# Determination of the Hamiltonian from the Equations of Motion with Illustration from Examples 

Chung-Ru Lee<br>Department of Mathematics<br>National University of Singapore*

(Dated: June 18, 2024)

#### Abstract

In this paper, we study the determination of Hamiltonian from a given equations of motion. It can be cast into a problem of matrix factorization after reinterpretation of the system as first order evolutionary equations in the phase space coordinates. We state the criterion on the evolution matrix for a Hamiltonian to exist. In addition, the proof is constructive and an explicit Hamiltonian with accompanied symplectic structure can be obtained. As an application, we will study a class of PT-symmetric systems for illustration.

## I. INTRODUCTION

It is known that a damped oscillator

$$
\begin{equation*}
\ddot{x}+\gamma \dot{x}+x=0 \quad(\gamma>0) \tag{1}
\end{equation*}
$$

appears to be a dissipative system and cannot be described as a Hamiltonian system. A common explanation for this is to observe that the total energy $\frac{1}{2} \dot{x}^{2}+\frac{1}{2} x^{2}$ is not conserved under time change.

Clearly the total energy (that is, the kinetic energy plus the potential) is non-conserved, as

$$
\frac{d}{d t}\left(\frac{1}{2} \dot{x}^{2}+\frac{1}{2} x^{2}\right)=-\gamma \dot{x}^{2}<0
$$

Decreases over time. However, it is still reasonable to suspect the existence of some other conserved quantities that could be treated as the Hamiltonian.

A formal way to prove that (11) is non-Hamiltonian is to employ the symplectic framework [1 -3$]$. Introduce the Hamiltonian vector field

$$
\begin{equation*}
\mathbf{X}_{H}=\frac{d}{d t}=\dot{p} \frac{\partial}{\partial p}+\dot{x} \frac{\partial}{\partial x} . \tag{2}
\end{equation*}
$$

Then it suffices to show that there does not exist an $H=H(\mathbf{p}, \mathbf{x})$ so that the fundamental equation of Hamiltonian mechanics

$$
\begin{equation*}
i_{\mathbf{X}_{H}} \omega=-d H \tag{3}
\end{equation*}
$$

holds, where $\omega$ is the canonical symplectic 2-form $\omega=d p \wedge d x$.

Indeed, from equation (11), we may put $\dot{x}=p$ and $\dot{p}=-\gamma p-x$. Thus, $i_{\mathbf{X}_{H}} \omega=-p d p-x d x-\gamma p d x$, and it is not a closed 1-form.

[^0]Nevertheless, Bateman (4) made the intelligent observation that a system of coupled oscillators with balanced energy loss-gain can be shown to be Hamiltonian (with a non-standard Hamiltonian form). The coupled equations of motion for the described system is:

$$
\left\{\begin{array}{l}
\ddot{x}+\gamma \dot{x}+x=-\lambda y  \tag{4}\\
\ddot{y}-\gamma \dot{y}+y=-\lambda x
\end{array}\right.
$$

The parameter $\lambda$ here indicates the coupling strength. Note that this system is PT-symmetric, meaning that it is invariant under parity alternation ( $x \leftrightarrow y$ ) and time reversal $(t \mapsto-t)$ composed.

Bender et al. [5, 6] studied this system further and concluded that these equations can be derived using a non-standard quadratic Hamiltonian
$H=p q+\frac{1}{2} \gamma(y q-x p)+\left(1-\frac{1}{4} \gamma^{2}\right) x y+\frac{1}{2} \lambda\left(x^{2}+y^{2}\right)$. Note that in convention $p=\dot{x}$ is the momentum in $x$ direction and $q=\dot{y}$ is the momentum in $y$-direction. However, here one would observe that this is not the case. In fact, $q=\dot{x}+\frac{\gamma}{2} x$ and $p=\dot{y}-\frac{\gamma}{2} y$ when the canonical Hamiltonian equations are applied.

For convenience, we will also use $\mathbf{x}=\left(x_{1}, x_{2}\right)$ and $\mathbf{p}=\left(p_{1}, p_{2}\right)$ to denote $(x, y)$ and $(p, q)$ respectively. We will also write $\xi=(\mathbf{p}, \mathbf{x})$ to denote the phase space coordinates.

Bender et al. [7] also noticed that from the system of equations (4),

$$
p q+x y+\frac{\lambda}{2}\left(x^{2}+y^{2}\right)
$$

is a conserved quantity under the conventional choice of momentum $\mathbf{p}=\dot{\mathbf{x}}$.

A subtle point here is that if one treats the above conserved quantity as the Hamiltonian of the system, one would not reach the correct equations of motion using the canonical Hamilton formulation.

This leads us to consider the question below: does there exist a suitably chosen symplectic structure so that (3) with the Hamiltonian defined as $H:=$ $p q+x y+\frac{\lambda}{2}\left(x^{2}+y^{2}\right)$ can produce the equations of motion

$$
\left\{\begin{array}{l}
\dot{p}=-\gamma p-x-\lambda y  \tag{5}\\
\dot{q}=\gamma q-\lambda x-y \\
\dot{x}=p \\
\dot{y}=q
\end{array}\right.
$$

which is equivalent to (4). The answer to this question is positive: simply let

$$
\begin{equation*}
\omega=d p \wedge d y+d q \wedge d x+\gamma d x \wedge d y \tag{6}
\end{equation*}
$$

from which the (nonzero) Poisson bracket follows:

$$
\{p, q\}=-\gamma \quad\{p, y\}=-1 \quad\{q, x\}=-1
$$

Another convenient way to state equation (3) is

$$
\begin{equation*}
\frac{d}{d t} \xi^{i}=\left\{\xi^{i}, H\right\} \tag{7}
\end{equation*}
$$

Here $\xi^{i}$ can be any entry of $\xi=\binom{\mathbf{p}}{\mathbf{x}}$. Equation (5) is then a natural consequence of (7) using the Poisson brackets above.

We can see, a dynamical system has two pieces, namely the symplectic form and the Hamiltonian. As emphasized by Souriau, to reestablish the equations of motion, what we should do is by varying either (or both) parts of the dynamical system [8].

We would like to study the extent of this proposal. The purpose of this paper is two-fold. We would like to provide a criterion for identifying Hamiltonian systems when given some equations of motion. We also want our proposition to be constructive: that is, coming up with a recipe for generating a corresponding set $(H, \omega)$ of quadratic Hamiltonian and symplectic structure for such a system.

## II. EVOLUTION MATRIX AND THE CRITERION

From the description above, three immediate questions emerge:

1. How to decide whether a system is Hamiltonian, given its equations of motion?
2. Is there a recipe for construction of the pair $(H, \omega)$ for such a given system?
3. When the association to $(H, \omega)$ is non-unique, what is the relation between the different sets? In particular, does there exist canonical representatives?

We shall provide an affirmative answer to all of these questions above.

For most physically interesting models, the Hamiltonian would be of the form

$$
\begin{equation*}
H=H_{0}+V \tag{8}
\end{equation*}
$$

where $H_{0}$ is the quadratic part, and $V=V(\mathbf{x})$ is a function of only the position (that comes from the potential energy). Then, the part of $V$ would not jeopardize the symplectic structure and one can adjust the Hamiltonian to include the non-linear interactions in the Hamiltonian flow.

In light of that, we will consider only the quadratic part of the Hamiltonian and start with the assumption that $H=H_{0}$. Equivalently, the equations of motion we consider will be linear.

For a system of (linear second order) equations of motion

$$
\begin{equation*}
\ddot{\mathbf{x}}-B_{1} \dot{\mathbf{x}}-B_{2} \mathbf{x}=0 \tag{9}
\end{equation*}
$$

we can always (but non-uniquely) reduce it to some first order evolutionary equations. If we set the phase space coordinates to be $\xi=\binom{\mathbf{p}}{\mathbf{x}}$, then this is to say that there exists some $M \in \mathrm{M}_{2 n}(\mathbb{R})$ so that

$$
\dot{\xi}=M \xi
$$

is equivalent to (9).
By a direct computation

$$
M=2 \underline{\omega}^{-1} \underline{H}
$$

where $\underline{\omega}=\left(\omega\left(\frac{\partial}{\partial \xi^{i}}, \frac{\partial}{\partial \xi^{j}}\right)\right)_{i j}$ and $\underline{H}=\frac{1}{2}\left(\frac{\partial^{2}}{\partial \xi^{j} \partial \xi^{i}} H\right)_{i j}$. Those matrices constitute the symplectic structure and the Hamiltonian, respectively. Therefore, a system is Hamiltonian only when one can write $M$ as a product of alternating and symmetric matrices.

The Main Theorems of this paper consists of three parts:

Theorem II.1. A system of first order evolutionary equations

$$
\dot{\xi}=M \xi
$$

allows a Hamiltonian $H$ with accompanied symplectic structure $\omega$ if and only if $M \in \mathrm{GL}_{2 n}(\mathbb{R})$ satisfies the criterion that $M$ and $-M$ are conjugate.

Theorem II.2. For any system $M=\left(\begin{array}{ll}M_{11} & M_{12} \\ M_{21} & M_{22}\end{array}\right)$ with $M_{21} \in \mathrm{GL}_{n}(\mathbb{R})$, one can find another system

$$
\begin{equation*}
\dot{\xi}=M_{\mathrm{std}} \cdot \xi \tag{10}
\end{equation*}
$$

so that the associated equations of motion are the same, and

$$
M_{\mathrm{std}}=\left(\begin{array}{ll}
B_{1} & B_{2} \\
\mathbb{1}_{n} & \mathbf{0}_{n}
\end{array}\right)
$$

is conjugate to $M$.
Theorem II.3. Suppose

$$
M \xi=\left(\begin{array}{ll}
M_{11} & M_{12}  \tag{11}\\
M_{21} & M_{22}
\end{array}\right)\binom{\mathbf{p}}{\mathbf{x}}
$$

and $M_{21}$ is invertible. If

$$
\begin{aligned}
& B_{1}=M_{21} M_{11} M_{21}^{-1}+M_{22} \\
& B_{2}=M_{21} M_{12}-M_{21} M_{11} M_{21}^{-1} M_{22}
\end{aligned}
$$

satisfies

1. $B_{1}$ allows a decomposition $B_{1}=A_{1} S_{1}$ into product of alternating and symmetric matrices and that
2. $S_{1} B_{2}$ is symmetric.
then the second order equations of motion derived from the evolutionary equations allows a Hamiltonian $H_{\text {can }}$ that is equipped with the canonical symplectic structure $\omega=\sum_{i} d p_{i} \wedge d x^{i}$.

To recap: Theorem II.1 states the criterion for which a system allows a Hamiltonian structure [9]. The other two Theorems concern the problem of shaping the corresponding $(H, \omega)$ at will. Theorem II.2 allow us to retain the conventional relation for the momentum $\mathbf{p}=\dot{\mathbf{x}}$ of the evolution matrix for a given system. Theorem II. 3 is about a special but common case where one can choose the canonical symplectic structure.

Detailed proofs and calculations can be found in the supplementary material, along with the recipe for maneuvering on actual cases.

From Theorem II.1 we know that a system is Hamiltonian only if the characteristic polynomial is an even function. That is,

$$
\begin{equation*}
\operatorname{det}\left(t \mathbb{1}_{2 n}-M\right)=\sum_{m=0}^{2 n} a_{2 m} t^{2 m} \tag{12}
\end{equation*}
$$

As a quick verification, we consider again the damped oscillator (11). In this case

$$
M=\left(\begin{array}{cc}
-\gamma & -1 \\
1 & 0
\end{array}\right)
$$

and so the characteristic polynomial is $t^{2}+\gamma t+1$, which can be Hamiltonian only when $\gamma=0$.

## III. A FEW ILLUSTRATIVE EXAMPLES

## A. Another PT-symmetric pair

We consider a PT-symmetric system

$$
\left\{\begin{array}{l}
\ddot{x}+\gamma \dot{y}+x=-\lambda y  \tag{13}\\
\ddot{y}-\gamma \dot{x}+y=-\lambda x
\end{array}\right.
$$

which can be written into the evolutionary equations with $M$ being

$$
M=\left(\begin{array}{cccc}
0 & -\gamma & -1 & -\lambda \\
\gamma & 0 & -\lambda & -1 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{array}\right)
$$

Note that is satisfies both the criterion of Theorem II.1 We yield the decomposition

$$
M=\left(\begin{array}{cccc}
0 & -\gamma & -1 & 0 \\
\gamma & 0 & 0 & -1 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{array}\right)\left(\begin{array}{llll}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & \lambda \\
0 & 0 & \lambda & 1
\end{array}\right)
$$

This is equivalent to saying that the system allows a Hamiltonian

$$
H=\frac{1}{2}\left(p^{2}+q^{2}\right)+\frac{1}{2}\left(x^{2}+y^{2}\right)+\lambda x y
$$

under the symplectic structure given by

$$
\omega=d p \wedge d x+d q \wedge d y-\gamma d x \wedge d y
$$

By Theorem II.3 observe that the system (13) has a Hamiltonian $H_{\text {can }}$ :
$\frac{1}{2}\left(p^{2}+q^{2}\right)+\frac{\gamma}{2}(q x-p y)+\lambda x y+\frac{1}{2}\left(1+\frac{\gamma^{2}}{4}\right)\left(x^{2}+y^{2}\right)$
with the canonical symplectic 2 -form on the phase space (that derives the canonical Hamiltonian equations).

To apply the standard stability analysis of the evolution matrix, we find the characteristic polynomial of $M$ :

$$
\operatorname{det}\left(t \mathbb{1}_{4}-M\right)=t^{4}+\left(2+\gamma^{2}\right) t^{2}+\left(1-\lambda^{2}\right)
$$

which has zeros at

$$
t^{2}=-\frac{1}{2}\left(2+\gamma^{2} \pm \sqrt{\gamma^{4}+4 \gamma^{2}+4 \lambda^{2}}\right)
$$

Oscillatory behavior occurs when $t^{2}<0$, which happens when $\lambda<1$. In contrast to Bender's case, the critical value for the existence of PT-symmetric phase in this model is independent of $\gamma$.

## B. An interactive pair of PT-symmetric systems

Consider a system with two cross-coupled PTsymmetric pairs, equipped with possibly distinct energy loss-gain coefficient. Here, the parity alternation means to switch $x^{i}$ and $y_{i}$, for both $i=1,2$ :

$$
\left\{\begin{array}{l}
\ddot{x}_{1}+\gamma_{1} \dot{x}_{1}+x_{1}=-\lambda_{1} x_{2}-\lambda_{2} y_{2}  \tag{14}\\
\ddot{y}_{1}-\gamma_{1} \dot{y}_{1}+y_{1}=-\lambda_{2} x_{2}-\lambda_{1} y_{2} \\
\ddot{x}_{2}+\gamma_{2} \dot{x}_{2}+x_{2}=-\lambda_{1} x_{1}-\lambda_{2} y_{1} \\
\ddot{y}_{2}-\gamma_{2} \dot{y}_{2}+y_{2}=-\lambda_{2} x_{1}-\lambda_{1} y_{1},
\end{array}\right.
$$

It also satisfies the criterion of Theorem II.1 and we may check that (14) comes from the pair $(H, \omega)$ with

$$
\begin{aligned}
H= & \sum_{i=1}^{2}\left(p_{i} q_{i}+x^{i} y_{i}\right)+ \\
& \lambda_{1}\left(x_{1} y_{2}+x_{2} y_{1}\right)+\lambda_{2}\left(x_{1} x_{2}+y_{1} y_{2}\right) \\
\omega= & \sum_{i=1}^{2}\left(d p_{i} \wedge d y_{i}+d q_{i} \wedge d x^{i}\right)+ \\
& \gamma_{1} d x_{1} \wedge d y_{1}+\gamma_{2} d x_{2} \wedge d y_{2} .
\end{aligned}
$$

Moreover, we can also write down the Hamiltonian $H_{\text {can }}$ that is accompanied by the canonical symplectic 2-form:

$$
\begin{aligned}
& \sum_{i=1}^{2}\left(p_{i} q_{i}+\left(1-\frac{1}{4} \gamma_{i}^{2}\right)\left(x^{i} y_{i}\right)-\frac{1}{2} \gamma_{i}\left(p_{i} x^{i}-q_{i} y_{i}\right)\right)+ \\
& \lambda_{1}\left(x_{1} y_{2}+y_{1} x_{2}\right)+\lambda_{2}\left(x_{1} x_{2}+y_{1} y_{2}\right) .
\end{aligned}
$$

## C. Higher degree terms: the Hénon-Heiles system

As an example for dealing with cases with higher degree terms, consider the Hénon-Heiles system with
balanced energy loss-gain

$$
\left\{\begin{array}{l}
\ddot{x}+\gamma \dot{y}+x=x^{2}-y^{2}  \tag{15}\\
\ddot{y}-\gamma \dot{x}+y=-2 x y,
\end{array}\right.
$$

with the recognition from (13), we try to write it as an Hamiltonian system with

$$
H=\frac{1}{2}\left(p^{2}+q^{2}\right)+\frac{1}{2}\left(x^{2}+y^{2}\right)+V(x, y)
$$

along with the symplectic structure defined by

$$
\omega=d p \wedge d x+d q \wedge d y-\gamma d x \wedge d y
$$

Now, reexpressing in evolutionary equations,

$$
\left\{\begin{array}{l}
\dot{p}=-\gamma q-x+x^{2}+y^{2}  \tag{16}\\
\dot{q}=\gamma p-y-2 x y \\
\dot{x}=p \\
\dot{y}=q
\end{array}\right.
$$

We can calculate the potential term by the fundamental equation (7). It satisfies

$$
\left\{\begin{aligned}
-\frac{\partial}{\partial x} V & =x^{2}-y^{2} \\
-\frac{\partial}{\partial y} V & =2 x y
\end{aligned}\right.
$$

Solving to get $V=y^{2} x-\frac{1}{3} x^{3}$ is then straightforward.
One can tune the parameter $\gamma$ to control the chaotic behavior of the system.

## IV. A REMARK: RELATION TO LAGRANGIAN MECHANICS

Despite its original root in Hamiltonian mechanics, the work in this paper can be adopted in the setting of Lagrangian mechanics to provide a straightforward algorithm for the construction of Lagrangian from the equations of motion once the pair $(H, \omega)$ is found. In fact, the Lagrangian $L$ can be yielded from

$$
\begin{equation*}
L=\theta\left(\mathbf{X}_{H}\right)-H \tag{17}
\end{equation*}
$$

where $\theta$ is a 1 -form satisfying $d \theta=\omega$. Note the formula we apply above is different from the usual Legendre transformation. We write it so to incorporate the possible case of non-canonical symplectic 2 -forms.

As an example, for our model system (13), the Lagrangian can be chosen to be

$$
L=\frac{1}{2}\left(\dot{x}^{2}+\dot{y}^{2}\right)-\frac{1}{2}\left(x^{2}+y^{2}\right)-\gamma x \dot{y}-\lambda x y
$$

by the formula (17). This will be further discussed in the follow-up works by the author.

## ACKNOWLEDGMENTS

The author wish to express sincere gratitude to Professor Chin-Rong Lee for his invaluable suggestions on the manuscript and for several enlightening
conversations that significantly enhanced this work. Additionally, the author acknowledges the funding support from the National University of Singapore, which was instrumental during the conduct of this research.

# Supplementary Material 

Chung-Ru Lee<br>Department of Mathematics<br>National University of Singapore*

(Dated: June 18, 2024)

#### Abstract

This piece of writing is the supplementary material for the article: Determination of the Hamiltonian from the Equations of Motion with Illustration from Examples.

## I. THE BASIC STRUCTURE

In the article, we claimed that

$$
\begin{equation*}
M=2 \underline{\omega}^{-1} \underline{H} \tag{1}
\end{equation*}
$$

where $\underline{\omega}=\left(\omega\left(\frac{\partial}{\partial \xi_{i}}, \frac{\partial}{\partial \xi_{j}}\right)\right)_{i j}$ and $\underline{H}=\frac{1}{2}\left(\frac{\partial^{2}}{\partial \xi_{j} \partial \xi_{i}} H\right)_{i j}$. Moreover, $\underline{\omega}^{-1}=\left(\left\{\xi_{i}, \xi_{j}\right\}_{\omega}\right)_{i j}$. Here the notation $\{-,-\}_{\omega}$ is the Poisson bracket defined by the symplectic 2-form $\omega$.

The upshot of this claim is that a system can be Hamiltonian only when one can write $M$ as a product of alternating and symmetric matrices, which is essential in the derivation of Theorem【I.1 Here, we will validate this claim by computation.

Starting with

$$
\begin{equation*}
i_{\mathbf{x}_{H}} \omega=-d H, \tag{2}
\end{equation*}
$$

where $\frac{d}{d t}=\mathbf{X}_{H}=\sum_{i=1}^{2 n} \dot{\xi^{i}} \frac{\partial}{\partial \xi^{i}}$. Of course, can write $\omega$ as

$$
\omega=\frac{1}{2} \sum_{i, j=1}^{2 n} \underline{\omega}_{i j} d \xi^{i} \wedge d \xi^{j}
$$

and $H$ as

$$
H=\sum_{i, j=1}^{2 n} \underline{H}_{i j} \xi_{i} \xi_{j}
$$

It follows that in Equation (2),

$$
i_{\mathbf{X}_{H}} \omega=\sum_{i, j} \omega_{i j} \dot{\xi}^{i} d \xi^{j} \quad \text { and } \quad d H=2 \sum_{i, j} H_{i j} d \xi^{j}
$$

Furthermore, since we already have $\dot{\xi}_{j}=\sum_{i} M_{i j} \xi_{i}$, we can compare the coefficients and obtain Equation (1).

[^1]
## II. PROOFS FOR THE THEOREMS

There are three Theorems stated in the paper, namely

Theorem II.1. A system of first order evolutionary equations

$$
\dot{\xi}=M \xi
$$

allows a Hamiltonian $H$ with accompanied symplectic structure $\omega$ if and only if $M \in \mathrm{GL}_{2 n}(\mathbb{R})$ satisfies the criterion that $M$ and $-M$ are conjugate.

Theorem II.2. For any system $M=\left(\begin{array}{ll}M_{11} & M_{12} \\ M_{21} & M_{22}\end{array}\right)$ with $M_{21} \in \mathrm{GL}_{n}(\mathbb{R})$, one can find another system

$$
\begin{equation*}
\dot{\xi}=M_{\mathrm{std}} \cdot \xi \tag{3}
\end{equation*}
$$

so that the associated equations of motion are the same, and

$$
M_{\mathrm{std}}=\left(\begin{array}{ll}
B_{1} & B_{2} \\
\mathbb{1}_{n} & \mathbf{0}_{n}
\end{array}\right)
$$

is conjugate to $M$.
Theorem II.3. Suppose

$$
M \xi=\left(\begin{array}{ll}
M_{11} & M_{12}  \tag{4}\\
M_{21} & M_{22}
\end{array}\right)\binom{\mathbf{p}}{\mathbf{x}}
$$

and $M_{21}$ is invertible. If

$$
\begin{aligned}
& B_{1}=M_{21} M_{11} M_{21}^{-1}+M_{22} \\
& B_{2}=M_{21} M_{12}-M_{21} M_{11} M_{21}^{-1} M_{22}
\end{aligned}
$$

satisfies

1. $B_{1}$ allows a decomposition $B_{1}=A_{1} S_{1}$ into product of alternating and symmetric matrices and that
2. $S_{1} B_{2}$ is symmetric.
then the second order equations of motion derived from the evolutionary equations allows a Hamiltonian $H_{\text {can }}$ that is equipped with the canonical symplectic structure $\omega=\sum_{i} d p_{i} \wedge d x_{i}$.

Here, we provide proofs for them.
Proof of Theorem II.1. Suppose $M=A S$, where $A$ is alternating and $S$ is symmetric. Then any conjugate of $M$ would allow such decomposition. In fact, the decomposition $M=A S$ is compatible with $\mathrm{GL}_{2 n}(\mathbb{R})$-conjugation in the sense that

$$
\Lambda^{-1} M \Lambda=\left(\Lambda^{-1} A \Lambda^{-t}\right)\left(\Lambda^{t} S \Lambda\right)
$$

where $\Lambda^{-1} A \Lambda^{-t}$ (resp. $\Lambda^{t} S \Lambda$ ) is still antisymmetric (resp. symmetric).

Therefore, it suffices to construct the decomposition for one representative in the conjugacy class.

In [? ], such decomposition can be found for the rational canonical form of $M$. Let us describe the procedure here.

Suppose $M \in \mathrm{GL}_{2 n}(\mathbb{R})$ is in the rational canonical form, namely it is by assumption a direct sum $M=$ $\bigoplus_{k} M_{k}$ of matrices of the form

$$
M_{k}^{t}=\left(\begin{array}{cccccccc}
0 & 1 & 0 & 0 & 0 & \ldots & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\
0 & 0 & 0 & 0 & 0 & \ldots & 0 & 1 \\
a_{0} & 0 & a_{2} & 0 & a_{4} & \ldots & a_{2 r_{k}-2} & 0
\end{array}\right)
$$

with $r_{k} \in \mathbb{Z}$. Note that we wrote the transpose of $M_{k}$ just to save space.

In this case $M_{k}$ has a decomposition $M_{k}=A_{k} S_{k}$, where

$$
\begin{aligned}
& A_{k}=\left(\begin{array}{cc}
0 & -1 \\
1 & 0
\end{array}\right) \oplus\left(\begin{array}{cccccccc}
0 & -y_{r_{k}-2} & 0 & -y_{r_{k}-3} & \ldots & -y_{1} & 0 & -y_{0} \\
y_{r_{k}-2} & 0 & y_{r_{k}-3} & . \cdot & . & 0 & 0 & y_{0} \\
0 & -y_{r_{k}-3} & . \cdot & . \cdot & . & . & -y_{0} & \\
\vdots & . \cdot & . \cdot & . \cdot & . \cdot & & \\
y_{0} & & & & & &
\end{array}\right), \\
& S_{k}=(1) \oplus\left(\begin{array}{cccccccc} 
& & & & & & & \\
& & & & & & & b_{0} \\
& & & 0 \\
& & & & & & -b_{0} & 0 \\
\hline
\end{array}\right)
\end{aligned}
$$

Here $b_{i}$ and $y_{i}$ satisfies

$$
\begin{aligned}
b_{0} & =a_{0} \\
y_{0} b_{0} & =1
\end{aligned}
$$

in addition to

$$
\begin{aligned}
b_{0} y_{m}-\sum_{l=1}^{m} b_{l} y_{m-l} & =0 \\
\sum_{l=1}^{m} b_{l} y_{m-l} & =-a_{2 r_{k}-2-2 m}
\end{aligned}
$$

Here the domain of $m$ is $m=1,2, \ldots, r_{k}-2$ for the first equation, and an extra term of $m=r_{k}-1$ for the second (so there are a total of $2 r_{k}-1$ variables and $2 r_{k}-1$ equations). Note that from these equations the matrices $A_{k}$ and $S_{k}$ can be solved.

Proof of Theorem II.2. For any admissible

$$
M=\left(\begin{array}{ll}
M_{11} & M_{12} \\
M_{21} & M_{22}
\end{array}\right)
$$

adjust so that $M_{21}=\mathbb{1}_{n}$ with a conjugation by $\left(\begin{array}{ll}M_{12} & \\ & \mathbb{1}_{n}\end{array}\right)$. Then, $M_{22}=\mathbf{0}$ can be achieved
through a $\left(\begin{array}{cc}\mathbb{1}_{n} & M_{22} \\ & \mathbb{1}_{n}\end{array}\right)$-conjugation.
We say that a system with evolutionary equations $\dot{\xi}=M \xi$ (referred to as the system of $M$ in short) is admissible if both $M$ and $M_{12}$ are invertible. Before we prove Theorem II.3, let us state and proof a lemma:

Lemma II.4. Two admissible evolution systems $M$ and $W$ are in association to the same equations of motion if and only if they are equivalent under a $P$ conjugation, where $P$ is a subgroup of $\mathrm{GL}_{2 n}(\mathbb{R})$ of the form

$$
P=\left\{\left.\left(\begin{array}{ll}
T & X \\
& \mathbb{1}_{n}
\end{array}\right) \right\rvert\, T \in \mathrm{GL}_{n}(\mathbb{R}), X \in \mathrm{M}_{n}(\mathbb{R})\right\} .
$$

Proof. By a computation that is straightforward, we know that the system $\dot{\xi}=M \xi$ is associated to

$$
\begin{equation*}
\ddot{\mathbf{x}}-B_{1} \dot{\mathbf{x}}-B_{2} \mathbf{x}=0 \tag{5}
\end{equation*}
$$

where $B_{1}$ and $B_{2}$ are defined as in the Theorem statement. Moreover, $B_{1}$ and $B_{2}$ are invariant under $P$-conjugation.

This, along with Theorem II.2, proves that if $M$ and $W$ are associated to the same set of equations of motion (5), then they are both $P$-conjugate to

$$
\left(\begin{array}{ll}
B_{1} & B_{2} \\
\mathbb{1}_{n} & \mathbf{0}_{n}
\end{array}\right)
$$

and are therefore $P$-conjugates themselves.
Remark II.1. Let $\mathcal{A} \subset \mathrm{GL}_{2 n}(\mathbb{R})$ be the set of admissible matrices of dimension $2 n \times 2 n$. In simple words, Lemma II.4 says that the map

$$
\begin{aligned}
\varphi: \mathcal{A} & \rightarrow \mathbb{R}^{n \times 2 n} \\
& M \mapsto\left(B_{1}, B_{2}\right)
\end{aligned}
$$

factors through the quotient map

$$
\pi: \mathcal{A} \rightarrow \mathcal{A} / P
$$

Moreover, the pushforward map $\mathcal{A} / P \rightarrow \mathbb{R}^{n \times 2 n}$ is a bijection since the stabilizer of any such $M_{\text {std }}$ in Theorem $\llbracket .2$ intersects $P$ trivially.

From the perspective of Remark II.1 it should be natural to ask if there exists a section for the map $\varphi$. It is noted that Theorem $\llbracket .2$ has answered the question for us.

Proof of Theorem II.3. By Theorem II.2, we may assume that $M$ is in the form

$$
M=\left(\begin{array}{ll}
B_{1} & B_{2} \\
\mathbb{1}_{n} & \mathbf{0}_{n}
\end{array}\right)
$$

Assume the conditions in the Theorem statement.
Then with $S_{2}:=-S_{1} B_{2}$, we have

$$
M=\left(\begin{array}{cc}
B_{1} & B_{2} \\
\mathbb{1}_{n} & \mathbf{0}
\end{array}\right)=\left(\begin{array}{cc}
A_{1} & -S_{1}^{-1} \\
S_{1}^{-1} & \mathbf{0}
\end{array}\right)\left(\begin{array}{ll}
S_{1} & \\
& S_{2}
\end{array}\right) .
$$

Furthermore, we can decompose additively $S_{1} A_{1} S_{1}=S_{1} B_{1}=X-X^{t}$ for some $X \in M_{n}(\mathbb{R})$ (for instance, one can let $X=\frac{1}{2} S_{1} B_{1}$ ). It follows that $M$ is $P$-conjugate to

$$
\left(\begin{array}{cc} 
& -\mathbb{1}_{n} \\
\mathbb{1}_{n} &
\end{array}\right)\left(\begin{array}{cc}
S_{1}^{-1} & S_{1}^{-1} X \\
X^{t} S_{1}^{-1} & X^{t} S_{1}^{-1} X+S_{2}
\end{array}\right)=: M_{\mathrm{can}} .
$$

The second factor in this product defines $H_{\text {can }}$.

## III. A QUICK RECIPE FOR MANEUVER

Let us write down a recipe for the construction of the Hamiltonian and accompanied symplectic structure. We will break the procedure into several steps:

1. Suppose one is given an evolutionary system $M=\left(\begin{array}{ll}M_{11} & M_{12} \\ M_{21} & M_{22}\end{array}\right)$ that is admissible. Then one may compute the associated equations of motion

$$
\ddot{\mathrm{x}}-B_{1} \dot{\mathbf{x}}-B_{2} \mathbf{x}=0
$$

by the formulae

$$
\begin{aligned}
& B_{1}=M_{21} M_{11} M_{21}^{-1}+M_{22} \\
& B_{2}=M_{21} M_{12}-M_{21} M_{11} M_{21}^{-1} M_{22}
\end{aligned}
$$

If started with the equations of motion, one can skip this step.
2. If $B_{1}$ and $-B_{1}$ are conjugates, one can write $B_{1}=A_{1} S_{1}$, where $A_{1}$ (resp. $S_{1}$ ) is alternating (resp. symmetric). There might be multiple ways to write down the decomposition.
3. See if $S_{2}:=-S_{1} B_{2}$ is symmetric for any one of the decomposition above.
4. If so, then

$$
M=\left(\begin{array}{cc}
A_{1} & -S_{1}^{-1} \\
S_{1}^{-1} & \mathbf{0}
\end{array}\right)\left(\begin{array}{ll}
S_{1} & \\
& S_{2}
\end{array}\right)=2 \underline{\omega}^{-1} \underline{H} .
$$

5. If any of the steps above fails, one has to apply the formula in the Proof of Theorem 【I.1.

As an example, let us consider the model in §III.A in the main article.

1. We start with the equations of motion

$$
\ddot{\mathbf{x}}-\left(\begin{array}{cc}
0 & -\gamma \\
\gamma & 0
\end{array}\right) \dot{\mathbf{x}}-\left(\begin{array}{cc}
-1 & -\lambda \\
-\lambda & -1
\end{array}\right) \mathbf{x}=0
$$

2. Note that
$B_{1}=\left(\begin{array}{cc}0 & -\gamma \\ \gamma & 0\end{array}\right)=\left(\begin{array}{cc}0 & -\gamma \\ \gamma & 0\end{array}\right)\left(\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right)=: A_{1} S_{1}$
and

$$
B_{2}=\left(\begin{array}{ll}
-1 & -\lambda \\
-\lambda & -1
\end{array}\right)
$$

3. Moreover, $S_{2}:=-S_{1} B_{2}=\left(\begin{array}{cc}1 & \lambda \\ \lambda & 1\end{array}\right)$ is symmetric.
4. Therefore we have
$M=\left(\begin{array}{cccc}0 & -\gamma & -1 & 0 \\ \gamma & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0\end{array}\right)\left(\begin{array}{llll}1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & \lambda \\ 0 & 0 & \lambda & 1\end{array}\right)=2 \underline{\omega}^{-1} \underline{H}$.

## IV. HIGHER DEGREE TERMS

When there exists non-linear terms in describing the time derivative of $\xi$, we start by extracting the linear terms $M$ and solve for the system with evolution matrix $M$. Afterwards, $M$ would provide the relation between the coordinate systems ( $\mathbf{p}, \mathbf{x}$ ) and ( $\mathbf{x}, \dot{\mathbf{x}}$ ), which we would want to fix (this will come with the condition that $\left\{x_{i}, V\right\}=0$ for each $i=1,2, \ldots, n)$.

We can then write down the associated equations of motion

$$
\begin{equation*}
\ddot{\mathbf{x}}-B_{1} \dot{\mathbf{x}}-B_{2} \mathbf{x}=\Delta . \tag{6}
\end{equation*}
$$

We will assume that $\Delta=\Delta(\mathbf{x}) \in \mathbb{R}^{n}$, which represents the higher degree terms, should come from the potential energy and only depends on the position x .

Then it suffices to solve for

$$
\sum_{j=1}^{n} m_{i j}\left\{p_{j}, V\right\}=\sum_{j, k=1}^{n} m_{i j}\left\{p_{j}, x_{k}\right\} \frac{\partial V}{\partial x_{k}}=\Delta_{i}
$$

Here $m_{i} j$ is the $(i, j)$-entry of $M_{21}$. In other words,

$$
\begin{equation*}
\left(\frac{\partial}{\partial x_{i}} V\right)_{i}=M_{21}^{-1} A_{12}^{-1} \Delta \tag{7}
\end{equation*}
$$

The existence of such $V$ would be apparent when $\omega$ is reasonably simple (say, is canonical).
