emotional cues from speech. The review also emphasizes the importance of annotated datasets and evaluation metrics for benchmarking and comparing different SER models.

### **3 Structure & Setup of Model**

In the architecture of my study, I employed CNN in combination with the Short-time Fourier Transform (STFT) as essential components. The CNN is a powerful deep learning algorithm known for its effectiveness in processing complex data such as speech signals. By leveraging the hierarchical feature extraction capabilities of CNN, I aimed to capture meaningful patterns and representations from the input audio data.

To conduct the experiments, I partitioned the dataset into a training set and a separate test set, following a split ratio of 75% for training and 25% for testing. This division allowed me to train the model on a substantial portion of the data and evaluate its performance on unseen instances during the testing phase. Such a train-test split is commonly employed in machine learning tasks to assess the generalization capability of the model.

During the training phase, the CNN model learned to classify and assign appropriate labels to the input audio data based on the information contained in the dataset. Through this training process, the CNN model acquired the ability to recognize and differentiate various emotions present in the speech data.

Subsequently, I evaluated the trained CNN model on the test set, consisting of unseen data samples. This evaluation phase allowed me to assess the model's performance on instances that were not part of the training process. By comparing the predicted labels generated by the model with the ground truth labels of the test set, I obtained a measure of the model's accuracy and its ability to generalize to new, unseen data samples.

Overall, the combination of the CNN architecture and the STFT feature extraction technique enabled the classification of emotions from speech data. The training and testing phases, conducted on distinct subsets of the dataset, facilitated the assessment of the model's performance and its capability to accurately label unseen audio data based on the learned patterns.

#### **3.1 Architecture**

This part defines a CNN model architecture with multiple convolutional and dense layers, along with dropout layers for regularization. The use of activation functions, max pooling, and flattening operations allows the model to learn and extract meaningful features from the input data. Here, I discuss my model architecture in detail:

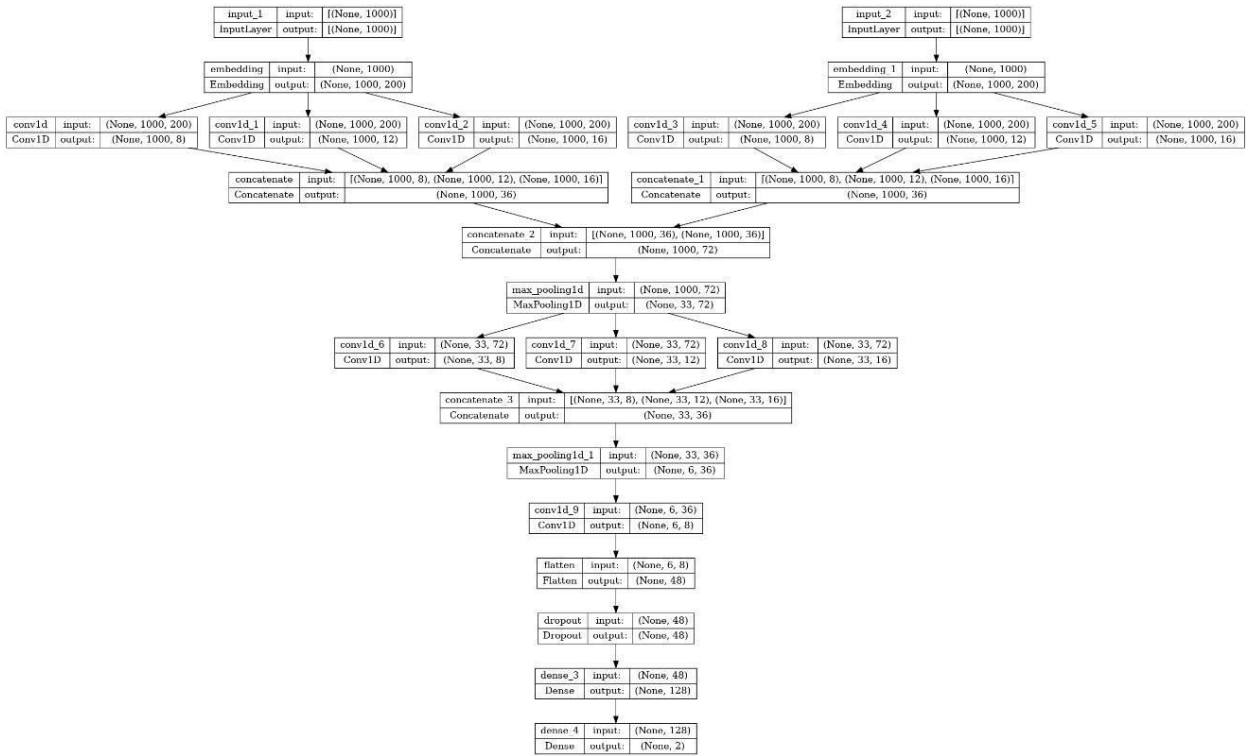

Fig. 1: CNN Architecture Used in the Model

- a. **Convolution Layer:** I used the sequential model to create the architecture. The sequential model allows for the sequential stacking of layers, which is a common approach in building CNN architectures. The model starts with a Conv2D layer, which performs 2D convolution on the input data. This layer has 32 filters, each with a size of 2x2, and applies the Rectified Linear Unit (ReLU) activation function to introduce non-linearity to the output. The input\_shape parameter specifies the shape of the input data that the model expects.
- b. **Max Pooling Layer:** Following the convolutional layer, a MaxPooling2D layer is added. This layer performs 2D max pooling with a pool size of 2x2, reducing the spatial dimensions of the input and capturing the most salient features. The purpose of this layer is to downsample the feature maps and extract the most relevant information.
- c. **Dropout Layer:** To prevent overfitting, a Dropout layer with a dropout rate of 0.25 is inserted after the max pooling layer. Dropout randomly deactivates a certain percentage of neurons during training, which helps in regularizing the model and reducing the likelihood of overfitting.
- d. **Convolution, Max Pooling & Dropout Layer:** The process of convolution, max pooling, and dropout is repeated with a larger number of filters in the subsequent layers. Another Conv2D layer with 64 filters of size 3x3 is added, followed by another MaxPooling2D layer and a Dropout layer with the same configuration as before.

- e. **Flatten Layer:** The output of the second dropout layer is then flattened using the Flatten layer. This flattens the multidimensional feature maps into a one-dimensional vector, which can be fed into the dense layers of the network.
- f. **Dense Layer:** The next step is to add a fully connected Dense layer with 128 units and the ReLU activation function. This dense layer serves as a hidden layer and allows the model to learn more complex representations from the flattened input.
- g. **Dropout Layer:** To further regularize the model, another Dropout layer with a dropout rate of 0.5 is included after the dense layer. This additional dropout layer helps in preventing overfitting by randomly deactivating neurons during training.
- h. **Dense Layer:** Finally, the model ends with a Dense layer with the number of units equal to the number of classes (NUM\_CLASSES). This layer uses the softmax activation function to produce the output probabilities for each class, indicating the predicted probability of each class given the input.

The created model is then returned by the function as the output.

## 3.2 Methodology

In the methodology section of this study, two key components were employed: Convolutional Neural Network (CNN) and Short-time Fourier Transform (STFT). These techniques play a fundamental role in analyzing and processing speech data to facilitate the recognition of emotions.

1. *Convolutional Neural Network (CNN)* is a type of deep learning algorithm that has gained significant popularity and success in various fields, including image and speech processing. CNNs are particularly effective in capturing spatial and temporal patterns within data. They consist of multiple layers, including convolutional, pooling, and fully connected layers, that enable the network to learn and extract intricate features from the input data. The convolutional layers perform localized feature extraction by convolving filters over the input, capturing relevant information at different spatial scales. The pooling layers downsample the feature maps, reducing their dimensionality while retaining the most salient features. Finally, the fully connected layers integrate the extracted features and make predictions based on the learned representations. By leveraging the hierarchical architecture and weight sharing, CNNs can effectively learn discriminative representations and classify input data, making them well-suited for speech emotion recognition tasks.
2. *Short-time Fourier Transform (STFT)* is a widely used technique for analyzing the frequency content of time-varying signals, such as speech. It breaks down the signal into

its constituent frequency components by dividing it into short overlapping windows and applying the Fourier Transform to each window. The resulting spectrogram represents the distribution of different frequency components over time, providing insights into the spectral characteristics of the signal. STFT is particularly useful in capturing changes in spectral energy and identifying acoustic cues related to emotional content. By analyzing the spectrogram derived from STFT, meaningful features such as pitch, formants, and energy variations can be extracted, contributing to the identification and discrimination of different emotions.

In this study, the CNN architecture was utilized to leverage its powerful feature extraction capabilities in capturing relevant patterns and representations from speech data. The STFT technique was employed to transform the speech signals into their spectrogram representations, enabling the extraction of essential acoustic features related to emotions. By combining these two methodologies, the aim was to develop a robust and accurate system for speech emotion recognition. It is worth noting that the specific configurations and parameters of the CNN and STFT techniques may vary depending on the specific requirements and characteristics of the dataset and research objectives. Therefore, adaptations and optimizations were made accordingly to suit the context of this study.

### 3.3 Used Tools

In the development of my model, I have used Python and Kaggle. More of the details are included below:

1. **Python:** I employed the Python programming language as the primary tool for implementation. Python is a versatile and widely adopted language known for its simplicity, readability, and extensive range of libraries and frameworks. Its rich ecosystem of data science and machine learning libraries, such as TensorFlow, Keras, and scikit-learn, provided me with the necessary resources to efficiently build and train my model for speech emotion recognition. Python's syntax and structure enabled me to write clean and organized code, facilitating the implementation and maintenance of the model. The availability of various pre-built functions and modules allowed me to leverage existing solutions and implement complex operations with ease. Moreover, Python's interactive nature and vast community support made it convenient to troubleshoot issues and seek assistance whenever needed.
2. **Kaggle:** In addition to Python, I utilized Kaggle as a valuable resource throughout the development process. Kaggle is an online platform that hosts a diverse range of datasets,

competitions, and collaborative environments for data science projects. It provides a convenient avenue for accessing and exploring publicly available datasets relevant to speech emotion recognition. By leveraging Kaggle's extensive collection of datasets, I was able to access a diverse range of speech data and train my model on a representative and comprehensive sample.

Furthermore, Kaggle's community-driven environment allowed me to connect and collaborate with other data scientists, researchers, and practitioners in the field. I could benefit from shared insights, discussions, and code repositories related to speech emotion recognition, enhancing the quality and effectiveness of my work.

- 3. GPU Resources of Kaggle:** In addition to its role as a platform for data science collaboration, Kaggle offers another valuable resource for model development: access to GPU (Graphics Processing Unit) resources. GPUs are specialized hardware components that excel in parallel processing and are particularly well-suited for accelerating computations in machine learning and deep learning tasks. Kaggle provides users with the option to utilize GPUs for training and inference tasks, which can significantly speed up the processing time and enhance the performance of models. GPUs excel in handling the heavy computational load involved in training deep learning models, as they can perform operations in parallel across multiple cores, enabling faster training and optimization of complex neural networks. By leveraging Kaggle's GPU resources, I was able to harness the power of accelerated computing for my speech emotion recognition model. The availability of GPUs allowed me to train and fine-tune my model using larger datasets, more complex architectures, and increased computational demands, leading to improved performance and efficiency. The parallel processing capabilities of GPUs expedited the training process, enabling me to iterate and experiment with different configurations and hyperparameters more rapidly. Moreover, Kaggle's GPU infrastructure alleviated the need for individual users to have access to high-end GPUs on their local machines, making it more accessible for researchers and practitioners with limited hardware resources. This accessibility further facilitated the development and experimentation of deep learning models for speech emotion recognition. It is important to note that Kaggle provides GPU resources within certain limitations and guidelines, which may vary depending on the specific competition or project. Users typically have a set allocation of GPU usage, and it is essential to manage the utilization responsibly and efficiently. In conclusion, Kaggle's provision of GPU resources proved invaluable in the development of my speech emotion recognition model. The ability to leverage GPUs for accelerated computations expedited the training process, improved model performance,

and provided access to robust hardware resources that might not be readily available to individual researchers.

Overall, the combination of Python and Kaggle played a crucial role in the development of my model for speech emotion recognition. Python's versatility and extensive libraries empowered me to implement sophisticated algorithms and handle the complexities of data processing and model training. Kaggle, on the other hand, provided a valuable platform for accessing relevant datasets and fostering collaboration within the data science community.

### **3.4 Dataset**

The dataset employed in this study is the RAVDESS (Ryerson Audio-Visual Database of Emotional Speech and Song), which holds significant prominence and widespread usage in the domain of Speech SER. RAVDESS serves as a comprehensive collection of recordings comprising emotional speech and song, facilitating researchers in exploring and analyzing various facets of human emotional expression through vocal signals.

Fig. 2: RAVDESS Dataset Sample (Livingstone et al., 2018)

Figure 2 demonstrates a sample example of RAVDESS dataset. The speech audio files utilized in this study are in the format of 16-bit, 48kHz .wav files sourced from the RAVDESS (Ryerson Audio-Visual Database of Emotional Speech and Song). The complete dataset, comprising speech and song recordings along with associated audio and video files, is available for access on Zenodo, amounting to a total size of 24.8 GB. The construction and perceptual validation of the RAVDESS dataset are extensively documented in an Open Access paper published in PLoS ONE, providing detailed insights into its development and credibility.

The files included in this portion of the RAVDESS dataset encompass a total of 1440 files, resulting from 60 trials per actor multiplied by 24 actors. Within the RAVDESS, there are 24 professional actors, equally divided between 12 females and 12 males, who vocalize two

lexically-matched statements in a neutral North American accent. The speech emotions covered in this dataset include calm, happy, sad, angry, fearful, surprise, and disgust expressions. Each expression is produced at two levels of emotional intensity: normal and strong, with an additional neutral expression.

The file naming convention for the 1440 files follows a specific structure, utilizing a 7-part numerical identifier (e.g., 03-01-06-01-02-01-12.wav). These identifiers serve to define the characteristics of each stimulus:

- Modality (01 = full-AV, 02 = video-only, 03 = audio-only).
- Vocal channel (01 = speech, 02 = song).
- Emotion (01 = neutral, 02 = calm, 03 = happy, 04 = sad, 05 = angry, 06 = fearful, 07 = disgust, 08 = surprised).
- Emotional intensity (01 = normal, 02 = strong). Note: There is no strong intensity for the 'neutral' emotion.
- Statement (01 = "Kids are talking by the door", 02 = "Dogs are sitting by the door").
- Repetition (01 = 1st repetition, 02 = 2nd repetition).
- Actor (01 to 24, with odd-numbered actors being male and even-numbered actors being female).

As an example, consider the filename 03-01-06-01-02-01-12.wav, which can be interpreted as follows:

- Audio-only (03).
- Speech (01).
- Fearful (06).
- Normal intensity (01).
- Statement "dogs" (02).
- 1st Repetition (01).
- 12th Actor (12).
- Female, as the actor ID number is even.

The recordings for this research were conducted in a professional recording studio at Ryerson University, ensuring a controlled and consistent environment. To maintain consistency among actors, specific guidelines were followed. Actors wore black t-shirts, had minimal makeup, were clean-shaven, wore contact lenses if necessary, and refrained from wearing distinctive jewelry. Throughout the recording process, actors remained standing, although a seat was provided for them to rest and prepare between different emotional conditions.

To ensure appropriate microphone levels, actors produced several highly angry expressions as a reference, allowing adjustments to be made accordingly. The recording session commenced with practice trials for each emotional expression in speech, followed by the completion of all speech trials. Afterward, actors were given a 60-minute break before proceeding to practice trials and subsequent recordings for the singing condition. The order of recording was carefully planned to conduct speech trials before singing trials, eliminating potential influences from the singing condition. Trials were organized in blocks based on emotions, starting with low-intensity emotions and progressing to their highly intense counterparts, enabling actors to immerse themselves in and sustain the desired emotional state for all productions within a specific emotional category.

To guide the actors' performances, a dialog script was provided. The description of each emotional condition incorporated emotional labels derived from the prototype model of emotion, ensuring that the actors understood the intended emotion. Additionally, a vignette depicting a scenario related to each intensity level of the emotion was given. Actors were given sufficient time to prepare their emotional state using their preferred induction technique. In the singing condition, actors were instructed to follow the basic notated pitches while having the freedom to vary acoustic characteristics to convey the desired emotion.

During the recording process, actors had the flexibility to repeat a trial until they felt comfortable with their production. The performances of the actors were observed in a separate control room through video and audio feeds, allowing for real-time monitoring. Feedback was provided if a production was deemed ambiguous by both operators. However, actors were not given specific instructions on how to express each emotion, allowing them to exhibit their own interpretation. Multiple takes were recorded for each production, and subsequently, all takes were reviewed by the three investigators. Clips containing hand movements or gestures were excluded, as well as trials that contained lexical errors. After removing erroneous clips, the selection criteria for inclusion in the dataset were productions that clearly conveyed the specified emotion and intensity through both facial expressions and voice. Through consensus among the investigators, the two best takes were chosen for each production.

Furthermore, the RAVDESS dataset offers additional attributes, such as gender, age, and native language, which provide opportunities to explore potential correlations between these factors and emotional expressions in speech. This rich metadata allows researchers to conduct more comprehensive investigations and gain insights into the interplay between emotions and various

demographic characteristics.

The group of twenty-four professional actors selected for this study was specifically recruited for the purpose of creating stimuli. These actors, residing in Toronto, Ontario, Canada, had a mean age of 26.0 years with a standard deviation of 3.75, ranging from 21 to 33 years. The group consisted of an equal distribution of 12 male and 12 female actors. Among them, 20 identified themselves as Caucasian, 2 as East-Asian, and 2 as Mixed, with one being East-Asian Caucasian and the other Black-Canadian First Nations Caucasian. Eligible actors were required to have English as their first language, speak with a neutral North American accent, and not possess any distinctive physical features like beards, facial tattoos, hair colorings, or facial piercings. Additionally, participants underwent testing to assess their ability to identify text presented at a distance of 1.5 meters without wearing glasses.

The selection of professional actors for this study was based on several factors. Previous research has demonstrated that actors are more easily recognized for their portrayals of emotions compared to lay individuals (Elfenbein et al., 2002). While a recent study found minimal differences in vocal expression accuracy between actors and non-actors (Anikin et al., 2019), it remains uncertain whether the same holds true for facial expressions or dynamic audio-visual expressions. Moreover, the use of trained individuals is common in psychological tasks, such as music performance (Juslin et al., 2004). Actors are frequently recruited for studies involving emotional expression due to their extensive training in realistically conveying emotions (Livingstone et al., 2018).

The Toronto accent represents Standard North American English commonly encountered in Hollywood movies. However, it's important to note that the linguistic phenomenon called Canadian raising, where diphthongs are raised before voiceless consonants, is not prominent in the Toronto region and is absent in the stimulus statements of the RAVDESS dataset. Canadian raising can be found in various parts of Canada, northeastern New England, the Pacific Northwest, and the Upper Midwest.

The RAVDESS dataset offers high-quality audio recordings that ensure reliable and consistent data for training and evaluating SER models. It provides a balanced distribution of emotions across different actors, allowing for a fair representation of various emotional states in the collected samples.

To maintain the integrity and quality of the dataset, the RAVDESS recordings underwent

rigorous acoustic analysis and validation by domain experts. This meticulous curation process guarantees the reliability and suitability of the data for SER research purposes.

The utilization of the RAVDESS dataset in this research not only serves as a standardized benchmark for evaluating the proposed SER methodologies but also enables comparison and benchmarking against other state-of-the-art approaches in the field. The availability of such a well-structured and diverse dataset contributes to the advancement of SER research and facilitates the development of more accurate and robust emotion recognition systems.

## **4 Implementation**

I have incorporated my AI model into a voice emotion recognition application that analyzes and detects the emotions present in a user's voice. The application utilizes a set of predefined emotion labels, including sadness, happiness, anger, surprise, neutral, and others. By leveraging advanced algorithms and machine learning techniques, the app can accurately identify and classify the emotional state conveyed through the user's voice.

Through the integration of my AI model, the voice emotion recognition app provides users with valuable insights into their emotional expressions, allowing them to better understand and manage their emotions. By simply speaking into the app, users can receive real-time feedback on their emotional state, gaining awareness of their feelings and potentially facilitating self-reflection and emotional well-being.

The app's functionality extends beyond mere emotion detection. It offers a user-friendly interface that presents the detected emotions in an intuitive and visually appealing manner, enhancing the overall user experience. Additionally, the app may provide additional features such as historical emotion tracking, allowing users to monitor their emotional patterns over time and identify any potential trends or correlations.

By incorporating my AI model into this voice emotion recognition app, I aim to contribute to the field of emotion recognition technology and its practical applications. The ability to accurately detect emotions from voice recordings opens up opportunities for numerous domains, including mental health, virtual assistants, customer service, and entertainment. This integration represents a step forward in the development of intelligent systems that can understand and respond to human emotions, ultimately enhancing human-computer interaction and improving overall user satisfaction.

### **4.1 UI/UX**

In this section of the thesis, the user interface (UI) and user experience (UX) of the application are showcased. The app's design process involved the utilization of a powerful design tool known as Figma.

Figma played a pivotal role in crafting an aesthetically pleasing and intuitive user interface for the application. As a collaborative design platform, Figma provided a comprehensive set of

features and functionalities that facilitated the creation of a visually appealing and interactive app layout.

By leveraging Figma's capabilities, the app's UI was meticulously designed, taking into consideration key principles of user-centered design and usability. The goal was to create an interface that would not only capture the attention of users but also ensure a seamless and engaging user experience.

The Figma tool enabled the development of wireframes, prototypes, and mockups, allowing for iterative design improvements and feedback incorporation. Its collaborative nature allowed multiple team members to work concurrently on the app's UI, fostering efficient communication and coordination among designers, developers, and other stakeholders.

Through Figma's rich library of design elements, icons, and components, the app's visual elements were carefully selected and customized to align with the overall app concept and brand identity. The tool's versatility enabled the creation of a consistent and visually appealing UI across different screens and functionalities of the application.

Furthermore, Figma's interactive prototyping capabilities provided a means to simulate user interactions and transitions within the app, enabling designers to test and refine the UX design. This iterative process allowed for the identification and resolution of potential usability issues, ensuring that the final app design offered a smooth and intuitive user experience.

Overall, the utilization of Figma as the design tool for the app's UI/UX exemplifies the commitment to delivering a well-crafted and user-centric application. By harnessing Figma's robust features, the design team was able to translate their creative vision into a visually stunning and user-friendly interface, enhancing the overall usability and appeal of the app.

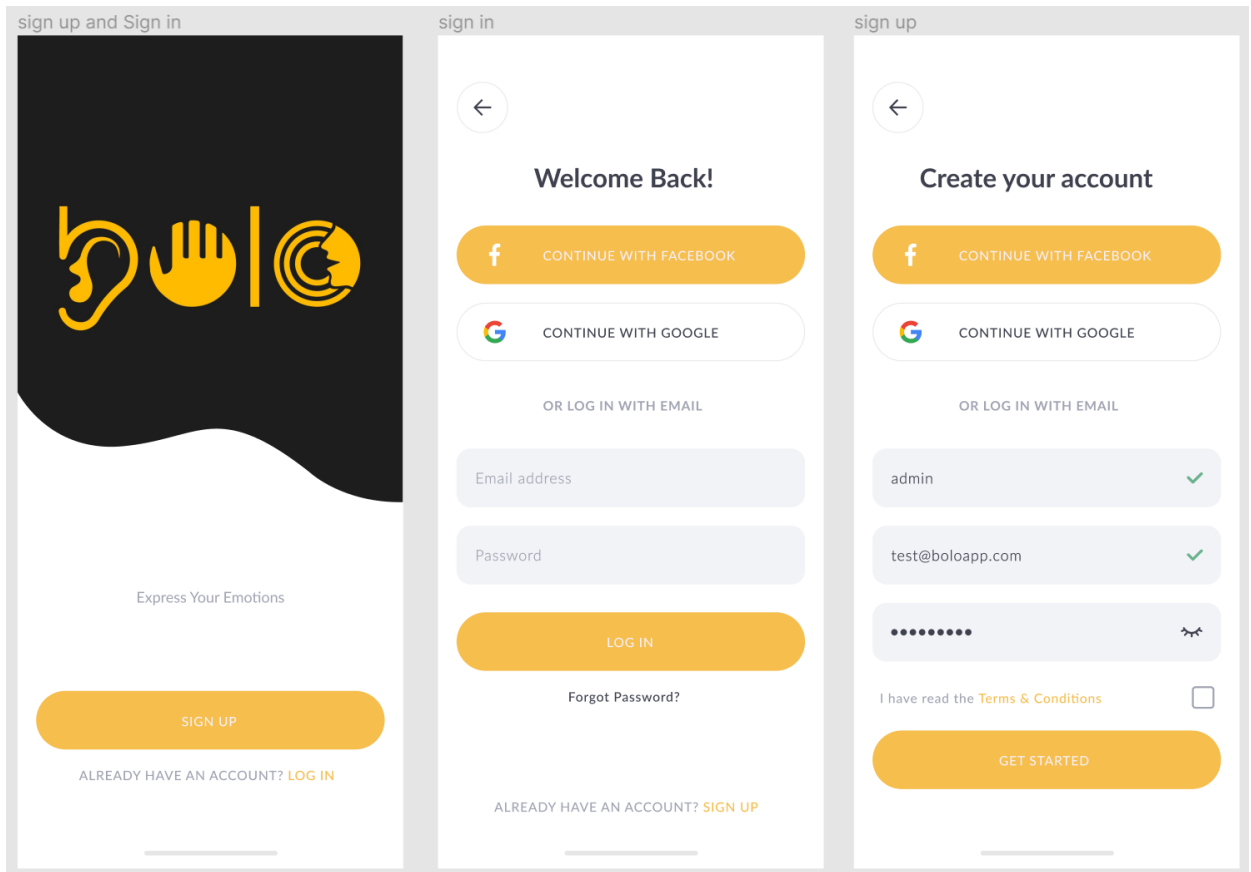

Fig. 3: The Sign Up & Sign In Options

Figure 3 illustrates the login and registration features within the application, providing users with convenient sign-in and sign-up options. Within the app's interface, users are presented with a visually represented depiction, that prominently displays the login and registration functionalities. These options serve as entry points for users to access the app's features and personalized content. The sign-in option enables users who have previously registered to securely log into their accounts. By entering their designated credentials, such as a username or email address and a password, users can gain access to their personalized profiles and data. On the other hand, the sign-up option allows new users to create an account and join the app's community. By selecting this option, users are guided through a streamlined registration process, typically involving the provision of essential information, such as a unique username, a valid email address, and a secure password. This step ensures that users' accounts are created securely and efficiently. The design of these login and registration features takes into consideration key principles of usability and visual appeal, ensuring that users can effortlessly engage with the app's functionality while maintaining a cohesive and visually appealing user interface.

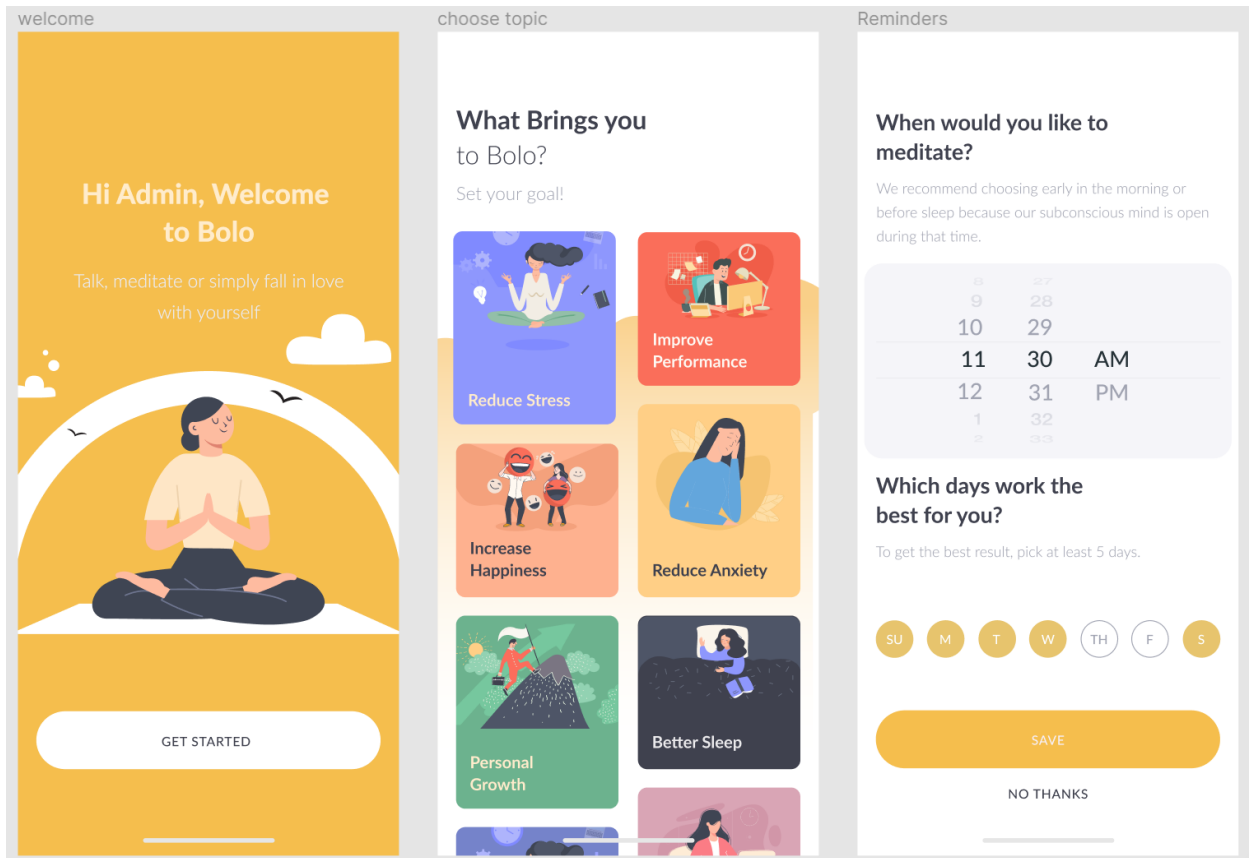

Fig. 4: User Choices

Figure 4 provides a visual representation of the app's welcome screen, presenting users with personalized options tailored to their individual preferences and goals. This intuitive design aims to enhance user engagement and satisfaction by offering a range of choices to cater to their specific needs. The welcome screen serves as a warm and inviting entry point for users. It greets them upon accessing the app and sets the stage for a personalized experience. The design of this screen takes into account both functionality and aesthetics, ensuring that users feel welcomed and encouraged to explore the app further. After selecting the "Get Started" option, users are presented with a selection of personalized choices, carefully curated to address common areas of interest and well-being. These choices encompass a range of objectives, including stress reduction, performance improvement, happiness enhancement, anxiety reduction, personal growth, better sleep, and meditation reminders. Each option represents a specific area that users can focus on and benefit from within the app. By offering these personalized choice options, the app demonstrates its commitment to meeting the diverse needs and goals of its users. This approach acknowledges that individuals may have different priorities and areas they wish to work on, and provides them with tailored content and features accordingly. By presenting users with these choices, the app empowers them to take an active role in their well-being journey. Users have the freedom to select the option that resonates with them the most, aligning with

their specific goals and preferences. Furthermore, the inclusion of reminders for meditation emphasizes the app's focus on promoting mindfulness and self-care. These reminders serve as gentle prompts to encourage users to engage in regular meditation practices, which have been shown to have numerous mental and physical health benefits. This thoughtful design approach enhances user engagement and satisfaction by tailoring the app's content and features to individual preferences. By empowering users to select their areas of focus and providing reminders for meditation, the app aims to support users in their journey towards improved well-being and a more fulfilling life.

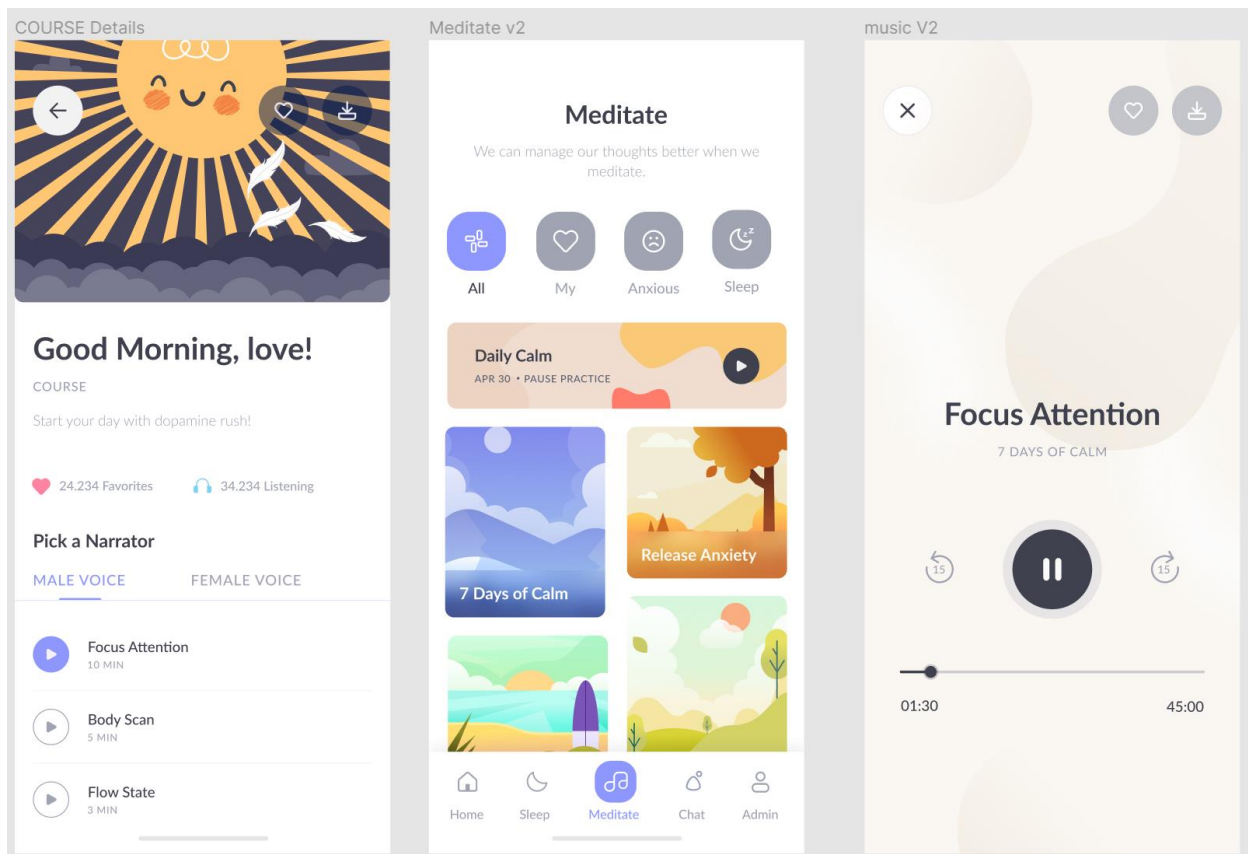

Fig. 5: Meditation Options

Figure 5 illustrates a diverse range of meditation options available within the app, catering to different preferences and meditation techniques. This visual representation highlights the app's commitment to providing users with a comprehensive selection of meditation practices to suit their individual needs and goals. Users can observe various meditation options, including focus: attention, body scan, and flow state. Each option represents a distinct meditation technique or approach, designed to cultivate specific mental states and experiences. The inclusion of the focus: attention meditation option suggests that the app offers practices centered around enhancing concentration and mindfulness. This technique typically involves directing one's attention to a specific object, such as the breath or a chosen focal point, in order to develop a greater sense of presence and awareness. The body scan meditation option, indicates that the

app provides practices that emphasize the systematic observation and awareness of bodily sensations. This technique involves sequentially scanning different parts of the body, bringing attention to physical sensations and promoting relaxation and body awareness. The presence of the flow state meditation option suggests that the app offers practices aimed at fostering a state of deep focus, immersion, and optimal performance. Flow state meditation typically involves engaging in an activity that fully captivates one's attention and challenges their skills, leading to a state of heightened focus, enjoyment, and effortless concentration. By offering these various kinds of meditation options, the app seeks to accommodate different meditation styles and objectives. This diversity recognizes that individuals have unique preferences and goals when it comes to their meditation practice. Whether users are seeking improved focus, relaxation, or a state of flow, they can choose the meditation technique that resonates with them the most. By offering multiple options, the app encourages users to explore different techniques and discover what works best for them. This approach enhances user engagement and satisfaction, as individuals can personalize their meditation practice and adapt it to their evolving needs. These diverse choices cater to different meditation techniques and objectives, allowing users to select the approach that aligns with their preferences and goals.

## 5 Testing & Results

In this section of the thesis, the focus shifts towards testing and analyzing the performance of the developed system. A comprehensive evaluation of the system's capabilities and effectiveness will be discussed, providing valuable insights into its performance in detecting and recognizing emotions in voice recordings.

The performance evaluation aims to assess the accuracy, reliability, and overall effectiveness of the AI model integrated into the voice emotion recognition system. Rigorous testing procedures have been employed to ensure the validity and robustness of the results obtained.

The evaluation process involves subjecting the system to a diverse range of voice samples, encompassing different emotions, speaking styles, and environmental conditions. This extensive testing enables a comprehensive assessment of the system's ability to accurately identify and classify various emotional states, including but not limited to sadness, happiness, anger, surprise, and neutral expressions.

Various performance metrics and evaluation techniques have been employed to analyze the system's performance. These metrics provide quantitative measures of accuracy, precision, recall, and F1 score, among others, allowing for a thorough evaluation of the system's performance in emotion recognition.

Additionally, the evaluation process includes comparing the system's results with human-labeled ground truth data to assess the system's agreement with human perception. This comparison helps gauge the system's performance in relation to human judgment and provides insights into its ability to capture and interpret emotional cues in the voice accurately.

Furthermore, the evaluation includes testing the system's robustness and generalizability by assessing its performance on unseen data, including recordings from different individuals, diverse linguistic backgrounds, and varying recording conditions. This analysis ensures that the system can effectively handle real-world scenarios and demonstrates its adaptability to different user profiles.

The discussion of the results obtained from the performance evaluation will provide an in-depth analysis of the system's strengths, limitations, and areas for improvement. Not only will the thesis present quantitative performance metrics, but it will also offer qualitative insights into

the system's performance, highlighting specific cases, challenges, and successes encountered during the testing phase.

Overall, this section of the thesis serves as a comprehensive exploration of the testing and results of the voice emotion recognition system. Through meticulous evaluation procedures and a thorough analysis of the system's performance, valuable insights will be gained, enabling a deeper understanding of the system's capabilities and paving the way for future enhancements and advancements in the field of voice emotion recognition.

## **5.1 Performance Evaluation**

The performance evaluation section involves a detailed analysis of the developed system's effectiveness, which includes assessing various parameters to gauge its performance accurately. To ensure a comprehensive evaluation, several key metrics and comparisons with other models have been employed.

During the performance evaluation, critical parameters such as training and validation accuracies, loss, and epoch are utilized to measure the system's performance. These metrics provide valuable insights into the model's ability to learn and generalize from the training data and its performance on unseen validation data. By examining these parameters, the system's accuracy and efficiency can be assessed, allowing for a thorough evaluation of its overall performance.

In addition to evaluating internal metrics, the developed model is compared with other well-established models like LSTM (Long Short-Term Memory) and DNN (Deep Neural Network). This comparison aims to identify the strengths and weaknesses of each model and determine which one performs the best in terms of accuracy and reliability. By benchmarking against existing models, a fair assessment of the system's performance can be obtained, highlighting its comparative advantages and contributions.

The comparison with LSTM and DNN models provides valuable insights into the effectiveness of the developed system in relation to alternative approaches. This analysis helps researchers and practitioners understand the unique characteristics and capabilities of the proposed model, enabling them to make informed decisions regarding its deployment in real-world scenarios.

Furthermore, the performance evaluation involves assessing the system's performance across

various datasets and scenarios to ensure its robustness and generalizability. By testing the system on diverse datasets, including those with different emotional expressions and speaking styles, its ability to handle various real-world scenarios can be evaluated. This analysis ensures that the developed model is not limited to specific datasets or conditions, but rather exhibits consistent and reliable performance across different contexts.

Through a comprehensive performance evaluation, including parameter analysis and model comparisons, the strengths, weaknesses, and overall effectiveness of the developed system can be thoroughly examined. The findings derived from this evaluation provide valuable insights for further improvements and advancements in the field of voice emotion recognition, ultimately leading to more accurate and reliable systems for detecting and interpreting emotions from voice data.

Fig. 6: Performance Evaluation for CNN Model

Figure 6 displays the performance evaluation results obtained for my CNN model. The evaluation provides valuable insights into the model's performance and its ability to accurately classify emotions from voice data.

The training accuracy of the CNN model is approximately 0.6, indicating that it can correctly predict emotions with a reasonable level of accuracy during the training phase. However, it is important to note that the validation accuracy is 0.54, which suggests that the model's performance may be slightly lower when applied to unseen data during the validation phase.

Analyzing the loss function during different epochs provides further information about the model's learning progress. At the beginning of training, when epoch is 0, the loss function for training is 3.00. This value indicates the magnitude of errors or discrepancies between the predicted and actual emotions during the initial phase of training. As the model undergoes further training, there is a significant improvement in the loss function, with a value of 1.25 when epoch reaches 100. This decrease in the loss function suggests that the model is learning and adjusting its parameters to better fit the training data, resulting in reduced prediction errors.

Similarly, for the validation phase, the loss function is observed to decrease from approximately 2.75 at epoch 0 to 1.50 at epoch 100. This reduction in the loss function during validation demonstrates that the model's performance improves over time, making more accurate predictions on unseen data.

Overall, the performance evaluation of the CNN model presented in Figure 6 highlights its learning capabilities and potential for accurately classifying emotions from voice data. However, the validation accuracy and loss function values indicate that further refinement and optimization may be necessary to enhance the model's generalization and prediction accuracy on unseen data. These findings provide valuable insights for future iterations and improvements in the CNN model for voice emotion recognition.

Table 1 provides a comprehensive comparison of various models, namely CNN (Convolutional Neural Network), LSTM (Long Short-Term Memory), and DNN (Deep Neural Network). The purpose of this comparison is to evaluate and contrast the performance of these models in the context of emotion recognition.

Table 1: Comparison Among Different Models

| Model Name | Precision | Recall | F1-Score | Accuracy |
|------------|-----------|--------|----------|----------|
| CNN        | 0.5444    | 0.5444 | 0.5444   | 0.5444   |
| LSTM       | 0.4944    | 0.4944 | 0.4944   | 0.4944   |
| DNN        | 0.5583    | 0.5583 | 0.5583   | 0.5583   |

To assess the effectiveness of each model, several parameters have been employed, including precision, recall, F1 score, and accuracy. These metrics play a crucial role in measuring different aspects of model performance and determining their overall effectiveness in accurately predicting emotions.

Precision refers to the ability of a model to correctly identify positive predictions among all the instances it labels as positive. It provides insights into the model's capability to avoid false positives. Recall, on the other hand, assesses the model's ability to correctly identify all positive instances out of all the actual positive instances in the dataset. It measures the model's sensitivity to detecting positive cases. The F1 score combines both precision and recall, providing a balanced measure of a model's performance by considering both false positives and false negatives.

In addition to precision, recall, and F1 score, accuracy is also used as a performance metric. Accuracy indicates the overall correctness of the model's predictions, measuring the proportion of correct predictions out of the total predictions made.

By comparing these metrics across the different models, Table 1 allows for a comprehensive assessment of their performance in emotion recognition. This comparison enables researchers and practitioners to identify the strengths and weaknesses of each model, as well as to determine which model demonstrates the highest level of precision, recall, F1 score, and accuracy in predicting emotions accurately.

Ultimately, this comparison serves as a valuable reference for selecting the most appropriate model for emotion recognition tasks, based on the specific requirements and priorities of the application or research endeavor at hand.

Table 1 presents a comprehensive comparison of performance metrics among different models, namely CNN, LSTM, and DNN, in the context of emotion recognition. The evaluation metrics used for comparison include precision, recall, F1-score, and accuracy.

Specifically, the CNN model achieved a precision, recall, F1-score, and accuracy of 0.5444, indicating a balanced performance in terms of correctly classifying positive instances and overall accuracy.

For the LSTM model, the precision, recall, F1-score, and accuracy values are reported as 0.4944, demonstrating its ability to accurately identify positive predictions. The recall, F1-score, and accuracy metrics provide further insights into the model's performance in terms of correctly identifying positive instances, the balance between precision and recall, and the overall correctness of predictions.

As for the DNN model, it achieved a precision, recall, F1-score, and accuracy of 0.5583, indicating a relatively higher level of accuracy in correctly labeling positive predictions compared to the other models.

Comparing these metrics across the different models allows for a comprehensive evaluation of their performance in the emotion recognition task. These quantitative measures offer valuable information for researchers and practitioners to assess the strengths and weaknesses of each model and make informed decisions regarding their applicability in specific scenarios or research endeavors.

## **5.2 Result Summary**

Among the three compared models, the DNN model emerges as the top performer in terms of overall performance. It exhibits the highest precision, recall, F1-score, and accuracy values, indicating its superior ability to accurately classify and predict emotions.

On the other hand, the CNN model's performance falls in between the other two models. While it demonstrates reasonable precision, recall, F1-score, and accuracy, it does not outperform the DNN model in terms of overall effectiveness.

Interestingly, the precision, recall, F1-score, and accuracy metrics for all the models show a similar pattern. This observation suggests that the number of false positives (incorrectly

predicted positive instances) is roughly equal to the number of false negatives (incorrectly predicted negative instances). This balance between false positives and false negatives can influence the precision, recall, F1-score, and accuracy metrics, resulting in comparable values across the models.

The comparable patterns in performance metrics across the models indicate the presence of certain similarities and consistencies in their prediction capabilities. Further analysis and investigation would be necessary to understand the specific factors contributing to these similar performance patterns and to identify any distinguishing characteristics among the models.

Overall, the DNN model stands out as the most effective and accurate among the compared models, while the CNN model exhibits a moderate level of performance. The similarity in performance metrics suggests a balanced trade-off between false positives and false negatives within the models' predictions.

## 6 Conclusion

In conclusion, this study has provided evidence to support the superiority of the DNN model over other models, such as CNN and LSTM, in the specific context of speech emotion recognition. The findings highlight the potential of the DNN model in various applications, particularly in the field of mental health, where the ability to accurately detect and understand emotions through voice can contribute significantly to assessing individuals' emotional well-being. Mobile applications, for instance, can leverage the capabilities of the DNN model to offer valuable insights and support in mental health-related interventions.

While the CNN model did not perform as well as the DNN model in this study, it is important to recognize that there are still opportunities for improvement and refinement. Future iterations of the CNN model could explore modifications and enhancements to potentially enhance its performance and make it more competitive with the DNN model.

Moving forward, further research and development are required to explore additional techniques and methodologies aimed at enhancing the accuracy and overall performance metrics of speech emotion recognition models. This includes investigating advanced algorithms, exploring different architectural designs, and incorporating novel feature extraction techniques to extract more informative representations from the audio data.

By continuously advancing the accuracy and performance of speech emotion recognition models, we can unlock a range of applications and opportunities to improve mental health interventions, communication systems, and various other domains where understanding and interpreting human emotions from speech are crucial.

The significance of speech emotion recognition in digital healthcare applications, as demonstrated in this thesis, cannot be overstated. The ability to accurately detect and interpret emotions from speech holds immense potential for transforming healthcare practices and enhancing patient care. By incorporating speech emotion recognition technology into digital healthcare applications, we can unlock several important benefits.

Firstly, speech emotion recognition can contribute to improved mental health assessment and intervention. Mental health conditions often involve emotional disturbances, and traditional diagnostic methods rely heavily on subjective evaluations. By leveraging speech emotion recognition, healthcare professionals can have an objective and quantitative measure of a

patient's emotional state, allowing for more accurate assessments and personalized treatment plans. This technology can aid in the early detection of mental health issues, facilitate remote monitoring, and provide timely interventions.

Furthermore, speech emotion recognition can enhance patient-doctor communication and patient-centered care. By analyzing patients' emotional cues during conversations, healthcare providers can gain valuable insights into their emotional well-being, satisfaction levels, and overall engagement. This knowledge can help doctors tailor their communication styles, adjust treatment strategies, and establish a more empathetic and supportive therapeutic relationship. Digital healthcare applications equipped with speech emotion recognition can serve as virtual companions, offering emotional support and guidance to patients in real-time.

Speech emotion recognition can also play a vital role in monitoring and managing chronic conditions. Patients with chronic illnesses often experience emotional fluctuations that impact their overall well-being and treatment adherence. By integrating speech emotion recognition into digital healthcare platforms, healthcare providers can track emotional patterns over time, detect distress signals, and intervene when necessary. This technology can facilitate personalized interventions, provide timely support, and ultimately improve the quality of life for individuals living with chronic conditions.

Additionally, speech emotion recognition in digital healthcare applications can contribute to the advancement of telemedicine and remote healthcare services. With the increasing demand for remote consultations and virtual healthcare, the ability to accurately capture and analyze emotional cues from speech can enhance the effectiveness of remote patient-doctor interactions. Healthcare providers can gain valuable insights into patients' emotional states, even in the absence of in-person visual cues, enabling more comprehensive and empathetic care delivery regardless of physical distance.

Overall, this thesis underscores the importance of speech emotion recognition in digital healthcare applications. By harnessing this technology, healthcare professionals can achieve more accurate assessments, enhance patient-doctor communication, improve mental health interventions, monitor chronic conditions effectively, and advance remote healthcare services. As further research and development progress in this field, the potential for speech emotion recognition to revolutionize the digital healthcare landscape is vast, promising more patient-centric, accessible, and efficient care delivery.
