Domino tilings of three-dimensional cylinders: regularity of hamiltonian disks

Raphael de Marreiros

June 18, 2024

Abstract

We consider tree-dimensional domino tilings of cylinders $\mathcal{D} \times [0, N] \subset \mathbb{R}^3$, where $\mathcal{D} \subset \mathbb{R}^2$ is a balanced quadriculated disk and $N \in \mathbb{N}$. A flip is a local move in the space of tilings: two adjacent and parallel dominoes are removed and then replaced in a different position. The twist is a flip invariant that associates an integer number to a domino tiling. A disk \mathcal{D} is called regular if any two tilings of $\mathcal{D} \times [0, N]$ sharing the same twist can be connected trough a sequence of flips once extra vertical space is added to the cylinder. We prove that hamiltonian disks with narrow and small bottlenecks are regular. In particular, we show that the absence of a bottleneck in a hamiltonian disk implies regularity.

1 Introduction

Problems involving domino tilings have been widely studied. In particular, lots of results are known for two-dimensional domino tilings. In this context, a region is a finite union of unit squares with vertices in \mathbb{Z}^2 and a domino is a 2×1 rectangle. Kasteleyn [8] established a connection between the number of domino tilings (i.e., coverings by dominoes with disjoint interiors) of a region and the Pffafian of a skew-symmetric matrix, as a consequence, the exact number of domino tilings of a $m \times n$ rectangle is derived. Conway and Lagarias [5] and Thurston [16] used arguments from combinatorial group theory to develop a criterion to decide whether a region admits a tiling. Cohn, Kenyon and Propp [4] studied random tilings to investigate properties of a typical domino tiling of a large region.

²⁰²⁰ Mathematics Subject Classification. Primary 05B45; Secondary 52C22, 05C70. Keywords and phrases. Three-dimensional tilings, dominoes, flip.

In this paper, we are interested in the problem of connectivity of domino tilings via local moves. A *flip* is a local move involving two dominoes: two adjacent and parallel dominoes are removed and replaced in a different position after a rotation of 90°. The flip connectivity problem consists in characterize the connected components under flips of the space of domino tilings $\mathcal{T}(\mathcal{R})$ of a given region \mathcal{R} .

Thurston [16] proved that the space of domino tilings of a planar simply connected region is flip connected, so that any two tilings can be joined by a sequence of flips. Saldanha, Tomei, Casarin and Romualdo [15] showed, for planar non-simply-connected regions, the existence of a flip invariant called flux. Moreover, it is proved that two domino tilings can be joined by a sequence of flips if and only if they have the same flux.

Domino tilings, along with the questions previously discussed, can be easily generalized to higher dimensions. However, the arguments used in two dimensions do not straightforwardly extend to higher dimensions. Recently, Chandgotia, Sheffield and Wolfram [2] developed new tools to extend the results in [4] to 3D domino tilings. In a different vein, the transition of dimensions can drastically change the a priori expected result. For instance, Pak and Yang [12] showed that the counting tiling problem is computationally more complex in dimension three. Similarly, the space of tilings of a contractible 3D region is not necessarily flip connected, e.g. the $3 \times 3 \times 2$ box (see Figure 1 of [7]).

In the last decade, significant progresses have been made towards the flip connectivity problem of domino tilings in dimensions greater than two [3, 7, 14]. We are particularly interested in three-dimensional domino tilings of cylinders. A quadriculated disk $\mathcal{D} \subset \mathbb{R}^2$ is a 2D region homeomorphic to a disk; unit squares in \mathcal{D} are colored in black and white alternately, so that adjacent squares (i.e. squares sharing an edge) have different colors. A disk \mathcal{D} is balanced if it contains the same number of white and black unit squares. A cylinder is a region of the form $\mathcal{D} \times [0, N]$, where \mathcal{D} is a balanced quadriculated disk and $N \in \mathbb{N}$. For certain cylinders, the flip connectivity problem is somewhat simple. A disk \mathcal{D} is called trivial if it is a 2×2 square or its unit squares are adjacent to at most other two unit squares. It is not difficult to show that if \mathcal{D} is trivial then any two tilings of $\mathcal{D} \times [0, N]$ can be joined by a sequence of flips. However, as we shall see, the discussion is much more subtle for nontrivial disks.

Milet and Saldanha [11] exhibited, for certain 3D cubiculated regions, a flip invariant called twist. In this case, the twist of a tiling is defined by a combinatorial formula that in some sense counts pair of dominoes in opposite directions. The twist is closely related to an invariant studied in physics called Hopf number; for details, see Freedman, Hastings, Nayak and Qi [6] and Bednik [1]. A more general definition of the twist, in terms of

homology, is provided by Freire, Klivans, Saldanha and Milet [7]. For contractible regions, as cylinders, the twist of a tiling is an integer.

A balanced nontrivial disk \mathcal{D} is regular if any two tilings of $\mathcal{D} \times [0, N]$ with the same twist can be joined by a sequence of flips once extra vertical space is added; more precisely, any two tilings with the same twist are equivalent under the relation \sim defined in Section 2. Saldanha [14] showed that rectangles $[0, L] \times [0, M]$ with LM even are regular if and only if $\min\{L, M\} > 2$. Furthermore, it is proved in [13], for a regular disk \mathcal{D} , that the cardinality of the largest connected component under flips of $\mathcal{D} \times [0, N]$ is $\Theta(N^{-\frac{1}{2}}|\mathcal{T}(\mathcal{D} \times [0, N])|)$.

The domino group $G_{\mathcal{D}}$ of a disk \mathcal{D} is defined in [14]; we recall its construction in Section 2. Notably, the domino group plays a key role in determining the regularity of a disk. Indeed, the twist defines a homomorphism from the even domino group $G_{\mathcal{D}}^+$ (a normal subgroup of index two of $G_{\mathcal{D}}$) to the integers \mathbb{Z} . For nontrivial disks, this homomorphism is surjective, so that $G_{\mathcal{D}}$ is infinite. It turns out that a disk \mathcal{D} is regular if and only if this homomorphism is an isomorphism. In this case, $G_{\mathcal{D}}$ is isomorphic to $\mathbb{Z} \oplus \mathbb{Z}/(2)$.

In order to decide the regularity of a disk \mathcal{D} , it is important to investigate the existence of a bottleneck. A bottleneck is defined by a domino $d \subset \mathcal{D}$ that disconnects \mathcal{D} , i.e., a domino such that $\mathcal{D} \setminus d$ is not connected. Indeed, it follows from [10] that, in many cases, for disks with bottlenecks we have a surjective homomorphism $\phi \colon G_{\mathcal{D}}^+ \to F_2$, where F_2 is the free group of rank two. In such cases, there exists a constant $c \in (0,1)$ such that the cardinality of the largest flip connected component of $\mathcal{D} \times [0,N]$ is $O(c^N | \mathcal{T}(\mathcal{D} \times [0,N])|)$.

In this paper, we prove that a large class of disks is regular; in particular, the disks in Figures 1 and 2. The strategy of the proof is similar to the one used in [14] to derive the regularity of large rectangles. We consider a particular family that generates the even domino group and then we show that this family can be reduced to only one element. The first result shows the regularity of disks with hamiltonian cycles and without bottlenecks. The second results shows the regularity of a hamiltonian disk obtained by introducing narrow and small bottlenecks into an initially bottleneck-free disk.

Theorem 1. Let \mathcal{D} be a nontrivial hamiltonian quadriculated disk. Suppose that there exists no domino $d \subset \mathcal{D}$ such that $\mathcal{D} \setminus d$ is not connected. Then, \mathcal{D} is regular.

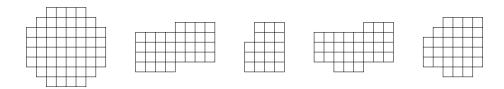

Figure 1: Examples of disks whose regularity follows from Theorem 1.

Theorem 2. Let \mathcal{D}_0 be a disk satisfying the hypothesis of Theorem 1. Consider pairwise disjoint disks $\mathcal{D}_1, \ldots, \mathcal{D}_k$ such that $|\mathcal{D}_i| < |\mathcal{D}_0| - 2$ and $\mathcal{D}_i \cap \mathcal{D}_0$ is a line segment of length two. If $\mathcal{D} = \bigcup_{i=0}^k \mathcal{D}_i$ is a hamiltonian disk then \mathcal{D} is regular.

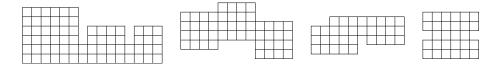

Figure 2: Examples of disks whose regularity follows from Theorem 2.

Theorem 1 motivates the question of when a bottleneck-free disk has a hamiltonian cycle, which is equivalent to determining when an 2-edge-connected solid grid graph is hamiltonian. Zamfirescu and Zamfirescu [17] showed that certain grid graphs with width greater than two are hamiltonian. Conversely, Keshavarz-Kohjerdi and Bagheri [9] established conditions that a hamiltonian rectangular truncated grid graph must satisfy. As a consequence, the first two disks in Figure 3 are not hamiltonian. On the other hand, it is easy to obtain examples of disks with small bottlenecks that fail to be hamiltonian, as the last two disks in Figure 3. Although our results do not apply to these four disks, a computation shows their regularity. On a positive note, the inequality in Theorem 2 regarding the size of the pairwise disjoint disks is tight (see Theorem 4 of [10]).

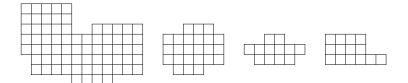

Figure 3: Four regular disks.

This paper is divided as follows. In Section 2 we present the construction of the domino group and exhibit a particular family of generators. In Section 3 we show some advantages of working with hamiltonian cycles and prove two technical lemmas. We prove Theorems 1 and 2 in Section 4.

The author thanks Nicolau Saldanha and Caroline Klivans for providing insightful comments and suggestions. The author thanks for the support and hospitality of Brown University, where part of this work was completed. The support of CNPq, FAPERJ, Projeto Arquimedes (PUC-Rio) and CAPES are appreciated.

2 Definitions

In this section, we provide the necessary background to establish Theorems 1 and 2. The presented definitions are included to make the text self-contained, a more detailed explanation is available in [14].

Domino tilings of cylinders are drawn floor by floor, as in Figure 4. Vertical dominoes, i.e. dominoes parallel to z-axis, correspond to two unit squares contained in adjacent floors. Horizontal dominoes, i.e. dominoes parallel to either the x-axis or the y-axis, are represented as planar dominoes.

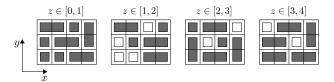

Figure 4: A domino tiling of the cylinder $[0,4] \times [0,3] \times [0,4]$.

For a fixed balanced quadriculated disk \mathcal{D} , the cylinder $\mathcal{D} \times [0, N]$ of base \mathcal{D} and height N is denoted by \mathcal{R}_N . Recall that $\mathcal{T}(\mathcal{R}_N)$ is the set of tilings of \mathcal{R}_N . For N even, we have the vertical tiling $\mathbf{t}_{\text{vert},N} \in \mathcal{T}(\mathcal{R}_N)$ formed only by vertical dominoes. The concatenation of $\mathbf{t}_1 \in \mathcal{T}(\mathcal{R}_{N_1})$ and $\mathbf{t}_2 \in \mathcal{T}(\mathcal{R}_{N_2})$ is the tiling $\mathbf{t}_1 * \mathbf{t}_2 \in \mathcal{T}(\mathcal{R}_{N_1+N_2})$ obtained from the union of \mathbf{t}_1 and the translation of \mathbf{t}_2 by $(0,0,N_1)$.

We write $\mathbf{t}_1 \approx \mathbf{t}_2$ if there exists a sequence of flips joining \mathbf{t}_1 and \mathbf{t}_2 (so, necessarily, $N_1 = N_2$). We write $\mathbf{t}_1 \sim \mathbf{t}_2$ if $N_1 \equiv N_2 \pmod{2}$ and there exist $M_1, M_2 \in 2\mathbb{N}$ such that $N_1 + M_1 = N_2 + M_2$ and $\mathbf{t}_1 * \mathbf{t}_{\text{vert},M_1} \approx \mathbf{t}_2 * \mathbf{t}_{\text{vert},M_2}$. Notice that if $\mathbf{t}_1 \not\sim \mathbf{t}_2$ then $\mathbf{t}_1 \not\approx \mathbf{t}_2$. On the other hand, for instance, it is not difficult to construct two tilings of $[0, 4]^2 \times [0, 2]$ which are equivalent under \sim but not equivalent under \approx ; see Figure 5 of [14].

A plug $p \subset \mathcal{D}$ is balanced subregion of \mathcal{D} , i.e., a union of an equal number of white and black unit squares in \mathcal{D} . In particular, a domino is a plug. We highlight the empty plug $\mathbf{p}_{\bullet} = \emptyset$ and the full plug $\mathbf{p}_{\bullet} = \mathcal{D}$. Given a plug p we obtain another plug by taking its complement $p^{-1} = \mathcal{D} \setminus p$ (throughout this paper we abuse notation and ignore boundaries). We denote by |p| the number of unit squares in p and by \mathcal{P} the set of plugs in \mathcal{D} . A plug is compatible with a domino $d \subset \mathcal{D}$ if their interiors are disjoint. The set of plugs compatible with d is denoted by \mathcal{P}_d .

Consider $N \geq 2$ and two plugs $p_0, p_N \in \mathcal{P}$. The $cork \mathcal{R}_{0,N;p_0,p_N}$ is defined as:

$$\mathcal{R}_{0,N;p_0,p_N} = (\mathcal{D} \times [1,N-1]) \cup (p_0^{-1} \times [0,1]) \cup (p_N^{-1} \times [N-1,N]).$$

For instance, $\mathcal{R}_{0,N;\mathbf{p}_{\circ},\mathbf{p}_{\circ}} = \mathcal{R}_{N}$. A floor is a triple $f = (p_{1}, f^{*}, p_{2})$, where p_{1} and p_{2} are two plugs with disjoint interiors and f^{*} is a set of planar dominoes that defines a tiling of $\mathcal{D} \setminus (p_{1} \cup p_{2})$. Notice that the inverse $f^{-1} = (p_{2}, f^{*}, p_{1})$ of a floor f is also a floor. A floor f is called vertical if $f^{*} = \emptyset$.

There is an identification between tilings of corks (in particular, cylinders) and sequences of floors. Indeed, as in Figure 4, tilings are essentially drawn by exhibiting their corresponding sequences of floors. Therefore, a tiling $\mathbf{t} \in \mathcal{T}(\mathcal{R}_{0,N;p_1,p_2})$ can be described as a concatenation of floors: $\mathbf{t} = f_1 * f_2 * \dots * f_N$. Similarly, a tiling can be described as a concatenation of tilings of corks and floors.

An important fact is that pairs of vertical floors can be moved through flips. For instance, consider a tiling $\mathbf{t} = \mathbf{t}_1 * \mathbf{t}_2$ with $\mathbf{t}_1 \in \mathcal{T}(\mathcal{R}_{0,N_1;\mathbf{p}_0,p_1})$ and $\mathbf{t}_2 \in \mathcal{T}(\mathcal{R}_{0,N_2;p_1,\mathbf{p}_0})$. It turns out that $\mathbf{t} * \mathbf{t}_{\text{vert},2} \approx \mathbf{t}_1 * \mathbf{t}_{\text{vert},p_1} * \mathbf{t}_2$, where $\mathbf{t}_{\text{vert},p_1}$ is the tiling of $\mathcal{R}_{0,2;p_1,p_1}$ formed only by vertical dominoes (see Lemma 5.2 of [14]). Therefore, the relation \sim allows the addition of an arbitrary even number of vertical floors between two floors of a tiling.

Consider a tiling $\mathbf{t} \in \mathcal{T}(\mathcal{R}_{0,N;p_1,p_2})$. The inverse of \mathbf{t} is the tiling $\mathbf{t}^{-1} \in \mathcal{T}(\mathcal{R}_{0,N;p_2,p_1})$ obtained by reflecting \mathbf{t} on the xy plane. In the language of floors, if $\mathbf{t} = f_1 * f_2 * \ldots * f_N$ then $\mathbf{t}^{-1} = f_N^{-1} * f_{N-1}^{-1} * \ldots * f_1^{-1}$. It follows from Lemma 4.2 of [14] that $\mathbf{t} * \mathbf{t}^{-1} \sim \mathbf{t}_{\text{vert},p_1}$.

We now recall the definition of the domino group $G_{\mathcal{D}}$ of a disk \mathcal{D} . As a set, the domino group is the quotient of $\bigcup_{N\geq 1} \mathcal{T}(\mathcal{R}_N)$ by the equivalence relation \sim . We do the usual abuse of notation and instead of thinking about equivalence classes we denote an element of $G_{\mathcal{D}}$ by \mathbf{t} . The operation in $G_{\mathcal{D}}$ is given by the concatenation. The identity element is $\mathbf{t}_{\text{vert},2}$ and the inverse of a tiling \mathbf{t} is the tiling \mathbf{t}^{-1} . The even domino group $G_{\mathcal{D}}^+$ is the subgroup of $G_{\mathcal{D}}$ defined by the tilings of even height. Therefore, $G_{\mathcal{D}}^+$ is a normal subgroup of index two of $G_{\mathcal{D}}$. In general, $G_{\mathcal{D}}^+$ encapsulates all the information of $G_{\mathcal{D}}$; the existence of a tiling of $\mathcal{D} \times [0, 1]$ implies that $G_{\mathcal{D}}$ is a semidirect product of $G_{\mathcal{D}}^+$ and $\mathbb{Z}/(2)$.

The rest of this section is dedicated to the study of the domino group. First, we define two large classes of disks. Secondly, for a disk \mathcal{D} in these classes we construct a special family of tilings that generates the even domino group $G_{\mathcal{D}}^+$.

Let \mathcal{D} be a disk. A path of length k is a sequence $\gamma = (s_1, s_2, \ldots, s_k)$ of distinct unit squares in \mathcal{D} such that s_i and s_{i+1} are adjacent for all i. We say that γ is a cycle if the initial and final squares s_1 and s_k are also adjacent. A hamiltonian path (resp. hamiltonian cycle) is a path (resp. cycle) of length $|\mathcal{D}|$. A disk \mathcal{D} is called path-hamiltonian (resp. hamiltonian) if it has a hamiltonian path (resp. cycle). Figure 5 shows examples of hamiltonian cycles and paths, their orientation and initial square are indicated by an arrow.

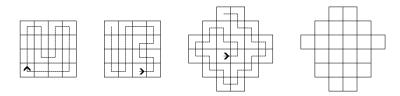

Figure 5: The first and the second example show a hamiltonian cycle and a hamiltonian path in $[0,4]^2$. The third disk is path-hamiltonian but not hamiltonian. The fourth disk is neither path-hamiltonian nor hamiltonian.

From now on, until the end of this section, consider a fixed disk \mathcal{D} with a hamiltonian path $\gamma = (s_1, s_2, \ldots, s_{|\mathcal{D}|})$. We proceed towards the construction of a family of tilings that generates the even domino group $G_{\mathcal{D}}^+$. We first need the concept of whether a domino respects γ . A two-dimensional domino $d \subset \mathcal{D}$ respects γ if, for some i, it is equal the union of s_i and s_{i+1} . A three-dimensional domino $d \subset \mathcal{R}_N$ respects γ if its projection on \mathcal{D} is either a unit square or a planar domino that respects γ . In view of Fact 2.1, it will be important to consider planar dominoes in \mathcal{D} that do not respect γ ; the set of such dominoes is denoted by \mathcal{D}_{γ} .

Fact 2.1 (Lemma 8.1 of [14]). Let \mathcal{D} be a disk with a hamiltonian path $\gamma = (s_1, \dots, s_{|\mathcal{D}|})$. If $\mathbf{t} \in \mathcal{T}(\mathcal{R}_{0,2N;p,p})$ is a tiling whose dominoes respect γ then $\mathbf{t} \sim \mathbf{t}_{vert,p}$.

We construct, for each plug $p \in \mathcal{P}$, a tiling $\mathbf{t}_p \in \mathcal{T}(\mathcal{R}_{0,|p|;p,\mathbf{p}_o})$ whose dominoes respect γ ; by convention $\mathbf{t}_{\mathbf{p}_o} = \emptyset$. It suffices to describe the horizontal dominoes contained in each floor of \mathbf{t}_p . The construction is by induction on |p|. Consider two unit squares of opposite colors $s_i, s_j \subset p$ with i < j and j - i is minimal. The horizontal dominoes of the first floor are obtained by placing dominoes along $(s_{i+1}, s_{i+2}, \ldots, s_{j-1})$, more precisely, $s_{i+1} \cup s_{i+2}$, $s_{i+3} \cup s_{i+4}, \ldots, s_{j-2} \cup s_{j-1}$. Similarly, the horizontal dominoes of the second floor are obtained by placing dominoes along $(s_i, s_{i+1}, \ldots, s_j)$. The concatenation of these two floors with $\mathbf{t}_{p \setminus (s_i \cup s_j)}$ defines \mathbf{t}_p ; for instance, see Figure 6. We remark that different choices of unit squares at minimal distance yield distinct tilings, which are connected through flips.

Figure 6: A disk with a hamiltonian path, a plug p and the tiling \mathbf{t}_p .

Consider a floor $f = (p_1, f^*, p_2)$. Let $f_{\text{vert}} = (p_2, \emptyset, p_2^{-1})$ be a vertical floor. Then, set $\mathbf{t}_f = \mathbf{t}_{p_1}^{-1} * f * f_{\text{vert}} * \mathbf{t}_{p_2^{-1}} \in \mathcal{T}(\mathcal{R}_N)$ where $N = |p_1| + |p_2^{-1}| + 2$. Notice that dominoes in \mathbf{t}_f that do not respect γ must be in the floor f.

Fact 2.2 (Lemma 8.2 of [14]). Let \mathcal{D} be a disk with a hamiltonian path γ . Consider N even and a tiling $\mathbf{t} \in \mathcal{T}(\mathcal{R}_N)$ with floors f_1, f_2, \ldots, f_N , so that $\mathbf{t} = f_1 * f_2 * \ldots * f_N$. Then,

$$\mathbf{t} \sim \mathbf{t}_{f_1} * \mathbf{t}_{f_2^{-1}}^{-1} * \ldots * \mathbf{t}_{f_i^{(-1)(i+1)}}^{(-1)^{(i+1)}} * \ldots * \mathbf{t}_{f_N^{-1}}^{-1}.$$

Remark 2.3. We notice that in [14] there is a typo in the result above and the -1 indices on the floors of even parity are missing.

We now consider a particular case of the construction above. Consider a domino $d \subset \mathcal{D}$ with a compatible plug $p \in \mathcal{P}_d$. Let $f = (p, d, (p \cup d)^{-1})$ be a floor and set $\mathbf{t}_{d,p;\gamma} = \mathbf{t}_f$; when the context is clear we write $\mathbf{t}_{d,p}$ instead of $\mathbf{t}_{d,p;\gamma}$. If $d \notin \mathcal{D}_{\gamma}$ then Fact 2.1 implies that $\mathbf{t}_{d,p} \sim \mathbf{t}_{\text{vert}}$. However, if $d \in \mathcal{D}_{\gamma}$ then $d \times [|p|, |p| + 1]$ is the only domino in $\mathbf{t}_{d,p}$ that does not respect. For instance, see Figure 7 below.

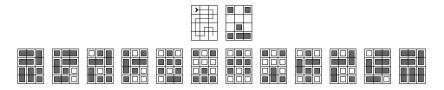

Figure 7: The first row shows the disk $\mathcal{D} = [0,3] \times [0,4]$ with a hamiltonian path γ , and a domino d with a compatible plug p. The second row shows $\mathbf{t}_{d,p;\gamma} = \mathbf{t}_p^{-1} * f * f_{\text{vert}} * \mathbf{t}_{p \cup d}$.

Fact 2.4 (Lemma 8.3 of [14]). Let \mathcal{D} be a disk with a hamiltonian path γ . Consider a floor $f = (p, f^*, \tilde{p})$. Suppose that $f^* = \{d_1, d_2, \dots, d_k\}$. Let $p_1 = p$ and $p_{i+1} = p_i \cup d_i$. Then,

$$\mathbf{t}_f \sim \mathbf{t}_{d_1,p_1} * \ldots * \mathbf{t}_{d_i,p_i} * \ldots * \mathbf{t}_{d_k,p_k}$$

Facts 2.2 and 2.4 imply that the even domino group $G_{\mathcal{D}}^+$ is generated by the set of tilings of the form $\mathbf{t}_{d,p}$. It is possible to reduce this family of generators through the flux between a domino and a plug, which we now define. In order to define the flux, it is important to distinguish whether a unit square is black or white. To facilitate this distinction, we utilize the cycle γ . For a unit square s_i define $\operatorname{color}(s_i) = (-1)^i$; then, s_i is identified as white if $\operatorname{color}(s_i) = +1$ and as black if $\operatorname{color}(s_i) = -1$.

Consider a domino $d \in \mathcal{D}_{\gamma}$, so that $d = s_k \cup s_l$ with l-k > 1. The domino d decomposes the region $\mathcal{D} \setminus d$ into three subregions:

$$\mathcal{D}_{d,-1} = \bigcup_{i=1}^{k-1} s_i, \qquad \mathcal{D}_{d,0} = \bigcup_{i=k+1}^{l-1} s_i, \qquad \mathcal{D}_{d,+1} = \bigcup_{i=l+1}^{|\mathcal{D}|} s_i.$$

Clearly, each region $\mathcal{D}_{d,j}$ comes with a hamiltonian path $\gamma_{d,j}$. The regions $\mathcal{D}_{d,-1}$ and $\mathcal{D}_{d,+1}$ are not necessarily balanced and nonempty. However, $\mathcal{D}_{d,0}$ is always balanced and nonempty, as $(s_k, s_{k+1}, \ldots, s_l)$ is a cycle. The union of $\mathcal{D}_{d,-1}$ and $\mathcal{D}_{d,+1}$ is denoted by $\mathcal{D}_{d,\pm 1}$.

For $p \in \mathcal{P}_d$, we define a triple $\operatorname{flux}(d,p) = (\operatorname{flux}_{-1}(d,p), \operatorname{flux}_0(d,p), \operatorname{flux}_{+1}(d,p)) \in \mathbb{Z}^3$. The coordinate $\operatorname{flux}_j(d,p)$ is computed by summing $\operatorname{color}(s_i) = (-1)^i$ for each unit square s_i in $p \cap \mathcal{D}_{d,j}$. Notice that $\operatorname{flux}_{-1}(d,p) + \operatorname{flux}_0(d,p) + \operatorname{flux}_{+1}(d,p) = 0$, as p is a balanced subregion of \mathcal{D} . It turns out that if $p_1, p_2 \in \mathcal{P}_d$ and $\operatorname{flux}(d,p_1) = \operatorname{flux}(d,p_2)$ then $\mathbf{t}_{d,p_1} \sim \mathbf{t}_{d,p_2}$ (see Lemma 8.4 of [14]). We then have the following fact.

Fact 2.5 (Corollary 8.6 of [14]). Consider a disk \mathcal{D} with a hamiltonian path γ . For each domino $d \in \mathcal{D}_{\gamma}$, let Φ_d be the set of the possible triples flux (d, \cdot) . For each $\phi \in \Phi_d$, consider a plug $p_{d,\phi} \in \mathcal{P}_d$ such that flux $(d, p_{d,\phi}) = \phi$. The even domino group $G_{\mathcal{D}}^+$ is generated by the family of tilings $(\mathbf{t}_{d,p_{d,\phi}})$.

3 Hamiltonian disks

In this section, we highlight some advantages of utilizing hamiltonian disks and establish two technical lemmas. The following lemma demonstrates that the relative position between two dominoes that do not respect a cycle must satisfy certain properties.

Lemma 3.1. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, s_2, \ldots, s_{|\mathcal{D}|})$. Consider two dominoes $\tilde{d} = s_i \cup s_j$ and $d = s_k \cup s_l$ that do not respect γ . Suppose that $l - k \geq 5$. If i < k < j < l (resp. k < j < l < i) then $\max\{k-i, l-j\} \geq 3$ (resp. $\max\{j-k, i-l\} \geq 3$).

Proof. Let i < k < j < l, the other case is similar. Suppose, for a contradiction, that k-i < 3 and l-j < 3. Since $|\mathcal{D}_{\tilde{d},0}|$ is even and positive, j-i is an odd number; analogously, l-k is odd. Thus, either k-i=1=l-j or k-i=2=l-j. In the first case, (s_i, s_k, s_l, s_j) defines a cycle of length four and therefore corresponds to a 2×2 square in \mathcal{D} . In the second case, $(s_k, s_{i+1}, s_i, s_j, s_{j+1}, s_l)$ defines a cycle of length six and therefore corresponds to a 3×2 rectangle in \mathcal{D} . Then, γ essentially follows one of the four patterns shown in Figure 8.

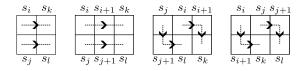

Figure 8: Four possible configurations of γ .

However, in any of these four possibilities we have a contradiction with the fact that s_1 and $s_{|\mathcal{D}|}$ are adjacent. Indeed, in the first three cases the cycle (s_i, \ldots, s_j) defines two regions in \mathcal{D} that separates s_1 and $s_{|\mathcal{D}|}$. The fourth case follows by the same argument once we observe that s_j and s_k are not adjacent, as $l - k \geq 5$.

Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, s_2, \ldots, s_{|\mathcal{D}|})$. By relabeling unit squares, we can choose any unit square in \mathcal{D} to be the initial square of γ . We will have need that a hamiltonian cycle starts at a corner, i.e., a unit square that is adjacent to only other two unit squares. Let s_{SW} be the southwesternmost unit square in \mathcal{D} , i.e.,

$$s_{SW} = [a, a+1] \times [b, b+1], \text{ where}$$

 $b = \min\{y \in \mathbb{Z} : (x, y) \in \mathcal{D} \text{ for some } x \in \mathbb{Z}\} \text{ and } a = \min\{x \in \mathbb{Z} : (x, b) \in \mathcal{D}\}$

Notice that s_{SW} is a corner of \mathcal{D} . Moreover, if s is a unit square adjacent to s_{SW} then $\mathcal{D} \setminus (s \cup s_{SW})$ is a path-hamiltonian disk.

A hamiltonian cycle corresponds to a simple closed curve in \mathbb{R}^2 that passes through the center of every unit square in \mathcal{D} , as in Figure 5. Therefore, γ divides the plane into two connected components, one of the components is bounded and the other is unbounded. The bounded connected component is called the *interior* of γ , the unbounded component is called the *exterior* of γ . We say that a domino $d = s_k \cup s_l$ is contained in the interior (resp. exterior) of γ if the line segment between the centers of s_k and s_l intersects the interior (resp. exterior) of γ ; for instance, see Figure 9. Notice that, except by $s_1 \cup s_{|\mathcal{D}|}$, every domino that does not respect γ is contained in either the interior or the exterior of γ . This fact help us to prove the following result.

Figure 9: The first (resp. second) example shows dominous contained in the interior (resp. exterior) of a cycle γ .

Lemma 3.2. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. Consider two distinct dominoes $d, \tilde{d} \in \mathcal{D}_{\gamma}$. There exist dominoes d_1, d_2, \ldots, d_n with $d_1 = \tilde{d}$ and $d_n = d$ such that, for each $i \in \{1, 2, \ldots, n-1\}$, one of the following holds:

- 1. d_{i+1} is the union of a unit square in $\mathcal{D}_{d_i,0}$ and a unit square in $\mathcal{D}_{d_i,\pm 1}$.
- 2. $d_{i+1} \subset \mathcal{D}_{d_i,0}$ and $\mathcal{D}_{d_i,0} \setminus \mathcal{D}_{d_{i+1},0}$ is a disk.
- 3. $d_{i+1} \subset \mathcal{D}_{d_i,\pm 1}$ and $\mathcal{D}_{d_i,\pm 1} \setminus \mathcal{D}_{d_{i+1},\pm 1}$ is a disk.

Proof. Throughout the proof, we say that two dominoes $\bar{d}_1, \bar{d}_2 \in \mathcal{D}_{\gamma}$ form a good pair if the result holds for $d = \bar{d}_1$ and $\tilde{d} = \bar{d}_2$. We need to show that any two dominoes that do

not respect γ form a good pair. The proof is by induction on $|\mathcal{D}|$, with the base case being when $|\mathcal{D}| = 4$. In this case, \mathcal{D} is a 2×2 square and the result follows trivially.

In order to prove the induction step, we first consider the case in which there exists a domino \hat{d} that disconnects \mathcal{D} ; clearly $\hat{d} \in \mathcal{D}_{\gamma}$. By possibly changing the orientation of γ $(s_1 = s_{SW} \text{ still holds})$ we may assume that \hat{d} and $s_1 \cup s_{|\mathcal{D}|}$ are disjoint. Notice that \hat{d} defines two other disks $\mathcal{D}_1 = \mathcal{D} \setminus \mathcal{D}_{\hat{d},0}$ and $\mathcal{D}_2 = \mathcal{D} \setminus \mathcal{D}_{\hat{d},\pm 1}$ such that $\mathcal{D} = \mathcal{D}_1 \cup \mathcal{D}_2$ and $\mathcal{D}_1 \cap \mathcal{D}_2 = \hat{d}$; for instance, see Figure 10. The cycle γ induces hamiltonian cycles γ_1 in \mathcal{D}_1 and γ_2 in \mathcal{D}_2 ; the union of the initial and final squares of γ_1 and γ_2 constitute $s_1 \cup s_{|\mathcal{D}|}$ and \hat{d} , respectively. Hence, by the induction hypothesis, it suffices to show that $s_1 \cup s_{|\mathcal{D}|}$ and \hat{d} form a good pair. On the other hand, since \hat{d} is disjoint from $s_1 \cup s_{|\mathcal{D}|}$, we have that $\mathcal{D}_{s_1 \cup s_{|\mathcal{D}|},0} \setminus \mathcal{D}_{\hat{d},0} = \mathcal{D}_1 \setminus (s_1 \cup s_{|\mathcal{D}|})$ is a disk.

Figure 10: A hamiltonian disk \mathcal{D} with a domino \hat{d} that disconnects \mathcal{D} and the induced hamiltonian disks $\mathcal{D} \setminus \mathcal{D}_{\hat{d},0}$ and $\mathcal{D} \setminus \mathcal{D}_{\hat{d},\pm 1}$.

Now, suppose there exists no domino that disconnects \mathcal{D} . Therefore, every domino $\hat{d} \in \mathcal{D}_{\gamma} \setminus \{s_1 \cup s_{|\mathcal{D}|}\}$ forms a good pair with a domino \bar{d} composed of a unit square in $\mathcal{D}_{\hat{d},0}$ and a unit square in $\mathcal{D}_{\hat{d},\pm 1}$. Notice that if \hat{d} is contained in the interior of γ then \bar{d} is contained in the exterior of γ . By possibly altering the orientation of γ , as in the previous paragraph, it is not difficult to see that the 2×2 square that contains $s_1 = s_{SW}$ also contains a domino that forms a good pair with $s_1 \cup s_{|\mathcal{D}|}$. Thus, the result follows once we prove that any two dominoes in the exterior of γ form a good pair.

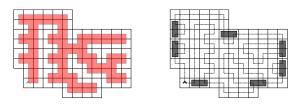

Figure 11: A disk \mathcal{D} with the interior of a hamiltonian cycle shown in red, and the dominoes in $\partial \mathcal{D}$ that are distinct from $s_1 \cup s_{|\mathcal{D}|}$ and do not respect γ .

Let $\partial \mathcal{D} \subset \mathcal{D}$ be the union of the unit squares not contained in the topological interior of \mathcal{D} . Let d^1, d^2, \ldots, d^j be the dominoes in $\partial \mathcal{D}$ that are distinct from $s_1 \cup s_{|\mathcal{D}|}$ and do not respect γ ; see Figure 11. Clearly, these dominoes are contained in the exterior of γ . Notice that every domino in the exterior of γ is contained in the pairwise disjoint union

 $\bigcup_{m=1}^{J} \mathcal{D}_{d^m,0} \cup d^m.$ Since γ induces a hamiltonian cycle in $\mathcal{D}_{d^m,0} \cup d^m$, it follows from the the induction hypothesis that d^m form a good pair with every domino in $\mathcal{D}_{d^m,0}$ that does not respect γ . We are left to show that d^r and d^s form a good pair for any $r, s \in \{1, 2, \ldots, j\}$.

The fact that there is no domino that disconnects \mathcal{D} implies that every non-corner unit square in $\partial \mathcal{D}$ is adjacent to a unit square not in $\partial \mathcal{D}$, so that the region $\mathcal{D} \setminus \partial \mathcal{D}$ is connected. Therefore, by possibly relabeling the dominoes d^1, d^2, \ldots, d^j , we may assume that for each m we have a unit square in $\mathcal{D}_{d^{m+1},0}$ adjacent to a unit square in $\mathcal{D}_{d^m,0} \subset \mathcal{D}_{d^{m+1},\pm 1}$. Hence, d^m and d^{m+1} form a good pair.

4 Regularity of disks

In this section, we prove Theorems 1 and 2. We demonstrate that if a disk \mathcal{D} with a hamiltonian cycle γ satisfies the conditions of these theorems then even domino group $G_{\mathcal{D}}^+$ is cyclic. To this end, we reduce the family of generators of $G_{\mathcal{D}}^+$, defined in Section 2, to only one element. Recall that this family is composed of tilings $\mathbf{t}_{d,p}$ where d is a domino that does not respect γ and p is a plug compatible with d. The next two results provide an initial reduction of this family of generators. Indeed, Lemmas 4.1 and 4.2 imply that, instead of considering all possible triples flux (d, \cdot) , it suffices to consider all possible nonzero integers flux (d, \cdot) .

Lemma 4.1. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. Consider a domino $d \in \mathcal{D}_{\gamma}$ and a plug $p \in \mathcal{P}_d$. If $\text{flux}_0(d, p) = 0$ then $\mathbf{t}_{d,p} \sim \mathbf{t}_{vert}$.

Proof. Suppose that $p \cap \mathcal{D}_{d,0} = \emptyset$; otherwise, consider $\tilde{p} = p \cap \mathcal{D}_{d,\pm 1}$ so that flux $(d,p) = \text{flux}(d,\tilde{p})$ and therefore $\mathbf{t}_{d,p} \sim \mathbf{t}_{d,\tilde{p}}$. Then, the tiling $\mathbf{t}_{d,p}$ covers the region $\mathcal{D}_{d,0} \times [|p|,|p|+2]$ solely with vertical dominoes. Let \mathbf{t}_1 be the tiling obtained from $\mathbf{t}_{d,p}$ by performing vertical flips along $\gamma_{d,0}$ so that the restriction of \mathbf{t}_1 to $(\mathcal{D}_{d,0} \cup d) \times [|p|,|p|+1]$ is occupied only by horizontal dominoes. Notice that $\mathcal{D}_{d,0} \cup d$ is a disk. Indeed $\mathcal{D}_{d,0} \cup d$ does not enclose a unit square, as $\mathcal{D}_{d,0} \cup d$ is defined by the cycle $(s_k, s_{k+1}, \ldots, s_l)$ and neither s_1 nor $s_{|\mathcal{D}|}$ is contained in the interior of \mathcal{D} . Since the space of tilings of a disk is connected under flips, there exists a sequence of horizontal flips that takes \mathbf{t}_1 to the tiling \mathbf{t}_2 whose restriction to $(\mathcal{D}_{d,0} \cup d) \times [|p|,|p|+1]$ corresponds to the tiling induced by $(s_k, s_{k+1}, \ldots, s_l)$. Thus, $\mathbf{t}_{d,p} \approx \mathbf{t}_1 \approx \mathbf{t}_2$ and every domino in \mathbf{t}_2 respects γ ; for instance, Figure 12 shows these sequence of flips for a specific hamiltonian disk. It follows from Fact 2.1 that $\mathbf{t}_2 \approx \mathbf{t}_{\text{vert}}$. \square

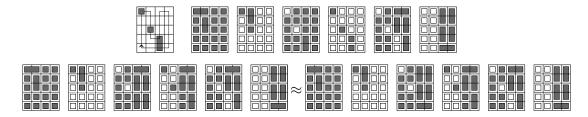

Figure 12: The first row shows a hamiltonian disk with a domino d and a compatible plug p, and the tiling $\mathbf{t}_{d,p}$. The second row shows tilings \mathbf{t}_1 and \mathbf{t}_2 such that $\mathbf{t}_{d,p} \approx \mathbf{t}_1 \approx \mathbf{t}_2$.

Lemma 4.2. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. Consider a domino $d \in \mathcal{D}_{\gamma}$ and $p_1, p_2 \in \mathcal{P}_d$. If $\text{flux}_0(d, p_1) = \text{flux}_0(d, p_2)$ then $\mathbf{t}_{d,p_1} \sim \mathbf{t}_{d,p_2}$.

Proof. Suppose that $d = s_k \cup s_l$ with k < l; notice that $l - k \ge 3$. Consider the hamiltonian cycle $\tilde{\gamma} = (s_{k+1}, s_k, \dots, s_1, s_{|\mathcal{D}|}, s_{|\mathcal{D}|-1}, \dots, s_{k+2})$ obtained by changing the initial square of γ ; for instance, see Figure 13.

Figure 13: A disk with a hamiltonian cycle γ , a domino d and the cycle $\tilde{\gamma}$ obtained from γ .

We claim that if p is a plug compatible with d then $\mathbf{t}_{d,p;\gamma} \sim \mathbf{t}_{d,p;\tilde{\gamma}}$. Notice that a domino in $\mathbf{t}_{d,p;\tilde{\gamma}}$ which does not respect γ and does not project on d is of the form $d_1 \times [N-1,N]$ with $d_1 = s_1 \cup s_{|\mathcal{D}|}$. Then, $\mathbf{t}_{d,p;\tilde{\gamma}}$ is \sim - equivalent to a concatenation of $\mathbf{t}_{d,p;\gamma}$ and possibly tilings $\mathbf{t}_{d_1,\hat{p};\gamma}$. However, for any plug \hat{p} compatible with d_1 , we have flux $(d_1,\hat{p};\gamma) = (0,0,0)$. Thus, by Lemma 4.1, $\mathbf{t}_{d_1,\hat{p};\gamma} \sim \mathbf{t}_{\text{vert}}$. Therefore, $\mathbf{t}_{d,p;\tilde{\gamma}} \sim \mathbf{t}_{d,p;\tilde{\gamma}}$.

Let $\hat{p_1}$ be the plug formed by the union of the unit squares in $p_2 \cap \mathcal{D}_{d,0;\gamma}$ and $p_1 \cap \mathcal{D}_{d,\pm 1;\gamma}$. Notice that $\text{flux}(d,\hat{p_1};\gamma) = \text{flux}(d,p_1;\gamma)$ and $\text{flux}(d,\hat{p_1};\tilde{\gamma}) = \text{flux}(d,p_2;\tilde{\gamma})$. Therefore, $\mathbf{t}_{d,p_1;\gamma} \sim \mathbf{t}_{d,\hat{p_1};\tilde{\gamma}} \sim \mathbf{t}_{d,p_2;\tilde{\gamma}} \sim \mathbf{t}_{d,p_2;\tilde{\gamma}}$.

We now deal with tilings that have large flux, more specifically, tilings $\mathbf{t}_{d,p}$ such that $|\operatorname{flux}_0(d,p)| \geq 2$. In Lemma 4.3, we show that in some cases such tilings can be decomposed as a concatenation of tilings with smaller flux. As a consequence, it follows that the even domino group of a bottleneck-free disk is generated by tilings with $|\operatorname{flux}_0(\cdot,\cdot)| = 1$.

Lemma 4.3. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. Consider a domino $d \in \mathcal{D}_{\gamma}$ such that $\mathcal{D} \setminus d$ is connected. Let p be a plug compatible with d such that $|\operatorname{flux}_0(d,p)| \geq 2$. Then, there exist plugs $p_0, p_1, p_2 \in \mathcal{P}$ and a domino $\tilde{d} \in \mathcal{D}_{\gamma}$ that does not disconnect \mathcal{D} such that:

- 1. $\mathbf{t}_{d,p} \sim \mathbf{t}_{\tilde{d},p_1}^{\epsilon_1} * \mathbf{t}_{d,p_0} * \mathbf{t}_{\tilde{d},p_2}^{\epsilon_2}$ for some $\epsilon_1, \epsilon_2 \in \{-1,1\}$.
- 2. $\max\{|\operatorname{flux}_0(\tilde{d}, p_1)|, |\operatorname{flux}_0(d, p_0)|, |\operatorname{flux}_0(\tilde{d}, p_2)|\} < |\operatorname{flux}_0(d, p)|.$

Proof. Since $\mathcal{D} \setminus d$ is connected, there exist $s_i \in \mathcal{D}_{d,\pm 1}$ and $s_j \in \mathcal{D}_{d,0}$ such that $\tilde{d} = s_i \cup s_j$ is a domino. Notice that $\mathcal{D} \setminus \tilde{d}$ is connected. Suppose that $s_i \in \mathcal{D}_{d,-1}$, the other case is similar. We have $s_i \neq s_1$, as s_1 is a corner. First, consider the case $\operatorname{color}(s_j) = \operatorname{sign}(\operatorname{flux}_0(d,p))$.

Let $d = s_k \cup s_l$ with k < l. It follows from Lemma 3.1 that $\max\{k - i, l - j\} \ge 3$, as $|\operatorname{flux}_0(d, p)| \ge 2$. Then, by Lemma 4.2, we may assume that p satisfies the conditions:

- (i) $s_i \cup s_j \subset p$ and $p \cap \mathcal{D}_{d,0}$ (resp. $p \cap \mathcal{D}_{d,\pm 1}$) contains only unit squares of the same color of s_j (resp. s_i).
- (ii) If $\operatorname{color}(s_k) = \operatorname{color}(s_j)$ and $l j \ge 3$ (resp. $k i \ge 3$) then p contains a unit square in $\{s_{j+1}, s_{j+2}, \dots, s_{l-1}\}$ (resp. $\{s_{i+1}, s_{i+2}, \dots, s_{k-1}\}$).
- (iii) If $\operatorname{color}(s_k) \neq \operatorname{color}(s_j)$ and i > 2 then p contains a unit square in $\{s_1, s_2, \ldots, s_{i-1}\}$.
- (iv) If $\operatorname{color}(s_k) \neq \operatorname{color}(s_i)$ and i = 2 (therefore $s_l \neq s_{|\mathcal{D}|}$) then p contains $s_{|\mathcal{D}|}$.

Let $\hat{p} = p \cup d$ be a plug. By construction,

$$\mathbf{t}_{d,p} \sim \mathbf{t}_p^{-1} * (p,\emptyset,p^{-1}) * (p^{-1},\emptyset,p) * f * f_{\mathrm{vert}} * (\hat{p},\emptyset,\hat{p}^{-1}) * (\hat{p}^{-1},\emptyset,\hat{p}) * \mathbf{t}_{\hat{p}}$$

where $f = (p, d, \hat{p}^{-1})$ and $f_{\text{vert}} = (\hat{p}^{-1}, \emptyset, \hat{p})$. Thus, $\mathbf{t}_{d,p}$ contains four vertical dominoes in $\tilde{d} \times [|p|+1, |p|+5]$. Perform three flips (Figure 14 shows these flips for a specific hamiltonian disk) to conclude that

$$\mathbf{t}_{d,p} \sim \ldots * (p^{-1}, \tilde{d}, p \smallsetminus \tilde{d}) * (p \smallsetminus \tilde{d}, d, (\hat{p} \smallsetminus \tilde{d})^{-1}) * ((\hat{p} \smallsetminus \tilde{d})^{-1}, \emptyset, \hat{p} \smallsetminus \tilde{d}) * ((\hat{p} \smallsetminus \tilde{d}, \tilde{d}, (\hat{p} \smallsetminus \tilde{d})^{-1}) * \ldots$$

Then, it follows from Fact 2.2 that $\mathbf{t}_{d,p} \sim \mathbf{t}_{\tilde{d},p \smallsetminus \tilde{d}}^{-1} * \mathbf{t}_{d,p \smallsetminus \tilde{d}} * \mathbf{t}_{\tilde{d},\hat{p} \smallsetminus \tilde{d}}$.

Figure 14: A domino d and a plug p in a hamiltonian disk, and the effect of thee flips in the tiling described by $(p^{-1}, \emptyset, p) * f * f_{\text{vert}} * (p \cup d, \emptyset, (p \cup d)^{-1})$.

A careful analysis shows that if the plug p satisfies the four conditions above then $\max\{|\operatorname{flux}_0(d,p \setminus \tilde{d})|, |\operatorname{flux}_0(\tilde{d},\hat{p} \setminus \tilde{d})|, |\operatorname{flux}_0(\tilde{d},p \setminus \tilde{d})|\} < |\operatorname{flux}_0(d,p)|.$ We are left with the case $\operatorname{color}(s_j) \neq \operatorname{sign}(\operatorname{flux}_0(d,p))$. In this case, we derive similar conditions that p must satisfy, so that $s_i \cup s_j \subset p^{-1}$ and $\mathbf{t}_{d,p} \sim \mathbf{t}_{\tilde{d},p} * \mathbf{t}_{d,p \cup \tilde{d}} * \mathbf{t}_{\tilde{d},p \cup d}^{-1}$. Analogously, we then have $\max\{|\operatorname{flux}_0(d,p \cup \tilde{d})|, |\operatorname{flux}_0(\tilde{d},p \cup d)|, |\operatorname{flux}_0(\tilde{d},p)|\} < |\operatorname{flux}_0(d,p)|.$

Henceforth, we restrict our attention to tilings $\mathbf{t}_{d,p}$ such that $|\operatorname{flux}_0(d,p)| = 1$. The goal is to show that given two such tilings $\mathbf{t}_{d,p}$ and $\mathbf{t}_{\tilde{d},\tilde{p}}$ we have $\mathbf{t}_{d,p} \sim \mathbf{t}_{\tilde{d},\tilde{p}}^{\pm 1}$. We first show a partial result in this direction.

Lemma 4.4. Let \mathcal{D} be a disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. Consider a domino $\tilde{d} \in \mathcal{D}_{\gamma}$ and a plug $\tilde{p} \in \mathcal{P}_d$ such that $|\operatorname{flux}_0(\tilde{d}, \tilde{p})| = 1$. Then, for each $d \in \mathcal{D}_{\gamma}$ there exists $p \in \mathcal{P}_d$ such that $|\operatorname{flux}_0(d, p)| = 1$ and $\mathbf{t}_{d,p}^{\pm 1} \sim \mathbf{t}_{\tilde{d},\tilde{p}}$.

Proof. Take dominoes d_1, d_2, \ldots, d_n as in Lemma 3.2. Then, $d_1 = \tilde{d}$, $d_n = d$ and there are three possibilities for the relative position of d_i and d_{i+1} . We claim that there exist plugs $p_1, p_2, \ldots, p_n \in \mathcal{P}$ such that $p_1 = \tilde{p}$, $|\operatorname{flux}_0(d_{i+1}, p_{i+1})| = |\operatorname{flux}_0(d_i, p_i)|$ and $\mathbf{t}_{d_{i+1}, p_{i+1}} \sim \mathbf{t}_{d_i, p_i}^{\pm 1}$. Notice that the claim implies the desired result.

From now on, we use Lemma 4.2 repeatedly without further mention. In order to prove the claim, we analyze the possible relative positions of d_i and d_{i+1} . First, suppose that $d_{i+1} = s_k \cup s_l$ with $s_k \subset \mathcal{D}_{d_i,0}$ and $s_l \subset \mathcal{D}_{d_i,\pm 1}$. Since $|\operatorname{flux}_0(d_i, p_i)| = 1$, we may assume that either $p_i = d_{i+1}$ or $p_i^{-1} = d_i \cup d_{i+1}$. Now, as in the proof of Lemma 4.3, if $p_i = d_{i+1}$ then $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},\mathbf{p}_{\circ}}^{-1} * \mathbf{t}_{d_{i+1},d_i}$ and therefore, by Lemma 4.1, $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},d_i}$. Similarly, if $p_i^{-1} = d_i \cup d_{i+1}$ then $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},\mathbf{p}_{\circ} \setminus (d_i \cup d_{i+1})} * \mathbf{t}_{d_i,\mathbf{p}_{\circ} \setminus d_i} * \mathbf{t}_{d_{i+1},\mathbf{p}_{\circ} \setminus d_{i+1}}^{-1}$ and consequently $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},\mathbf{p}_{\circ} \setminus (d_i \cup d_{i+1})}$. In both cases we obtain a plug p_{i+1} such that $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},p_{i+1}}$ and $|\operatorname{flux}_0(d_{i+1},p_{i+1})| = |\operatorname{flux}_0(d_i,p_i)|$.

Secondly, suppose that $d_{i+1} = s_k \cup s_l$ with $s_k, s_l \subset \mathcal{D}_{d_i,0}$ and that $\mathcal{D}_{d_i,0} \setminus \mathcal{D}_{d_{i+1},0}$ is a disk. Then, $\mathcal{D}_i = (\mathcal{D}_{d_i,0} \cup d_i) \setminus \mathcal{D}_{d_{i+1},0}$ is also a disk and has a hamiltonian cycle γ_i induced by γ . Let $\gamma_{i,1}$ and $\gamma_{i,2}$ be the paths obtained from γ_i by disconnecting the adjacent unit squares in d_i and d_{i+1} . There are two cases: $|\gamma_{i,1}|$ and $|\gamma_{i,2}|$ are both either even or odd.

We obtain tilings $\mathbf{t}_{i,1} \in \mathcal{T}(\mathcal{D}_i \times [0,1])$ and $\mathbf{t}_{i,2} \in \mathcal{T}((\mathcal{D}_i \setminus d_i) \times [0,1])$ by placing dominoes along $\gamma_{i,1}$ and $\gamma_{i,2}$; for instance, see Figure 15. If $|\gamma_{i,1}|$ and $|\gamma_{i,2}|$ are even then $(d_i \cup d_{i+1}) \times [0,1] \notin \mathbf{t}_{i,1}$ and $d_{i+1} \times [0,1] \in \mathbf{t}_{i,2}$. If $|\gamma_{i,1}|$ and $|\gamma_{i,2}|$ are odd then $d_i \times [0,1] \notin \mathbf{t}_{i,1}$, $d_{i+1} \times [0,1] \in \mathbf{t}_{i,1}$ and $d_{i+1} \times [0,1] \notin \mathbf{t}_{i,2}$. Let $f_{i,1}^*$ and $f_{i,2}^*$ be the set of planar dominoes that describes $\mathbf{t}_{i,1}$ and $\mathbf{t}_{i,2}$, respectively.

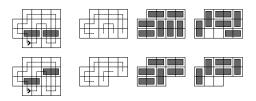

Figure 15: Two examples of a disk with a hamiltonian cycle γ and dominoes d_i and d_{i+1} , the disk \mathcal{D}_i with paths $\gamma_{i,1}$ and $\gamma_{i,2}$, and the tilings $\mathbf{t}_{i,1}$ and $\mathbf{t}_{i,2}$. In the first (resp. second) example $|\gamma_{i,1}|$ and $|\gamma_{i,2}|$ are both even (resp. odd).

Consider the tiling $\mathbf{t}_{d_i,p_i} = \mathbf{t}_{p_i}^{-1} * f * f_{\text{vert}} * \mathbf{t}_{p_i \cup d_i}$. We may assume that $p_i \cap \mathcal{D}_{d_i,0} \subset \mathcal{D}_{d_{i+1},0}$, as $|\operatorname{flux}_0(d_i,p_i)| = 1$. Then, \mathbf{t}_{d_i,p_i} covers the region $(\mathcal{D}_{d_i,0} \setminus \mathcal{D}_{d_{i+1},0}) \times [|p_i|,|p_i|+2]$ only with vertical dominoes. Since \mathcal{D}_i is a disk, as in the proof of Lemma 4.1, we have a sequence of flips that takes \mathbf{t}_{d_i,p_i} to the tiling $\mathbf{t} = \mathbf{t}_{p_i}^{-1} * (p_i, f_{i,1}^*, (\mathcal{D}_i \cup p_i)^{-1}) * ((\mathcal{D}_i \cup p_i)^{-1}, f_{i,2}^*, p_i \cup d_i) * \mathbf{t}_{p_i \cup d_i}$. From Facts 2.2 and 2.4, if $|\gamma_{i,1}|$ and $|\gamma_{i,2}|$ are odd (resp. even) then \mathbf{t} is \sim -equivalent to \mathbf{t}_{d_{i+1},p_i} (resp. $\mathbf{t}_{d_{i+1},p_i \cup d_i}^{-1}$). Thus, in any case, we have a plug p_{i+1} such that $\mathbf{t}_{d_i,p_i} \sim \mathbf{t}_{d_{i+1},p_{i+1}}^{\pm 1}$ and flux₀ $(d_{i+1},p_{i+1}) = \operatorname{flux}_0(d_i,p_i)$. Finally, notice that a completely analogous argument holds in the third possible case, when $d_{i+1} = s_k \cup s_l$ with $s_k, s_l \subset \mathcal{D}_{d_i,\pm 1}$ and $\mathcal{D}_{d_i,\pm 1} \setminus \mathcal{D}_{d_{i+1},\pm 1}$ is a disk.

For hamiltonian disks without bottlenecks, we now prove the existence of a domino that, in some sense, connects the family of tilings with flux equals +1 and the family of tilings with flux equals -1. As a corollary, we obtain that the even domino group of a bottleneck-free hamiltonian disk is cyclic.

Lemma 4.5. Let \mathcal{D} be a nontrivial disk with a hamiltonian cycle $\gamma = (s_1, \ldots, s_{|\mathcal{D}|})$ where $s_1 = s_{SW}$. If there is no domino that disconnects \mathcal{D} then there exist a domino $d \in \mathcal{D}_{\gamma}$ such that $\mathbf{t}_{d,p}^{-1} \sim \mathbf{t}_{d,p^{-1} \setminus d}$ for every plug $p \in \mathcal{P}_d$ with flux₀(d,p) = 1.

Proof. Notice that s_1 is contained in a 3×3 square $\tilde{\mathcal{D}}$, since there is no domino that disconnects \mathcal{D} and $s_1 = s_{SW}$. By possibly changing the orientation of γ , we may assume that in $\tilde{\mathcal{D}}$ the cycle γ follows one of the three patterns shown in Figure 16; we say that γ is of type i if it follows the i-th possible pattern.

Figure 16: Three possible patterns of γ .

Let d be the domino adjacent and parallel to $s_1 \cup s_{|\mathcal{D}|}$. Suppose that γ is either of type 1 or type 3, the case where γ is of type 2 is similar to the case where γ is of type 1. By hypothesis, $\text{flux}_0(d, p^{-1} \setminus d) = -1$. Then, by Lemma 4.2, it suffices to consider the case in which $p^{-1} \setminus d = s_{|\mathcal{D}|} \cup s_i$, where $s_i \subset \tilde{\mathcal{D}} \setminus d$ is the unit square adjacent to s_2 . Let $s_j \subset \tilde{\mathcal{D}} \setminus s_2$ be the unit square adjacent to s_i .

Consider $\mathbf{t}_{d,p^{-1} \setminus d} = \mathbf{t}_{p^{-1} \setminus d}^{-1} * f * f_{\text{vert}} * \mathbf{t}_{p^{-1}}$. Insert vertical floors around f and f_{vert} to obtain a tiling $\mathbf{t}_1 \sim \mathbf{t}_{d,p^{-1} \setminus d}$. The restriction of \mathbf{t}_1 to $\tilde{\mathcal{D}} \times [|p^{-1} \setminus d|, |p^{-1} \setminus d| + 7]$ is shown in the first row of Figure 17. Let \mathbf{t}_i be the tiling whose restriction to $\tilde{\mathcal{D}} \times [|p^{-1} \setminus d|, |p^{-1} \setminus d| + 7]$ is as in the i-th first row of Figure 17 and which is equal to \mathbf{t}_1 outside this region. Clearly,

 $\mathbf{t}_1 \approx \mathbf{t}_2$ and $\mathbf{t}_3 \approx \mathbf{t}_4 \approx \mathbf{t}_5$. Notice that \mathbf{t}_2 restricted to $\tilde{\mathcal{D}} \times [|p^{-1} \setminus d| + 2, |p^{-1} \setminus d| + 6]$ is a tiling of a $3 \times 3 \times 4$ box. Since the 3×4 rectangle is a regular disk (see Lemma 9.2 of [14]), we have $\mathbf{t}_2 \sim \mathbf{t}_3$.

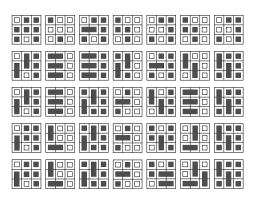

Figure 17: The *i*-th row shows the restriction to $\tilde{\mathcal{D}}$ of seven floors of a tiling \mathbf{t}_i .

We focus on \mathbf{t}_4 if γ is of type 1. Let f_1, f_2, \ldots, f_7 be the seven floors of \mathbf{t}_4 whose restriction is shown in Figure 17. By Facts 2.1 and 2.2 we have $\mathbf{t}_4 \sim \mathbf{t}_{f_2^{-1}}^{-1} * \mathbf{t}_{f_3} * \mathbf{t}_{f_4^{-1}}^{-1} * \mathbf{t}_{f_6^{-1}}^{-1} * \mathbf{t}_{f_7}$, since all other floors of \mathbf{t}_4 contains only dominoes that respect γ . Now, it follows from Fact 2.4 and Lemma 4.1 that $\mathbf{t}_4 \sim \mathbf{t}_{f_4^{-1}}^{-1}$. On the other hand, $\mathbf{t}_{f_4^{-1}}^{-1} = \mathbf{t}_{d,s_1 \cup s_j}^{-1}$. Finally, by Lemma 4.2, $\mathbf{t}_{d,s_1 \cup s_j}^{-1} \sim \mathbf{t}_{d,p}^{-1}$. Similarly, if γ is of type 3 then $\mathbf{t}_5 \sim \mathbf{t}_{d,p}^{-1}$.

Corollary 2.1. Let \mathcal{D} be a nontrivial hamiltonian balanced quadriculated disk. Suppose that there is no domino that disconnects \mathcal{D} . If $d_1, d_2 \in \mathcal{D}_{\gamma}$ and $p_1, p_2 \in \mathcal{P}$ are such that $|\operatorname{flux}_0(d_1, p_1)| = 1 = |\operatorname{flux}_0(d_2, p_2)|$ then $\mathbf{t}_{d_1, p_1}^{\pm 1} \sim \mathbf{t}_{d_2, p_2}$.

Proof. Take d as in Lemma 4.5. By Lemma 4.4, there are plugs p and \tilde{p} with $|\operatorname{flux}_0(d,p)| = 1 = |\operatorname{flux}_0(d,\tilde{p})|$ such that $\mathbf{t}_{d_1,p_1}^{\pm 1} \sim \mathbf{t}_{d,p}$ and $\mathbf{t}_{d_2,p_2}^{\pm 1} \sim \mathbf{t}_{d,\tilde{p}}$. The result now follows from Lemma 4.2, we have either $\mathbf{t}_{d,p} \sim \mathbf{t}_{d,\tilde{p}}$ or $\mathbf{t}_{d,p} \sim \mathbf{t}_{d,p^{-1} \setminus d}^{-1} \sim \mathbf{t}_{d,\tilde{p}}^{-1}$ depending on whether $\operatorname{flux}_0(d,p) = \operatorname{flux}_0(d,\tilde{p})$ or $\operatorname{flux}_0(d,p) = -\operatorname{flux}_0(d,\tilde{p})$.

Proof of Theorem 1. Since \mathcal{D} is nontrivial, the twist $\operatorname{Tw}: G_{\mathcal{D}}^+ \to \mathbb{Z}$ is a surjective homomorphism (see Lemma 6.2 of [14]). It follows from Lemma 4.3 and Corollary 2.1 that the even domino group $G_{\mathcal{D}}^+$ is cyclic. Therefore, the twist is an isomorphism.

Our approach to prove Theorem 2 relies on utilizing the established regularity of bottleneck-free hamiltonian disks. To this end, we need an additional lemma concerning generators $\mathbf{t}_{d,p}$ where $\mathcal{D} \setminus d$ is not connected.

Lemma 4.6. Consider a disk \mathcal{D} satisfying the hypothesis of Theorem 2. Let $d \in \mathcal{D}_{\gamma}$ be a domino that disconnects \mathcal{D} and consider a plug $p \in \mathcal{P}_d$. Then, $\mathbf{t}_{d,p}$ is \sim -equivalent to a concatenation of tilings $\mathbf{t}_{\tilde{d},\tilde{p}}^{\pm 1}$ with $\mathcal{D} \setminus \tilde{d}$ connected.

Proof. We first show the existence of a domino $d_1 \subset \mathcal{D}_0$ such that $\mathcal{D} \setminus d_1$ is not connected and $\mathbf{t}_{d,p} \sim \mathbf{t}_{d_1,p}$. Suppose that $d \subset \mathcal{D}_i$ for some i > 0, otherwise take $d_1 = d$. Let $d_1 \subset \mathcal{D}_0$ be the domino that contains the line segment of length two $\mathcal{D} \cap \mathcal{D}_i$, so that $\mathcal{D} \setminus d_1$ is not connected. We have that either $\mathcal{D}_{d_1,0} = \mathcal{D}_i$ or $\mathcal{D}_{d_1,\pm 1} = \mathcal{D}_i$; without loss of generality, suppose the former. Notice that $\mathcal{D}_{d_1,0} \setminus \mathcal{D}_{d,0}$ is a hamiltonian disk, as d and d_1 disconnect \mathcal{D} . Since $|\mathcal{D}_i| < |\mathcal{D}_0| - 2$, by Lemma 4.2 we may assume that $p \subset \mathcal{D}_{d,0} \cup \mathcal{D}_0 \setminus d_1$. Thus, as in the proof of Lemma 4.1, $\mathbf{t}_{d,p} \sim \mathbf{t}_{d_1,p}^{\pm 1}$.

Let $d_2 \subset \mathcal{D}_0$ be the domino adjacent and parallel to d_1 . Let d_3 and d_4 be the dominoes obtained after performing a flip in d_1 and d_2 . Again, from the fact that $|\mathcal{D}_i| < |\mathcal{D}_0| - 2$ and Lemma 4.2, we may further assume that $d_2 \subset p^{-1}$. Then, a vertical flip modifies $\mathbf{t}_{d_1,p}$ so that it now contains the dominoes $d_2 \times [|p|,|p|+1]$ and $d_2 \times [|p|+1,|p|+2]$. Now, a horizontal flip takes $d_1 \times [|p|,|p|+1]$ and $d_2 \times [|p|,|p|+1]$ to $d_3 \times [|p|,|p|+1]$ and $d_4 \times [|p|,|p|+1]$. Thus, by Facts 2.2 and 2.4, $\mathbf{t}_{d_1,p} \sim \mathbf{t}_{d_3,p} * \mathbf{t}_{d_4,p\cup d_3} * \mathbf{t}_{d_2,p\cup d_1}^{-1}$. Therefore, $\mathbf{t}_{d_1,p}$ is \sim -equivalent to a concatenation of tilings $\mathbf{t}_{d_i,p_i}^{\pm 1}$. If $d_i \notin \mathcal{D}_{\gamma}$ then, by Fact 2.1, $\mathbf{t}_{d_i,p_i}^{\pm 1} \sim \mathbf{t}_{\text{vert}}$. Otherwise, notice that if $d_i \in \mathcal{D}_{\gamma}$ then either d_i is a domino that does not disconnect \mathcal{D} or flux $_0(d_i,p_i) = 0$. The result then follows from Lemma 4.1.

Proof of Theorem 2. Lemmas 4.3, 4.4 and 4.6 imply that the even domino group $G_{\mathcal{D}}^+$ is generated by tilings $\mathbf{t}_{d,p}$ with $d \subset \mathcal{D}_0$ and $p \in \mathcal{P}_d$ such that $\mathcal{D} \setminus d$ is connected and $|\operatorname{flux}_0(d,p)| = 1$. By Lemma 4.2, we may further restrict to plugs contained in \mathcal{D}_0 . We claim that each such tiling $\mathbf{t}_{d,p}$ is equivalent under \sim to a tiling of $\mathcal{D} \times [0,2N]$ whose restriction to $(\mathcal{D} \setminus \mathcal{D}_0) \times [0,2N]$ is composed solely of vertical dominoes. Notice that the desired result follows from the claim, since Theorem 1 implies that \mathcal{D}_0 is regular.

The hamiltonian cycle γ of \mathcal{D} induces a hamiltonian cycle γ_0 of \mathcal{D}_0 . The dominoes that respect γ_0 and does not respect γ are exactly the dominoes $d_i \subset \mathcal{D}_0$ that contain the line segment $\mathcal{D}_0 \cap \mathcal{D}_i$. Let \mathbf{t} be the tiling of $\mathcal{D} \times [0, 2N]$ obtained from the tiling $\mathbf{t}_{d,p;\gamma_0}$ of $\mathcal{D}_0 \times [0, 2N]$ by covering the region $(\mathcal{D} \setminus \mathcal{D}_0) \times [0, 2N]$ with vertical dominoes. It follows from Facts 2.2 and 2.4 that \mathbf{t} is \sim -equivalent to a concatenation of $\mathbf{t}_{d,p;\gamma}$ and possibly tilings $\mathbf{t}_{d_i,p_i;\gamma}^{\pm 1}$ such that flux $_0(d_i,p_i)=0$. Thus, by Lemma 4.1, we have $\mathbf{t} \sim \mathbf{t}_{d,p;\gamma}$ and the claim follows.
