Abstract

We initiate the study of the information paradox of rotating Kerr black holes by employing the recently proposed island rule. It is known that the scalar field theory near the Kerr black hole horizon can be reduced to the 2-dimensional effective theory. Working within the framework of the 2-dimensional effective theory and assuming the small angular momentum limit, we demonstrate that the entanglement entropy of Hawking radiation from the non-extremal Kerr black hole follows the Page curve and saturates the Bekenstein-Hawking entropy at late times. In addition, we also discuss the effect of the black hole rotation on the Page time and scrambling time. For the extreme Kerr black hole, the entanglement entropy at late times also approximates the Bekenstein-Hawking entropy of the extreme Kerr black hole. These results imply that entanglement islands can provide a semi-classical resolution of the information paradox for rotating Kerr black holes.

I. INTRODUCTION

According to Hawking's calculation [\[1\]](#page-24-1), black holes can emit particles with a thermal spectrum of temperature proportional to the surface gravity of the event horizon—a process later known as Hawking radiation—causing black holes to evaporate and eventually vanish. This suggests that a black hole formed by the collapse of pure-state matter eventually evaporates into Hawking radiation in a maximally mixed state [\[2,](#page-24-2) [3\]](#page-24-3). The process of black hole evaporating violates the basic quantum principle of unitarity, which states that the final state resulting from the complete evaporation of a black hole that collapsed from zeroentropy pure-state matter must also be a pure state, rather than a maximally mixed state. Therefore, the information swallowed by the black hole cannot be recovered via Hawking radiation, giving rise to the well-known black hole information paradox [\[4\]](#page-24-4). It is widely accepted that a deeper understanding of the black hole information paradox can provide meaningful insights into the theory of quantum gravity.

The black hole information paradox can also be explained from the perspective of von Neumann entropy or entanglement entropy. Hawking's calculation suggests that the entropy of Hawking radiation increases linearly during black hole evaporation [\[4\]](#page-24-4). At late times, it will exceed the Bekenstein-Hawking entropy or the thermodynamic entropy of the black hole. If the black hole is initially in a pure state, the unitary evolution principle of quantum mechanics suggests that the entanglement entropy of the black hole should be equal to that of the radiation. If the entropy of radiation calculated by Hawking is treated as the entanglement entropy of radiation, the entanglement entropy of the black hole will exceed its thermodynamic entropy at late times [\[5\]](#page-24-5). This contradicts the principle that the entanglement entropy of a system should be less than its thermodynamic entropy, based on the consideration of the number of degrees of freedom. If black hole evaporation is really an unitary process, the entanglement entropy of Hawking radiation would decrease at late times and eventually reach zero when the black hole is completely evaporated.

Due to black hole evaporation is such a complex process, Page suggested that the entire system of the black hole and its radiation should be in a random pure state $[6, 7]$ $[6, 7]$. It is also proved by Page [\[8\]](#page-24-8) that the random pure state is almost maximally entangled as long as the number of degrees of freedom of one subsystem is much smaller than the number of degrees of freedom of the entire system. According to the Page's theorem, the entanglement entropy of radiation is roughly equal to its coarse-grained entropy at early times, and is approximately equal to the Bekenstein-Hawking entropy of the black hole at late times. As can be seen from Fig.[\(1\)](#page-3-0), the entanglement entropy of the radiation increases from zero and reaches a maximum at the so-called Page time, and then decreases to zero. It is generally believed that being able to reproduce the Page curve in some particular theory means a resolution of the black hole information paradox [\[9\]](#page-24-9).

However, the assumption of unitary evolution of black hole evaporation was not justified until the discovery of AdS/CFT correspondence [\[10\]](#page-24-10). The AdS/CFT correspondence, which states that the quantum gravity in AdS space is dual to a CFT on its boundary, provides the evidence of information conservation during black hole evaporation. This comes from the observation that the evaporation process of black hole in the AdS space can be described

FIG. 1: An illustration for the time evolution of the entanglement entropy of Hawking radiation. The red line and the red dashed line represent Hawking's results, the orange line represents the thermodynamic entropy of the black hole, and the red line and the blue line collectively constitute the Page curve.

by a unitary process of the dual CFT on the boundary. Although the unitary evolution was criticized by the firewall paradox [\[11\]](#page-24-11), it is generally believed that the black hole information paradox can be resolved in the framework of the AdS/CFT correspondence.

Recently, a breakthrough was made in calculating the entanglement entropy of Hawking radiation and reproducing the Page curve within the framework of the AdS/CFT correspondence [\[12–](#page-25-0)[16\]](#page-25-1). The advancement is mainly based on the pioneering work of Ryu-Takayanagi [\[17\]](#page-25-2), which relates the entanglement entropy of a boundary region to the area of a minimal surface in the bulk. When considering the quantum corrections, the RT proposal was generalized to the prescription of Quantum Extreme Surface (QES) [\[18](#page-25-3)[–22\]](#page-25-4). This provides a way to compute the entanglement entropy of the Hawking radiation, which is usually summarized as the island rule. The island rule specifies the entanglement entropy of Hawking radiation by the following formulas

$$
S_{Rad} = \min \{ \text{ext} \left[S_{\text{gen}} \right] \}, \tag{1.1}
$$

$$
S_{\text{gen}} = \frac{\text{Area} \left[\partial I \right]}{4G_N} + S_{\text{field}} \left(R \cup I \right) \quad , \tag{1.2}
$$

where G_N denotes the Newton constant, R is the radiation and I is the entanglement island, *∂I* is the boundary of the island, and S_{field} denotes the entanglement entropy of the quantum

fields (including gravitational field) in the radiation region *R* and the island region *I*. The term *S*gen in Eq.[\(1.2\)](#page-3-1) represents the generalized entropy. By extremizing the generalized entropy S_{gen} , one can determine the location of the island. The minimum value is then chosen to be the entanglement entropy of the Hawking radiation if there are more than one extremum. The island formula can be derived from the Euclidean path integral on the replicated manifold [\[15,](#page-25-5) [16\]](#page-25-1), even without the need for holography. It is shown that replica wormholes are the saddle points in the Euclidean path integral when the entanglement islands emerge. In addition, it is argued that the replica wormholes derivation of island formula is valid not only for the eternal black holes but also for the evaporating black holes [\[23,](#page-25-6) [24\]](#page-25-7). More recently, it is shown that the Ryu-Takayanagi conjecture in AdS/BCFT when the bulk is asymptotically AdS_3 can be derived from the replica path integral and the topological phase transition of the Ryu-Takayanagi surface corresponds to the formation of the replica wormhole on the Karch-Randall brane [\[25\]](#page-25-8).

For the two dimensional evaporating black hole in JT gravity [\[13\]](#page-25-9), entanglement islands that emerge inside the horizon of the black hole after the Page time contribute nontrivialy to the entanglement entropy of the radiation, which allows the reproduction of the Page curve. A similar resolution of the information paradox would also be true for eternal black holes. It is shown that after the Page time, the entanglement entropy of the radiation from the eternal black hole is also modified by the emergence of an island. However, in this case, the island extends to the outer vicinity of the event horizon [\[26\]](#page-25-10). As a result, the entanglement entropy of the radiation saturates the value of the Bekenstein-Hawking entropy of the black hole. Therefore, the island rule can also provide a resolution of information paradox for the eternal black holes.

The proposal of island rule was initially inspired by studies of two-dimensional black holes in JT gravity. It has since been applied to investigate a wide class of black hole spacetimes across different dimensions, various asymptotic behaviors, and higher derivative gravity theories [\[27](#page-26-0)[–108\]](#page-31-0). The island rule has been shown to provide the resolution of the information paradox for these black holes by reproducing the Page curves. However, the proposal of the island rule does not mean a complete solution to the information paradox, as many aspects of its exact physical meaning still need clarification. In addition, among the works mentioned above, the rotating black holes are rarely considered due to the complexity of their spacetime geometry. Rotating black hole, also known as Kerr black hole, is a type of black hole that possesses mass and angular momentum. It is characterized by a ring-shaped singularity and an ergoregion outside of the horizon. Kerr black holes are probably the commonest in the realistic four-dimensional universe. Therefore, it is important to address the information paradox in this type of rotating black hole.

In four or high-dimensional spacetime, it is hard to calculate the entanglement entropy of the conformal field. Usually, the two-dimensional s-wave approximation [\[31\]](#page-26-1) is employed to calculate the entanglement entropy of the matter fields. On the other side, it is well known that the scalar field theory near the Kerr black hole horizon can be reduced to the 2-dimensional effective theory. We reduce the scalar field theory in 4-dimensional Kerr spacetime to a 2-dimensional field theory following the method in [\[109\]](#page-31-1). In the present work, we will work with the 2-dimensional effective theory of the four dimensional Kerr black hole. Due to the nonlinearity of Einstein's equations in higher-dimensional spacetimes, we will ignore the backreaction of the matter field on the spacetime to simplify this analysis.

Note that the Kerr black hole has a significant effect caused by rotation, superradiance [\[110,](#page-31-2) [111\]](#page-31-3), which may result in the instability of the spacetime [\[112\]](#page-31-4). Both Hawking evaporating and superradiance process contribute the radiation outside of the Kerr black hole. It is a rather complicated case when taking the both effects into account. We will consider the case that Hawking radiation dominates over the superradiance by assuming the mass of the Kerr black hole is much larger than its angular momentum.

By assuming the small angular momentum limit, we demonstrate that the entanglement entropy of Hawking radiation from the non-extremal Kerr black hole saturates the coarsegrained entropy of the black hole and follows the Page curve. In addition, we discuss the effect of the black hole rotation on the Page time and scrambling time. For the extreme Kerr black hole, the entanglement entropy at late times also approximates the coarse-grained entropy of the extreme Kerr black hole. These results imply that entanglement islands can provide a semi-classical resolution of the information paradox for the rotating Kerr black holes.

This paper is arranged as follows. In Section [II,](#page-6-0) we briefly review the basic facts about the Kerr black hole and its reduced 2-dimensional effective theory. In Section [III,](#page-11-0) we calculate the entanglement entropy for Hawking radiation in a non-extremal eternal Kerr black hole and reproduce the Page curve. Additionally, we discuss the Page time and scrambling time for non-extremal Kerr black holes. In Section [IV,](#page-20-0) we consider the extremal Kerr black hole case and show that the entanglement entropy of Hawking radiation in the late stage approaches the Bekenstein–Hawking entropy. Section [V](#page-23-0) provides discussion and conclusions.

II. KERR BLACK HOLE AND ITS 2-DIMENSIONAL REDUCTION

A. Kerr black holes

The metric of the Kerr black holes in Boyer-Lindquist coordinates is given by

$$
ds^{2} = -\frac{\Delta - a^{2} \sin^{2} \theta}{\Sigma} dt^{2} - \frac{2a \sin^{2} \theta (r^{2} + a^{2} - \Delta)}{\Sigma} dt d\phi
$$

$$
+ \frac{(r^{2} + a^{2})^{2} - \Delta a^{2} \sin^{2} \theta}{\Sigma} \sin^{2} \theta d\phi^{2} + \frac{\Sigma}{\Delta} dr^{2} + \Sigma d\theta^{2}, \qquad (2.1)
$$

where

$$
\Sigma = r^2 + a^2 \cos^2 \theta, \quad \Delta = r^2 - 2Mr + a^2 = (r - r_+)(r - r_-). \tag{2.2}
$$

Here *M* is the mass of the Kerr black hole and *a* is its rotation parameter. When $M > a$, there are two solutions r_+ and r_- to the equation $\Delta = 0$. The metric [\(2.1\)](#page-6-2) describes the non-extremal Kerr black holes and r_+ and r_- represent the outer and inner horizons, respectively. When $M = a$, the inner and outer horizons coincide and the metric (2.1) describes the extremal Kerr black holes.

The surface gravity κ at the outer horizon can be written as

$$
\kappa = \sqrt{-\frac{1}{2} \left(\nabla^a \xi_b \right) \left(\nabla_a \xi^b \right)} = \frac{r_+ - r_-}{2 \left(r_+^2 + a^2 \right)} , \qquad (2.3)
$$

where ∇_a is the covariant derivative operator, and ξ^a is a non-null Killing vector at the event horizon. The Hawking temperature is given by

$$
T_H = \frac{\kappa}{2\pi} = \frac{r_+ - r_-}{4\pi (r_+^2 + a^2)}.
$$
\n(2.4)

The Bekenstein-Hawking entropy is given by

$$
S_{BH} = \frac{\pi \left(r_+^2 + a^2 \right)}{G_N} \,. \tag{2.5}
$$

The angular velocity of the event horizon is given by

$$
\Omega_H = \frac{a}{r_+^2 + a^2} \,. \tag{2.6}
$$

In particular, for extreme black holes with the equal inner and outer horizons, the surface gravity $\kappa = 0$, which results in the vanishing Hawking temperature.

B. Dimensional reduction of Kerr metric

In this subsection, we will consider the action of a scalar field in the background of four dimensional Kerr black hole and follow the line of [\[109\]](#page-31-1) to show how to obtain the two dimensional effective theory. The procedure also allows us get the reduced two-dimensional metric.

The action for the scalar field φ in 4-dimensional Kerr spacetime is given as

$$
S\left[\varphi\right] = \frac{1}{2} \int_{V} \mathrm{d}^{4}x \sqrt{-g} \varphi \nabla^{2} \varphi , \qquad (2.7)
$$

where g is the determinant of the 4-dimensional Kerr metric. In terms of the metric (2.1) , by taking the limit $r \to r_{+}$, the action can be approximated as

$$
S\left[\varphi\right] = \int_{V} \mathrm{d}^{4}x \varphi \sin \theta \left[-\frac{\left(r_{+} + a^{2}\right)^{2}}{\Delta} \partial_{t}^{2} - \frac{2a\left(r_{+}^{2} + a^{2}\right)}{\Delta} \partial_{t} \partial_{\phi} + \partial_{r} \Delta \partial_{r} - \frac{a^{2}}{\Delta} \partial_{\phi}^{2} \right] \varphi \tag{2.8}
$$

To transform the Boyer-Lindquist coordinates of the Kerr black hole to the locally nonrotating coordinate system, we introduce the following coordinate transformation

$$
\begin{cases} \psi = \phi - \Omega_H t, \\ \xi = t. \end{cases} \tag{2.9}
$$

By substituting the coordinate transformation into the action of the scalar field, one can get

$$
S\left[\varphi\right] = \frac{a}{2\Omega_H} \int_V d^4x \varphi \sin\theta \left[-\frac{1}{f\left(r\right)} \partial_\xi^2 + \partial_r f\left(r\right) \partial_r \right] \varphi , \qquad (2.10)
$$

where

$$
f(r) = \frac{\Omega_H \Delta}{a} \,. \tag{2.11}
$$

It is obvious that the angular derivative terms in the action disappears completely. Then, by expanding the scalar field φ in terms of spherical harmonics as $\varphi(x)$ = $\sum_{l,m} \varphi_{lm}(\xi, r) Y_{lm}(\theta, \psi)$, we can get the effective two dimensional action as

$$
S\left[\varphi\right] = \frac{a}{2\Omega_H} \sum_{l,m} \int_V d\xi dr \varphi_{lm} \left\{ \partial_\xi \left[-\frac{1}{f\left(r\right)} \partial_\xi \varphi_{lm} \right] + \partial_r \left[f\left(r\right) \partial_r \varphi_{lm} \right] \right\} . \tag{2.12}
$$

The effective 2-dimensional metric can be obtained from the above action as:

$$
ds^{2} = -f(r) d\xi^{2} + \frac{1}{f(r)} dr^{2}.
$$
 (2.13)

Thus, we have shown that the four-dimensional scalar field can be reduced to a twodimensional one by taking the near-horizon limit. Close to the outer horizon r_{+} , the nonextremal Kerr spacetime can be approximated by Rindler space. For extremal Kerr spacetime, where $r_{+} = r_{-}$, the near-horizon geometry can be approximated by AdS₂ geometry $|113|$.

In the following chapters, we will work with the two dimensional effective geometry to study the information paradox of the non-extremal and the extremal Kerr black holes. We will calculate the entanglement entropy of Hawking radiation in a 4-dimensional Kerr spacetime by utilizing an effective 2-dimensional spacetime framework. For non-extremal Kerr black holes, both Hawking radiation and superradiation processes contribute to the emitted radiation. To ensure that Hawking radiation dominates over superradiation, the black hole's mass must be substantially greater than its rotational energy. Therefore, we will work in the small angular momentum limit, i.e. $a \ll M$.

Furthermore, we assume the radiation is described by the conformal field with the central charge *c*. To neglect backreaction effects, we assume the black hole is macroscopic, with the central charge *c* satisfying the condition $1 \ll c \ll M$. The radiation dynamics can be semiclassically described as a 2-dimensional conformal field theory (CFT). By disregarding the grey-body factor, we can approximate the entanglement entropy in the 4-dimensional Kerr spacetime using the analysis of the 2-dimensional CFT.

In principle, any number and any size of islands can exist. However, when there is more than one island, the situation becomes more complex. For simplicity, we restrict our discussion to cases with either no island or only one island. We will confirm that this restriction is sufficient to solve the information paradox and to provide a reasonable Page curve.

C. Tortoise coordinates of non-extremal case

According to the reduced 2-dimensional metric given in Eq.[\(2.13\)](#page-7-1), the corresponding tortoise coordinate $r^*(r)$ is given by:

$$
r^{*}(r) = \int f^{-1}(r) dr = \int \frac{r_{+}^{2} + a^{2}}{(r - r_{+})(r - r_{-})} dr = \frac{r_{+}^{2} + a^{2}}{r_{+} - r_{-}} \ln \left| \frac{r - r_{+}}{r - r_{-}} \right| + C , \qquad (2.14)
$$

FIG. 2: Penrose diagram of the non-extremal Kerr black hole. Here, *r*[−] represents the inner horizon of the black hole, r_+ represents the outer horizon, \mathcal{J}_- is past null infinity, \mathcal{J}_+ is future null infinity, and \mathcal{I}_0 is spacelike infinity.

where *C* is an integration constant. For simplicity, we can set $C = 0$. We then perform the following coordinate transformations:

$$
u = \xi - r^*, \quad v = \xi + r^* \,. \tag{2.15}
$$

The metric in the *u* and *v* coordinates is given by

$$
ds^{2} = -f(r) du dv = -\frac{(r - r_{+}) (r - r_{-})}{r_{+}^{2} + a^{2}} du dv
$$
 (2.16)

In order to eliminate coordinate singularities, the Kruskal coordinates is defined as

Up wedge:
$$
V = \frac{e^{\kappa v}}{\kappa}, \quad U = \frac{e^{-\kappa u}}{\kappa}
$$
 (2.17)

Down wedge:
$$
V = -\frac{e^{\kappa v}}{\kappa}, \quad U = -\frac{e^{-\kappa u}}{\kappa}
$$
 (2.18)

Right wedge:
$$
V = \frac{e^{\kappa v}}{\kappa}, \quad U = -\frac{e^{-\kappa u}}{\kappa}
$$
 (2.19)

Left wedge:
$$
V = -\frac{e^{\kappa v}}{\kappa}, \quad U = \frac{e^{-\kappa u}}{\kappa}
$$
 (2.20)

Note that the spacetime has been maximally extended. The corresponding Penrose diagram for the Kerr black hole in Kruskal coordinates is shown in Figure [2.](#page-9-0) The metric of the two-dimensional effective spacetime in *U* and *V* coordinates is given by

$$
ds^2 = -\Omega^2 dU dV , \qquad (2.21)
$$

where the conformal factor Ω is given by:

$$
\Omega = \sqrt{f(r)} \exp(-\kappa r^*) \tag{2.22}
$$

This procedure shows that the spacetime is conformally flat, which means that in the Kruskal coordinates, the geodesic distance $d(x_1, x_2)$ between two spacetime points x_1 and x_2 is given by

$$
d(x_1, x_2) = \Omega(x_1) \Omega(x_2) [U(x_2) - U(x_1)] [V(x_1) - V(x_2)] . \qquad (2.23)
$$

D. Tortoise coordinates for the extremal case

For extremal black holes, where $r_+ = r_- = M = a$, we use r_h to denote the horizon radius. According to the reduced 2-dimensional metric given in Eq.[\(2.13\)](#page-7-1), the tortoise coordinate *r* ∗ (*r*) is defined as

$$
r^*(r) = -\left| \int f^{-1}(r) dr \right| = -\left| \int \frac{r_h^2 + a^2}{(r - r_h)^2} dr \right| = -\frac{2r_h^2}{|r - r_h|} + C \,. \tag{2.24}
$$

Set $C = 0$ for simplicity. In the extreme case, the reduced two-dimensional metric in u and *v* coordinates is given by

$$
ds^{2} = -f(r) du dv = -\frac{(r - r_{h})^{2}}{2r_{h}^{2}} du dv .
$$
 (2.25)

The Kruskal coordinates is defined as follows:

Left wedge:
$$
V = -\frac{e^{\kappa v}}{\kappa}, \quad U = \frac{e^{-\kappa u}}{\kappa}
$$
 (2.26)

Right wedge:
$$
V = \frac{e^{\kappa v}}{\kappa}, \quad U = -\frac{e^{-\kappa u}}{\kappa}
$$
 (2.27)

where the parameter κ is given by $\kappa = 1/r_h$. Note that κ is not the surface gravity of the extremal black hole. The Penrose diagram for the extremal Kerr black hole is shown in Figure [3.](#page-11-2) The metric for the extremal Kerr black hole in the Kruskal coordinates has the same form of the non-extremal Kerr black hole as given in Eq.[\(2.21\)](#page-10-1). The extremal black hole spacetime is also conformally flat, similar to the non-extremal Kerr black hole. The geodesic distance can also be calculated from Eq.[\(2.23\)](#page-10-2).

FIG. 3: A Penrose diagram of the region of spacetime covered by Kruskal coordinates of an extremal Kerr black hole. Here, r_h represents the horizon of the black hole, \mathcal{J}_- is past null infinity, \mathcal{J}_+ is future null infinity, and \mathcal{I}_0 is spacelike infinity.

III. PAGE CURVE FOR NON-EXTREMAL KERR BLACK HOLE

A. Entanglement Entropy without island

Without considering the contributions of the island, we will compute the entanglement entropy of the Hawking radiation from a non-extremal Kerr black hole in the late stage of evaporation. The Hawking radiation is collected in the regions R_{\pm} , as shown in Figure [4.](#page-12-0) We assume this region is far from the horizon of the black hole, and the dynamics of the Hawking radiation can be approximated by a conformal field theory in flat spacetime. Without island, as shown in Figure [4,](#page-12-0) the end-points of the entanglement wedge of the radiation are the boundaries b_+ and b_- of the right region R_+ and the left region $R_-,$ respectively.

Assuming there is no island forming in the late stage, we should calculate the entanglement entropy of the CFT for the region outside $[b_-, b_+]$. If the whole system is in a pure state at $t = 0$, then the entropy of the region $[b_-, b_+]$ is equal to that of the outside region. Therefore, the entanglement entropy of the radiation region is given by:

$$
S_R = \frac{c}{3} \ln d(b_+, b_-) \tag{3.1}
$$

where $d(b_+, b_-)$ is the geodesic distance between the boundary points b_+ and b_- . For b_+

FIG. 4: Penrose diagram of an eternal non-extremal Kerr black hole without island. The Hawking radiation is assumed to be located in the regions R_{\pm} , with boundaries b_{\pm} .

we have $(\xi, r) = (t_b, r_b)$, and for *b*₋ we have $(\xi, r) = (-t_b + i\beta/2, r_b)$ with $\beta = \frac{2\pi}{\kappa}$ $\frac{2\pi}{\kappa}$ being the inverse Hawking temperature.

From equations [\(2.21\)](#page-10-1), [\(2.23\)](#page-10-2), and [\(3.1\)](#page-11-3), the entanglement entropy of the Hawking radiation in Kerr spacetime takes the form of:

$$
S_R = \frac{c}{6} \ln \{ \Omega(b_+) \Omega(b_-) [U(b_-) - U(b_+)] [V(b_+) - V(b_-)] \} . \tag{3.2}
$$

When we substitute the coordinates of b_+ and $b_-,$ the entanglement entropy of the Hawking radiation can be expressed as:

$$
S = \frac{c}{3} \ln \left[\frac{2\sqrt{f(r_b)}}{\kappa} \cosh(\kappa t_b) \right].
$$
 (3.3)

Without island, Eq.[\(3.3\)](#page-12-1) shows the entanglement entropy of the Hawking radiation as a function of time. At the late stage of evaporation, the entropy can be approximated as:

$$
S^{(late)} \approx \frac{c}{3} \ln \left[4 \sqrt{\frac{(r_b - r_+)(r_b - r_-)(r_+^2 + a^2)}{(r_+ - r_-)^2}} \right] + \frac{c}{3} \kappa t_b \approx \frac{c}{3} \kappa t_b \,. \tag{3.4}
$$

Consequently, without the island, the information that falls into the black hole cannot escape, and the entanglement entropy grows linearly with time. The entanglement entropy

FIG. 5: Penrose diagram of an eternal non-extremal Kerr black hole with the island. The Hawking radiation is assumed to be located in the regions R_{\pm} , with boundaries b_{\pm} . The island region, denoted as *I*, has boundaries a_{\pm} .

of the Hawking radiation will increase linearly towards infinity and eventually exceed the Bekenstein-Hawking entropy of the Kerr black hole. Assuming the eternal Kerr black hole is sustained by feeding it pure state matter, the total von Neumann entropy of the black hole will not change. For an eternal Kerr black hole, the maximum entanglement entropy of the Hawking radiation will be twice the Bekenstein-Hawking entropy of a one-sided Kerr black hole, taking into account contributions from both the left and right wedges in the conformal diagram. Therefore, no-island computation leads to the information paradox for the eternal Kerr black holes. The next section will show how the inclusion of the island can resolve the black hole information problem and yield the expected Page curve for an eternal non-extremal Kerr black hole.

B. Entanglement Entropy with Island

Now, we calculate the entanglement entropy of the radiation by consider the contribution from the island. As shown in Figure [5,](#page-13-1) an island region *I* with boundaries a_+ and a_- is introduced in the Penrose diagram. We will follow the island rule, which is outlined in $Eq.(1.1)$ $Eq.(1.1)$ and $Eq.(1.2)$ $Eq.(1.2)$, to study the information paradox of Kerr black hole.

The von Neumann entropy of the matter fields in the region $R \cup I$ is given by:

$$
S_{field}(R \cup I) = \frac{c}{6} \ln \frac{d(a_+,a_-) d(b_+,b_-) d(a_+,b_+) d(a_-,b_-)}{d(a_+,b_-) d(a_-,b_+)} , \qquad (3.5)
$$

where a_+ and a_- are the boundaries of the island region *I*, and b_+ and b_- represent the boundaries of the radiation regions R_+ and R_- , respectively.

For the area term in the generalized entropy, we consider the cutoff surface $r = r_a$ at constant coordinate time *t*, where the metric can be described by:

$$
ds_2^2 = \Sigma d\theta^2 + \frac{(r^2 + a^2)^2 - \Delta a^2 \sin^2 \theta}{\Sigma} \sin^2 \theta d\phi^2
$$
 (3.6)

The determinant of the induced metric at the cutoff surface is:

$$
\sigma = \left[\left(r_a^2 + a^2 \right) - \Delta a^2 \sin^2 \theta \right] \sin^2 \theta . \tag{3.7}
$$

Then the area of the boundary of the island at $r = r_a$ is given by:

Area
$$
(r = r_a) = 2\pi \int_0^{\pi} \sqrt{(r_a^2 + a^2)^2 - (r_a - r_-)(r_a - r_+)} a^2 \sin^2 \theta \sin \theta d\theta
$$
. (3.8)

The above integral results in a rather complicated expression for the area term, which makes the analysis very difficult to proceed. Note that the location of island is unknown in advance. However, previously studies have shown that for the eternal black holes, the location of island extends a scale proportional to the Planck length beyond the horizon. In addition, we assume that the mass parameter *M* of the black hole is much greater than its rotational parameter *a*, i.e. *a* is a small parameter. Combining these two aspects, the second term under the square root can be safely neglected, which gives a compact expression for the area term as

Area
$$
(r = r_a) = 4\pi \left(r_a^2 + a^2 \right)
$$
. (3.9)

By taking the island contribution, the generalized entropy is defined as:

$$
S_{\text{gen}} = \frac{2 \text{Area} (r = r_a)}{4 G_N} + S_{field} (R \cup I) \tag{3.10}
$$

In the following, we will extremize the generalized entropy given in Eq.[\(3.10\)](#page-14-0) at different stages of evaporation. By selecting the minimal value as the location of the island, we can determine the entanglement entropies of the radiation at early times and late times. Page demonstrated that when the subsystem is much smaller than the total system, the entanglement entropy can be approximated by the thermodynamic entropy of the subsystem [\[6,](#page-24-6) [114\]](#page-31-6). Therefore, we expect that in the following discussions, the entanglement entropy of the radiation will initially increase linearly at early times and approach twice the Bekenstein-Hawking entropy of the non-extremal Kerr black hole at late times.

1. Early Stages of Evaporation

Now we will demonstrate that there is no island appearing in the early stages of nonextremal eternal Kerr black hole evaporation, and that the entanglement entropy increases linearly with time.

Assume that the system is in a pure state at $t = 0$. By using Eq.[\(3.5\)](#page-14-1), the generalized entropy at the early stages of black hole evaporation takes the form:

$$
S_{\text{gen}} = \frac{2\pi (r_a^2 + a^2)}{G_N} + \frac{c}{3} \ln \left\{ \frac{\cosh \left[\kappa (r_b^* - r_a^*)\right] - \cosh \left[\kappa (t_b - t_a)\right]}{\cosh \left[\kappa (r_b^* - r_a^*)\right] + \cosh \left[\kappa (t_b + t_a)\right]} \right\} + \frac{c}{6} \ln \left[\frac{2^4 f(r_a) f(r_b) \cosh^2 (\kappa t_a) \cosh^2 (\kappa t_b)}{\kappa^4} \right]. \tag{3.11}
$$

At early times, where t_a and t_b are much less than r_b , the entropy can be approximated as:

$$
S_{\text{gen}}^{(early)} \approx \frac{2\pi (r_a^2 + a^2)}{G_N} + \frac{c}{6} \ln \left[\frac{2^4 f(r_a) f(r_b) \cosh^2(\kappa t_a) \cosh^2(\kappa t_b)}{\kappa^4} \right] \,. \tag{3.12}
$$

To extremize the variations of t_a and r_a in the above Equation [\(3.12\)](#page-15-1), we have:

$$
\frac{\partial S_{\text{gen}}^{(early)}}{\partial t_a} = \frac{c\kappa \sinh\left(\kappa t_a\right)}{3\cosh\left(\kappa t_a\right)} = 0\,,\tag{3.13}
$$

$$
\frac{\partial S_{\text{gen}}^{(early)}}{\partial r_a} = \frac{c}{6} \left[\frac{24\pi r_a \left(r_a - r_+ \right) \left(r_a - r_- \right) + cG_N \left(2r_a - r_+ - r_- \right)}{cG_N \left(r_a - r_+ \right) \left(r_a - r_- \right)} \right] = 0 \,. \tag{3.14}
$$

Neglecting the higher-order term $o(cG_N)$, the positions of the island boundaries a_+ and $a_$ are approximately given by:

$$
t_a = 0, \quad r_a \approx \frac{cG_N (r_+ + r_-)}{24\pi r_+ r_-} \approx \frac{c(r_+ + r_-)}{24\pi r_+ r_-} \ell_p^2 = \frac{cM}{12\pi a^2} \ell_p^2 \,, \tag{3.15}
$$

where ℓ_p is the Planck length. We should discard all Planck scale physics. Therefore, this indicates that no island exists in the early stage of evaporation in an eternal non-extremal Kerr black hole.

2. Late Stages of Evaporation

We now calculate the entanglement entropy of the radiation in the Kerr black hole and verify whether the configuration of the island can resolve the information paradox in the late stages of black hole evaporation. At late times, the contribution from radiation outside the cutoff will correspondingly increase as more radiation enters the cutoff surface. While the coarse-grained entropy can continue to grow linearly, a sustained linear increase in the fine-grained entropy would violate unitarity. To solve the information paradox, we must limit the growth of the entanglement entropy.

At the late stages of evaporation, we have $t_a, t_b \gg \kappa$. Since the geodesic distance between the left wedge and the right wedge in the Penrose diagram shown in Figure [5](#page-13-1) is very large, we have:

$$
d(a_{+}, a_{-}) \approx d(b_{+}, b_{-}) \approx d(a_{\pm}, b_{\mp}) \gg d(a_{\pm}, b_{\pm}) . \tag{3.16}
$$

Therefore the generalized entropy in equation [\(3.10\)](#page-14-0) can be approximated as:

$$
S_{\text{gen}}^{(\text{late})} \approx \frac{2\pi (r_a^2 + a^2)}{G_N} + \frac{c}{6} \ln \left[(r_a - r_+) (r_a - r_-) (r_b - r_+) (r_b - r_-) \right] + \frac{c}{3} \ln \left[\frac{8 (r_+^2 + a^2)}{(r_+ - r_-)^2} \right] + \frac{c}{3} \ln \left\{ \cosh \left[\kappa (r_a^* - r_b^*) \right] - \cosh \left[\kappa (t_a - t_b) \right] \right\} \ . \tag{3.17}
$$

By finding the partial derivative with respect to t_a of the above equation and setting it to zero, we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial t_a} = \frac{c}{3} \cdot \frac{-\kappa \sinh\left[\kappa \left(t_a - t_b\right)\right]}{\cosh\left[\kappa \left(r_a^* - r_b^*\right)\right] - \cosh\left[\kappa \left(t_a - t_b\right)\right]} = 0. \tag{3.18}
$$

Solving this equation, we find $t_a = t_b$. Substituting $t_a = t_b$ back into $S_{gen}^{\text{(late)}}$ and then finding the extremum with respect to r_a , we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial r_a} = \frac{4\pi r_a}{G_N} + \frac{c}{3} \cdot \frac{(r_+ - r_-)}{(r_a - r_-)} \cdot \frac{\sinh\left[\kappa\left(r_a^* - r_b^*\right)\right]}{\cosh\left[\kappa\left(r_a^* - r_b^*\right)\right] - 1} + \frac{c}{6} \cdot \frac{2r_a - r_+ - r_-}{(r_a - r_+) \left(r_a - r_- \right)} = 0 \,. \tag{3.19}
$$

Solving this equation, we find $t_a = t_b$. Substituting it back into $S_{gen}^{\text{(late)}}$ and then finding the extremum with respect to r_a , we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial r_a} = \frac{4\pi r_a}{G_N} + \frac{c}{3} \cdot \frac{(r_+ - r_-)}{(r_a - r_-)} \cdot \frac{\sinh\left[\kappa \left(r_a^* - r_b^*\right)\right]}{\cosh\left[\kappa \left(r_a^* - r_b^*\right)\right] - 1} + \frac{c}{6} \cdot \frac{2r_a - r_+ - r_-}{(r_a - r_+)\left(r_a - r_- \right)} = 0. \tag{3.20}
$$

This is a rather complicated equation for r_a . By expanding $\partial S_{\text{gen}}^{(\text{late})}/\partial r_a$ at r_+ and neglecting higher-order terms, we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial r_a} \approx -\frac{c}{3} \sqrt{\frac{(r_b - r_-)}{(r_b - r_+)(r_+ - r_-)}} \cdot \frac{1}{(r_a - r_+)^{\frac{1}{2}}} + \frac{12\pi r_+ r_b - cG_N - 12\pi r_+^2}{3G_N (r_b - r_+)} = 0. \quad (3.21)
$$

Solving this equation, we find the location of the island as

$$
r_a \approx r_+ + \frac{c^2 G_N^2 (r_b - r_+)(r_b - r_-)}{(r_+ - r_-) \left[12\pi r_+(r_b - r_+) - cG_N\right]^2} \,. \tag{3.22}
$$

It can seen that the location of the island extends a scale proportional to the Planck length beyond the event horizon as expected. In addition, increasing the rotation parameter *a* reduces the leading term of *ra*, while it increases the subleading term.

Since $r_a - r_+$ is a rather small quantity and $r_a^* \to -\infty$ when $r \to (r_+)_+$, we have the following approximation:

$$
\cosh\left[\kappa\left(r_a^* - r_b^*\right)\right] - 1 \approx \frac{e^{-\kappa r_a^*} e^{\kappa r_b^*}}{2} - 1 \approx \frac{\left(r_+ - r_-\right)^2 \left[12\pi r_+\left(r_b - r_+\right) - cG_N\right]^2}{2c^2 G_N^2 \left(r_b - r_-\right)^2} \,. \tag{3.23}
$$

Substituting these approximations back into Equation [\(3.17\)](#page-16-1), the generalized entropy at the late stages of evaporation is:

$$
S_{\text{gen}}^{\text{(late)}} = \frac{c}{3} \ln \left\{ \frac{4 \left(r_+{}^2 + a^2\right) \left(r_b - r_+\right) \left[12 \pi r_+ \left(r_b - r_+\right) - cG_N\right]}{cG_N \left(r_b - r_+\right)} + \frac{2 \pi \left(r_+{}^2 + a^2\right)}{G_N} \approx 2S_{\text{BH}} \,. \tag{3.24}
$$

In the above expression for the entanglement entropy of the radiation, the leading term $2S_{\text{BH}}$ comes from the area of the boundary of the island. The subleading term originates from the quantum effects of the matter field, which is negligible in comparison with the leading term. Thus, in the late stages of black hole evaporation, the entanglement entropy of the Hawking radiation will approach a constant value of twice of the Bekenstein-Hawking entropy of the eternal Kerr black hole. The result also demonstrates that the single-island assumption is reasonable.

Along with the previously obtained results, we can draw the Page curve for a nonextremal Kerr black hole, as shown in Figure [6.](#page-18-1) During the early stage, the generalized entropy increases almost linearly, while during the late stage, the increase in entanglement entropy ceases. Finally, the generalized entropy of the Hawking radiation will asymptotically approach twice the Bekenstein-Hawking entropy. Therefore, the generalized entropy

FIG. 6: Evolution diagram of the entanglement entropy of Hawking radiation emitted by a nonextremal Kerr black hole. The solid red line and the dashed red line represent results without the island, while the dark blue line represents the thermodynamic entropy of the black hole. The solid red line and the dark blue line together constitute the Page curve of the eternal non-extremal Kerr black hole.

of Hawking radiation from the non-extremal Kerr black hole follows the Page curve, which implies that the island rule can be properly applied to resolve the information paradox of the non-extremal Kerr black holes.

C. Page time and Scrambling time

In this subsection, we will discuss the Page time and scrambling time. More precisely, the Page time is when the entanglement entropy in Hawking radiation is maximal. For an evaporating black hole, the Page time is when the entanglement entropy begins to decrease. In the case of eternal black holes, the entanglement entropy of the Hawking radiation remains approximately constant after the Page time. At that point, we can determine the Page time by comparing the no-island and island entropy stages. The two curves intersect approximately at the point where a transition from a no-island state to an island state occurs, and the entanglement entropy becomes stable. Thus, the Page time can be calculated as:

$$
t_{\rm Page} = \frac{6S_{\rm BH}}{c\kappa} = \frac{3\beta S_{\rm BH}}{c\pi} , \qquad (3.25)
$$

It is obvious that the Page time decreases as the rotation parameter *a* increases.

According to the Hayden-Preskill protocol [\[115\]](#page-31-7), the scrambling time determines how long it takes for information that falls into the black hole to be decoded from the outgoing Hawking radiation. The information eventually enters the island region, and the scrambling time is also the time it takes for information to enter the island. Since the island region is part of the radiation region, once the lost information enters the island region, it purifies the radiation entropy.

The escaped information is stored in the Hawking radiation, and after the scrambling time, an external observer can retrieve the information that fell into the black hole from the radiation. We assume that the information falling into the black hole can be immediately decoded. The relationship between the position of the island boundary and the scrambling time is as follows: a light ray emitted from the cutoff surface intersects the boundary of the island at $r = r_a$ after one scrambling time.

In the case of an external non-extremal Kerr black hole, the position of the island boundary is fixed near the outer horizon. Therefore, the scrambling time is actually the time it takes for a light ray released from the cutoff surface to travel to the island. For example, assume an observer at $r = r_b$ sends out a light signal at time t_1 and reaches the island boundary at $r = r_a$ at time t_2 . The distance between these two points in the ingoing null direction is given by:

$$
V(t_1, b) - V(t_2, a) = (t_1 + r_b^*) - (t_2 + r_a^*)
$$
 (3.26)

Then the time required for information sent from the cutoff surface at $r = r_b$ towards the Kerr black hole to reach the island boundary at $r = r_a$ will be:

$$
\Delta t = (r_b^* - r_a^*) - [V(t_1, r_b) - V(t_2, r_a)],
$$
\n(3.27)

where $V(t_2, r_a)$ should be greater than or equal to $V(t_1, r_b)$. The minimum time required for the information to be retrieved from the Kerr black hole is given by:

$$
t_{\rm scr} = \Delta t = r_b^* - r_a^* \,. \tag{3.28}
$$

Incorporating the coordinates of the island boundary, the expression for the scrambling time is given by

$$
t_{\rm scr} = \frac{1}{\kappa} \ln \left\{ \frac{(r_+ - r_-) \left[12\pi r_+ (r_b - r_-) - cG_N \right]}{cG_N (r_b - r_-)} \right\}
$$

= $\frac{\beta}{2\pi} \ln (S_{\rm BH}) + \frac{\beta}{2\pi} \ln \left\{ \frac{(r_+ - r_-) \left[12\pi r_+ (r_b - r_-) - cG_N \right]}{\pi c (r_b - r_-) (r_+^2 + a^2)} \right\}$
 $\approx \frac{\beta}{2\pi} \ln (S_{\rm BH}) + \frac{\beta}{2\pi} \ln \left\{ \frac{12 (r_+^2 - a^2)}{c (r_+^2 + a^2)} \right\}.$ (3.29)

It can be seen that increasing the rotation parameter a reduces the leading term of r_a , while it increases the subleading term. However, assuming that the black hole's rotation parameter *a* is much smaller than its mass *M* and the central charge *c* is much larger than 1 but much smaller than its mass *M*, the last term can be neglected. Then, one can find that the scrambling time is logarithmically smaller than the lifetime of the black hole and is negligible compared to the Page time $t_{\text{Page}} = 3\beta S_{\text{BH}}/\pi$. It agrees with the result predicted by the Hayden-Preskill protocol [\[115,](#page-31-7) [116\]](#page-31-8). This verifies the conclusion that if a non-extremal Kerr black hole acts as a quantum computer, it can perform fast-scrambling.

IV. EXTREMAL KERR BLACK HOLES

Since the extremal Kerr black hole has different Penrose diagram compared to the nonextremal Kerr black hole, the entanglement entropy of Hawking radiation for extremal Kerr black holes cannot obtained by straightforwardly taking the limit *r*[−] → *r*⁺ for non-extremal Kerr black holes. In this chapter, we will recalculate the entanglement entropy of Hawking radiation for extremal Kerr black holes using a method similar to that used for non-extremal Kerr black holes.

As shown in Figure [7,](#page-21-0) the Hawking radiation is collected in the region *R*. We assume that this region is far from the event horizon of the black hole, allowing the dynamics of the Hawking radiation to be approximated by a conformal field theory in flat spacetime. We assume that the entire system is in a pure state at $t = 0$. In the early stages of evaporation of extremal Kerr black holes, the radiation region extends from the inner boundary *b* to the spacial infinity, which makes the geodesic length for the radiation divergent. Therefore, this approach is ineffective. However, from the physical consideration, we believe that the entanglement entropy of the radiation at early time is linearly increasing with the time.

FIG. 7: Penrose diagram of an eternal extremal Kerr black hole without island. The Hawking radiation is assumed to be located in the regions *R*, with boundaries *b*.

We now consider the question that whether one can get a finite entanglement entropy of the radiation for the extremal Kerr black hole at late times. It is expected that at late times, the entanglement island emerges. As shown in Figure [8,](#page-22-0) we introduce an island region *I* with its boundary denoted as a . In this diagram the singularity ring $r = 0$ can be safely crossed and the *r <* 0 region is also meaningful. The Cauchy surface must intersect the surface $r = 0$. It is assumed that the intersection point is at $a_0 = (t_0, 0)$. To determine the entanglement entropy of the Hawking radiation, the geodesic we seek must include the point a_0 . However, because the extremal Kerr spacetime has a singularity at a_0 , the expression for the geodesic distance is not well-defined. This makes calculating the entanglement entropy of Hawking radiation in the extremal case quite challenging. In [\[63\]](#page-28-0), a similar problem is encountered when studying the extremal dilaton black holes.

One key observation is that the complementary region [*a, b*] of the radiation and the island does not contain any singularity. Thus, in the late stages of extremal Kerr black hole evaporation, the geodesic length between *a* and *b* is well-defined and the generalized entropy can be calculated from this geodesic length. In this sense, it is possible to find the island's position and study the behavior of entanglement entropy at late times by extremalizing the generalized entropy.

FIG. 8: Penrose diagram of an eternal extremal Kerr black hole with the island. The Hawking radiation is assumed to be located in the regions *R*, with boundary *b*. The island region, denoted as *I*, has boundary *a*.

In the late stages of evaporation, we should have $r_a \approx r_h$. Using the same approximation as in Equation [\(3.8\)](#page-14-2), we obtain the generalized entropy of Hawking radiation for the extremal case as:

$$
S_{\text{gen}}^{\text{(late)}} = \frac{Area\left(\partial I\right)}{4G_N} + \frac{c}{6}\ln\left(d\left(a,b\right)\right)
$$

$$
\approx \frac{\pi\left(r_a^2 + a^2\right)}{G_N} + \frac{c}{6}\left\{\frac{2r_h^2\left(r_a - r_h\right)\left(r_b - r_h\right)\left[\cosh\left(\frac{r_a^* - r_b^*}{r_h}\right) - \cosh\left(\frac{\xi_a - \xi_b}{r_h}\right)\right]}{r_h^2 + a^2}\right\} \ . \tag{4.1}
$$

By finding the partial derivative with respect to t_a of the above equation and setting it to zero, we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial t_a} = \frac{c}{6} \frac{-\sinh\left(\frac{t_a - t_b}{r_h}\right)}{\cosh\left(\frac{r_a^* - r_b^*}{r_h}\right) - \cosh\left(\frac{t_a - t_b}{r_h}\right)} = 0. \tag{4.2}
$$

Solving this equation, we find $t_a = t_b$. Substituting it back into $S_{\text{gen}}^{(\text{late})}$ and taking the partial derivative with respect to r_a , we have:

$$
\frac{\partial S_{\text{gen}}^{(\text{late})}}{\partial r_a} = \frac{2\pi r_a}{G_N} + \frac{c}{6} \left\{ \frac{2r_h \sinh\left(\frac{r_a^* - r_b^*}{r_h}\right)}{\left(r_a - r_h\right)^2 \left[\cosh\left(\frac{r_a^* - r_b^*}{r_h}\right) - 1\right]} + \frac{1}{r_a - r_h} \right\} = 0. \tag{4.3}
$$

Setting $r_a = r_h + \alpha$ √ $\overline{cG_N}$, and then substituting and neglecting higher-order terms of cG_N , we have:

$$
r_a \approx r_h + \sqrt{\frac{cG_N}{6\pi}} \,. \tag{4.4}
$$

Using the approximation in Equation [\(4.1\)](#page-22-1), the entanglement entropy in the late stages of extremal Kerr black hole evaporation is given by:

$$
S_{\text{gen}}^{(\text{late})} \approx \frac{\pi (r_h^2 + a^2)}{G_N} + \sqrt{\frac{2cr_h^2}{3G_N}} - \frac{cr_h}{3(r_b - r_h)} + \frac{c}{12} \ln \left[\frac{cG_N (r_b - r_h)^2}{6\pi} \right] \approx S_{\text{BH}} \,. \tag{4.5}
$$

The leading term, which comes from the area of the island, is the Bekenstein-Hawking entropy of the eternal extremal Kerr black hole. The subleading term arises from the quantum effects of the matter field and is negligible compared to the leading term. Therefore, in the late stages of black hole evaporation, the entanglement entropy of Hawking radiation is finite and approach the Bekenstein-Hawking entropy.

V. CONCLUSION AND DISCUSSION

In this paper, we investigated the black hole information problem in four-dimensional Kerr spacetime. We first reduced the four-dimensional Kerr metric to a two-dimensional form and then calculated the entanglement entropy of the radiation region within this twodimensional framework. In gravitational systems, the quantum entanglement entropy is the minimum of all extremal values of the sum of the island's area entropy and the von Neumann entropy of the radiation in the entanglement region. We began by studying non-extremal Kerr black holes. In the early stages of evaporation, no island form because insufficient radiation is produced initially. Consequently, the contribution to the entanglement entropy mainly comes from the radiation itself, and no island exist. In the late stages of black hole evaporation, radiation becomes the dominant term, and the radiation region primarily entangled with the island region. By introducing an island region within the Kerr spacetime, we obtained a scrambling time following the Hayden-Preskill protocol, consistent with the Page time. We further studied extremal Kerr black holes. In the early stages of black hole evaporation, calculating the von Neumann entropy of the matter fields is challenging since the island is located at $r < 0$. However, in the late stages, we showed that the entanglement entropy of Hawking radiation will approach the Bekenstein-Hawking entropy.

For future directions, it is meaningful to generalize the present work to the evaporating Kerr black hole. The Page curve for the evaporating Kerr black hole was previously studied in [\[117\]](#page-31-9). Note that there is a possible resolution to the information paradox for the evaporating Kerr black hole by treating it as a quantum wormhole [\[118\]](#page-31-10). It is also interesting to extend the discussion to other types of rotating black holes. This study has examined four-dimensional eternal Kerr black hole in asymptotically flat spacetime. In asymptotically flat spacetime, there is no need to couple the system with a bath to collect the radiation. We plan to address the information loss problem of the four-dimensional Kerr-AdS black hole using similar methods as presented here. In addition, further investigation into multi-island scenarios might provide a more detailed description of the Page curve at the Page time.
