# Improving Behrend's construction: Sets without arithmetic progressions in integers and over finite fields 

Christian Elsholtz* ${ }^{*}$ Zach Hunter ${ }^{\dagger}$ Laura Proske ${ }^{\ddagger}$ Lisa Sauermann ${ }^{\S}$

#### Abstract

We prove new lower bounds on the maximum size of subsets $A \subseteq\{1, \ldots, N\}$ or $A \subseteq \mathbb{F}_{p}^{n}$ not containing three-term arithmetic progressions. In the setting of $\{1, \ldots, N\}$, this is the first improvement upon a classical construction of Behrend from 1946 beyond lower-order factors (in particular, it is the first quasipolynomial improvement). In the setting of $\mathbb{F}_{p}^{n}$ for a fixed prime $p$ and large $n$, we prove a lower bound of $(c p)^{n}$ for some absolute constant $c>1 / 2$ (for $c=1 / 2$, such a bound can be obtained via classical constructions from the 1940s, but improving upon this has been a well-known open problem).

## 1 Introduction

The questions of estimating the maximum possible sizes of subsets of $\{1, \ldots, N\}$ and of $\mathbb{F}_{p}^{n}$ without threeterm arithmetic progressions are among the most central problems in additive combinatorics. Let us denote the maximum possible size of such subsets by $r_{3}(N)$ and $r_{3}\left(\mathbb{F}_{p}^{n}\right)$, respectively. So, formally, $r_{3}(N)$ is the maximum possible size of a subset $A \subseteq\{1, \ldots, N\}$ such that there do not exist distinct $x, y, z \in A$ with $x+z=2 y$, and similarly $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ is the maximum possible size of a subset $A \subseteq \mathbb{F}_{p}^{n}$ such that there do not exist distinct $x, y, z \in A$ with $x+z=2 y$. The problem of estimating $r_{3}(N)$ was raised by Erdôs and Turán [18] in 1936 , and has been intensively studied since then. It also has connections to problems in communication complexity, see [10, 23, 26]. The problem for $\mathbb{F}_{p}^{n}$ has also been studied for several decades (see [28], see also [36, p. 142] for a slightly different but related setting).
In a breakthrough result in 2017, Ellenberg and Gijswijt 15 proved that for any prime $p \geq 3$, there is an upper bound of the form

$$
\begin{equation*}
r_{3}\left(\mathbb{F}_{p}^{n}\right) \leq\left(c_{p} p\right)^{n} \tag{1.1}
\end{equation*}
$$

for some constant $c_{p}<1$ only depending on $p$ (and their constant $c_{p}$ converges to $0.841 \ldots$ for $p \rightarrow \infty$, see [3. Eq. (4.11)]). In the integer setting, in a more recent breakthrough Kelley and Meka [25] proved the upper bound

$$
r_{3}(N) \leq N \cdot \exp \left(-c(\log N)^{1 / 12}\right)
$$

for all $N \geq 3$, for some absolute constant $c>0$. This drastically improved upon all the previous bounds, obtained over many decades by Roth [33], Heath-Brown [24], Szemerédi [40, Bourgain [6, 7], Sanders [37, 38] and Bloom-Sisask [4]. Afterwards, using a modification of their method, this bound was improved to

$$
r_{3}(N) \leq N \cdot \exp \left(-c(\log N)^{1 / 9}\right)
$$

by Bloom and Sisask [5].

[^0]These upper bounds for $r_{3}(N)$ match the shape of a classical lower bound for this problem due to Behrend [2] from 1946, which is of the form

$$
\begin{equation*}
r_{3}(N) \geq N \cdot 2^{-(2 \sqrt{2}+o(1)) \sqrt{\log _{2} N}} \tag{1.2}
\end{equation*}
$$

Over the past almost eighty years, only the $o(1)$-term in this bound has been improved. In Behrend's original bound, this $o(1)$-term in the exponent encapsulated a factor of $\left(\log _{2} N\right)^{-1 / 4}$, so the bound was of the form $r_{3}(N) \geq \Omega\left(N \cdot 2^{-2 \sqrt{2} \sqrt{\log _{2} N}} \cdot\left(\log _{2} N\right)^{-1 / 4}\right)$. In 2010, Elkin [13] improved this factor to $\left(\log _{2} N\right)^{1 / 4}$ instead, and an alternative proof for the bound with this improved $o(1)$-term was found by Green and Wolf [22].
In this paper, we give the first improvement to Behrend's [2] classical lower bound beyond the $o(1)$-term in (1.2). As stated in the following theorem, we show that the constant factor $2 \sqrt{2} \approx 2.828$ in the exponent can be improved to $2 \sqrt{\log _{2}(24 / 7)} \approx 2.667$, proving that the classical bound (1.2) is not tight.

Theorem 1.1. We have

$$
r_{3}(N) \geq N \cdot 2^{-(C+o(1)) \sqrt{\log _{2} N}}
$$

with $C=2 \sqrt{\log _{2}(24 / 7)}<2 \sqrt{2}$.
Our proof of Theorem 1.1 is motivated by studying three-term progression free sets in $\mathbb{F}_{p}^{n}$, for a fixed relatively large prime $p$ and large $n$. In this setting, one can adapt Behrend's construction [2] (as noted by Tao and Vu in their book on additive combinatorics [41, Exercise 10.1.3] and also observed by Alon, see [19, Lemma 17]) to show

$$
\begin{equation*}
r_{3}\left(\mathbb{F}_{p}^{n}\right) \geq\left(\frac{p+1}{2}\right)^{n-o(n)} \tag{1.3}
\end{equation*}
$$

for any fixed prime $p$ and large $n$. Alternatively, such a bound can also be shown via an adaptation of an earlier construction in the integer setting due to Salem and Spencer [35] from 1942 (see [1, Theorem 2.13]). The asymptotic notation $o(n)$ in the bound (1.3) is for $n \rightarrow \infty$ with $p$ fixed. The best quantitative bound for the $o(n)$-term in this statement is due to relatively recent work of the first author and Pach 17, Theorem 3.10], but beyond the $o(n)$-term, this bound has not been improved (except for specific small primes $p$, see the discussion below).
Comparing the upper and lower bounds for $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ for a fixed (reasonably large) prime $p$ and large $n$ in (1.1) and (1.3), there is still a large gap. Both of these bounds are roughly of the form $(c p)^{n}$ with $0<c<1$, but with different values of $c$. For the upper bound, the best known constant due to Ellenberg-Gijswijt [15] is $c \approx 0.85$ (when the fixed prime is large enough). For the lower bound the constant $c=1 / 2$ from Behrend's construction [2] or alternatively the Salem-Spencer construction [35] has not been improved in more than eighty years despite a lot of attention, especially after the upper bound of Ellenberg-Gijswijt appeared (see e.g. the blog post [14] as well as the discussion thereafter). Here, we finally improve this constant in the lower bound to be strictly larger than $1 / 2$.

Theorem 1.2. There is a constant $c>1 / 2$ such that for every prime $p$ and every sufficiently large positive integer $n$ (sufficiently large in terms of $p$ ), we have $r_{3}\left(\mathbb{F}_{p}^{n}\right) \geq(c p)^{n}$.

Breaking the barrier of $1 / 2$ in this result for $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ relies on the same key insights as our lower bounds for $r_{3}(N)$ in Theorem 1.1 improving Behrend's construction. The problem for $\mathbb{F}_{p}^{n}$ (the so-called finite field model) was popularized in the hope that improved upper bounds for $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ would also lead to better upper bounds for $r_{3}(N)$ (see e.g. [21, 30, 43]). It turned out, however, that for $\mathbb{F}_{p}^{n}$ much stronger bounds hold than in the integer setting (for fixed $p$, the Ellenberg-Gijswijt bound stated in (1.1) is of the form $r_{3}\left(\mathbb{F}_{p}^{n}\right) \leq\left(p^{n}\right)^{1-\gamma_{p}}$ for some $\gamma_{p}>0$, but in the integer setting one cannot hope for a bound of the form $r_{3}(N) \leq N^{1-\gamma}$ for some fixed $\gamma>0$, as shown by Salem-Spencer [35] and Behrend [2]). Nevertheless, this paper establishes a connection between lower bounds for $r_{3}(N)$ and for $r_{3}\left(\mathbb{F}_{p}^{n}\right)$.
Our proof of Theorem 1.2 shows that one can take any $c<\sqrt{7 / 24}$, for example $c=0.54$. Even though this may not seem like a large improvement over $1 / 2$, it is the first qualitative improvement over the constant $1 / 2$ from the constructions of Salem-Spencer and Behrend from the 1940's. Both of these constructions lead to three-term progression free subsets of $\mathbb{F}_{p}^{n}$ only consisting of vectors with all entries in $\{0,1, \ldots,(p-1) / 2\}$, i.e. they only use roughly half of the available elements in $\mathbb{F}_{p}$ in each coordinate. The restriction of all entries
to $\{0,1, \ldots,(p-1) / 2\}$ is crucial in these constructions, as it ensures that there is no "wrap-around" over $\mathbb{F}_{p}$. However, such an approach cannot be used to obtain three-term progression free subset $A \subseteq \mathbb{F}_{p}^{n}$ of size $|A|>((p+1) / 2)^{n}$, so $c=1 / 2$ is a significant barrier for this problem. In light of this, it may actually be considered a surprise that it is possible to obtain a constant $c>1 / 2$.
For very small primes, better bounds were obtained with specific constructions depending on the particular prime. For example, in $\mathbb{F}_{3}^{n}$ a lower bound of $2.2202^{n-o(n)}$ was recently obtained by Romera-Paredes et al. [32] using artifical intelligence building upon traditional methods from previous bound [9, 12, 42]. Naslund [29] informed us about forthcoming work with an approach related to Shannon capacity, proving a lower bound of $2.2208^{n-o(n)}$ for the maximum size of three-term progression free subsets of $\mathbb{F}_{3}^{n}$. In $\mathbb{F}_{5}^{n}$, the best known lower bounds is $\left(35^{1 / 3}\right)^{n-o(n)}$ due to the first and third author, Pollak, Lipnik and Siebenhofer (see [16]), note that $35^{1 / 3} \approx 3.271$.
Our methods for improving the lower bounds for $r_{3}(N)$ and $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ can be applied more generally for finding three-term progression free subsets in finite abelian groups. We recall that a three-term arithmetic progression in a finite abelian group $G$ consists of three distinct elements $x, y, z \in G$ with $x+z=y+y$ (see e.g. [11]), and let us denote the maximum possible size of a three-term progression free subset of $G$ by $r_{3}(G)$. Brown and Buhler [8] proved in 1982 that $r_{3}(G) \leq o(|G|)$ for all finite abelian groups $G$ (where the asymptotic notation $o(|G|)$ is for growing group size $|G|)$. Frankl, Graham and Rödl [20] gave a different proof of this statement in 1987, and further upper bounds were obtained by Meshulam [28] and Lev [27].
Of course, every finite abelian group $G$ can be written in the form $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$, and the problem of estimating $r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right)$ has been most intensively studied in the case $m_{1}=\cdots=m_{n}$, i.e. in the setting of $\mathbb{Z}_{m}^{n}$. In breakthrough work, Croot-Lev-Pach 11 proved the upper bound $r_{3}\left(\mathbb{Z}_{4}^{n}\right) \leq 3.611^{n}$ by introducing a new polynomial method, which also led to the Ellenberg-Gijswijt bound for $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ stated in (1.1). Using similar methods, Petrov and Pohoata [31] studied upper bounds for $r_{3}\left(\mathbb{Z}_{8}^{n}\right)$.

Generalizing Theorem 1.2, we show that for any integer $m \geq 2$ (not necessarily prime) and sufficiently large $n$, we have $r_{3}\left(\mathbb{Z}_{m}^{n}\right) \geq(c m)^{n}$ for some absolute constant $c>1 / 2$. For odd $m$, the best previous lower bound for this problem has (as in the case of prime $m$ ) been of the form $((m+1) / 2)^{n-o(n)}$ (based on the SalemSpencer construction [35] or the Behrend construction [2]). For even $m$, the best previous lower bound has been $((m+2) / 2)^{n-o(n)}$ due to the first author and Pach [17, Theorem 3.11].
In fact, we show the following more general lower bound for arbitrary abelian groups $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$.
Theorem 1.3. Consider integers $m_{1}, \ldots, m_{n}$ (for some positive integer $n$ ), and let $m$ be such that $2 \leq m_{i} \leq$ $m$ for $i=1, \ldots, n$. Then we have

$$
r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right) \geq \frac{(7 / 24)^{n / 2}}{10^{6} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

Note that Theorem 1.3 immediately implies that for any fixed constant $c<\sqrt{7 / 24}$ and for every integer $m \geq 2$, we have $r_{3}\left(\mathbb{Z}_{m}^{n}\right) \geq(c m)^{n}$ if $n$ is sufficiently large with respect to $m$ and $c$. In particular, it implies Theorem 1.2 .
It is plausible that by slight modifications of our method, one can obtain better numerical bounds in our results above. In particular, our construction relies on certain explicit two-dimensional building blocks of area close to $7 / 24$, and an improved choice for these building blocks with larger area would automatically carry over to numerical improvements of the constant $C=2 \sqrt{\log _{2}(24 / 7)}$ in Theorem 1.1 and the constant $7 / 24$ in Theorem 1.3. We see the main contribution of this paper as introducing this method, and using it to break the lower bounds for $r_{3}(N)$ and $r_{3}\left(\mathbb{F}_{p}^{n}\right)$ in (1.2) and (1.3) originating from the 1940's.
In the next section we give an overview of our proof approach and state some key propositions, from which we will deduce Theorems 1.1 to 1.3 in Section 3. To prove these propositions, we need to find suitable two-dimensional building blocks, and these will be constructed in Section 4.
Notation. As usual, for a point $x \in \mathbb{R}^{n}$, we denote the coordinates of $x$ by $x_{1}, \ldots, x_{n}$. For real numbers $a, a^{\prime} \in \mathbb{R}$, we write $a \equiv a^{\prime} \bmod 1$ if $a-a^{\prime} \in \mathbb{Z}$. For two points $x \in \mathbb{R}^{n}$ and $y \in \mathbb{R}^{n}$, we write $x \equiv y \bmod 1$ if we have $x_{i} \equiv y_{i} \bmod 1$ for all $i=1, \ldots, n$ (i.e. if we have $x-y \in \mathbb{Z}^{n}$ ). For a measurable subset $S \subseteq \mathbb{R}^{n}$, we denote its measure by $\mu(S)$.
Acknowledgements. We would like to thank Daniel Carter, Zachary Chase, Ben Green, Eric Naslund, and Benny Sudakov for interesting discussions and helpful comments.

## 2 Proof Overview

The first step in our constructions for large three-term progression free subsets of $\{1, \ldots, N\}$ or $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ is to take a (randomized) embedding into a (high-dimensional) torus. This way, we can reduce both problems to finding a large subset of the torus without a three-term arithmetic progression such that the first and third term are reasonably far away from each other. Note that we cannot aim to find a large subset of the torus without any three-term arithmetic progressions, since it is well-known that any three-term progression free subset of the torus has measure zero (see for example [34]). So it is essential to only forbid three-term arithmetic progressions with far-away first and third term in our desired subset of the torus.
The following proposition states that there is indeed such a large-measure subset of a (high-dimensional) torus without three-term arithmetic progressions with far-away first and third term. Proving this proposition is the main difficulty of this paper.

Proposition 2.1. For any $0<\delta<1$ and any even positive integer $n$, there exists a measurable subset $S \subseteq[0,1)^{n}$ with measure $\mu(S) \geq 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2}$ such that for any $x, y, z \in S$ with $x+z \equiv 2 y \bmod 1$ we have $\left|x_{i}-z_{i}\right|<\delta$ for $i=1, \ldots, n$.

The deductions of Theorems 1.1 to 1.3 from Proposition 2.1 will be discussed in Section 3
We remark that it is easy to show a weaker version of Proposition 2.1] with a bound of $\mu(S) \geq \delta^{2} \cdot(1 / 2)^{n+o(n)}$ for the measure of $S$. Indeed, there one can take $S \subseteq[0,1 / 2)^{n}$ to be an appropriately chosen sphere shell of width on the order of $\delta^{2}$ (notice that then for $x, y, z \in S$ we have $x+z \equiv 2 y \bmod 1$ if and only if $x+z=2 y$, since $S \subseteq[0,1 / 2)^{n}$ ). From this weaker statement one can deduce (1.2) with Behrend's original constant $2 \sqrt{2}$, this approach to proving Behrend's bound (with an improved $o(1)$-term) is due to Green-Wolf [22]. Obtaining the stronger bound on $\mu(S)$ in Proposition 2.1 (having a factor of $(7 / 24)^{n / 2}$ instead of $(1 / 2)^{n}=(1 / 4)^{n / 2}$ ), which leads to our improvement upon the constant $2 \sqrt{2}$, is much more difficult. In particular, for $n$ large in terms of $\delta$, any subset $S \subseteq[0,1)^{n}$ whose measure is as large as in Proposition 2.1 will have points $x, y, z \in S$ with $x+z \equiv 2 y \bmod 1$ but $x+z \neq 2 y$, so the "modulo 1 " cannot just be ignored like in the previous approach. In fact, there will always be $x, y, z \in S$ with $x+z \equiv 2 y \bmod 1$ and $x=z \neq y$. Therefore, in the conclusion of Proposition [2.1] it is crucial to bound the absolute values of the coordinates of $x-z$ and not of $x-y$ (which, as the step length of the "modulo 1 " arithmetic progression $x, y, z$, would maybe be more natural to consider), since the analogous statement for $x-y$ would be false.
In order to prove Proposition 2.1, we use subsets of a two-dimensional torus as building blocks. These twodimensional building blocks need to satisfy a somewhat technical condition, summarized in the following proposition.

Proposition 2.2. Let $0<\varepsilon<1$. Then there exists a measurable subset $T \subseteq[0,1)^{2}$ with measure $\mu(T) \geq$ $7 / 24-\varepsilon$ and a measurable function $f: T \rightarrow\left[0,100 / \varepsilon^{2}\right]$, such that for any $x, y, z \in T$ with $x+z \equiv 2 y \bmod 1$ we have

$$
f(x)+f(z) \geq 2 f(y)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2} .
$$

To deduce Proposition 2.1 from Proposition 2.2 we define the set $S \subseteq[0,1)^{n}$ in Proposition 2.1] to be a subset of the $(n / 2)$-fold product set $T^{n / 2} \subseteq[0,1)^{n}$ consisting of those points $\left(\left(x_{1}, x_{2}\right),\left(x_{3}, x_{4}\right), \ldots,\left(x_{n-1}, x_{n}\right)\right) \in$ $T^{n / 2}$ where $f\left(x_{1}, x_{2}\right)+f\left(x_{3}, x_{4}\right)+\cdots+f\left(x_{n-1}, x_{n}\right)$ is contained in some small interval. In other words, the set $S \subseteq[0,1)^{n}$ can be viewed as a "slice" of the product set $T^{n / 2} \subseteq[0,1)^{n}$ with respect to the function $f\left(x_{1}, x_{2}\right)+f\left(x_{3}, x_{4}\right)+\cdots+f\left(x_{n-1}, x_{n}\right)$. It is then not hard to show, using the conditions on the set $T$ and the function $f$ in Proposition 2.2, that such a set $S$ satisfies the conditions in Proposition 2.1. The details of this proof are given at the end of this section.
In order to prove Proposition 2.2, we explicitly construct the desired subset $T \subseteq[0,1)^{2}$ and the function $f$. The set $T$ is a carefully chosen union of polygons in $[0,1)^{2}$. The construction is somewhat ad-hoc and it seems plausible that the constant $7 / 24$ in Propositions 2.2 and 2.1 (and consequently also the constants in Theorems 1.1 and (1.3) can be improved by finding a better construction of such a set $T$. However, the main novelty of this paper is our overall approach for proving Theorems 1.1 to 1.3 , and showing that this approach can be used to beat the long-standing bounds on these problems.
The proof of Proposition 2.2 can be found in Section 4 We finish this section by showing that Proposition 2.2 indeed implies Proposition 2.1.

Proof of Proposition [2.1] assuming Proposition 2.2. For $n=2$, Proposition 2.1 is trivially true (for example, we can take $\left.S=[0, \delta)^{2}\right)$. So we may assume that $n \geq 4$.
Define $\varepsilon=1 / n$ and let $T \subseteq[0,1)^{2}$ and the function $f$ be as in Proposition 2.2. Note that then the ( $n / 2$ )-fold product set $T^{n / 2} \subseteq[0,1)^{n}$ has measure

$$
\mu\left(T^{n / 2}\right)=\mu(T)^{n / 2} \geq(7 / 24-\varepsilon)^{n / 2} \geq\left(1-\frac{24}{7} \varepsilon\right)^{n / 2} \cdot\left(\frac{7}{24}\right)^{n / 2} \geq 10^{-2} \cdot\left(\frac{7}{24}\right)^{n / 2}
$$

where we used that for all $a \in[0,6 / 7]$ we have $1-a \geq 10^{-(7 / 6) a}$ (indeed, for $a=0$ we have $1-0=10^{-(7 / 6) \cdot 0}$, for $a=6 / 7$ we have $1-(6 / 7)=1 / 7>1 / 10=10^{-(7 / 6) \cdot(6 / 7)}$, and the function $10^{-(7 / 6) a}$ is concave on the interval $[0,6 / 7]$ ) and therefore (recalling that $\varepsilon=1 / n \leq 1 / 4$ )

$$
\left(1-\frac{24}{7} \varepsilon\right)^{n / 2} \geq\left(10^{-(7 / 6) \cdot(24 / 7) \varepsilon}\right)^{n / 2}=10^{-2 \varepsilon n}=10^{-2}
$$

On the set $T^{n / 2}$, let us consider the function taking value $f\left(x_{1}, x_{2}\right)+f\left(x_{3}, x_{4}\right)+\cdots+f\left(x_{n-1}, x_{n}\right)$ for each $\left(\left(x_{1}, x_{2}\right),\left(x_{3}, x_{4}\right), \ldots,\left(x_{n-1}, x_{n}\right)\right) \in T^{n / 2}$. This is a measurable function, with values in the interval $\left[0,100 n^{3}\right]$ (noting that $n \cdot 100 / \varepsilon^{2}=100 n^{3}$ ). Thus, for every integer $j=0, \ldots,\left\lfloor 100 n^{3} \cdot\left(2 / \delta^{2}\right)\right\rfloor$, the set

$$
S_{j}=\left\{\left(\left(x_{1}, x_{2}\right), \ldots,\left(x_{n-1}, x_{n}\right)\right) \in T^{n / 2} \mid j \cdot \delta^{2} / 2 \leq f\left(x_{1}, x_{2}\right)+\cdots+f\left(x_{n-1}, x_{n}\right)<(j+1) \cdot \delta^{2} / 2\right\}
$$

is measurable, and the union of these sets $S_{j}$ for $j=0, \ldots,\left\lfloor 100 n^{3} \cdot\left(2 / \delta^{2}\right)\right\rfloor$ is the entire product set $T^{n / 2}$. Thus, there exists some $j \in\left\{0, \ldots,\left\lfloor 100 n^{3} \cdot\left(2 / \delta^{2}\right)\right\rfloor\right\}$ such that

$$
\mu\left(S_{j}\right) \geq \frac{\mu\left(T^{n / 2}\right)}{\left\lfloor 100 n^{3} \cdot\left(2 / \delta^{2}\right)\right\rfloor+1} \geq \frac{10^{-2} \cdot(7 / 24)^{n / 2}}{4 \cdot 100 n^{3} \delta^{-2}} \geq 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2}
$$

It remains to show that for any $x, y, z \in S_{j}$ with $x+z \equiv 2 y \bmod 1$ we have $\left|x_{i}-z_{i}\right|<\delta$ for $i=1, \ldots, n$. Indeed, for every $h=1, \ldots, n / 2$ we have $\left(x_{2 h-1}, x_{2 h}\right),\left(y_{2 h-1}, y_{2 h}\right),\left(z_{2 h-1}, z_{2 h}\right) \in T$ and $\left(x_{2 h-1}, x_{2 h}\right)+$ $\left(z_{2 h-1}, z_{2 h}\right) \equiv 2\left(y_{2 h-1}, y_{2 h}\right) \bmod 1$ and so by the condition in Proposition 2.2 we obtain

$$
f\left(x_{2 h-1}, x_{2 h}\right)+f\left(z_{2 h-1}, z_{2 h}\right) \geq 2 f\left(y_{2 h-1}, y_{2 h}\right)+\left(x_{2 h-1}-z_{2 h-1}\right)^{2}+\left(x_{2 h}-z_{2 i h}\right)^{2}
$$

Summing this up for $h=1, \ldots, n / 2$, and recalling the definition of $S_{j}$, yields

$$
\begin{aligned}
2 \cdot(j+1) \cdot \delta^{2} / 2 & >f\left(x_{1}, x_{2}\right)+\cdots+f\left(x_{n-1}, x_{n}\right)+f\left(z_{1}, z_{2}\right)+\cdots+f\left(z_{n-1}, z_{n}\right) \\
& \geq 2 f\left(y_{1}, y_{2}\right)+\cdots+2 f\left(y_{n-1}, y_{n}\right)+\left(x_{1}-z_{1}\right)^{2}+\cdots+\left(x_{n}-z_{n}\right)^{2} \\
& \geq 2 \cdot j \cdot \delta^{2} / 2+\left(x_{1}-z_{1}\right)^{2}+\cdots+\left(x_{n}-z_{n}\right)^{2}
\end{aligned}
$$

and hence

$$
\left(x_{1}-z_{1}\right)^{2}+\cdots+\left(x_{n}-z_{n}\right)^{2}<2 \cdot \delta^{2} / 2=\delta^{2}
$$

This implies that $\left|x_{i}-z_{i}\right|<\delta$ for $i=1, \ldots, n$, as desired.

## 3 Deduction of main results

In this section we derive Theorems 1.1 to 1.3 from Proposition 2.1. We start with Theorem 1.3, and first prove the following version of it for the case of even $n$.

Proposition 3.1. Consider integers $m_{1}, \ldots, m_{n}$ (for some positive integer $n$ ), and let $m$ be such that $2 \leq$ $m_{i} \leq m$ for $i=1, \ldots, n$. If $n$ is even, we have

$$
r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right) \geq \frac{(7 / 24)^{n / 2}}{10^{5} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

As mentioned in the previous section, this statement is deduced from Proposition 2.1 by considering a (randomized) embedding of $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ into the torus $[0,1)^{n}$. For a subset $S \subseteq[0,1)^{n}$ as in Proposition 2.1, one can then show that its pre-image is a three-term progression free subset. Using the lower bound on $\mu(S)$ in Proposition 2.1, this gives a lower bound for $r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right)$.

Proof. Let $\delta=1 / m$, and let $S \subseteq[0,1)^{n}$ be a measurable subset as in Proposition 2.1. For any $a \in[0,1]^{n}$, let us now define a map $\varphi_{a}: \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}} \rightarrow[0,1)^{n}$ as follows. Every point in $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ can be represented (uniquely) by an $n$-tuple $\left(r_{1}, \ldots, r_{n}\right) \in\left\{0,1, \ldots, m_{1}-1\right\} \times \cdots \times\left\{0,1, \ldots, m_{n}-1\right\}$. Let us now define $\varphi_{a}\left(r_{1}, \ldots, r_{n}\right)=\left(q_{1}, \ldots, q_{n}\right)$ for the unique point $q=\left(q_{1}, \ldots, q_{n}\right) \in[0,1)^{n}$ with $\left(q_{1}, \ldots, q_{n}\right) \equiv$ $\left(a_{1}+r_{1} / m_{1}, \ldots, a_{n}+r_{n} / m_{n}\right) \bmod 1$.
Note that the map $\varphi_{a}: \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}} \rightarrow[0,1)^{n}$ is injective for any $a \in[0,1]^{n}$. Furthermore, note that for any $a \in[0,1]^{n}$ and any $x, z \in \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ we either have $\varphi_{a}(x)_{i}=\varphi_{a}(z)_{i}$ or $\left|\varphi_{a}(x)_{i}-\varphi_{a}(z)_{i}\right| \geq$ $1 / m_{i} \geq 1 / m=\delta$ (indeed, the different values occurring as the $i$-th coordinate of points in the image $\varphi_{a}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right)$ form an arithmetic progression with step-width $\left.1 / m_{i}\right)$. Hence for any $a \in[0,1]^{n}$ and any distinct $x, z \in \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$, there exists a coordinate $i \in\{1, \ldots, n\}$ such that $\left|\varphi_{a}(x)_{i}-\varphi_{a}(z)_{i}\right| \geq \delta$. We claim that for any $a \in[0,1]^{n}$, the pre-image $\varphi_{a}^{-1}(S)$ of the set $S$ from Proposition [2.1] is a threeterm progression free subset of $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$. Indeed, suppose that for some $a \in[0,1]^{n}$, there exist distinct $x, y, z \in \varphi_{a}^{-1}(S) \subseteq \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ with $x+z=2 y$. Then, as shown above, there must be a coordinate $i \in\{1, \ldots, n\}$ such that $\left|\varphi_{a}(x)_{i}-\varphi_{a}(z)_{i}\right| \geq \delta$. On the other hand, having $x+z=2 y$ means that $x_{i}+z_{i} \equiv 2 y_{i} \bmod m_{i}$ for all $i=1, \ldots, n$, where $\left(x_{1}, \ldots, x_{n}\right),\left(y_{1}, \ldots, y_{n}\right),\left(z_{1}, \ldots, z_{n}\right) \in\left\{0,1, \ldots, m_{1}-1\right\} \times$ $\cdots \times\left\{0,1, \ldots, m_{n}-1\right\}$ are the $n$-tuples corresponding to $x, y, z \in \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$, respectively. Hence we obtain $\left(x_{i} / m_{i}\right)+\left(z_{i} / m_{i}\right) \equiv 2\left(y_{i} / m_{i}\right) \bmod 1$ for $i=1, \ldots, n$, and consequently

$$
\varphi_{a}(x)_{i}+\varphi_{a}(z)_{i} \equiv\left(a_{i}+x_{i} / m_{i}\right)+\left(a_{i}+z_{i} / m_{i}\right) \equiv 2\left(a_{i}+y_{i} / m_{i}\right) \equiv 2 \varphi_{a}(y)_{i} \quad \bmod 1
$$

for $i=1, \ldots, n$. This means that $\varphi_{a}(x)+\varphi_{a}(z) \equiv 2 \varphi_{a}(y) \bmod 1$. Since $\varphi_{a}(x), \varphi_{a}(y), \varphi_{a}(z) \in S$, the condition for the set $S$ in Proposition 2.1] now implies that $\left|\varphi_{a}(x)_{i}-\varphi_{a}(z)_{i}\right|<\delta$ for all $i=1, \ldots, n$. This is a contradiction, so the pre-image $\varphi_{a}^{-1}(S) \subseteq \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ is indeed three-term progression free for any $a \in[0,1]^{n}$.
Finally, consider a uniformly random choice of $a \in[0,1]^{n}$. For any $x \in \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ we have $x \in \varphi_{a}^{-1}(S)$ if and only if $\varphi_{a}(x) \in S$, and this happens with probability $\mu(S)$. Hence

$$
\mathbb{E}\left[\left|\varphi_{a}^{-1}(S)\right|\right]=\sum_{x \in \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}} \mathbb{P}\left[x \in \varphi_{a}^{-1}(S)\right]=\left|\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right| \cdot \mu(S) \geq \frac{(7 / 24)^{n / 2}}{10^{5} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

recalling that $\mu(S) \geq 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2}=10^{-5}(1 / m)^{2} n^{-3} \cdot(7 / 24)^{n / 2}$. This implies that for some choice of $a \in[0,1]^{n}$ we must have

$$
\left|\varphi_{a}^{-1}(S)\right| \geq \frac{(7 / 24)^{n / 2}}{10^{5} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

As shown above, the set $\varphi_{a}^{-1}(S) \subseteq \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ is three-term progression free, so this establishes the desired lower bound for $r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right)$.

To deduce Theorem 1.3 from Proposition 3.1, we use the following simple fact.
Fact 3.2. For any finite abelian groups $G$ and $H$, we have

$$
r_{3}(G) \geq \frac{r_{3}(G \times H)}{|H|}
$$

Proof. Let $A \subseteq G \times H$ be a three-term progression free subset of $G \times H$ of size $|A|=r_{3}(G \times H)$. For any $h \in H$, let us define the map $\varphi_{h}: G \rightarrow G \times H$ by $\varphi_{h}(g)=(g, h)$ for all $g \in G$. For any $h \in H$, this map is injective and for any distinct $x, y, z \in G$, the images $\varphi_{h}(x), \varphi_{h}(y), \varphi_{h}(z) \in G \times H$ form a three-term arithmetic progression in $G \times H$ if and only if $x, y, z$ form a three-term arithmetic progression in $G$. Thus, for any $h \in H$, the pre-image $\varphi_{h}^{-1}(A) \subseteq G$ is a three-term progression free subset of $G$ and therefore has size $\left|\varphi_{h}^{-1}(A)\right| \leq r_{3}(G)$. On the other hand, by injectivity of $\varphi_{h}$ we have $\left|\varphi_{h}^{-1}(A)\right|=\left|A \cap \varphi_{h}(G)\right|$. As the images $\varphi_{h}(G)$ for all $h \in H$ form a partition of $G \times H$, this implies

$$
r_{3}(G \times H)=|A|=\sum_{h \in H}\left|A \cap \varphi_{h}(G)\right|=\sum_{h \in H}\left|\varphi_{h}^{-1}(A)\right| \leq|H| \cdot r_{3}(G)
$$

Rearranging yields the desired inequality.

Now, we are ready to prove Theorem 1.3
Proof of Theorem 1.3. Note that the inequality in the theorem statement holds trivially for $n \leq 2$ (since then the right-hand side is smaller than 1 ). So let us assume $n \geq 3$. If $n$ is even, then the desired lower bound for $r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right)$ follows immediately from Proposition 3.1. If $n$ is odd, applying Proposition 3.1 with $m_{n+1}=m$ yields

$$
r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}} \times \mathbb{Z}_{m}\right) \geq \frac{(7 / 24)^{(n+1) / 2}}{10^{5} m^{2}(n+1)^{3}} \cdot m_{1} \cdots m_{n} \cdot m \geq \frac{(7 / 24)^{n / 2}}{10^{6} m^{2} n^{3}} \cdot m_{1} \cdots m_{n} \cdot m
$$

Applying Fact 3.2 to $G=\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$ and $H=\mathbb{Z}_{m}$, we obtain

$$
r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right) \geq \frac{r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}} \times \mathbb{Z}_{m}\right)}{m} \geq \frac{(7 / 24)^{n / 2}}{10^{6} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

Theorem 1.2 is an immediate consequence of Theorem 1.3
Proof of Theorem 1.2. Let $1 / 2<c<\sqrt{7 / 24}$. Then, as long as $n$ is sufficiently large with respect to $p$, by Theorem 1.3 we have

$$
r_{3}\left(\mathbb{F}_{p}^{n}\right)=r_{3}\left(\mathbb{Z}_{p} \times \cdots \times \mathbb{Z}_{p}\right) \geq \frac{(7 / 24)^{n / 2}}{10^{6} p^{2} n^{3}} \cdot p^{n}=\frac{(\sqrt{7 / 24} \cdot p)^{n}}{10^{6} p^{2} n^{3}} \geq(c p)^{n}
$$

Finally, it remains to derive Theorem 1.1.
Proof of Theorem 1.1. As we are proving an asymptotic statement, we may assume that $N$ is sufficiently large. Let $n$ be an even positive integer with

$$
\begin{equation*}
\frac{2 \cdot \sqrt{\log _{2} N}}{\sqrt{\log _{2}(24 / 7)}} \leq n \leq \frac{2 \cdot \sqrt{\log _{2} N}}{\sqrt{\log _{2}(24 / 7)}}+2 \tag{3.1}
\end{equation*}
$$

Let $p_{1}, \ldots, p_{n}$ be the first $n$ primes. Defining $p=\max \left\{p_{1}, \ldots, p_{n}\right\}$, we have $p \leq 100 n \log _{2} n$ (this follows from the prime number theorem, but there are also easier proofs for this weaker bound, see e.g. [39, p. 150] for a relatively short elementary proof). In particular, we can observe that $p_{1} \cdots p_{n} \leq p^{n} \leq\left(100 n \log _{2} n\right)^{n} \leq$ $\left(n^{2} / 4\right)^{n} \leq\left(\log _{2} N\right)^{\sqrt{\log _{2} N}}<N$.
We claim that there are powers $m_{1}, \ldots, m_{n}$ of the primes $p_{1}, \ldots, p_{m}$, respectively, with $N / p \leq m_{1} \cdots m_{n} \leq N$ and $p_{i} \leq m_{i}<N^{1 / n} \cdot p_{i}$ for $i=1, \ldots, n$. Indeed, for each $i=1, \ldots, n$, start by defining $m_{i}^{\prime}$ to be the unique power of $p_{i}$ with $N^{1 / n} \leq m_{i}^{\prime}<N^{1 / n} \cdot p_{i}$. Note that then we have $m_{1}^{\prime} \cdots m_{n}^{\prime} \geq\left(N^{1 / n}\right)^{n}=N$, and $m_{i}^{\prime}<N^{1 / n} \cdot p$ for $i=1, \ldots, n$. As long as $m_{1}^{\prime} \cdots m_{n}^{\prime}>N$, let us decrease the product $m_{1}^{\prime} \cdots m_{n}^{\prime}$ by choosing an index $i$ with $m_{i}^{\prime}>p_{i}$ and dividing $m_{i}^{\prime}$ by $p_{i}$ (again obtaining a power of $p_{i}$ ). In each step the product $m_{1}^{\prime} \cdots m_{n}^{\prime}$ decreases by a factor of at most $p$. Thus, when the product $m_{1}^{\prime} \cdots m_{n}^{\prime}$ stops being larger than $N$, it must attain a value between $N / p$ and $N$. We can then define $m_{1}, \ldots, m_{n}$ to be the values of $m_{1}^{\prime}, \ldots, m_{n}^{\prime}$ at that point.
Note that $m_{1}, \ldots, m_{n}$ are coprime (as they are powers of the distinct primes $p_{1}, \ldots, p_{n}$ ), and hence $\mathbb{Z}_{m_{1} \cdots m_{n}} \cong$ $\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}$. Thus, for $m=\left\lfloor N^{1 / n} \cdot p\right\rfloor$, we obtain

$$
r_{3}(N) \geq r_{3}\left(m_{1} \cdots m_{n}\right) \geq r_{3}\left(\mathbb{Z}_{m_{1} \cdots m_{n}}\right)=r_{3}\left(\mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}}\right) \geq \frac{(7 / 24)^{n / 2}}{10^{5} m^{2} n^{3}} \cdot m_{1} \cdots m_{n}
$$

where at the last step we used Proposition 3.1 (and at the first two steps we used that every three-term progression free subset of $\mathbb{Z}_{m_{1} \ldots m_{n}}$ gives rise to a three-term progression free subset of $\left\{1, \ldots, m_{1} \ldots m_{n}\right\}$ and hence in particular to a three-term progression free subset of $\{1, \ldots, N\}$, recalling that $m_{1} \cdots m_{n} \leq N$ ). Rewriting the right-hand side yields

$$
r_{3}(N) \geq \frac{(7 / 24)^{n / 2}}{10^{5} m^{2} n^{3}} \cdot m_{1} \cdots m_{n} \geq \frac{(7 / 24)^{n / 2}}{10^{5}\left(N^{1 / n} p\right)^{2} n^{3}} \cdot(N / p)=\frac{1}{10^{5} p^{3} n^{3}} \cdot N \cdot(7 / 24)^{n / 2} \cdot N^{-2 / n}
$$

Recalling $p \leq 100 n \log _{2} n$, and recalling our choice of $n$, we can conclude that

$$
\begin{aligned}
r_{3}(N) & \geq \frac{1}{10^{5}\left(100 n \log _{2} n\right)^{3} n^{3}} \cdot N \cdot 2^{-\log _{2}(24 / 7) \cdot n / 2} \cdot 2^{-2\left(\log _{2} N\right) / n} \\
& \geq \frac{1}{10^{11} n^{6}\left(\log _{2} n\right)^{3}} \cdot N \cdot 2^{-\sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}-2} \cdot 2^{-\sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}} \\
& \geq \frac{1}{10^{12}\left(2 \sqrt{\log _{2} N}\right)^{6}\left(\log _{2} \log _{2} N\right)^{3}} \cdot N \cdot 2^{-2 \sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}} \\
& \geq \frac{N \cdot 2^{-2 \sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}}}{10^{14}\left(\log _{2} N\right)^{3}\left(\log _{2} \log _{2} N\right)^{3}} .
\end{aligned}
$$

This shows that $r_{3}(N) \geq N \cdot 2^{-\left(2 \sqrt{\log _{2}(24 / 7)}+o(1)\right) \cdot \sqrt{\log _{2} N}}$, as desired.
We remark that it is also possible to deduce Theorem 1.1 directly from Proposition 2.1, eliminating the need to use estimates for the size of the $n$-th prime as in the proof above. Indeed, following an idea of Green and Wolf [22], given $N$, for any even positive integer $n$ and any $a, b \in[0,1]^{n}$, one can consider the map $\varphi_{a, b}:\{1, \ldots, N\} \rightarrow[0,1)^{n}$ defined by $\varphi_{a, b}(x) \equiv a+x b \bmod 1$ for all $x \in\{1, \ldots, N\}$. For a uniformly random choice of $b \in[0,1]^{n}$, the probability of having some $t \in\{1, \ldots, N\}$ such that $t b \equiv v$ mod 1 for a vector $v \in \mathbb{R}^{n}$ with $\|v\|_{\infty} \leq N^{-1 / n} / 4$ is at most $N \cdot\left(N^{-1 / n} / 2\right)^{n} \leq 1 / 2$ (indeed, for every $t \in\{1, \ldots, N\}$ the vector $t b \bmod 1$ is uniformly distributed over $\mathbb{R}^{n} / \mathbb{Z}^{n}$ and so the probability of having $t b \equiv v \bmod 1$ for a vector $v \in \mathbb{R}^{n}$ with $\|v\|_{\infty} \leq N^{-1 / n} / 4$ is $\left.\left(N^{-1 / n} / 2\right)^{n}\right)$. So we can fix some $b \in[0,1]^{n}$ such that $t b \not \equiv v \bmod 1$ for any $t \in\{1, \ldots, N\}$ and any vector $v \in \mathbb{R}^{n}$ with $\|v\|_{\infty} \leq N^{-1 / n} / 4$. Let us now apply Proposition 2.1 with $\delta=N^{-1 / n} / 4$, yielding a measurable subset $S \subseteq[0,1)^{n}$ satisfying the conditions in the proposition. Now, for any $a \in[0,1]^{n}$ the pre-image $\varphi_{a, b}^{-1}(S) \subseteq\{1, \ldots, N\}$ is three-term progression free. Indeed, suppose there were $x, y, z \in \varphi_{a, b}^{-1}(S)$ with $x>y>z$ and $x+z=2 y$. Then we would have $\varphi_{a, b}(x)+\varphi_{a, b}(z) \equiv(a+x b)+(a+z b)=2 a+(x+z) b=2(a+y b) \equiv 2 \varphi_{a, b}(y) \bmod 1$ and hence $\left|\varphi_{a, b}(x)_{i}-\varphi_{a, b}(z)_{i}\right|<\delta$ for $i=1, \ldots, n$ by the conditions on $S$ (noting that $\left.\varphi_{a, b}(x), \varphi_{a, b}(y), \varphi_{a, b}(z) \in S\right)$, so $\left\|\varphi_{a, b}(x)-\varphi_{a, b}(z)\right\|_{\infty}<\delta=N^{-1 / n} / 4$. On the other hand, $(x-z) b=(a+x b)-(a+z b) \equiv \varphi_{a, b}(x)-\varphi_{a, b}(z)$ $\bmod 1$, which yields a contradiction to our choice of $b($ as $x-z \in\{1, \ldots, N\})$. Thus, the pre-image $\varphi_{a, b}^{-1}(S) \subseteq$ $\{1, \ldots, N\}$ is indeed three-term progression free for any $a \in[0,1]^{n}$. For uniformly random $a \in[0,1]^{n}$, the expected size of this pre-image is $\mathbb{E}\left[\left|\varphi_{a, b}^{-1}(S)\right|\right]=N \cdot \mu(S) \geq N \cdot 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2}$, since for any $x \in\{1, \ldots, N\}$ the vector $\varphi_{a, b}(x)$ is distributed uniformly over $[0,1]^{n}$. Thus, for some choice of $a \in[0,1]^{n}$ we must have $\left|\varphi_{a, b}^{-1}(S)\right| \geq N \cdot 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2}$, and so we obtain

$$
r_{3}(N) \geq N \cdot 10^{-5} \delta^{2} n^{-3} \cdot(7 / 24)^{n / 2} \geq \frac{1}{10^{7} n^{3}} \cdot N \cdot(7 / 24)^{n / 2} \cdot N^{-2 / n}
$$

for any choice of $n$. Optimizing $n$, we can again take $n$ as in (3.1) and obtain

$$
\begin{aligned}
r_{3}(N) & \geq \frac{1}{10^{7}\left(2 \sqrt{\log _{2} N}\right)^{3}} \cdot N \cdot 2^{-\sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}-2} \cdot 2^{-\sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}} \\
& \geq \frac{N \cdot 2^{-2 \sqrt{\log _{2}(24 / 7)} \cdot \sqrt{\log _{2} N}}}{10^{9}\left(\log _{2} N\right)^{3 / 2}}
\end{aligned}
$$

if $N$ is sufficiently large. This again shows $r_{3}(N) \geq N \cdot 2^{-\left(2 \sqrt{\log _{2}(24 / 7)}+o(1)\right) \cdot \sqrt{\log _{2} N}}$, with a slightly better bound for the $o(1)$-term compared to the previous proof.

## 4 Construction of the building blocks

In this section we prove Proposition 2.2, establishing the existence of our desired two-dimensional building blocks for our overall construction. Throughout this section we fix $0<\varepsilon<1$, as in the statement of Proposition 2.2.
We now define the desired subset $T \subseteq[0,1)^{2}$ as follows.

Figure 4.1: The set $T$ defined in Definition 4.1
Definition 4.1. Let us define

$$
\begin{aligned}
& T_{1}=\left\{\left.(a, b) \in\left[\frac{1}{2}, 1\right) \times[0,1) \right\rvert\, \frac{2}{3}<a+b \leq \frac{7}{6}\right\} \\
& T_{2}=\left\{\left.(a, b) \in\left[\frac{1}{2}, 1\right) \times\left[0, \frac{1}{2}\right) \right\rvert\, \frac{7}{6}+\varepsilon \leq a+b \leq \frac{17}{12}\right\} \\
& T_{3}=\left\{\left.(a, b) \in\left[0, \frac{1}{2}\right) \times\left[\frac{1}{2}, 1\right) \right\rvert\, \frac{7}{6}+\varepsilon \leq a+b \leq \frac{17}{12} \text { and } 2 a+b \geq \frac{3}{2}+\varepsilon\right\}
\end{aligned}
$$

and $T=T_{1} \cup T_{2} \cup T_{3} \subseteq[0,1)^{2}$.
For an illustration of these sets, see Figure 4.1. Note that the area $\mu(T)$ of the set $T$ can be computed as follows. First, the area of $T_{1}$ is given by

$$
\mu\left(T_{1}\right)=\left(\frac{1}{2}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{3}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{6}\right)^{2}+\frac{1}{2} \cdot\left(\frac{1}{6}\right)^{2}=\left(\frac{1}{2}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{3}\right)^{2}=\frac{9-2}{36}=\frac{7}{36} .
$$

Next, the area of $T_{2}$ is given by

$$
\begin{aligned}
\mu\left(T_{2}\right) & =\frac{1}{2} \cdot\left(\frac{1}{3}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{12}\right)^{2}-\mu(\{(a, b) \in[1 / 2,1) \times[0,1 / 2) \mid 7 / 6 \leq a+b<7 / 6+\varepsilon\}) \\
& \geq \frac{1}{2} \cdot\left(\frac{1}{3}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{12}\right)^{2}-\frac{\varepsilon}{2}=\frac{16-1}{288}-\frac{\varepsilon}{2}=\frac{15}{288}-\frac{\varepsilon}{2} .
\end{aligned}
$$

Finally, the area of $T_{3}$ is given by

$$
\begin{aligned}
\mu\left(T_{3}\right)=\mu( & \{(a, b) \in[1 / 4,1 / 3) \times[1 / 2,1) \mid 2 a+b \geq 3 / 2+\varepsilon\}) \\
& +\mu(\{(a, b) \in[1 / 3,1 / 2) \times[1 / 2,1) \mid 7 / 6+\varepsilon \leq a+b \leq 17 / 12\}) \\
=\frac{1}{2} \cdot( & \left(\frac{1}{12}\right) \cdot\left(\frac{1}{6}\right)+\left(\frac{1}{6}\right)^{2}-\frac{1}{2} \cdot\left(\frac{1}{12}\right)^{2}+\frac{1}{2} \cdot\left(\frac{1}{6}\right)^{2} \\
& \quad-\mu(\{(a, b) \in[1 / 4,1 / 3) \times[1 / 2,1) \mid 3 / 2 \leq 2 a+b<3 / 2+\varepsilon\})
\end{aligned}
$$

$$
\begin{aligned}
& \quad-\mu(\{(a, b) \in[1 / 3,1 / 2) \times[1 / 2,1) \mid 7 / 6 \leq a+b \leq 7 / 6+\varepsilon\}) \\
& \geq \frac{2+8-1+4}{288}-\frac{\varepsilon}{12}-\frac{\varepsilon}{6}=\frac{13}{288}-\frac{\varepsilon}{4}
\end{aligned}
$$

Thus, for the area of $T=T_{1} \cup T_{2} \cup T_{3}$ we obtain

$$
\begin{equation*}
\mu(T)=\mu\left(T_{1}\right)+\mu\left(T_{2}\right)+\mu\left(T_{3}\right) \geq \frac{7}{36}+\frac{15}{288}-\frac{\varepsilon}{2}+\frac{13}{288}-\frac{\varepsilon}{4} \geq \frac{56+15+13}{288}-\varepsilon=\frac{84}{288}-\varepsilon=\frac{7}{24}-\varepsilon \tag{4.1}
\end{equation*}
$$

It remains to show that there is a measurable function $f: T \rightarrow\left[0,100 / \varepsilon^{2}\right]$ such that the condition in Proposition 2.2 is satisfied. To define this function, we first need some more notation. Let us define the function $g:[0,1) \rightarrow[0,1 / 2)$ by setting

$$
g(t)= \begin{cases}t^{2} & \text { if } t \in[0,1 / 2) \\ (t-1 / 2)^{2} & \text { if } t \in[1 / 2,1)\end{cases}
$$

for all $t \in[0,1)$. Note that this function is measurable and satisfies $0 \leq g(t) \leq(1 / 2)^{2}=1 / 4$ for all $t \in[0,1)$. Furthermore, for any $t, t^{\prime} \in[0,1)$ with $2 t \equiv 2 t^{\prime} \bmod 1$, we have $g(t)=g\left(t^{\prime}\right)$.
Now, we can define the function $f: T \rightarrow\left[0,100 / \varepsilon^{2}\right]$ by

$$
\begin{equation*}
f(x)=\frac{24}{\varepsilon^{2}} \cdot\left(x_{1}+x_{2}\right)^{2}+6 \cdot g\left(x_{1}\right) \tag{4.2}
\end{equation*}
$$

for all $x \in T \subseteq[0,1)^{2}$, where we write the coordinates of $x$ as $x=\left(x_{1}, x_{2}\right)$ as usual. Note that $f$ is a measurable function and we indeed have $0 \leq f(x) \leq\left(24 / \varepsilon^{2}\right) \cdot 2^{2}+6 \cdot 1 / 4 \leq 100 / \varepsilon^{2}$ for all $x \in T$. We need to show that for any $x, y, z \in T$ with $x+z \equiv 2 y \bmod 1$ we have

$$
\begin{equation*}
f(x)+f(z) \geq 2 f(y)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2} \tag{4.3}
\end{equation*}
$$

In order to show this, we begin with some simple facts.
Fact 4.2. For any $s, t \in \mathbb{R}$, the following statements hold:
(i) $s^{2}+t^{2}=2 \cdot(s / 2+t / 2)^{2}+(s-t)^{2} / 2$.
(ii) $(s+t)^{2}+t^{2} \geq s^{2} / 2$.
(iii) If $t \geq 0$, then $(t+1 / 2)^{2} \geq t^{2}+1 / 4$.

Proof. For (i), we observe

$$
s^{2}+t^{2}=2 \cdot\left(\frac{s+t}{2}\right)^{2}+2 \cdot\left(\frac{s-t}{2}\right)^{2}=2 \cdot\left(\frac{s}{2}+\frac{t}{2}\right)^{2}+\frac{(s-t)^{2}}{2}
$$

Plugging $s+t$ and $t$ into this equation, we obtain

$$
(s+t)^{2}+t^{2}=2 \cdot\left(\frac{s+t}{2}+\frac{t}{2}\right)^{2}+\frac{s^{2}}{2} \geq \frac{s^{2}}{2}
$$

showing (ii). For (iii), we simply note that

$$
\left(t+\frac{1}{2}\right)^{2}=t^{2}+t+\frac{1}{4} \geq t^{2}+\frac{1}{4}
$$

if $t \geq 0$.
Fact 4.3. For the set $T \subseteq[0,1)^{2}$ in Definition 4.1, the following statements hold:
(i) For all $(a, b) \in T$, we have $2 / 3<a+b \leq 17 / 12$.
(ii) For all $(a, b) \in T$, we have $g(a) \geq(a-1 / 2)^{2}$.
(iii) For all $(a, b),\left(a^{\prime}, b^{\prime}\right) \in T$ with $a+a^{\prime}<1$, we have $a+b+a^{\prime}+b^{\prime}>11 / 6$.

Proof. Note that (i) follows immediately from the definition of $T$.
To show (ii), first note that $g(a)=(a-1 / 2)^{2}$ for all $a \in[1 / 2,1)$. So we have $g(a)=(a-1 / 2)^{2}$ for all $(a, b) \in T_{1} \cup T_{2}$. It remains to consider $(a, b) \in T_{3}$, then $g(a)=a^{2}$. Furthermore, by $2 a+b \geq 3 / 2+\varepsilon>3 / 2$ and $b<1$, we have $a>1 / 4$ and hence $g(a)=a^{2}>a^{2}-a+1 / 4=(a-1 / 2)^{2}$.
It remains to show (iii), so consider $(a, b),\left(a^{\prime}, b^{\prime}\right) \in T$ with $a+a^{\prime}<1$. Then we must have $a<1 / 2$ or $a^{\prime}<1 / 2$, so let us assume $a^{\prime}<1 / 2$ without loss of generality. This implies $\left(a^{\prime}, b^{\prime}\right) \in T_{3}$ and hence $a^{\prime}+b^{\prime} \geq 7 / 6+\varepsilon>7 / 6$ by the definition of $T_{3}$. Combining this with the lower bound in (i), we obtain

$$
a+b+a^{\prime}+b^{\prime}>\frac{2}{3}+\frac{7}{6}=\frac{11}{6}
$$

We can now derive various consequences for points $x, y, z \in T$ such that $x+z \equiv 2 y \bmod 1$, with the aim of proving (4.3).

Lemma 4.4. Let $T \subseteq[0,1)^{2}$ be defined as in Definition 4.1. Consider points $x, y, z \in T$ such that $x+z \equiv 2 y$ $\bmod 1$. Then we have either

$$
y_{1}+y_{2}=\frac{x_{1}+x_{2}}{2}+\frac{z_{1}+z_{2}}{2}
$$

or

$$
y_{1}+y_{2}=\frac{x_{1}+x_{2}}{2}+\frac{z_{1}+z_{2}}{2}-\frac{1}{2}
$$

Proof. Let $y^{\prime}=\left(y_{1}^{\prime}, y_{2}^{\prime}\right) \in[0,1)^{2}$ be the mid-point of $x=\left(x_{1}, x_{2}\right)$ and $z=\left(z_{1}, z_{2}\right)$ (given by $y_{1}^{\prime}=\left(x_{1}+z_{1}\right) / 2$ and $\left.y_{2}^{\prime}=\left(x_{2}+z_{2}\right) / 2\right)$. Note that

$$
\left(2 y_{1}, 2 y_{2}\right)=2 y \equiv x+z=\left(x_{1}, x_{2}\right)+\left(z_{1}, z_{2}\right)=\left(x_{1}+z_{1}, x_{2}+z_{2}\right)=\left(2 y_{1}^{\prime}, 2 y_{2}^{\prime}\right) \quad \bmod 1
$$

meaning that $2 y_{1} \equiv 2 y_{1}^{\prime} \bmod 1$ and $2 y_{2} \equiv 2 y_{2}^{\prime} \bmod 1$. Hence $y_{1}-y_{1}^{\prime} \in\{-1 / 2,0,1 / 2\}$ and $y_{2}-y_{2}^{\prime} \in$ $\{-1 / 2,0,1 / 2\}$. Since $\left(y_{1}, y_{2}\right) \notin[0,1 / 2)^{2}\left(\right.$ as $\left.T \cap[0,1 / 2)^{2}=\emptyset\right)$, we cannot have both $y_{1}-y_{1}^{\prime}=-1 / 2$ and $y_{2}-y_{2}^{\prime}=-1 / 2$. So we can conclude that $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \in\{-1 / 2,0,1 / 2,1\}$.
The assertion of the lemma is that $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \in\{-1 / 2,0\}$. Hence it suffices to prove $\left(y_{1}+y_{2}\right)-$ $\left(y_{1}^{\prime}+y_{2}^{\prime}\right)<1 / 2$. So let us assume for contradiction that $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \geq 1 / 2$.
Since $y_{2}-y_{2}^{\prime} \leq 1 / 2$, we must therefore have $y_{1} \geq y_{1}^{\prime}$. Similarly, we must have $y_{2} \geq y_{2}^{\prime}$, since $y_{1}-y_{1}^{\prime} \leq 1 / 2$. If $y_{1}^{\prime}<1 / 2$ (i.e. if $x_{1}+z_{1}<1$ ), by Fact 4.3(iii) we have

$$
y_{1}^{\prime}+y_{2}^{\prime}=\frac{\left(x_{1}+x_{2}\right)+\left(z_{1}+z_{2}\right)}{2}>\frac{11 / 6}{2}=\frac{11}{12}=\frac{17}{12}-\frac{1}{2} \geq y_{1}+y_{2}-\frac{1}{2}
$$

where the last inequality follows from Fact 4.3(i). This contradicts $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \geq 1 / 2$, so we must have $y_{1}^{\prime} \geq 1 / 2$.
Now, we obtain $1 / 2 \leq y_{1}^{\prime} \leq y_{1}<1$. Together with $y_{1}-y_{1}^{\prime} \in\{-1 / 2,0,1 / 2\}$, this implies $y_{1}=y_{1}^{\prime}$. So from $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \geq 1 / 2$, we obtain $y_{2} \geq y_{2}^{\prime}+1 / 2 \geq 1 / 2$.
Thus, we have $y_{1}=y_{1}^{\prime} \geq 1 / 2$ and $y_{2} \geq 1 / 2$, meaning that $\left(y_{1}, y_{2}\right) \in[1 / 2,1)^{2}$. By the definition of $T$, this implies $y_{1}+y_{2} \leq 7 / 6$ and hence

$$
y_{1}^{\prime}+y_{2}^{\prime}=\frac{\left(x_{1}+x_{2}\right)+\left(z_{1}+z_{2}\right)}{2}>\frac{2 / 3+2 / 3}{2}=\frac{2}{3}=\frac{7}{6}-\frac{1}{2} \geq y_{1}+y_{2}-\frac{1}{2}
$$

where the first inequality follows from Fact 4.3 (i). This is again a contradiction to $\left(y_{1}+y_{2}\right)-\left(y_{1}^{\prime}+y_{2}^{\prime}\right) \geq$ $1 / 2$.

Corollary 4.5. Let $T \subseteq[0,1)^{2}$ be defined as in Definition 4.1, and let $x, y, z \in T$ be points such that $x+z \equiv 2 y \bmod 1$. Then at least one of the following two statements holds
(a) $\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2} \geq 2 \cdot\left(y_{1}+y_{2}\right)^{2}+\varepsilon^{2} / 2$.
(b) $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$ and $\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2}=2 \cdot\left(y_{1}+y_{2}\right)^{2}+\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2} / 2$.

Proof. By Lemma 4.4, either $y_{1}+y_{2}=\left(x_{1}+x_{2}\right) / 2+\left(z_{1}+z_{2}\right) / 2$ or $y_{1}+y_{2}=\left(x_{1}+x_{2}\right) / 2+\left(z_{1}+z_{2}\right) / 2-1 / 2$ must hold. In the latter case, we have
$\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2} \geq 2 \cdot\left(\frac{x_{1}+x_{2}}{2}+\frac{z_{1}+z_{2}}{2}\right)^{2}=2 \cdot\left(y_{1}+y_{2}+1 / 2\right)^{2} \geq 2 \cdot\left(y_{1}+y_{2}\right)^{2}+1 / 2 \geq 2 \cdot\left(y_{1}+y_{2}\right)^{2}+\varepsilon^{2} / 2$,
where the first inequality follows from Fact 4.2 (i) and the second inequality from Fact 4.2 (iii). So let us now assume that $y_{1}+y_{2}=\left(x_{1}+x_{2}\right) / 2+\left(z_{1}+z_{2}\right) / 2$, then by Fact 4.2(i) we have
$\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2}=2 \cdot\left(\frac{x_{1}+x_{2}}{2}+\frac{z_{1}+z_{2}}{2}\right)^{2}+\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2} / 2=2 \cdot\left(y_{1}+y_{2}\right)^{2}+\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2} / 2$.
If $\left|x_{1}+x_{2}-z_{1}-z_{2}\right| \geq \varepsilon$, this implies the inequality in (a). And if $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$, then (b) holds.
Recall that our goal is to prove (4.3) for any $x, y, z \in T$ with $x+z \equiv 2 y \bmod 1$. If (a) in Corollary 4.5 holds, then it is not hard to show inequality (4.3). The next lemma helps with showing the inequality in case (b) in Corollary 4.5 holds.

Lemma 4.6. Let $T \subseteq[0,1)^{2}$ be defined as in Definition4.4, and let $x, z \in T$ be such that $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$. Suppose that $x_{1} \geq 1 / 2$ or $z_{1} \geq 1 / 2$. Then we have $x_{1}+z_{1} \geq 1$.

Proof. Recall that for all points $(a, b) \in T_{1}$ we have $a+b \leq 7 / 6$, whereas for all points $(a, b) \in T_{2} \cup T_{3}$ we have $a+b \geq 7 / 6+\varepsilon$. Since $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$, this means that we either have $x, z \in T_{1}$ or $x, z \in T_{2} \cup T_{3}$. If $x, z \in T_{1}$, then we have $x_{1} \geq 1 / 2$ and $z_{1} \geq 1 / 2$ and hence $x_{1}+z_{1} \geq 1$, as desired. So let us assume that $x, z \in T_{2} \cup T_{3}$. If $x, z \in T_{2}$, we similarly have $x_{1} \geq 1 / 2$ and $z_{1} \geq 1 / 2$ and hence $x_{1}+z_{1} \geq 1$. If $x, z \in T_{3}$, then we would have $x_{1}<1 / 2$ and $z_{1}<1 / 2$, which contradicts the assumption in the lemma.
So it only remains to consider the case that one of the points $x$ and $z$ is contained in the set $T_{2}$, and the other point in the set $T_{3}$. Let us assume without loss of generality that $x \in T_{2}$ and $z \in T_{3}$. Then we have
$x_{1}+z_{1}=x_{1}+2 z_{1}+z_{2}-\left(z_{1}+z_{2}\right) \geq x_{1}+3 / 2+\varepsilon-\left(z_{1}+z_{2}\right) \geq x_{1}+3 / 2+\varepsilon-\left(x_{1}+x_{2}+\varepsilon\right)=3 / 2-x_{2} \geq 1$,
where the first inequality follows from the definition of $T_{3}$, the second inequality follows from the assumption $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$, and the third inequality follows from the definition of $T_{2}$.

Corollary 4.7. Let $T \subseteq[0,1)^{2}$ be defined as in Definition 4.1, and let $x, y, z \in T$ be such that $x+z \equiv 2 y$ $\bmod 1$ and $\left|x_{1}+x_{2}-z_{1}-z_{2}\right|<\varepsilon$. Then we have

$$
g\left(x_{1}\right)+g\left(z_{1}\right) \geq 2 \cdot g\left(y_{1}\right)+\left(x_{1}-z_{1}\right)^{2} / 2
$$

Proof. Since $x+z \equiv 2 y \bmod 1$, we have $x_{1}+z_{1} \equiv 2 y_{1} \bmod 1$ and hence $2\left(x_{1} / 2+z_{1} / 2\right) \equiv 2 y_{1} \bmod 1$. So we have $g\left(y_{1}\right)=g\left(x_{1} / 2+z_{1} / 2\right)$, and therefore the claimed inequality is equivalent to

$$
g\left(x_{1}\right)+g\left(z_{1}\right) \geq 2 \cdot g\left(x_{1} / 2+z_{1} / 2\right)+\left(x_{1}-z_{1}\right)^{2} / 2
$$

If $x_{1} \geq 1 / 2$ or $z_{1} \geq 1 / 2$, then by Lemma 4.6 we have $x_{1} / 2+z_{1} / 2 \geq 1 / 2$ and hence $g\left(x_{1} / 2+z_{1} / 2\right)=$ $\left(x_{1} / 2+z_{1} / 2-1 / 2\right)^{2}$. Thus, by Fact 4.3 (ii) and Fact 4.2 (i), in this case we obtain
$g\left(x_{1}\right)+g\left(z_{1}\right) \geq\left(x_{1}-1 / 2\right)^{2}+\left(z_{1}-1 / 2\right)^{2}=2 \cdot\left(x_{1} / 2+z_{1} / 2-1 / 2\right)^{2}+\left(x_{1}-z_{1}\right)^{2} / 2=2 \cdot g\left(x_{1} / 2+z_{1} / 2\right)+\left(x_{1}-z_{1}\right)^{2} / 2$,
as desired.
It remains to consider the case that $x_{1}<1 / 2$ and $z_{1}<1 / 2$, then we also have $x_{1} / 2+z_{1} / 2<1 / 2$. Thus, observing that $g\left(x_{1}\right)=x_{1}^{2}$ and $g\left(z_{1}\right)=z_{1}^{2}$ and $g\left(x_{1} / 2+z_{1} / 2\right)=\left(x_{1} / 2+z_{1} / 2\right)^{2}$, by Fact 4.2(i) we obtain

$$
g\left(x_{1}\right)+g\left(z_{1}\right)=x_{1}^{2}+z_{1}^{2}=2 \cdot\left(x_{1} / 2+z_{1} / 2\right)^{2}+\left(x_{1}-z_{1}\right)^{2} / 2=2 \cdot g\left(x_{1} / 2+z_{1} / 2\right)+\left(x_{1}-z_{1}\right)^{2} / 2
$$

Finally, we are ready to prove Proposition 2.2
Proof of Proposition [2.2, Let $T \subseteq[0,1)^{2}$ be given as in Definition 4.1 and let $f: T \rightarrow\left[0,100 / \varepsilon^{2}\right]$ be the measurable function defined in (4.2). In order to prove the proposition it remains to show the inequality

$$
f(x)+f(z) \geq 2 \cdot f(y)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2}
$$

for $x, y, z \in T \subseteq[0,1)^{2}$ with $x+z \equiv 2 y \bmod 1$. For any such $x, y, z \in T$, one of the two statements in Corollary 4.5 holds. If (a) holds, then we have

$$
\begin{aligned}
f(x)+f(z) & =\frac{24}{\varepsilon^{2}} \cdot\left(x_{1}+x_{2}\right)^{2}+6 \cdot g\left(x_{1}\right)+\frac{24}{\varepsilon^{2}} \cdot\left(z_{1}+z_{2}\right)^{2}+6 \cdot g\left(z_{1}\right) \\
& \geq \frac{24}{\varepsilon^{2}} \cdot\left(\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2}\right) \\
& \geq \frac{24}{\varepsilon^{2}} \cdot\left(2 \cdot\left(y_{1}+y_{2}\right)^{2}+\varepsilon^{2} / 2\right) \\
& =2 \cdot \frac{24}{\varepsilon^{2}} \cdot\left(y_{1}+y_{2}\right)^{2}+12 \\
& \geq 2 \cdot \frac{24}{\varepsilon^{2}} \cdot\left(y_{1}+y_{2}\right)^{2}+2 \cdot 6 \cdot(1 / 4)+1+1 \\
& \geq 2 \cdot \frac{24}{\varepsilon^{2}} \cdot\left(y_{1}+y_{2}\right)^{2}+2 \cdot 6 \cdot g\left(y_{1}\right)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2} \\
& =2 \cdot f(y)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2} .
\end{aligned}
$$

If (b) in Corollary 4.5 holds, then in particular by Corollary 4.7 we have

$$
g\left(x_{1}\right)+g\left(z_{1}\right) \geq 2 \cdot g\left(y_{1}\right)+\left(x_{1}-z_{1}\right)^{2} / 2
$$

Together with the equation in (b), this yields

$$
\begin{aligned}
f(x)+f(z) & =\frac{24}{\varepsilon^{2}} \cdot\left(x_{1}+x_{2}\right)^{2}+6 \cdot g\left(x_{1}\right)+\frac{24}{\varepsilon^{2}} \cdot\left(z_{1}+z_{2}\right)^{2}+6 \cdot g\left(z_{1}\right) \\
& =\frac{24}{\varepsilon^{2}} \cdot\left(\left(x_{1}+x_{2}\right)^{2}+\left(z_{1}+z_{2}\right)^{2}\right)+6 \cdot\left(g\left(x_{1}\right)+g\left(z_{1}\right)\right) \\
& \geq \frac{24}{\varepsilon^{2}} \cdot\left(2 \cdot\left(y_{1}+y_{2}\right)^{2}+\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2} / 2\right)+6 \cdot\left(2 \cdot g\left(y_{1}\right)+\left(x_{1}-z_{1}\right)^{2} / 2\right) \\
& =2 \cdot\left(\frac{24}{\varepsilon^{2}} \cdot\left(y_{1}+y_{2}\right)^{2}+6 \cdot g\left(y_{1}\right)\right)+\frac{12}{\varepsilon^{2}} \cdot\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2}+3 \cdot\left(x_{1}-z_{1}\right)^{2} \\
& \geq 2 \cdot f(y)+\left(x_{1}-z_{1}\right)^{2}+2 \cdot\left(x_{1}+x_{2}-z_{1}-z_{2}\right)^{2}+2 \cdot\left(x_{1}-z_{1}\right)^{2} \\
& \geq 2 \cdot f(y)+\left(x_{1}-z_{1}\right)^{2}+\left(x_{2}-z_{2}\right)^{2}
\end{aligned}
$$

where in the last step we used Fact 4.2 (ii). In either case we proved the desired inequality, finishing the proof of Proposition 2.2.
