#### **Abstract**

We explore generating factual and accurate tables from the parametric knowledge of large language models (LLMs). While LLMs have demonstrated impressive capabilities in recreating knowledge bases and generating free-form text, we focus on generating structured tabular data, which is crucial in domains like finance and healthcare. We examine the table generation abilities of four state-of-the-art LLMs: GPT-3.5, GPT-4, Llama2-13B, and Llama2-70B, using three prompting methods for table generation: (a) full-table, (b) row-by-row; (c) cell-by-cell. For evaluation, we introduce a novel benchmark, WIKITABGEN which contains 100 curated Wikipedia tables. Tables are further processed to ensure their factual correctness and manually annotated with short natural language descriptions. Our findings reveal that table generation remains a challenge, with GPT-4 reaching the highest accuracy at 19.6%. Our detailed analysis sheds light on how various table properties, such as size, table popularity, and numerical content, influence generation performance. This work highlights the unique challenges in LLM-based table generation and provides a solid evaluation framework for future research. Our code, prompts and data are all publicly available.<sup>1</sup>

# 1 Introduction

Large language models (LLMs) (Brown et al., 2020; Chowdhery et al., 2022; Kadavath et al., 2022; Touvron et al., 2023a) are pre-trained on vast amounts of text which include scientific articles, encyclopedic knowledge, and importantly, tabular data (Elazar et al., 2023; Fang et al., 2024). Therefore, during pre-training, LLMs encode a significant amount of factual information in their parameters. Past work has shown that, based on their parametric knowledge, LLMs have the potential to elicit fairly accurate facts for tasks such as

Figure 1: An example LLM-based table generation task, using three alternative prompting methods.

recreating knowledge bases (KBs) (Petroni et al., 2019; AlKhamissi et al., 2022; Cohen et al., 2023) and generating Wikipedia-like articles (Shao et al., 2024). Given the promising results on free-form text and knowledge bases, our work explores the task of *generating tabular data* from the parametric knowledge of LLMs. Tabular data, being a structured representation, is widespread in real-world sources and, unlike free-form text, is typically used to represent large amounts of complex information. Tabular data is essential in sectors such as finance and healthcare (Chen et al., 2021; Johnson et al., 2016), where data is further analyzed using statistical methods, and visualization tools (Berant et al., 2018; Shen et al., 2021).

A key research question, is to what extent can the parametric knowledge of LLMs be used to generate factual and accurate tables. To this end, our work focuses on evaluating the capability of LLMs to generate tabular data, given an input description of the table's content and a list of its columns. Past research has focused on tabular reasoning over ex-

https://github.com/analysis-bots/WikiTabGen

isting input tables (Pasupat and Liang, 2015; Chen et al., 2020a, 2021), or on eliciting factual knowledge from LLMs in the context of KBs or freeform text (Petroni et al., 2019; Mallen et al., 2022). In contrast to these works, generating tables from LLMs' parametric knowledge presents unique challenges, as it requires understanding the table structure and perform long-form reasoning (Shaham et al., 2022) on potentially hundreds of entries.

To address the problem of long-form table generation we implement three distinct prompting methods: (a) generating the full table all at once, (b) row-by-row generation, and (c) cell-by-cell generation. The latter two methods use a modular prompting approach (Khot et al., 2023), where one instance of the LLM is prompted to generate table keys, i.e. unique identifiers of the table's entries, while another is prompted to generate either a full table row (row-by-row) or single table cell (cell-by-cell). Fig. 1 presents an example flow of LLM-based table generation in our setting. The target table is described as "the achievements of (long jumper) Susen Tidtke from 1987 to 2000" and has four table columns: year, competition, venue and position. The first two columns (underlined) are the key columns of the table. We then use either the full-table, row-by-row, or cell-by-cell method in order to generate the target table.

To evaluate the table generation capabilities of LLMs, we introduce the WIKITABGENbenchmark. Each instance consists of a table description, a list of columns and the ground-truth table. We build a robust evaluation set by processing 100 Wikipedia tables, avoiding tables that are incomplete or contain subjective information. While WIKITABGEN has 100 tables overall, we note that the average number of tokens per table is 1,457 tokens, significantly larger than in past tabular generation tasks (Parikh et al., 2020; Nan et al., 2022). WIKITAB-GEN contains diverse tables with respect to several properties, namely: their size (number of rows, columns and cells); the portion of numerical content (numbers and dates); and the table popularity, indicating its prevalence in the LLM pre-training data (Mallen et al., 2022). Our experiments and subsequent analysis describe how each of these properties affects table generation performance.

For our table generation experiments we evaluated four popular LLMs: GPT-3.5, GPT-4, Llama2-13B, and Llama2-70B (Touvron et al., 2023b; Achiam et al., 2023). Our results reveal that

generating tables from the parametric knowledge of LLMs remains an open problem, as our top-performing model GPT-4, with row-by-row prompting, achieves an F1 score of 19.6% (§5).

Our main contributions are as follows: (1) We formulate the problem of generating tables from the parametric knowledge of LLMs; (2) We implement and evaluate three prompt-based table generation methods; (3) We introduce WIKITABGEN, a new table generation benchmark; and (4) We conduct an extensive analysis of the table generation performance of state-of-the-art LLMs. Our paper highlights key challenges in table generation, with factors such as table size, numerical values, and popularity all playing a significant role in LLM performance. We hope that our methods, analysis, and evaluation benchmark will encourage future research on tabular data generation with LLMs.

# 2 Problem Definition

Given a short user description, our goal is to generate a corresponding table with factually accurate knowledge. A relational table (Codd, 1990) T=(R,C) comprises a set of rows  $R=\{r_1,r_2,\ldots\}$  and a set of columns  $C=\{c_1,c_2\ldots\}$ . A table cell, denoted r[c], contains the value of column c in row r. Key columns are a subset  $C_k\subset C$  that uniquely define each entry (row) in T and the corresponding cells do not contain null or empty values. For example, the table in Fig. 4 has the columns year and competition as its keys. Each table entry such as venue, corresponds to a unique year, competition pair.

Provided with a table description d and a list of desired table columns C, our task is to generate a corresponding table  $T(\hat{R},C)$ , where the generated rows  $\hat{R}$  contain factually accurate information.

An example problem is shown in Fig. 1. The table description is "Achievements of Susen Tiedke from 1987 to 2000", while the target columns are: year, competition, venue, and position. The first two are key columns, underlined in Fig. 1. Using one of our suggested prompting methods (§3), the LLM then generates in response a final results table  $T(\hat{R},C)$ , as shown in the bottom of the figure.

# 3 Prompting LLMs to Generate Tables

Given a table description and list of target columns C, we examine LLMs performance in generating the corresponding table  $T(\hat{R},C)$ . We focus exclusively on the knowledge stored in the LLM, with

Figure 2: An overview of our three separate prompting methods for table generation, given a short user description and table metadata (Fig. 1): (2.A) Full table directly generates the table given the user desc. and its columns; (2.B) Key-generation is used in both the row-by-row and cell-by-cell methods; (3.A) Row-by-row generates a table row given a unique key value, e.g. (1987, EU Junior Championship); (3.B) Cell-by-cell generates a single table cell given a key value and specific target column e.g.  $venue \rightarrow Birmingham$ .

retrieval-augmented methods (Lewis et al., 2020; Yoran et al., 2023) being orthogonal to our study.

We implement three prompting methods to generate tables, presented in Fig. 1. Our first approach (a) prompts the LLM to generate the full table all at once. However, as the target table may be quite large (e.g. evaluation tables in §4 have 1.5K tokens on average), we also experiment with a modular prompting approach (Khot et al., 2022). Therefore we introduce two additional prompting methods that generate tables in a gradual, (b) row-by-row or (c) cell-by-cell manner. An in-depth example of our prompting methods is provided in Fig. 2. Note that all prompts in the figure are appended with the table description and columns (prompt 1 in Fig. 2). Next, we detail the prompts used for each of our methods. All of our prompts can be found in §A and in our public repository.

- (a) Full-table. Given the table description and target columns The LLM is prompted to generate all table rows. Example prompts are prompts 1 and 2.A in Fig. 2 which are both concatenated and provided as input to the LLM.
- (b) Row-by-row. We implement a two-stage prompting method, prompting to separate instances of the LLM. First, we prompt the LLM for key generation to generate the values of all the key columns  $C_k$ . As key values are a unique identifier

for each table entry (§2), we prompt a second instance of the LLM, to generate the full table row, for a given key value. Thus, for each key cell  $\hat{r}_i[C_k]$  that was output by the first LLM, we generate a subsequent prompt to retrieve the remaining row entries  $\hat{r}_i[C\setminus C_k]$ . In total, we generate  $|\hat{R}|+1$  prompts, where  $|\hat{R}|$  is the number of key values output by the *key generation* prompted LLM.

In Fig. 2, box 2.B describes the key generation prompt. Given the table description, and key columns *competition* and *year*, the LLM generates a list of corresponding years and competitions which Susen Tiedtke participated in. Next, each key value returned by the first LLM, is used to generate the remaining row entries. Prompt 3.A prompts the *row generation* LLM to populate columns venue, position which correspond to key ("European Junior", "1987"). The generated values being "Birmingham", and "3rd". A new row-by-row prompt is then generated for the following keys, e.g. ("World Championship", "1991").

(c) Cell-by-cell. This is a two-stage approach that generates each table cell individually. The first stage is identical to row-by-row, using prompt 2.B to generate all key column values. Then, we use a separate prompt for each table cell, rather than a full row. For each column  $c \in C \setminus C_k$  we create a dedicated prompt to generate the cell  $\hat{r}_i[c]$ , based on the target column and the generated key for  $r_i$ .

(a) Number of cells per table

(b) Numeric columns ratio

(c) Table popularity

Figure 3: WIKITABGEN properties distribution: Number of Cells, Ratio of Numeric Columns, and Table Popularity.

In total, we use  $|\hat{R}| \cdot |C \setminus C_k| + 1$  prompts, one to generate the keys, and  $|\hat{R}| \cdot |C \setminus C_k|$  to generate each of the non-key cells.

Prompt 3.B in Fig. 2 describes the cell-by-cell method. Given key ("European Junior", "1987"), the corresponding cell in column venue is generated (Birmingham). The same prompt is then used for different keys and columns (position).

Generated Output Format. When prompting LLMs we instruct it to return the output in JSON format, also shown in Fig. 2. We chose JSON following past work (Singha et al., 2023) and based on our own results. Namely, observed better performance compared to formats such as CSV and SQL, when evaluated on our held-out development set (see §4). For the row-by-row and cell-by-cell methods, we process and merge all individual JSON responses to construct the full output table.

# 4 WIKITABGEN Benchmark

To evaluate our methods (§3), we introduce a new table generation benchmark called WIKITABGEN. An instance of WIKITABGEN consists of a short manually written description d, a list of target columns C and a corresponding table T=(R,C). As this benchmark targets LLM table generation, based on their parametric knowledge, we considered several key priniciples in its construction:

- *Information Coverage*: evaluation tables must contain complete information to avoid instances where the LLM generates accurate entries that are missing from the ground-truth tables.
- Factual Consistency: tables should include static factual data, to ensure consistent evaluation over time as LLMs evolve (Zhang and Choi, 2021).
- *Conciseness*: table cells should contain concise string, categorical or numeric information, to avoid long descriptive text which is more difficult to evaluate compared to the ground truth.
- Diversity: the benchmark should include a di-

30	•	er long jumpe	, ,	
	Year	Competition	Venue	Position

Figure 4: WIKITABGEN example table and meta-data.

verse set of tables in terms of structural properties such as size, data types (e.g., numeric data ratio), and the table "popularity" which may indicate the prevalence of its information during the LLM's pre-training (Mallen et al., 2022).

Following these principle, opted to use table from Wikipedia, as our evaluation benchmark. Wikipedia information is normally used to evaluate the closed-book performance of LLMs, as it contains factual and objective information (Kwiatkowski et al., 2019). This contrasts certain tabular datasets which may contain domain-specific data (Yu et al., 2018). Furthermore, as Wikipedia data forms part of LLMs pre-training data (Brown et al., 2020; Touvron et al., 2023a), we view it as ideal to gauge the extent to which such models memorize tabular data.

To build our benchmark, we iterate over the Wikipedia tables provided by Bhagavatula et al. (2015). First, we discard all tables that are "non-relational", i.e. contain a composite header, nested tables or inverted tables. We additionally remove tables that are too small, where |R| < 10 or |C| < 2. Next, we manually selected 119 random tables with diverse number of columns, rows and portion of numeric values (numbers and dates). To ensure evaluation coverage we removed columns with partial entries. In addition, columns containing long texts were omitted to ensure a concise

<sup>&</sup>lt;sup>2</sup>Creative Commons Attribution 4.0 International License.

evaluation. Lastly, we manually annotated each table with a short description in natural language to describe its contents. We chose to manually write table descriptions as the original table captions were often ambiguous or did not accurately describe the table. Furthermore, as Wikipedia tables may expand over time (e.g. new NBA championship teams), we made sure to specify the concrete time-frame in such examples, following Zhang and Choi (2021), e.g. "George Clooney Films released between 1983 and 2013"

As shown in Fig. 4, each table in WIKITABGEN is provided with additional metadata, consisting of its: text description; table size (number of columns, rows and cells); key-columns; numeric columns (containing numbers or dates); and table popularity. Inspired by Mallen et al. (2022), we define *table popularity* as the average number of monthly views to the Wikipedia page containing the said table. To measure pages views we use the Wikipedia API.<sup>3</sup>

Overall, WIKITABGEN has 119 examples, where 100 tables are used for evaluation (§5) and the remaining 19 are a held-out development set which we used when implementing our methods. In Fig. 3 we plot the distribution of three of the aforementioned properties in WIKITABGEN: size, numeric column ratio and popularity. In terms of size, our evaluation tables have 77.5 rows, 6.9 columns and 453 cells on average, with an average length of 1,497 tokens. The average percentage of numeric columns per table is 62% of columns, showcasing the prevalence of numerical data in our tables. In terms of table popularity, the average number of monthly views per table is 8,449. In §6 we further explore each of these properties and evaluate their effect on table generation performance.

## 5 Experimental Setting

We describe our experimental setting for evaluating the table generation capabilities of LLMs. All models were evaluated on the WIKITABGEN benchmark. Next, we list the LLMs, prompts and evaluation methods used for table generation. Last, we detail our different experimental scenarios.

## 5.1 Language Models and Prompts

In our experiments we evaluate four popular LLMs. The first two are the state-of-theart mdels from OpenAI (Achiam et al., 2023): GPT-3.5 (gpt-3.5-turbo-instruct-0914) and GPT-4 (gpt-4-1106-preview). In addition, we evaluate two open-source LLMs from MetaAI: (Touvron et al., 2023b): Llama2-13B (Llama-2-13b-chat-hf) and Llama2-70B (Llama-2-70b-chat-hf). The same prompts described in §3 were used across all four LLMs, with the generation temperature set to zero. When developing our prompting methods, we used the held-out set of 19 tables, described in §4. This set was reserved for prompt engineering (experimenting with different output formats JSON, CSV, etc.) and is not included in the evaluation set of WIKITABGEN.

#### 5.2 Evaluation Method

We evaluate the accuracy of LLM generated tables against the ground-truth tables. Unlike list QA (Amouyal et al., 2022), when evaluating table generation we compare two list of *table rows*, where each row has multiple cells. We use a two-step evaluation which first aligns rows based on their key values, then matches each cell in the row.

Given output table  $\hat{T}(\hat{R},C)$  and ground-truth table T(R,C), we first align the rows  $\hat{R}$  to their corresponding rows in R by matching their respective keys, namely  $\hat{r} \leadsto r \iff \hat{r}[C_k] = r[C_k]$ . For rows with multiple key columns, all values must be identical. We check for an *exact match* of the cell content and allow a  $\pm 0.1\%$  error for numeric values (in §B, we describe how we compare date values and handle null, missing and duplicate cells). A *correct* cell in  $T(\hat{R},C)$  is a cell  $\hat{r}[c]$  such that  $\hat{r} \leadsto r \land \hat{r}[c] = r[c]$  i.e. row  $\hat{r}$  is aligned with r in the ground-truth table, and their corresponding values in column c are identical. We then calculate Table Precision as  $\frac{\# Correct \ Cells}{\# \ Ground-Truth \ Cells}$  and  $\frac{\# Correct \ Cells}{\# \ Ground-Truth \ Cells}$  and corresponding F1 score.

For our analysis in §6, we also consider the precision, recall, and F1 scores separately for *keys* and *non-keys*. The *keys* scores are calculated based on the number of matching keys, where for each row all the cells of  $C_k$  must match. For non-key cell scores we consider only cells in  $C \setminus C_k$ . We provide the formulas in Appendix B.

#### **5.3** Table Generation Scenarios

In addition to the table generation scenario described in §2, where the generation request contains only the table description and list of columns, we considered two alternative scenarios where additional information is provided to the LLM:

**Table Row Example.** In this scenario, in addition to the description and list of columns, we also

<sup>3</sup>https://api.wikimedia.org

LLM M	Method	Method		Keys		Non-Keys		Overall		
		Recall	Precision	F1	Recall	Precision	F1	Recall	Precision	F1
CDT 2.5	Full tab.	44.6%	59.4%	46.4%	9.0%	13.3%	9.6%	15.4%	21.2%	16.1%

Table 1: Table generation performance metrics for the different models and prompting methods.

provide the LLM with an example row r[C] from the target table. We examine if such an example improves the LLM's performance in generating the rest of the table. We tested this scenario on all prompting methods (§3) by concatenating the first row of the target table to the table description.

Oracle Keys. This ablation provides the LLM the ground-truth set of keys cells  $R[C_k]$  and measures the model's performance in generating the remaining cells. This scenario is particularly relevant for applications where the keys are known in advance, and the task involves filling in the associated data. We conducted this experiment for both the row-by-row and cell-by-cell prompting methods by skipping the keys generation prompt (prompt 2.B in Fig. 2), and providing the ground-truth keys instead.

## 6 Results and Analysis

We begin by describing our main results for table generation, for each of our LLMs and prompting methods. Then, we present the results for our additional scenarios, when including the first table row or the ground-truth of key values. Next, we analyze the generation cost and accuracy trade-offs of each prompting methods. Lastly, we examine the effect of table properties (size, numeric data, and table popularity) on the LLM generation performance.

## **6.1 Table Generation Performance**

Tab. 1 presents the table generation results of our three prompting methods, when evaluated for each LLM on WIKITABGEN. We list the precision, recall, and F1 scores for keys, non-keys, and the full tables (averaged across all tables). GPT-4 is the top-performing model, consistently surpassing the

other LLMs, and reaches the highest overall F1 score, when using the row-by-row prompt (19.6%).

For all LLMs, we observe that the row-by-row and cell-by-cell methods significantly improve the *keys* generation performance (see keys F1 scores in Tab. 1). This demonstrates the effectiveness of separating the table generation into keys and non-key cells. Besides GPT-3.5, for GPT-4, Llama2-13B, and Llama2-70B, the top performance was using the row-by-row method. We note that the keys generation performance is significantly higher that for non-key cells (53.7% compared to 12.5%-19.5% for GPT-4).

#### 6.2 Additional Generation Scenarios

We measure the effect of providing additional information during table generation: (1) an example row, (2) the ground-truth table keys.

**Table Row Example.** Tab. 2 lists the performance results when including an example row from the target table (as we omit the example row from the F1 calculations our results slightly differ from Tab. 1). We chose to omit cell-by-cell evaluation, as row-by-row consistently outperformed the approach and due to the high cost of cell-by-cell (§6.3). The overall F1 score is consistently higher when an example row is added. As shown in the table, this improvement generally stems from better performance in the *non-keys* generation rather than in generating the table keys.

**Oracle Keys.** Tab. 3 describes the performance of all LLMs, using the row-by-row method, when given the ground-truth key values. As expected, the overall F1 scores are significantly higher when using oracle keys, because now  $\hat{R}[C_k] = R[C_k]$ . We observe an additional improvement in the non-

LLM I	Method	Keys F1 (%)		Non-Keys	F1 (%)	Overall F1 (%)	
		No-Example	Example	No-Example	Example	No-Example	Example
GPT-3.5	Full tab. Row-by-row	46.0 <b>49.6</b>	<b>49.0</b> 49.1	9.4 7.0	10.9 7.6	15.9 14.2	17.9 14.6

Llama2-70B	Full tab. Row-by-row	28.4 <b>39.8</b>	<b>31.3</b> 39.7	3.2 3.1	5.0 3.8	7.8 8.9	9.7 9.5

Table 2: Performance comparison with and without an example row, using full table and row-by-row methods.

LLM	Non-l	Keys F1 (%)	Overall F1 (%)		
	Base.	Orac.	Base.	Orac.	
GPT-3.5	7.2	17.6 (+10.4)	14.3	35.0 (+20.7)	
GPT-4	12.2	23.9 (+11.7)	19.6	40.0 (+20.4)	
Llama2-13B	2.6	10.3 (+7.7)	7.5	29.5 (+22.0)	
Llama2-70B	3.4	$12.8 \ (+9.4)$	9.3	31.4(+22.1)	

Table 3: Performance comparison of the row-by-row method with and without oracle keys.

keys F1, which is expected as more table rows were aligned to the target table (given the keys), and thus more cells were successfully matched.

## 6.3 Prompting Cost Analysis

We analyze the performance of our prompting methods as a function of their overall cost.

Our motivation for both the row-by-row and cell-by-cell methods was to generate larger tables, by breaking down table generation into two stages. Therefore, in Fig. 5 compare the performance of out three prompting methods as a function of table size. We measure the F1 scores on tables between 20 to 1,000+ cells. For smaller tables, with up to 500 cells, all prompting methods perform roughly the same. However, as the number of cells increases, both the row-by-row and cell-by-cell methods outperform the full table generation.

However, while outperforming full-table, as table size increase, both row-by-row and cell-by-cell require significantly more tokens in their prompts, shown in Fig. 6. Therefore, these methods incur much higher costs, in particular when employing commercial LLMs.<sup>4</sup> The output number of tokens is roughly similar for all approaches however, the two-stage approach have a significantly larger input due to the repeated use of distinct row and cell

Figure 5: Prompting performance w.r.t. table size.

Figure 6: Cost analysis of prompting methods.

generation prompts (prompts 3.A, 3.B in Fig. 2).

#### **6.4** Table Properties Effect on Performance

As noted in §4, we systematically measure the effect of table properties such as the size, numeric data and table popularity affect the LLM generation performance.

Fig. 7 displays the table F1 scores as a function of the number of table cells, percentage of numerical data columns (number or date cells) and the table popularity score. These results are provided for all four of experiments LLMs, using the full-table generation method. As our aim is to measure the effect each property has on the LLM (not to compare different methods), we consider this to be an apt choice of setting. A further breakdown of

<sup>&</sup>lt;sup>4</sup>Costs are calculated based on GPT-4 prompt sizes, with similar results also obtained for the other LLMs.

Figure 7: The effect of table size, the ratio of numeric columns, and table popularity on the generation performance of the full-table method, with four different LLMs.

the properties' effect on the keys and non-keys F1 scores is provided in §C.

As shown in Fig. 7a, the larger the table, the lower the F1 scores are for all LLMs. In §6.3 we observed this trend to be less apparent for the rowby-row and cell-by-cell methods.

Fig. 7b measures the effect of that the percentage of columns containing numbers or dates has on performance. We observe a decrease in F1 as the portion of numerical content is higher. We attribute the slight increase in fully numeric to the fact that such tables in WIKITABGEN contain demographic information where the key column is *year*, which is easier for the LLMs to generate.

Fig. 7c displays the positive effect of table popularity on performance. This potentially stems from the prevalence of more popular Wikipedia pages (or related entities) in the LLMs' training data. Unsurprising, the less common the tabular information is, the more difficult it is for the LLM to generate.

From this analysis, we conclude that generating tables from LLMs' parametric knowledge is more challenging when the tables are larger, have a high portion of numerical data, or concern less topics.

#### 7 Related Work

Machine reasoning on table using pre-trained LLMs has largely been explored in the context of data augmentation (Borisov et al., 2022; Zhang et al., 2023) to improve the performance on downstream tasks. The focus has largely been on tasks where a table is provided as input to the model namely: QA over tables (Chen et al., 2020b, 2022; Seedat et al., 2023), text-to-SQL translation (Deng et al., 2021; Wolfson et al., 2022), table editing (Li et al., 2023; Sui et al., 2023) and table-to-text generation (Parikh et al., 2020). Conversely, our approach receives only a user query and schema as

input, and is tasked with generating an entire table.

Closest to ours are the recent table generation datasets by Pal et al. (2023); Akhtar et al. (2024). In both works the LLM is provided with a user query (in text or SQL) and is tasked with generating a table, as the query answer. Pal et al. (2023) evaluate on tables from the Spider dataset (Yu et al., 2018), which contains domain-specific information that is less likely to be stored in the parametric knowledge of LLMs. Similar to us, Akhtar et al. (2024) rely on Wikipedia however, they automatically construct new tables which are relatively small (average of 6.7 rows, 4 columns). By comparison our evaluation is on larger tables with the median number of rows being 48 (average of 77.5 rows, 6.9 columns). This emphasizes our focus on extracting long-form tabular data from LLMs, thereby extending past attempts on KBs and text (Cohen et al., 2023; Mallen et al., 2022; Carlini et al., 2022).

Our key generation phase in §3 is an instance of a list question answering problem. The challenge of list QA in LLMs has been explored in recent works (Amouyal et al., 2022; Malaviya et al., 2023). However, we further expand this challenge by focusing on generating the entire table.

#### 8 Conclusion

This paper explores the capability of state-of-theart LLMs to generate entire tables, by relying exclusively on their parametric knowledge. We introduced three prompt-based table generation methods and evaluated them on our newly constructed benchmark, WIKITABGENOur results and analysis of four state-of-the-art models underscore the overall challenge which table generation poses to LLMs. We hope that WIKITABGEN and our comprehensive analysis will provide a concrete framework for future research on table generation using LLMs.

#### 9 Limitations

We now list the limitations to our work.

Our first limitation is the size of the WIKITAB-GEN evaluation benchmark, which contains 100 tables. We atribute this size mainly to the high generation costs of running state-of-the-art LLMs on large tables §6.3. As noted in §4, the tables in WIK-ITABGEN contain close to 1,500 tokens on average, evaluating them using commercial, state-of-the-art LLMs is non-trivial.

Second, all tables in WIKITABGEN are tied to a single source, i.e. Wikipedia articles. This choice was made to ensure that the underlying information exists in common LLMs training data. However, we did not examine the performance on tables generated from other sources, such as news articles or tables that require multi-source integration.

Third, our evaluation metric for generation performance is based on a strict, almost exact comparison of cell values (see §5.2 and §B). This approach can sometimes result in LLMs being penalized for minor formatting errors. However, we chose this rigorous method over more relaxed alternatives (such as those based on semantic similarity or fuzzy matching) because the WIKITABGEN table cells contain concise categorical or numeric information, often consisting of fewer than four tokens. Consequently, even minor inaccuracies can significantly impact the performance assessment.

# **A Table Generation Prompts**

In this section we provide the prompt templates used in each of our table generation methods. Figs. 8-11 present our prompt templates used for: full table generation method, keys generation, rowby-row, and cell-by-cell method.

#### **B** Evaluation Method Details

## **B.1** Cell Value Matching

We next describe our evaluation method in more detail, given an output table  $\hat{T}(\hat{R}, C)$  and ground-truth table T(R, C).

As described in §5.2, we use *exact* value comparison of cell textual content and allow a  $\pm 0.1\%$  error for numeric values. Before comparing textual cells, we first convert them to lower case, and remove non alphanumeric symbols and spaces.

As for date values, we first parse and convert cells with date values to a Python Date object, and then compare the canonical dates. This is to avoid cases where cells are deemed as a non-match due to differences in the date format. For example, in our evaluation process, two date values representing the same date, such as "2014-05-16" and "16th, May, 2014", will be considered the same.

We further treat "none", "n/a", "nan" and empty cells as identical in terms of value matching.

# **B.2** Precision and Recall Computation for Tables

For a given output table  $\hat{T}(\hat{R},C)$  and ground-truth table T(R,C), we first align the rows  $\hat{R}$  to their corresponding rows in R by matching their respective keys, namely  $\hat{r} \leadsto r \iff \hat{r}[C_k] = r[C_k]$ . For rows with composite keys, all key values must be identical, i.e.,  $\forall c_k \in C_k \hat{r}[c_k] = r[c_k]$ .

Recall that a *correct* cell in  $T(\hat{R}, C)$  is a cell  $\hat{r}[c]$  such that  $\hat{r}[c] = r[c] \land \hat{r} \leadsto r$ . Namely, row  $\hat{r}$  is aligned with a row r in the ground-truth table, and their corresponding cell values in column c are identical.

We next provide the precision and recall formulas we used for keys, non-keys, and tables.

For keys, we compare  $\hat{R}[C_k]$  and  $R[C_k]$  as follows. Let the number of matching keys  $\phi = |\{r \in \hat{R}, \forall c_k \in C_k \; \hat{r}[c_k] = r[c_k]\}|$  Then keys precision is calculated by  $\frac{\phi}{|\hat{R}|}$  and keys recall is given by  $\frac{\phi}{|R|}$ .

For non-keys, we compare  $\hat{R}[C \setminus C_k]$  and  $R[C \setminus C_k]$ . After aligning  $\hat{R}$  and R, we compute the number of *correct* keys, denoted by  $\psi = |\{(r,c), r \in C_k\}|\}$ 

 $\hat{R} \wedge c \in C \setminus C_k \wedge r \leadsto \hat{r} \wedge \hat{r}[c] = r[c]\}|$ . Then the non-keys precision is calculated by  $\frac{\psi}{|\hat{R}[C \setminus C_k]|}$  and non-keys recall is calculated by  $\frac{\psi}{|R|C \setminus C_k|}$ .

Last, for the table precision and recall, we perform a similar evaluation, now defining the number of correct cells, denoted by  $\tau$ , as all correct cells in the table. Namely,  $\tau = |\{(r,c), r \in \hat{R} \land c \in C \land r \leadsto \hat{r} \land \hat{r}[c] = r[c]\}|$ , then the *table precision* is simply calculated by  $\frac{\tau}{|\hat{R}[C]|}$  and *table recall* is calculated by  $\frac{\tau}{|R[C]|}$ .

# C Table Properties Effect on Performance

In §6.4 we examine how the table properties such as the size, amount of numeric data, and table popularity affect the generation performance. In Fig. 12 we present the effect of these three properties on both the keys F1, non-keys F1, and full table F1. We can see, for instance, that the table size negatively affects both the keys F1 and the non-keys F1 scores (see Fig. 12 (a) and Fig. 12 (b)), and the ratio of numeric columns has a negative effect, as expected, only the non-keys F1 (see Fig. 12 (e)). The table popularity also have a strong effect on both the keys F1 and the non-keys F1 (Fig. 12 (g) and Fig. 12 (h)).

#### Full-table generation template:

You are a retriever of facts. List all {table description}. The response will be formatted as JSON shown below. Each element of the response will contain {num columns} fields: {column1, column2, ...}

Do not output any additional text that is not in JSON format.

RESPONSE FORMAT: [{ column1: value1, column2: value2, ... }]

# Full-table generation (populated example):

You are a retriever of facts. List all achievements of Susen Tiedtke from 1987 to 2000. The response will be formatted as JSON shown below. Each element of the response will contain 4 fields: ['year', 'competition', 'venue', 'position']. Do not output any additional text that is not in JSON format.

RESPONSE FORMAT: [{ "year": \_year, "competition": \_competition, "venue": \_venue, "position": \_position }]

Figure 8: Full-table generation prompt.

#### **Keys generation template:**

You are a retriever of facts. We want to create a table with the detailed information about {table description}. The key columns in the table are {key1, (key2, ...)}. List all {key1, (key2, ...)} entities for the table. The response will be formatted as JSON list shown below.

RESPONSE FORMAT: [{ key: value1, key2: value2, ... }]

#### **Keys generation (populated example):**

You are a retriever of facts. We want to create a table with the detailed information about achievements of Susen Tiedtke from 1987 to 2000. The key columns in the table are competition, year. List all competition, year entities for the table. The response will be formatted as JSON list shown below.

RESPONSE FORMAT: [{ "competition": \_competition, "year": \_year }]

Figure 9: Key columns generation prompt.

#### Row generation template:

You are a retriever of facts. We want to create a table with the detailed information about {table description}. Columns in the table are {columns}. The key columns in the table are {key1, (key2, ...)}. Retrieve a single row whose key is ({key = value}). The response will be formatted as JSON dictionary shown below. Pay special attention to wrap all values in double quotes!

RESPONSE FORMAT: [{ column1: value1, column2: value2, ... }]

#### Row generation (populated example):

You are a retriever of facts. We want to create a table with the detailed information about achievements of Susen Tiedtke from 1987 to 2000. Columns in the table are year, competition, venue, position. The key columns in the table are competition, year. Retrieve a single row whose key is (year = 1987, competition = World Championships). The response will be formatted as JSON dictionary shown below. Pay special attention to wrap all values in double quotes!

RESPONSE FORMAT: { "year": 1987, "competition": World Championships, "venue": \_venue, "position": \_position }

Figure 10: Row-by-row (row generation) prompt.

#### Cell generation template:

You are a retriever of facts. We want to create a table with the detailed information about {table description}. Columns in the table are {column1, column2, ...}. The key columns in the table are {key1, (key2, ...)}. For the table row whose key is is ({key = value}) what is the value of attribute {column}. The response will be formatted as JSON dictionary shown below. Pay special attention to wrap all values in double quotes!

RESPONSE FORMAT: { column: value }

#### Cell generation (populated example):

You are a retriever of facts. We want to create a table with the detailed information about achievements of Susen Tiedtke from 1987 to 2000. Columns in the table are year, competition, venue, position. The key columns in the table are competition, year. For the table row whose key is (year = 1987, competition = World Championships) what is the value of attribute venue. The response will be formatted as JSON dictionary shown below. Pay special attention to wrap all values in double quotes! RESPONSE FORMAT: { "venue": \_venue }

Figure 11: Cell-by-cell (cell generation) prompt.

Figure 12: The effect of table size, the ratio of numeric columns, and table popularity on the generation performance of the full-table method, with four different LLMs. Additional breakdown of generation performance based on cells in key columns versus non-key columns.
