# Greedy Gray Codes for some Restricted Classes of Binary Words 

Nathanaël Hassler Vincent Vajnovszki<br>Laboratoire d'Informatique de Bourgogne<br>Dijon, France<br>nathanael.hassler@ens-rennes.fr vincent.vajnovszki@u-bourgogne.fr<br>Dennis Wong<br>Macao Polytechnic University<br>Macao, China<br>cwong@uoguelph.ca

We investigate the existence of greedy Gray codes, based on the choice of the first element in the code, for two classes of binary words: generalized Fibonacci words and generalized Dyck words.

## 1 Introduction

### 1.1 Constrained binary words

## 1's run constrained binary words

Let $n, p \in \mathbb{N}, p \geq 2$, and $F_{n}(p)$ be the set of length $n$ binary words with no $p$ consecutive 1's. $F_{n}(2)$ is counted by the Fibonacci numbers $f_{n}$, and in general, $F_{n}(p)$ is counted by the $p$-order Fibonacci numbers $f_{n}^{(p)}$. Now let $k \in \mathbb{N}$, and $F_{n}(p, k)$ be the subset of words in $F_{n}(p)$ of weight $k$ (i.e., with exactly $k$ 1's). $F_{n}(p, k)$ is counted by the univariate $p$-nomial coefficient.

## Prefix constrained binary words

Let $k, n, p \in \mathbb{N}$ with $(p+1) k \leq n$, and $C_{n}(p, k)$ be the set of length $n$ binary words of weight $k$ with the property that any prefix contains at least $p$ times as many 0 's as 1 's. In particular:

- $C_{n}(0, k)$ is the set of length $n$ binary words of weight $k$ (combinations in binary word representation),
- $C_{2 n}(1, n)$ is the set of length $2 n$ Dyck words, and it is counted by the Catalan numbers $\binom{2 n}{n}$ $\binom{2 n}{n-1}=\frac{1}{n+1}\binom{2 n}{n}$,
- $C_{3 n}(2, n)$ is in bijection with size $3 n$ ternary trees (see A001764 in [4]).

More generally, $C_{(p+1) n}(p, n)$ is counted by $\frac{1}{p n+1}\binom{(p+1) n}{n}$, known as the Pfaff-Fuss-Catalan numbers, and the cardinality of $C_{n}(p, k)$ is established for instance in [5] Equation (2)], using generating functions:

$$
\begin{equation*}
\left|C_{n}(p, k)\right|=\binom{n}{k}-p\binom{n}{k-1} . \tag{1}
\end{equation*}
$$

### 1.2 Gray codes and greedy algorithms

A Gray code for a class of combinatorial objects is a list that contains each object from the class exactly once such that any two consecutive objects in the list differ only by a 'small change' [3]. In this paper we restrict ourselves to Gray codes for restricted classes of same length and same weight binary words (the weight of a binary word being its number of 1 's). The 'small changes' we consider here are homogeneous transpositions: two binary words differ by a homogeneous transposition if one can be obtained from the other by transposing a 1 with a 0 , and there are no 1 's between the transposed bits. A Gray code is called homogeneous if consecutive words differ in a such a way. A list of words is suffix partitioned if words with the same suffix are consecutive in the list.

The next definition of the greedy Gray code algorithm is a specialisation of that introduced in [6] to particular cases of binary words, see also [7].
Definition 1.1. For a set $S$ of same length and same weight binary words the greedy Gray code algorithm to obtain a Gray code list $\mathscr{L}$ for the set $S$ is:

1. Initialize $\mathscr{L}$ with a particular word in $S$.
2. For the last word in $\mathscr{L}$, homogeneously transposes the leftmost possible 1 with the leftmost possible 0 , such that the obtained word is in $S$ but not in $\mathscr{L}$.
3. If at point 2 . a new word is obtained, then append it to the list $\mathscr{L}$ and return to point 2 .

In the following we will say that the list $\mathscr{L}$ is obtained by applying the greedy algorithm for $S$ to $\alpha$, where $\alpha$ is the initial word of $\mathscr{L}$. Depending on the choice of $\alpha$, it can happen that the obtained list $\mathscr{L}$ is not an exhaustive one for $S$.

## 2 Tail partitioned lists

The tail of a binary word is its unique suffix of the form $011 \cdots 1$, and the only words with no tail have the form $11 \cdots 1$. Note that 0 is also a tail, for the words ending by 0 .

A list of binary words is increasing (decreasing) tail partitioned if words with tails of length $\ell$ appear before (after) words with tail of length $\ell+1$, for any $\ell \geq 1$.
Definition 2.1. A list $\mathscr{L}$ of same length binary words is recursive tail partitioned if it is empty, or

- it is increasing or decreasing tail partitioned, and
- for any tail $t$, the list obtained by: (i) considering the sublist of $\mathscr{L}$ of words with tail $t$, then (ii) erasing the tail $t$ in each word of this sublist, is in turn recursive tail partitioned.
In the following • denotes the concatenation (of two words, or of each word in a list with a word) and the comma appends lists. With this notation, $\mathscr{L}$ is a recursive tail partitioned list if it is empty or has the form

$$
\begin{equation*}
\mathscr{L}=\mathscr{L}_{1} \cdot 01^{u}, \mathscr{L}_{2} \cdot 01^{u+1}, \mathscr{L}_{3} \cdot 01^{u+2}, \cdots, \mathscr{L}_{\ell+1} \cdot 01^{u+\ell} \tag{2}
\end{equation*}
$$

or the form

$$
\begin{equation*}
\mathscr{L}=\mathscr{L}_{1} \cdot 01^{u+\ell}, \mathscr{L}_{2} \cdot 01^{u+\ell-1}, \mathscr{L}_{3} \cdot 01^{u+\ell-2}, \cdots, \mathscr{L}_{\ell+1} \cdot 01^{u} \tag{3}
\end{equation*}
$$

for some $u, \ell \geq 0$, and each list $\mathscr{L}_{i}$, is in turn recursive tail partitioned.
We remark that the list in (2) is not necessarily the reverse of that in (3). Clearly, a recursive tail partitioned list (r-t partitioned list for short) is a suffix partitioned list.
Theorem 2.2. If the list $\mathscr{L}$ is a homogeneous and suffix partitioned Gray code for a set of (same length and same weight) binary words, then $\mathscr{L}$ is an r-t partitioned list.

## 3 Main results

### 3.1 Fibonacci words $F_{n}(2, k)$

In this subsection we show that for any $\alpha \in F_{n}(2, k)$, by applying the greedy algorithm for $F_{n}(2, k)$ to $\alpha$, a suffix partitioned list is obtained, and we characterize the words $\alpha$ such that the greedy algorithm yields an exhaustive list for $F_{n}(2, k)$. Moreover, for every $\alpha \in F_{n}(2, k)$ we characterize the last word in the obtained list.

For $n<2 k-1, F_{n}(2, k)$ is empty and in two particular cases $F_{n}(2, k)$ is a singleton set.
Fact 3.1. If $k=0$, then $F_{n}(2, k)=\left\{0^{n}\right\}$, and if $n=2 k-1$, then $F_{n}(2, k)=\left\{1(01)^{k-1}\right\}$.
For $\alpha \in F_{n}(2, k)$ we denote by $\mathscr{F}(\alpha)$ the list obtained by applying the greedy algorithm for $F_{n}(2, k)$ to $\alpha$.

For $n, k$ with $n \geq 2 k$, let $\alpha_{n, k}^{i}=0^{i} 1(01)^{k-1} 0^{n-2 k+1-i}$, for $0 \leq i \leq n-2 k+1$. Furthermore, let $\gamma_{n, k}:=$ $\alpha_{n, k}^{n-2 k+1}=0^{n-2 k}(01)^{k}$. We denote by $\operatorname{GenF}(n, k)$ the set of words $\alpha \in F_{n}(2, k)$ such that $\mathscr{F}(\alpha)$ is a homogeneous Gray code for $F_{n}(2, k)$. Equivalently, $\alpha \in \operatorname{Gen} F(n, k)$ if and only if $\mathscr{F}(\alpha)$ contains every word of $F_{n}(2, k)$.
Theorem 3.2. Let $n \in \mathbb{N}^{\star}$. Then for all $k$ with $n \geq 2 k$, we have

1. $\alpha_{n, k}^{i} \in \operatorname{GenF}(n, k)$ for all $0 \leq i \leq n-2 k$, and $\mathscr{F}\left(\alpha_{n, k}^{i}\right)$ is a suffix partitioned list, with $\gamma_{n, k}$ as last word.
2. $\gamma_{n, k} \in \operatorname{GenF}(n, k), \mathscr{F}\left(\gamma_{n, k}\right)$ is a suffix partitioned list and its last word is
(i) $\alpha_{n, k}^{0}$ if $k$ is even,
(ii) $\alpha_{n, k}^{n-2 k}$ if $k$ is odd.

In the next lemma, we extend the result of 1 . in Theorem 3.2 concerning the last element of $\mathscr{F}(\alpha)$ to each $\alpha \in F_{n}(2, k)$.
Lemma 3.3. Let $n \geq 2 k$. For any $\alpha \in F_{n}(2, k)$ with $\alpha \neq \gamma_{n, k}$, the last word of $\mathscr{F}(\alpha)$ is $\gamma_{n, k}$.
Now we generalise the property for $\mathscr{F}(\alpha)$ to be suffix partitioned to each word of $F_{n}(2, n)$.
Lemma 3.4. Let $n \geq 2 k-1$. For any $\alpha \in F_{n}(2, k), \mathscr{F}(\alpha)$ is a suffix partitioned list.
Now we are able to completely describe the set $\operatorname{GenF}(n, k)$.
Proposition 3.5. Let $n \geq 2 k-1$. Then

$$
\operatorname{GenF}(n, k)=\left\{0^{i} 1(01)^{k-1} 0^{n-2 k+1-i} \mid 0 \leq i \leq n-2 k+1\right\} .
$$

In particular, $|\operatorname{Gen} F(n, k)|=n-2 k+2$.

## $3.2 C_{n}(p, k)$

For $n, p, k$ such that $n \geq(p+1) k$ and $\alpha \in C_{n}(p, k)$, we denote by $\mathscr{D}_{p}(\alpha)$ the list obtained by applying the greedy algorithm for $C_{n}(p, k)$ to $\alpha$. Let also $\operatorname{Gen}_{p}(n, k)$ be the set of words $\alpha \in C_{n}(p, k)$ such that $\mathscr{D}_{p}(\alpha)$ is a homogeneous Gray code for $C_{n}(p, k)$. Equivalently, $\alpha \in \operatorname{Gen}_{p}(n, k)$ if and only if $\mathscr{D}_{p}(\alpha)$ contains every word of $C_{n}(p, k)$. Since the situation is a bit more complicated than the one for Fibonacci words, for clarity we first investigate the case $p \in \mathbb{N}$, explaining every details of the proofs. Then we explain how the results are generalised to any $p \in \mathbb{R}$, not necessarily describing each proof.

### 3.2.1 $p \in \mathbb{N}$

We start by investigating the case $p \in \mathbb{N}$. We fix such a $p$ throughout this section. For $n \geq(p+1) k$, let $\alpha_{n, k}^{i, j}:=0^{p j-i} 1^{j-1} 0^{i} 1\left(0^{p} 1\right)^{k-j} 0^{n-(p+1) k}\left(\right.$ resp. $\alpha_{n, k}=1^{k} 0^{n-k}$ ) for $i=0, \ldots, p-1$ and $j=1, \ldots, k$ if $p \geq 1$ (resp. if $p=0$ ), and $\beta_{n, k}^{i}:=0^{i} 1^{k} 0^{n-i-k}$ for $i=p k+1, \ldots, n-k$. Because it plays a special role, we will use different notation for $\beta_{n, k}^{n-k}$, so we set $\gamma_{n, k}:=\beta_{n, k}^{n-k}=0^{n-k} 1^{k}$.
Theorem 3.6. Let $n \geq(p+1) k$, with $k \geq 1$.

1. For all $0 \leq i \leq p-1$ and $1 \leq j \leq k$, we have $\alpha_{n, k}^{i, j} \in \operatorname{Gen}_{p}(n, k)$ (resp. $\alpha_{n, k} \in \operatorname{Gen}_{0}(n, k)$ ), and $\mathscr{D}_{p}\left(\alpha_{n, k}^{i, j}\right)\left(\right.$ resp. $\left.\mathscr{D}_{0}\left(\alpha_{n, k}\right)\right)$ is a suffix partitioned list with $\gamma_{n, k}$ as last word.
2. For all $j, p k+1 \leq j \leq n-k-1$, we have $\beta_{n, k}^{j} \in \operatorname{Gen}_{p}(n, k)$, and $\mathscr{D}_{p}\left(\beta_{n, k}^{j}\right)$ is a suffix partitioned list with $\gamma_{n, k}$ as last word.
3. $\gamma_{n, k} \in \operatorname{Gen}_{p}(n, k), \mathscr{D}_{p}\left(\gamma_{n, k}\right)$ is a suffix partitioned list and its last word is
(i) $0^{p} 1$ if $(n, k)=(p+1,1)$,
(ii) $\beta_{n, k}^{n-k-1}=0^{n-k-1} 1^{k} 0$ if $k$ is odd and $n \neq(p+1) k$,
(iii) $\alpha_{n, k}^{1, k-1}=0^{(k-1) p-1} 1^{k-2} 010^{p} 1$ if $k \geq 3$ is odd and $n=(p+1) k$ (resp. $\alpha_{n, k}=1^{k}$ if $p=0$ ),
(iv) $\alpha_{n, k}^{1, k}=0^{k p-1} 1^{k-1} 010^{n-(p+1) k}$ if $k$ is even (resp. $\alpha_{n, k}=1^{k} 0^{n-k}$ if $p=0$ ).

Lemma 3.7. Let $n \geq(p+1) k$. For all $\alpha \in C_{n}(p, k)$, with $\alpha \neq \gamma_{n, k}, \mathscr{D}_{p}(\alpha)$ ends with $\gamma_{n, k}$.
Lemma 3.8. Let $n \geq 1$. Then for all $k$ with $n \geq(p+1) k$, and for each $\alpha \in C_{n}(p, k), \mathscr{D}_{p}(\alpha)$ is a suffix partitioned list.

Proposition 3.9. Let $n \geq(p+1)$ k. If $p \geq 1$ then

$$
\begin{gathered}
\operatorname{Gen}_{p}(n, k)=\bigcup_{j=1}^{k}\left\{0^{p j-i} 1^{j-1} 0^{i} 1\left(0^{p} 1\right)^{k-j} 0^{n-(p+1) k} \mid 0 \leq i \leq p-1\right\} \\
\cup\left\{0^{i} 1^{k} 0^{n-i-k} \mid p k+1 \leq i \leq n-k\right\} .
\end{gathered}
$$

If $p=0$ then $\operatorname{Gen}_{0}(n, k)=\left\{0^{i} 1^{k} 0^{n-i-k} \mid 0 \leq i \leq n-k\right\}$. In particular,

$$
\left|\operatorname{Gen}_{p}(n, k)\right|=n-k+1-p .
$$

Remark 3.10. Propositions 3.5 and 3.9 highlight the fact that the choice of the first element for the greedy algorithm is crucial. Indeed, only a few elements will produce a Gray code for $F_{n}(2, k)$ or $C_{n}(p, k)$ with this algorithm.

### 3.2.2 $p \in \mathbb{R}_{+}$

The previous results can be generalized to $C_{n}(p, k)$ for any $p \in \mathbb{R}_{+}$. In particular we have the following result:

Theorem 3.11. Let $p \in \mathbb{R}_{+}$and $n \geq(p+1) k$. Then

$$
\left|\operatorname{Gen}_{p}(n, k)\right|=n-k+1-\lceil p\rceil .
$$

### 3.3 Algorithmic considerations

Building on the previous results, the last part presents CAT algorithms that greedily generate Gray code for $C_{n}(p, k)$ and $F_{n}(2, k)$, which we omit in this abstract.
