# CANONICAL FORM OF MATRIX FACTORIZATIONS FROM FUKAYA CATEGORY OF SURFACE 

CHEOL-HYUN CHO AND KYUNGMIN RHO

#### Abstract

This paper concerns homological mirror symmetry for the pair-of-pants surface (A-side) and the non-isolated surface singularity $x y z=0$ (B-side). Burban-Drozd classified indecomposable maximal Cohen-Macaulay modules on the B-side. We prove that higher-multiplicity band-type modules correspond to higher-rank local systems over closed geodesics on the A-side, generalizing our previous work for the multiplicity one case. This provides a geometric interpretation of the representation tameness of the band-type maximal Cohen-Macaulay modules, as every indecomposable object is realized as a geometric object.

We also present an explicit canonical form of matrix factorizations of $x y z$ corresponding to BurbanDrozd's canonical form of band-type maximal Cohen-Macaulay modules. As applications, we give a geometric interpretation of algebraic operations such as AR translation and duality of maximal Cohen-Macaulay modules as well as certain mapping cone operations.

## 1. Introduction

A version of Homological mirror symmetry (HMS) conjecture of Kontsevich [Kon95, Kon98] says that the derived wrapped Fukaya category of a symplectic manifold $\Sigma$ (A-side) and the singularity category of its mirror Landau-Ginzburg (LG) model $(X, W: X \rightarrow \mathbb{C})$ (B-side) are equivalent:

$$
D^{\pi}(W \operatorname{Fuk}(\Sigma)) \simeq D_{\operatorname{sing}}\left(W^{-1}(0)\right)
$$

HMS between punctured Riemann spheres $\Sigma=S^{2} \backslash\{n$ points $\}(n \geq 3)$ and the corresponding LG models was established in [AAE ${ }^{+} 13$ ].

In the case of the 3-punctured sphere, the corresponding LG model is given by $\left(\mathbb{C}^{3}, x y z\right)$.

This equivalence has been shown on the level of generators, which in this case consist of any two of three non-closed curves $L_{\mathrm{xy}}, L_{\mathrm{yz}}$ and $L_{\mathrm{zx}}$ on the A-side (Figure 4), and the corresponding objects on the B-side (Remark 4.9). This work of Abouzaid-Auroux-Efimov-Katzarkov-Orlov [AAE ${ }^{+}$13] inspired a lot of further developments in homological mirror symmetry. However, it is hard to compare more complicated objects in both sides directly from this equivalence.

On the other hand, it is known that the following three categories are equivalent [Eis80, Buc21, Orl03]:

$$
\underline{M F}(x y z) \stackrel{\substack{\text { Eisenbud } \\ \simeq}}{\longrightarrow} \mathrm{CM}(A) \stackrel{\substack{\text { Buchweitz } \\ \simeq}}{\sim} D_{\text {sing }}\left(\hat{X}_{0}\right)
$$

Here, $\underline{\operatorname{MF}}(x y z)$ is the homotopy category of matrix factorizations of $x y z, \underline{\mathrm{CM}}(A)$ is the stable category of maximal Cohen-Macaulay modules over $A:=\mathbb{C}[[x, y, z]] /(x y z)$, and $D_{\text {sing }}\left(\hat{X}_{0}\right)$ is the singularity category of $\hat{X}_{0}:=\operatorname{Spec}(A)$. In this paper, we work with power series rings instead of polynomial rings (Remark 1.5).

In a recent work [BD17a], Burban-Drozd developed a new representation-theoretic method to deal with maximal Cohen-Macaulay modules over certain non-isolated surface singularities including $A$. As a consequence, they classified all indecomposable classes of such modules, which fall into band-type (continuous series) and string-type (discrete series). This proves that those singularities have tame CohenMacaulay representation type.

Thus, a natural question is which objects of the Fukaya category correspond to the indecomposable maximal Cohen-Macaulay modules over $A$ (Remark 9.8.8 in [BD17a]). Especially, it is of great interest whether their symplectic counterparts are realized as geometric objects in the Fukaya category. This question will be answered in the present paper by giving an explicit correspondence:

Theorem 1.1. Under homological mirror symmetry, there is a one-to-one correspondence

$$
\begin{gathered}
\text { \{closed geodesics } \left.{ }^{1} \text { in } \Sigma \text { with an indecomposable local system }\right\} / \sim \sim_{\text {gauge equivalence }} \stackrel{1: 1}{\leftrightarrow} \\
\{\text { band-type indecomposable objects in } \underline{\mathrm{CM}(A)\} / \sim \text { isomorphism },}
\end{gathered}
$$

where $\Sigma$ is given a hyperbolic metric with three cusps.
In our setting of the Fukaya category of $\Sigma$, objects are oriented immersed curves in $\Sigma$ with a local system. We call them loop-type or arc-type according to whether the curve is a loop (closed curve) or an arc (starting and ending at $\partial \Sigma$ ). Closed geodesics are representatives in certain (but not all) free homotopy classes of oriented loops in $\Sigma$. Thus, Theorem 1.1 describes a correspondence between indecomposable objects of loop-type in the Fukaya category and band-type in the category of maximal Cohen-Macaulay modules. A similar correspondence between arc-type and string-type objects can be also made, but we do not cover them in the present paper (see Remark 4.9).

In our previous work [CJKR22], we already established a correspondence between loop-type objects of rank $\rho=1$ and band-type objects of multiplicity $\mu=1$, and found a canonical form of matrix factorizations for that case. The main purpose of the present paper is to extend it to a correspondence between looptype objects of arbitrary geometric $\operatorname{rank} \rho$ and band-type objects of arbitrary algebraic multiplicity $\mu$.

To convert objects of Fukaya category into matrix factorizations, we use the localized mirror functor

$$
\mathscr{F}^{\mathrm{L}}: D^{\pi}(W \operatorname{Fuk}(\Sigma)) \longrightarrow \underline{\mathrm{MF}}(x y z)
$$

developed by the first author with Hong-Lau in [CHL17]. In the present work, we elaborate its computational aspect to apply it to higher-rank local systems. In particular, we give an explicit formula (2.6) for resulting matrix factorizations, and use it to deduce matrix factorizations of higher-rank local systems directly from the result on rank 1 cases (Proposition 2.5). It presents us a canonical form of matrix factorizations for higher-rank objects in terms of loop data, extending the previous version for rank 1 case in [CJKR22].

Burban-Drozd also provided a canonical form of maximal Cohen-Macaulay modules in terms of band data. But the corresponding matrix factorizations under Eisenbud's equivalence were not known, due to the complexity of Macaulayfication process. With the help of homological mirror symmetry, we now have a candidate. Indeed, we demonstrate that our canonical form of matrix factorizations fits perfectly into this framework under an explicit conversion formula between loop data and band data. The presence of this conversion formula suggests that it would have been hardly attainable otherwise.

For the proof, we define the notion of $(\lambda, \Lambda)$-substitution pair and use its homological property. It enables us to extend the Macaulayfication result as well as conversion formula obtained in [CJKR22] to higher-multiplicity cases (Theorem 4.14).

After all, it turns out that the geometric $\operatorname{rank} \rho$ and the algebraic multiplicity $\mu$ coincide in a majority of cases. But surprisingly, there are a few (countably many) exceptions called degenerate cases, where two parameters differ by 1 as $\rho=\mu-1$. This can be interpreted as an inevitable phenomenon following from the elimination of the regular module $A$ that occurs when we take the stable category $\underline{\mathrm{CM}}(A)=\mathrm{CM}(A) \backslash\{A\}$.

Analyzing the correspondence of objects in those cases is quite tricky both on geometric and algebraic sides: The geometric loop is freely homotopic to the reference loop (Seidel Lagrangian), so we perturb it to prevent an immersed cylinder (\$3.5). On algebraic side, the corresponding module has one exceptional Macaulayfying element, which does not appear as a family of $\lambda$ and cannot be obtained from the above $(\lambda, \Lambda)$-substitution process. So we perform an additional computation for this case and find that the existence of such an element causes the degeneration $\rho=\mu-1$ (\$4.5).

[^0]Applications. The correspondence obtained in Theorem 1.1 can be used to relate natural geometric symmetries to algebraic operations. Here we present some of them, while expecting that there will be further interesting translations between two languages. The first two are from geometry to algebra, and the last two are the other way around. (These applications were not presented and have been postponed from [CJKR22] to include general relations between higher rank/multiplicity objects.)

First, taking the duality functor $\operatorname{Hom}_{A}(-, A)$ of modules in $\underline{C M}(A)$ corresponds to flipping loops in Fuk ( $\Sigma$ ) (see figures in Example 5.7). We show the commutativity of the following diagram of functors in ( $A_{\infty}$-) categorical level (Proposition $5.9+$ Proposition 5.6). Then we give a clear description of these operations in terms of loop/band data (\$5.1.5).

Second, we consider the AR translation, which is given by the shift functor of the triangulated category $\underline{\mathrm{CM}}(A)$. It is not easy to compute in terms of band data, but it is equivalent to reversing the orientation of underlying loops in Fuk ( $\Sigma$ ) (Proposition 5.5 + Proposition 5.11), which we can compute in a geometric way. We will give an algorithm to compute them using conversion to the loop data (Proposition 5.12).

We remark here that an indecomposable object in degenerate cases and its image under operations in (1.2) are invariant under operations in (1.1). Conversely, if an indecomposable object is invariant under operations in (1.1), either it or its image under operations in (1.2) is of degenerate case.

Third, categories involved in HMS typically possess natural triangulated structures. Along with the parameterization by band or loop data, higher multiplicity/rank objects are given by some iterated mapping cones (or twisted complexes in $A_{\infty}$-categories) involving lower multiplicity/rank objects. Proposition 5.22 gives an explicit way to understand higher rank local systems in Fukaya category as twisted complexes of lower rank objects.

Finally, periodic objects in both sides are decomposed into as many pieces as the number of repetitions ${ }^{2}$. We give an explicit formula for this decomposition (Theorem 3.21). It shows that non-primitive loops in the Fukaya category are decomposable (Corollary 3.22), which is not obvious on the A-side.
Geometric interpretation of tameness. In Theorem 1.1, we showed that all band-type indecomposable maximal Cohen-Macaulay modules over $A$ correspond to explicit geometric objects (rather than abstract twisted complexes) in the Fukaya category. It gives a geometric interpretation ${ }^{3}$ of their representationtameness, which was already proven algebraically in [BD17a]. It is geometrically intuitive that there are only countably many closed geodesics (or free homotopy classes of loops) in $\Sigma$. Then an indecomposable local system lying on a fixed loop of rank $\rho \in \mathbb{Z}_{\geq 1}$ is determined by its holonomy up to gauge equivalence, which can be represented (up to basis change) by the $\rho \times \rho$ Jordan block $J_{\rho}(\eta) \in \mathrm{GL}_{\rho}(\mathbb{C})$ with some eigenvalue $\eta \in \mathbb{C}^{\times}$. As a result, the elements of sets in Theorem 1.1 are parameterized by closed geodesics in $\Sigma$, a rank $\rho$ (discrete parameters), and an eigenvalue of holonomy $\eta$ (continuous parameter). That is, they consist of countably many one-parameter families.

[^1]Relation with other mirror symmetries of surfaces. Recently, there have been many studies on homological mirror symmetry between $\mathbb{Z}$-graded partially wrapped Fukaya categories (or topological Fukaya categories) of graded marked surfaces (A-side), derived categories of modules over gentle algebras, and derived categories of coherent sheaves on certain non-commutative curves (B-side). Gentle algebras have long been an intriguing topic in representation theory since they are derived tame, closed under derived equivalences, and have well-understood indecomposable objects in their derived categories (see [SZ03], [BD17b] and references therein). Their connection with the Fukaya categories was first established in [HKK17], graded marked surfaces corresponding to them were constructed in [LP20], and independently, a closely related algebraic model was constructed in [OPS18]. Their relation with certain non-commutative curves was first found in [BD11], extended to nodal stacky curves in [LP18], and again generalized to much broader class of non-commutative nodal curves in [BD18].

It is especially remarkable that indecomposable objects on each side are classified, have a concrete one-to-one correspondence and therefore the derived tameness of gentle algebras can be understood in a (symplectic) geometric way. Also, many purely representation-theoretic problems concerning derived equivalence of finite-dimensional algebras have been attacked and solved using geometric insights and techniques (e.g. [PPP19, APS23, Opp19, KŠ22, CJS22, CHS23, CK24, AP24]).

The triangulated categories which are the focus of the present work are related to $\mathbb{Z}_{2}$-graded Fukaya categories (using oriented Lagrangian curves as objects) of surfaces (A-side). Their mirrors are usually given by certain categories of matrix factorizations or equivalently, singularity categories of LandauGinzburg models (B-side). There have been many well-studied homological mirror symmetries. For example, the mirrors of genus two and higher genus closed surfaces were constructed in [Sei08] and [Efi12], respectively. In [AS21], spherical objects in $\mathbb{Z}_{2}$-graded Fukaya categories of closed surfaces were related with simple closed curves with a rank 1 local system. Mirrors of punctured spheres and their cyclic covers were established in [AAE $\left.{ }^{+} 13\right]$. A non-commutative mirror model of punctured surfaces were also discovered in [Boc16], and a related functor was constructed in [CHL15]. Going in a different direction, [AEK21] considers Fukaya categories of singular surfaces and show the reverse direction (switching A- and B-sides) of homological mirror symmetry.

On the level of all indecomposable objects in $\mathbb{Z}_{2}$-graded Fukaya categories, nevertheless, their classification and correspondence under mirror symmetry are not known in full generality. Compared to the situation of $\mathbb{Z}$-graded mirror symmetry, however, it is apparent that there will be much utility of establishing such a strong bridge between curves in Fukaya categories and matrix factorizations (in the global sense of [Orl12]). It will provide more applications of homological mirror symmetry, relating new tame triangulated categories arising from representation theory (other than finite-dimensional algebras) with Fukaya categories of surfaces.

Towards global $\mathbb{Z}_{2}$-graded mirror symmetry. Our previous work [CJKR22] and the present work aim to ignite this new direction of development in the homological mirror symmetry program. There are many good reasons to start with the pair-of-pants surface and its mirror $x y z=0$, which has been of great interest:

Most importantly, the pair serves as a building block to construct more complicated mirror pairs. For example, the idea of constructing the mirror of general Riemann surfaces using their pair-of-pants decompositions appeared in many places in the literature including [Lee16, Nad16, PS19, PS21, PS22]. (The last four uses a sheaf-theoretic version of Fukaya categories, which is different from (but equivalent to) the Floer-theoretic version used in this paper.) See also the well-written survey in [Boc21, §9.4] and references therein. A common approach, often referred to as a local-to-global principle, involves proving the compatibility of categorical gluing on both sides, based on the mirror symmetry of the local pair. Moreover, as explained in [CHL18], copies of the localized mirror functor employed in this paper (as its name implies) can be also glued together in order to obtain a mirror functor in the global setting.

Independently of the above gluing formalism, mirror symmetry of the pair-of-pants surface also played a central role in $\left[\mathrm{AAE}^{+} 13\right]$ and [HJL24]. The authors consider its cyclic and abelian covers, respectively, and construct their mirror LG model using the symmetry given by the deck transformation groups.

On the other hand, representation theory and classification of objects on B-side have been explicitly developed only for the local model $\mathbb{C}[[x, y, z]] /(x y z)$ in [BD17a]. So we will need to work out the corresponding theory for more general (non-affine) normal crossing surface singularities appearing as mirrors of other Riemann surfaces. After establishing it, we hope to generalize our present results to mirror symmetry of more general Riemann (orbi-)surfaces, which will enhance our understanding of geometric and algebraic tame categories and give many fruitful applications.
1.1. Proof of main theorem. In this subsection, we deduce Theorem 1.1 from several results summarized from the body of the paper. The approach to prove it will be completed through the following two steps:
I. Compute matrix factorizations corresponding to canonical forms of local systems over loops in $\Sigma$.
II. Convert them into Burban-Drozd's canonical form of maximal Cohen-Macaulay modules.
I. Canonical forms of loops with a local system and corresponding matrix factorizations. We take the following specific representatives of free homotopy classes of loops in $\Sigma$ : Given a loop word

$$
w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, l_{2}^{\prime}, m_{2}^{\prime}, n_{2}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}
$$

( $\tau \in \mathbb{Z}_{\geq 1}$ ), consider the loop $L\left(w^{\prime}\right)$ described in Figure 1. We restrict to normal loop words (Definition 3.5) so that they (up to shifting) produce only one loop in each hyperbolic free homotopy class. Then they are also in one-to-one correspondence with closed geodesics in $\Sigma$ (Proposition 3.8).

We introduce a loop datum $\left(w^{\prime}, \eta, \rho\right)$ to parameterize loops with a local system, which consists of a normal loop word $w^{\prime} \in \mathbb{Z}^{3 \tau}\left(\tau \in \mathbb{Z}_{\geq 1}\right)$, a holonomy parameter $\eta \in \mathbb{C}^{\times}$, and a (geometric) rank $\rho \in \mathbb{Z}_{\geq 1}$. The associated canonical form of a loop with a local system, denoted by $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$, is given by the loop $L\left(w^{\prime}\right)$ together with a rank $\rho$ local system whose holonomy is represented by $J_{\rho}(\eta)^{4}$ (up to basis change).

## Proposition 1.2 (Corollary 3.11). There is a one-to-one correspondence

\{closed geodesics in $\Sigma$ with an indecomposable local system\}/ ~gauge equivalence
$\stackrel{1: 1}{\leftrightarrows}$ \{non-periodic loop data\} $/ \sim \sim_{\text {shifting }}$.

$$
\begin{aligned}
& \left(\begin{array}{ccccccc}
z I_{\rho} & -y^{m_{1}^{\prime}-1} I_{\rho} & 0 & 0 & \cdots & 0 & -x^{-l_{1}^{\prime}} J_{\rho}(\lambda)^{-1} \\
-y^{-m_{1}^{\prime}} I_{\rho} & x I_{\rho} & -z^{n_{1}^{\prime}-1} I_{\rho} & 0 & \cdots & 0 & 0 \\
0 & -z^{-n_{1}^{\prime}} I_{\rho} & y I_{\rho} & -x^{\prime}-1 \\
I_{2} & \cdots & 0 & 0 \\
0 & 0 & -x^{-l_{2}^{\prime}} I_{\rho} & z I_{\rho} & \ddots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \ddots & \ddots & -y^{m_{\tau}^{\prime}-1} I_{\rho} & 0 \\
0 & 0 & 0 & \cdots & -y^{-m_{\tau}^{\prime} I_{\rho}} & x I_{\rho} & -z^{n_{\tau}^{\prime}-1} I_{\rho} \\
-x^{l_{1}^{\prime-1}} J_{\rho}(\lambda) & 0 & 0 & \cdots & 0 & -z^{-n_{\tau}^{\prime}} I_{\rho} & y I_{\rho}
\end{array}\right)_{3 \tau \rho \times 3 \tau \rho} \\
& \text { where } x^{a}, y^{a}, z^{a} \text { are regarded as } 0 \text { if } a<0 \\
& \varphi\left(w^{\prime}, \lambda, \rho\right)
\end{aligned}
$$

Figure 1. Canonical form of a loop-type object in Fuk ( $\Sigma$ ) and MF $\underline{\text { M }}$ ( $y z$ )

[^2]The localized mirror functor converts each loop with a local system $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ into a matrix factorization $\mathscr{F}^{\llcorner }\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)$. The corresponding canonical form of matrix factorization of $x y z$ is

$$
\begin{equation*}
\left(\varphi\left(w^{\prime}, \lambda, \rho\right), \psi\left(w^{\prime}, \lambda, \rho\right)\right)^{5} \tag{1.3}
\end{equation*}
$$

where $\lambda$ is either $\eta$ or $-\eta$ depending on $w^{\prime}$ (see Definition 4.10). Its first component is shown in Figure 1 and the second one is determined by the first (Definition 3.16).

There are some exceptions called degenerate cases (i.e., $\left.w^{\prime}=(2,2,2)^{\tau}, \eta=(-1)^{\tau}\right)$, where the second factor $\psi\left(w^{\prime}, \lambda, \rho\right)$ is not defined, and we use an alternative form (Definition 3.24)

$$
\begin{equation*}
\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right)\right) . \tag{1.4}
\end{equation*}
$$

To integrate (1.3) and (1.4) into a unified notation, we denote them as $\left(\varphi_{(\mathrm{deg})}\left(w^{\prime}, \lambda, \rho\right), \psi_{(\mathrm{deg})}\left(w^{\prime}, \lambda, \rho\right)\right)$. Namely, it defaults to (1.3) in the general case but adopts (1.4) only in the degenerate cases. Then the relation between the canonical form of loops with a local system and the canonical form of matrix factorizations is summarized as:

Theorem 1.3 (Theorem $3.17+$ Theorem $3.25+$ Proposition 3.27). For a loop datum $\left(w^{\prime}, \eta, \rho\right)$ and $\lambda= \pm \eta$ determined by the conversion formula Definition 4.10, there is an isomorphism in MF (xyz)

$$
\mathscr{F}^{\mathbb{L}}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right) \cong\left(\varphi_{(\mathrm{deg})}\left(w^{\prime}, \lambda, \rho\right), \psi_{(\mathrm{deg})}\left(w^{\prime}, \boldsymbol{\lambda}, \rho\right)\right) .
$$

II. Canonical forms of maximal Cohen-Macaulay modules and corresponding matrix factorizations. Burban-Drozd's classification and canonical form of maximal Cohen-Macaulay modules are best handled in the category of triples $\operatorname{Tri}(A)$, which was introduced and shown to be equivalent to $\operatorname{CM}(A)$ in the same work. The canonical form $\Theta(w, \lambda, \mu)$ of a band-type indecomposable object in $\operatorname{Tri}(A)$ is described in Figure 12. It is parameterized by a band datum $(w, \lambda, \mu)$, which consists of a band word

$$
w=\left(l_{1}, m_{1}, n_{1}, l_{2}, m_{2}, n_{2}, \ldots, l_{\tau}, m_{\tau}, n_{\tau}\right) \in \mathbb{Z}^{3 \tau}
$$

( $\tau \in \mathbb{Z}_{\geq 1}$ ), an eigenvalue $\lambda \in \mathbb{C}^{\times}$, and an (algebraic) multiplicity $\mu \in \mathbb{Z}_{\geq 1}$.

Figure 2. Canonical form of a band-type indecomposable object in $\operatorname{Tri}(A)$ and the corresponding loop with a local system

[^3]We denote by $M(w, \lambda, \mu)$ the corresponding object in CM $(A)$, and refer to it as the canonical form of a band-type indecomposable maximal Cohen-Macaulay module over $A$.

When we take the stable category $\underline{\mathrm{CM}}(A)=\mathrm{CM}(A) /\{A\}$, we lose exactly one isomorphism class $[A]$ of indecomposable objects containing the regular module $A$ (Definition A.14). In $\operatorname{CM}(A)$, it is written in the canonical form as $A=M((0,0,0), 1,1)$. This implies that for the band datum $((0,0,0), 1,1)$, there is no corresponding loop datum.

In §4.3, we define a conversion formula between loop data and band data. It induces a bijection

$$
\begin{aligned}
\{\text { non-periodic loop data }\} / \sim_{\text {shifting }} & \stackrel{1: 1}{\leftrightarrow}(\{\text { non-periodic band data }\} \backslash\{((0,0,0), 1,1)\}) / \sim_{\text {shifting }} . \\
\left(w^{\prime}, \eta, \rho\right) & \leftrightarrow(w, \lambda, \mu)
\end{aligned}
$$

Note that the set on the left side already appeared in Proposition 1.2. The set on the right side is in bijection with

$$
\{\text { band-type indecomposable objects in } \underline{\mathrm{CM}}(A)\} / \sim_{\text {isomorphism }}
$$

by Burban-Drozd's classification (Theorem 4.7). In most cases, we have $\rho=\mu \in \mathbb{Z}_{\geq 1}$. However, for nonperiodic degenerate cases, the correspondence is given by

$$
\left(w^{\prime}=(2,2,2), \eta=-1, \rho\right) \quad \leftrightarrow \quad(w=(0,0,0), \lambda=1, \mu)
$$

with $\rho=\mu-1 \in \mathbb{Z}_{\geq 1}$.
The conversion formula indeed relates band-type indecomposable objects in $\underline{\mathrm{MF}}(x y z)$ and $\underline{\mathrm{CM}}(A)$ in their canonical forms under Eisenbud's equivalence:

Theorem 1.4 (Theorem 4.14 + Theorem 4.17). For a non-periodic loop datum ( $w, \eta, \rho$ ) and band datum $(w, \lambda, \mu)$ related under the conversion formula, there is an isomorphism in $\underline{\mathrm{CM}}(A)$

$$
\operatorname{coker} \varphi_{(\operatorname{deg})}\left(w^{\prime}, \lambda, \rho\right)^{6} \cong M(w, \lambda, \mu)
$$

Mirror symmetry correspondence. Summing up, we have equivalence of categories and correspondence between loop/band-type indecomposable objects as follows (where $w^{\prime}$ and $w$ are non-periodic):

|  | localized mirror functor |  | Eisenbud |  | Burban - -Drozd |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\Phi^{\text {L }}$ |  | coker |  | $\mathrm{F}_{\text {BD }}$ |  |
| $D^{\pi}(W \operatorname{Fuk}(\Sigma))$ | $\longrightarrow$ | $\underline{\text { MF }}(x y z)$ | $\xrightarrow{\simeq}$ | $\underline{\mathrm{CM}}(A)$ | $\stackrel{\sim}{\leftrightharpoons}$ | $\underline{\operatorname{Tri}}(A)$ |
| $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ | $\stackrel{\cong}{\#}$ | $\varphi_{(\text {deg })}\left(w^{\prime}, \lambda, \rho\right)$ | $\leftrightarrow$ | $M(w, \lambda, \mu)$ | $\rightarrow$ | $\Theta(w, \lambda, \mu)$ |

Note that objects in each category are parameterized by loop data or band data. The conversion formula between loop data and band data realizes the one-to-one correspondence between loop/band-type indecomposable objects (up to isomorphism) in each category as
\{closed geodesics in $\Sigma$ with an indecomposable local system $\} / \sim$ gauge equivalence
$\stackrel{1: 1}{\leftrightarrows}$ \{non-periodic loop data $\} / \sim_{\text {shifting }}$
$\stackrel{\text { 1:1 }}{\leftrightarrow}(\{$ non-periodic band data $\} \backslash\{((0,0,0), 1,1)\}) / \sim_{\text {shifting }}$
$\stackrel{\text { l:1 }}{\leftrightarrow}$ \{band-type indecomposable objects in $\underline{\mathrm{CM}}(A)\} / \sim_{\text {isomorphism }}$.
It proves our main Theorem 1.1.

[^4]Periodic case. In each category, objects corresponding to periodic loop/band data are decomposable: Consider a loop datum ( $w^{\prime}, \eta, \rho$ ) with a periodic normal loop word $w^{\prime}=\left(\tilde{w}^{\prime}\right)^{N} \in \mathbb{Z}^{3 \tau}(N \in \mathbb{Z} \geq 2)$. Its corresponding band datum $(w, \lambda, \mu)$ has also a periodic band word $w=\tilde{w}^{N} \in \mathbb{Z}^{3 \tau}$. Denote by $\lambda_{0}, \ldots, \lambda_{N-1} \in \mathbb{C}^{\times}$ and $\eta_{0}, \ldots, \eta_{N-1} \in \mathbb{C}^{\times}$the $N$-th roots of $\lambda$ and $\eta$, respectively. Then we have decompositions

$$
\mathscr{L}\left(w^{\prime}, \eta, \rho\right) \cong \bigoplus_{k=0}^{N-1} \mathscr{L}\left(\tilde{w}^{\prime}, \eta_{k}, \rho\right), \quad \varphi_{(\mathrm{deg})}\left(w^{\prime}, \lambda, \mu\right) \cong \bigoplus_{k=0}^{N-1} \varphi_{(\mathrm{deg})}\left(\tilde{w}^{\prime}, \lambda_{k}, \mu\right)^{7}, \quad M(w, \lambda, \mu) \cong \bigoplus_{k=0}^{N-1} M\left(\tilde{w}, \lambda_{k}, \mu\right)
$$

in Fuk $(\Sigma), \underline{\mathrm{MF}}(x y z)$, and $\underline{\mathrm{CM}}(A)$, respectively. (See Corollary $3.22+$ (3.6), Theorem $3.21+(3.5)$, and (4.7).)
The loop datum $\left(\tilde{w}^{\prime}, \eta_{k}, \rho\right)$ and the band datum $\left(\tilde{w}, \lambda_{k}, \mu\right)$ also correspond to each other for each $k$ under the conversion formula. Therefore, by Theorem 1.3 and Theorem 1.4, the above three decompositions are compatible with each other in non-degenerate cases. In degenerate cases, the first and the second are still compatible with each other, while the second and the third are not, due to the shifting of rank/multiplicity $\rho=\mu-1$ (see (4.8) and (4.9)).
Remark 1.5. In this paper, we consider matrix factorizations over the power series ring $S:=\mathbb{C}[[x, y, z]]$ and maximal Cohen-Macaulay modules over its quotient $A:=\mathbb{C}[[x, y, z]] /(x y z)$, instead of the polynomial ring $\tilde{S}:=\mathbb{C}[x, y, z]$ and its quotient $\tilde{A}:=\mathbb{C}[x, y, z] /(x y z)$. To distinguish the latter, we denote by $\operatorname{MF}[x y z]$ the category of matrix of matrix factorizations of $x y z$ over $\tilde{S}$, and by $\mathrm{CM}(\tilde{A})$ the category of maximal CohenMacaulay modules over $\tilde{A}$ (see [BH98]). Their stable categories and other variations are defined in the same way as in $\S A .3$ and $\S A .4$.

There are obvious faithful functors $\underline{\mathrm{MF}}[x y z] \rightarrow \underline{\mathrm{MF}}(x y z)$ and $\underline{\mathrm{CM}}(\tilde{A}) \rightarrow \underline{\mathrm{CM}}(A)$ (see [BH98, Theorem 2.1.3, Corollary 2.1.8]), which are essentially surjective (indeed, every indecomposable object in $\underline{\mathrm{CM}(A) ~ i s ~}$ obtained as an image of the functor). Still there are some objects in MF $[x y z]$ that are not isomorphic to each other but become isomorphic in $\underline{\mathrm{MF}}(x y z)$. For example, the below diagram shows a family of matrix factorizations $\left(\lambda \in \mathbb{C}^{\times}\right)$that are notzero objects in $\underline{\mathrm{MF}}[x y z]$ but becomes zero objects in $\underline{\mathrm{MF}}(x y z)$. (Note that the vertical isomorphisms exist only in the latter category.)

They come from a loop with holonomy $\lambda$ that is homotopic to one of the boundary circles in $\Sigma$, which was excluded in our correspondence in Theorem 1.1. Thus, $\underline{\mathrm{MF}}[x y z]$ has more objects than $\underline{\mathrm{MF}}(x y z)$. It would be interesting to know how many objects in the gap, and whether they are also realized in a geometric way.

Acknowledgement. This work started as an attempt to understand the mirror A-side of Igor Burban and Yuriy Drozd's representation theory of maximal Cohen-Macaulay modules over non-isolated surface singularities in [BD17a], and we are grateful to Igor Burban for explanations, discussions and many great advice on this work. We thank Yong-Geun Oh, Henning Krause, Juan Omar Gomez and Sibylle Schroll for their interest on this project as well as helpful comments, Wassilij Gnedin for carefully reading and revising the draft from a representation-theoretic perspective, Severin Barmeier, Dongwook Choa, Wonbo Jeong, Sangjin Lee and Sangwook Lee for many useful discussions in symplectic geometry, and Hanwool Bae for explaining to us his thesis. The second author is also grateful to Jongil Park, Jae-Hoon Kwon, Hansol Hong, Philsang Yoo and Igor Burban for many great comments in his thesis defense [Rho23], where most parts of this work were discussed. We also thank Kyoungmo Kim for sharing his idea and helpful discussions on this topic and other joint works. The second author was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(RS-2023-00248895), and the German Research Foundation SFB-TRR 358/1 2023 - 491392403.

[^5]
## 2. Localized Mirror Functor and Its Computation

This section is devoted to an elaboration of the computational aspect of the localized mirror functor [CHL17] applied to the pair-of-pants surface. Especially, we develop a formula for finding each component of the matrix factorization corresponding to a higher-rank local system ( $E, \nabla$ ) over a loop $L$. Every convention and notation for such an object $\mathscr{L}=(L, E, \nabla)$ is based on our geometric setting of the compact Fukaya category (with immersed loops with a local system) explained in Section A.2.
2.1. Localized mirror functor for pair-of-pants surface. We call a smooth surface with boundary $\Sigma$ diffeomorphic to the complement in $S^{2}$ of three distinct points a pair-of-pants surface. Consider a marked loop $\mathbb{L}=\left(\mathbb{L}, e_{\mathbb{L}}, o_{\mathbb{L}}\right)$ in $\Sigma$ described in Figure 3, which is called the Seidel Lagrangian. (Note that its selfintersections are transversal. See also [Sei11].) Assume that the areas of two triangles bounded by $\mathbb{L}$ in $\Sigma$ are the same ${ }^{8}$. We put on its domain a trivial line bundle $E_{\mathbb{L}}=S^{1} \times \mathbb{C}$ equipped with a flat connection $\nabla_{\mathbb{L}}$ whose holonomy is -1 at the point $\star$ marked in Figure 3. We assume that the triple $\left(\mathbb{\square}, E_{\mathbb{\unrhd}}, \nabla_{\mathbb{L}}\right)$ is an object of Fuk $(\Sigma)$ and still denote it as $\mathbb{L}$ for simplicity.

Figure 3. Seidel Lagrangian $\mathbb{L}$ in $\Sigma$

Figure 4. Generating objects of $D^{\pi} W \operatorname{Fuk}(\Sigma)$

Since $\mathbb{L}$ has 3 self-intersections, we have

$$
\chi^{0}(\mathbb{L}, \mathbb{L})=\left\{e_{\mathbb{L}}, \bar{X}, \bar{Y}, \bar{Z}\right\}, \quad \chi^{1}(\mathbb{L}, \mathbb{L})=\left\{o_{\mathbb{L}}, X, Y, Z\right\} .
$$

We trivialize $E_{\llbracket}$ over $S^{1} \backslash \star$ as in Proposition A.7, which yields identifications $E_{\mathbb{L}} \mid \bullet \cong \mathbb{C}$ for each $\bullet \in \chi(\mathbb{\mathbb { L }}, \mathbb{\mathbb { L }})$. Then we have $\operatorname{Hom}_{\mathbb{C}}\left(\left.E_{\mathbb{\square}}\right|_{\bullet},\left.E_{\mathbb{Z}}\right|_{\bullet}\right)^{9} \cong \operatorname{Span}_{\mathbb{C}}\{\bullet\}$ as noted in Remark A.8, and hence

$$
\operatorname{hom}^{0}(\mathbb{L}, \mathbb{\mathbb { L }})=\operatorname{Span}_{\mathbb{C}}\left\{e_{\mathbb{L}} \bar{X}, \bar{Y}, \bar{Z}\right\} \quad \operatorname{hom}^{1}(\mathbb{L}, \mathbb{L})=\operatorname{Span}_{\mathbb{C}}\left\{o_{\mathbb{\unrhd}}, X, Y, Z\right\} .
$$

Seidel Lagrangian $\mathbb{L}$ is very special and useful because it has a weak bounding cochain (or it is weakly unobstructed) in the sense of [FOOO09]. It enables $\mathbb{L}$ to serve as a reference of the localized mirror functor.
Proposition 2.1. [CHL17] A linear combination $b=x X+y Y+z Z \in \operatorname{hom}^{1}(\mathbb{L}, \mathbb{L})$ is $a$ weak bounding cochain for any $x, y, z \in \mathbb{C}$. That is,

$$
\begin{equation*}
\mathfrak{m}_{0}^{b}(\mathbb{L}):=\sum_{i=1}^{\infty} \mathfrak{m}_{i}(\underbrace{b, \ldots, b}_{i})=x y z \cdot e_{\mathbb{L}} \tag{2.1}
\end{equation*}
$$

and hence $(\mathbb{L}, b)$ has the disk potential $W^{\mathbb{L}}=x y z$.
Proof. All $\mathfrak{m}_{1}$-terms in the left side vanish because there are no bigons. There are several non-zero $\mathfrak{m}_{2}$ terms such as $\mathfrak{m}_{2}(X, Y)=\bar{Z}=-\mathfrak{m}_{2}(Y, X)$ coming from the front and back triangles, but they cancle each other because the holonomy -1 contributes only to the back triangle. The only non-zero higher $\mathfrak{m}_{\geq 3}$-term is $\mathfrak{m}_{3}(X, Y, Z)=x y z \cdot e_{\mathbb{L}}$, which comes from the front triangle bounded by $\mathbb{L}$ passing through $e_{\mathbb{L}}$ (Remark A.9.(3)). This is the only surviving term in $\mathfrak{m}_{0}^{b}(\mathbb{L})$, which gives the disk potential $W^{\mathbb{L}}=x y z$.

[^6]Such a pair $(\mathbb{L}, b)$ defines an $A_{\infty}$-functor from Fukaya category to the $A_{\infty}$-category $\mathrm{MF}_{A_{\infty}}(x y z)$ of matrix factorizations of $x y z$, called the localized mirror functor [CHL17]. (Here we follow the convention in [CHL15].) It is based on the deformation theory of $A_{\infty}$-operations, as we will see below:

For any object $\mathscr{L}=(L, E, \nabla)$ in $W \operatorname{Fuk}(\Sigma)^{10}$, note that two sets $\chi \cdot(L, \mathbb{L})\left(\bullet \in \mathbb{Z}_{2}\right)$ are finite sets of the same cardinality $\tau:=\frac{1}{2}|L \cap \mathbb{L}|$. Therefore, two $\mathbb{C}$-vector spaces

$$
\begin{equation*}
\operatorname{hom}^{\bullet}(\mathscr{L}, \mathbb{L})=\bigoplus_{p \in \chi^{\cdot}(L, \mathbb{Q})} \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{p}, \mathbb{C}\right)=\bigoplus_{p \in \chi^{\bullet}(L, \mathbb{L})}\left(\left.E\right|_{p}\right)^{*} \quad\left(\bullet \in \mathbb{Z}_{2}\right) \tag{2.2}
\end{equation*}
$$

have the same finite dimension $\tau \rho$, where $\rho$ is the rank of $E$.
We define the deformed differential

$$
\mathfrak{m}_{1}^{0, b}: \operatorname{hom}(\mathscr{L}, \mathbb{L}) \rightarrow \operatorname{hom}(\mathscr{L}, \mathbb{L}), \quad f \mapsto \mathfrak{m}_{1}^{0, b}(f):=\sum_{i=0}^{\infty} \mathfrak{m}_{1+i}(f, \underbrace{b, \ldots, b}_{i}),
$$

which is a $\mathbb{C}$-linear map of degree 1 and satisfies $\left(\mathfrak{m}_{1}^{0, b}\right)^{2}=x y z \cdot \mathrm{id}_{\text {hom }(\mathscr{L}, \mathrm{L})}$ by the following lemma, which we recall for the reader's convenience:
Lemma 2.2. [CHL17] For a weak bounding cochain $(\mathbb{L}, b)$ with disk potential $W^{\mathbb{}}$, we have

$$
\left(\mathfrak{m}_{1}^{0, b}\right)^{2}=W^{\mathbb{L}} \cdot \operatorname{id}_{\operatorname{hom}(\mathscr{L}, \mathrm{L})} .
$$

Proof. For any $f \in \operatorname{hom}^{\bullet}(\mathscr{L}, \mathbb{L})\left(\bullet \in \mathbb{Z}_{2}\right)$, we can write

$$
\begin{aligned}
\mathfrak{m}_{1}^{0, b}\left(\mathfrak{m}_{1}^{0, b}(f)\right) & =\sum_{j=0}^{\infty} \sum_{i=0}^{\infty} \mathfrak{m}_{1+j}(\mathfrak{m}_{1+i}(f, \underbrace{b, \ldots, b}_{i}), \underbrace{b, \ldots, b}_{j}) \\
& =-\sum_{l_{0}, l_{1} \geq 0} \sum_{k=1}^{\infty}(-1)^{|f|-1} \mathfrak{m}_{2+l_{0}+l_{1}}^{b,}(f, \underbrace{b, \ldots, b}_{l_{0}}, \mathfrak{m}_{k}(\underbrace{b, \ldots, b}_{k}), \underbrace{b, \ldots, b}_{l_{1}}),
\end{aligned}
$$

where the second identity follows from the $A_{\infty}$-relations (A.1). Using the identity $\sum_{k=1}^{\infty} \mathfrak{m}_{k}(b, \ldots, b)=W^{\mathbb{L}}$. $e_{\square}$ and the fact that $e_{\Perp}$ is a unit (A.2), we can rewrite it as

$$
\sum_{l_{0}, l_{1} \geq 0}(-1)^{|f|} \mathfrak{m}_{2+l_{0}+l_{1}}(f, \underbrace{b, \ldots, b}_{l_{0}}, W^{\mathbb{L}} \cdot e_{\mathbb{\unrhd}}, \underbrace{, \ldots, b, b}_{l_{1}})=(-1)^{|f|^{\prime}} \mathfrak{m}_{2}\left(f, W^{\mathbb{L}} \cdot e_{\Perp}\right)=W^{\mathbb{L}} \cdot f,
$$

which proves the claim.
Restricting the domain of $\mathfrak{m}_{1}^{0, b}$ to each degree summand yields two maps

$$
\begin{equation*}
\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L})=\bigoplus_{p \in \chi^{0}(L, \mathbb{L})}\left(\left.E\right|_{p}\right)^{*} \underset{\Psi^{\llcorner }(\mathscr{L}):=\mathrm{m}_{1}^{0, b}}{\stackrel{\Phi^{\mathrm{L}}(\mathscr{L}):=\mathrm{m}_{1}^{0, b}}{\rightleftarrows}} \bigoplus_{s \in \chi^{1}(L, \mathbb{L})}\left(\left.E\right|_{s}\right)^{*}=\operatorname{hom}^{1}(\mathscr{L}, \mathbb{L}) \tag{2.3}
\end{equation*}
$$

satisfying

$$
\begin{equation*}
\Psi^{\mathbb{}}(\mathscr{L}) \Phi^{\mathbb{L}}(\mathscr{L})=x y z \cdot \mathrm{id}_{\mathrm{hom}^{0}(\mathscr{L}, \mathrm{~L})} \quad \text { and } \quad \Phi^{\mathbb{L}}(\mathscr{L}) \Psi^{\mathbb{L}}(\mathscr{L})=x y z \cdot \mathrm{id}_{\operatorname{hom}^{1}(\mathscr{L}, \mathrm{~L})} . \tag{2.4}
\end{equation*}
$$

As hom ${ }^{\bullet}(\mathscr{L}, \mathbb{L})\left(\bullet \in \mathbb{Z}_{2}\right)$ are $\mathbb{C}$-vector spaces of dimension $\tau \rho$, extension of scalar to the ring $S:=\mathbb{C}[[x, y, z]]$ yields two free $S$-modules $S \otimes_{\mathbb{C}} \operatorname{hom}^{\bullet}(\mathscr{L}, \mathbb{L})$ of $\operatorname{rank} \tau \rho$. Now we view each of $\Phi^{\mathbb{L}}(\mathscr{L})$ and $\Psi^{\mathbb{L}}(\mathscr{L})$ as a map between those $S$-modules, regarding $x, y$ and $z$ as variables in the ring $S$. Then the relation (2.4) still holds just by replacing $\operatorname{id}_{\text {hom }}{ }^{*} \mathscr{L}$, L) $)$ with $\operatorname{id}_{S \otimes \mathrm{hom}^{*}(\mathscr{L}, \mathrm{~L})}$, so the pair

$$
\mathscr{F}^{\llcorner }(\mathscr{L}):=\left(\Phi^{\llcorner }(\mathscr{L}), \Psi^{\mathbb{L}}(\mathscr{L})\right)
$$

produces a $\tau \rho \times \tau \rho$ matrix factorization of $x y z$ in $S$.

[^7]Theorem 2.3. [CHL17] The localized mirror functor $\mathscr{F}^{\mathbb{L}}: W \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{MF}_{A_{\infty}}(x y z)$ is defined as follows:

- For an object $\mathscr{L}=(L, E, \nabla)$ in $W \operatorname{Fuk}(\Sigma)$, its mirror object in $\mathrm{MF}_{A_{\infty}}(x y z)$ is given by

$$
\mathscr{F}^{\mathbb{L}}(\mathscr{L})=\left(\Phi^{\mathbb{L}}(\mathscr{L}), \Psi^{\mathbb{L}}(\mathscr{L})\right) .
$$

- Higher components $\left\{\mathscr{F}_{k}^{\square}\right\}_{k \geq 1}$ are given by

$$
\begin{aligned}
& \mathscr{F}_{k}^{\mathrm{L}}: \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \otimes \cdots \otimes \operatorname{hom}\left(\mathscr{L}_{k-1}, \mathscr{L}_{k}\right) \rightarrow \operatorname{hom}_{\mathrm{MF}_{A \infty}(x y z)}\left(\mathscr{F}^{\mathbb{L}}\left(\mathscr{L}_{0}\right), \mathscr{F}^{\mathbb{L}}\left(\mathscr{L}_{k}\right)\right) \\
& \quad\left(f_{1}, \ldots, f_{k}\right) \mapsto \mathfrak{m}_{k+1}^{0, \ldots, 0, b}\left(f_{1}, \ldots, f_{k},-\right):=\sum_{i=0}^{\infty} \mathfrak{m}_{k+1+i}(f_{1}, \ldots, f_{k},-, \underbrace{b, \ldots, b}_{i}),
\end{aligned}
$$

whose images are $\mathbb{C}$-linear maps $\operatorname{hom}\left(\mathscr{L}_{k}, \mathbb{L}\right) \rightarrow \operatorname{hom}\left(\mathscr{L}_{0}, \mathbb{L}\right)$, also viewed as module homomorphisms $S \otimes \operatorname{hom}\left(\mathscr{L}_{k}, \mathbb{L}\right) \rightarrow S \otimes \operatorname{hom}\left(\mathscr{L}_{0}, \mathbb{L}\right)$ over $S=\mathbb{C}[[x, y, z]]$.

Then, $\mathscr{F}^{\mathbb{L}}$ is an $A_{\infty}$-functor. Moreover, it induces an equivalence from the derived wrapped Fukaya category $D^{\pi} W \operatorname{Fuk}(\Sigma)^{11}$ to the homotopy category $\underline{\mathrm{MF}}[x y z]^{12}$ of matrix factorizations of $x y z$.

The last statement recovers the result of [AAE $\left.{ }^{+} 13\right]$ for $\Sigma$. It follows from the fact that $\mathscr{F}^{\mathrm{L}}$ sends the three generating arcs $L_{\mathrm{xy}}, L_{\mathrm{yz}}$, and $L_{\mathrm{zx}}$ of $D^{\pi} W \operatorname{Fuk}(\Sigma)$ in Figure 4 to the three generating matrix factorizations $z \cdot x y, x \cdot y z$, and $y \cdot z x$ of MF $[x y z]$, respectively. The functor induces an isomorphism on cohomology of hom spaces between those objects and hence we can apply Theorem 4.2 in [CHL17].
2.2. Computation of localized mirror functor. Note in (2.2) that hom ( $\mathscr{L}, \mathbb{L}$ ) allows a decomposition into $\rho$-dimensional vector spaces $\left(\left.E\right|_{p}\right)^{*}$ for $p \in \chi(L, \mathbb{L})$. Correspondingly, the operation $\mathfrak{m}_{1}^{0, b}$ (and hence $\Phi^{\mathbb{L}}(\mathscr{L})$ and $\left.\Psi^{\mathbb{L}}(\mathscr{L})\right)$ is decomposed into several $\left(\left(\left.E\right|_{s}\right)^{*},\left(\left.E\right|_{p}\right)^{*}\right)$-components ${ }^{13}$ for $p, s \in \chi(L, \mathbb{L})$.

For $p \in \chi(L, \mathbb{L})$ and $f=\left.f\right|_{p} \in\left(\left.E\right|_{p}\right)^{*} \subseteq \operatorname{hom}(\mathscr{L}, \mathbb{L})$, we have

$$
\begin{aligned}
\mathfrak{m}_{1}^{0, b}(f) & =\sum_{i=0}^{\infty} \mathfrak{m}_{1+i}(f, \underbrace{b, \ldots, b}_{i}) \quad\left(b=x X+y Y+z X \in \operatorname{hom}^{1}(\mathbb{L}, \mathbb{L})\right) \\
& =\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\
\epsilon\{(x, X),(y, Y),(z, Z)\}}} x_{1} \ldots x_{i} \mathfrak{m}_{1+i}\left(f, X_{1}, \ldots, X_{i}\right),
\end{aligned}
$$

and

$$
\mathfrak{m}_{1+i}\left(f, X_{1}, \ldots, X_{i}\right)=\sum_{s \in \chi(L, \mathbb{L})} \sum_{u \in \mathscr{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)} \operatorname{sign}(u) \operatorname{hol}_{s}(\partial u)\left(f, X_{1}, \ldots, X_{i}\right) .
$$

Therefore, the $\left(\left.E\right|_{s}\right)^{*}$-component of $\mathfrak{m}_{1}^{0, b}(f)$ is

$$
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \in\{(x, X),(y, Y),(z, Z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)} \operatorname{sign}(u) \operatorname{hol}_{s}(\partial u)\left(f, X_{1}, \ldots, X_{i}\right)
$$

So it comes from immersed polygons (also called deformed strips) $u$ bounded by $L$ and $\mathbb{L}$, whose angles consist of $p, X_{1}, \ldots, X_{i}$ and $\bar{s}$ in a counterclockwise order, for some $X_{1}, \ldots, X_{i} \in\{X, Y, Z\}$. (See Figure 5.) Such a deformed strip contributes a monomial $x_{1} \cdots x_{i}$, where $x_{j}$ is $x, y$ or $z$ depending on whether $X_{j}$ is $X, Y$ or $Z$.

[^8]

Figure 5. A deformed strip which contributes a monomial $x_{1} \cdots x_{i}$ to the $\left(\left.E\right|_{s}\right)^{*}$-component of $\mathfrak{m}_{1}^{0, b}\left(\left.f\right|_{p}\right)$
The sign of the deformed strip $u$ is given by

$$
\operatorname{sign}(u)= \begin{cases}1 & \text { if orientation of } \mathbb{L}=\text { orientation of } \partial u, \\ (-1)^{i+1} & \text { otherwise }\end{cases}
$$

It follows from formula (A.6) and the fact that the orientation of $\mathbb{L}$ along any angle $X_{j}$ is preserved (because all $X_{j}$ 's have odd-degrees) and the degrees of $p$ and $s$ are always different.

The holonomy operation of $\partial u$ at $s$ is by definition given as

$$
\begin{aligned}
& \operatorname{hol}_{s}(\partial u): \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{p},\left.E_{\mathbb{\unrhd}}\right|_{p}\right) \otimes \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{\mathbb{\unrhd}}\right|_{X_{1}},\left.E_{\mathbb{\unrhd}}\right|_{X_{1}}\right) \otimes \cdots \otimes \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{\mathbb{\unrhd}}\right|_{X_{i}},\left.E_{\mathbb{\square}}\right|_{X_{i}}\right) \rightarrow \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{s},\left.E_{\mathbb{\square}}\right|_{s}\right), \\
& \quad\left(f, X_{1}, \ldots, X_{i}\right) \mapsto P\left((\partial u)_{i+1}\right) \circ X_{i} \circ P\left((\partial u)_{i}\right) \circ X_{i-1} \circ \cdots \circ X_{1} \circ P\left((\partial u)_{1}\right) \circ f \circ P\left((\partial u)_{0}\right) .
\end{aligned}
$$

Under the identification $\operatorname{Hom}_{\mathbb{C}}\left(\left.E_{\mathbb{Q}}\right|_{X_{j}},\left.E_{\mathbb{Q}}\right|_{X_{j}}\right)=\operatorname{Span}_{\mathbb{C}}\left\{X_{j}\right\} \cong \mathbb{C} \quad(j \in\{1, \ldots, i\})$, the generator $X_{j}$ corresponds to 1 . Note that $(\partial u)_{j}$ lies on $\mathbb{Q}$ for $j \in\{1, \ldots, i+1\}$, and under the identification $\operatorname{Hom}_{\mathbb{C}}\left(\left.E_{\mathbb{Z}}\right|_{X_{j-1}},\left.E_{\mathbb{L}}\right|_{X_{j}}\right) \cong$ $\mathbb{C} \quad\left(j \in\{1, \ldots, i+1\}, X_{0}:=p, X_{i+1}:=\bar{s}\right)$, in view of Proposition A.7, $P\left((\partial u)_{j}\right)$ corresponds $(-1)^{\#\left((\partial u)_{j} \cap \star_{\mathbb{L}}\right)}$, where $\#\left((\partial u)_{j} \cap \star_{\mathbb{L}}\right)$ is the number of times $(\partial u)_{j}$ passes through the point $\star$ on $\mathbb{L}$. Therefore, we can replace $\operatorname{hol}_{s}(\partial u)\left(f, X_{1}, \ldots, X_{i}\right)$ with

$$
(-1)^{\#\left(\partial u \cap \star_{\mathbb{L}}\right)} f \circ P\left((\partial u)_{0}\right)
$$

where $\#\left(\partial u \cap \star_{\mathbb{L}}\right)$ is the total number of times $\partial u$ passes through the point $\star$ on $\mathbb{L}$, and $P\left((\partial u)_{0}\right) \in$ $\operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{s},\left.E\right|_{p}\right)$ is the parallel transport from $\left.E\right|_{s}$ to $\left.E\right|_{p}$ along the side of $u$ lying in $L$.

We summarize the above discussion into the following formula:
Proposition 2.4. The $\left(\left(\left.E\right|_{s}\right)^{*},\left(\left.E\right|_{p}\right)^{*}\right)$-component of $\mathfrak{m}_{1}^{0, b}: \operatorname{hom}(\mathscr{L}, \mathbb{L}) \rightarrow \operatorname{hom}(\mathscr{L}, \mathbb{L})$ (and hence of $\Phi^{\mathbb{L}}(\mathscr{L})$ $\operatorname{or} \Psi^{\mathbb{\unrhd}}(\mathscr{L})$ ) is the $\mathbb{C}$-linear map $\mathfrak{m}_{1}^{0, b}:\left(\left.E\right|_{p}\right)^{*} \rightarrow\left(\left.E\right|_{s}\right)^{*}$ that maps $f \in\left(\left.E\right|_{p}\right)^{*}$ to

$$
\begin{equation*}
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \epsilon\{(x, X),(y, Y),(z, Z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)}(-1)^{(i+1) \mathrm{q}_{o(L) \neq o}(\partial u)+\#\left(\partial u \cap \star_{\mathbb{L}}\right)} f \circ P\left((\partial u)_{0}\right) \tag{2.5}
\end{equation*}
$$

It is also an $S$-module map $S \otimes\left(\left.E\right|_{p}\right)^{*} \rightarrow S \otimes\left(\left.E\right|_{S}\right)^{*}$, by considering $x, y$ and $z$ as variables in $S=\mathbb{C}[[x, y, z]]$.
If we choose a point $\star$ on $L$ so that $\operatorname{hol}_{\star}(E)$ is represented by a matrix $H \in \mathrm{GL}_{\rho}(\mathbb{C})$, trivialize $\left.E\right|_{S^{1} \backslash \star} \cong$ $\left(S^{1} \backslash \star\right) \times \mathbb{C}^{\rho}$ as in Proposition $A .7$ and thus $\left(\left.E\right|_{p}\right)^{*} \cong\left(\left.E\right|_{s}\right)^{*} \cong \mathbb{C}^{\rho}$, then it is represented by the $\rho \times \rho$ matrix

$$
\begin{equation*}
\left.\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \epsilon\{(x, X),(y, Y),(z, Z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathcal{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)}(-1)^{(i+1) \mathbb{1}_{o(L) \nmid) \neq o(\partial u)}+\#\left(\partial u \cap \star_{\mathbb{L}}\right)}\left(H^{T}\right)^{\#\left(\partial u \cap \star_{L}\right)\left(\mathbb{1}_{0}(L)=o(\partial u)-\mathbb{1}_{0(L) \neq 0}(\partial u)\right.}\right) \tag{2.6}
\end{equation*}
$$

where $\#\left(\partial u \cap \star_{L}\right)$ is the number of times $\partial u$ passes through the point $\star$ on L. Note that the entries can be also viewed as elements in $\mathbb{C}[[x, y, z]]$.
2.3. Illustration with an example. In this section, we illustrate the computation of the localized mirror functor with a concrete example. Namely, we will find the mirror matrix factorization of the loop with a local system $\mathscr{L}:=\mathscr{L}((3,-2,2), \eta, 1)^{14}$ for any $\eta \in \mathbb{C}^{\times}$. It is an object $(L, E, \nabla)$ of Fuk $(\Sigma)$ that consists of the underlying loop $L:=L(3,-2,2)$ described in Figure 6, a trivial line bundle $E$ over the domain $S^{1}$ of $L$, and a flat connection $\nabla$ on $E$ whose holonomy is $\eta$ at the point $\star$ on $L$ marked in Figure 6.

Note that $L$ and $\mathbb{L}$ have 6 intersections, say $p, q, r$, and $s, t, u$. According to their degrees, we have

$$
\chi^{0}(L, \mathbb{L})=\{p, q, r\}, \quad \chi^{1}(L, \mathbb{L})=\{s, t, u\} .
$$

We trivialize $E$ over $S^{1} \backslash \star$ as in Proposition A.7, which yields identifications $\left.E\right|_{\bullet} \cong \mathbb{C}$ for each $\bullet \in \chi(L, \mathbb{L})$. Then we have $\operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{\bullet},\left.E_{\mathbb{Z}}\right|_{\bullet}\right) \cong \operatorname{Span}_{\mathbb{C}}\{\bullet\}$ as noted in Remark A.8, and hence

$$
\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L})=\operatorname{Span}_{\mathbb{C}}\{p, q, r\}, \quad \operatorname{hom}^{1}(\mathscr{L}, \mathbb{L})=\operatorname{Span}_{\mathbb{C}}\{s, t, u\}
$$

Then two restricted operations $\mathfrak{m}_{1}^{0, b}: \operatorname{Hom}^{0}(\mathscr{L}, \mathbb{L}) \rightarrow \operatorname{Hom}^{1}(\mathscr{L}, \mathbb{L})$ and $\mathfrak{m}_{1}^{0, b}: \operatorname{Hom}^{1}(\mathscr{L}, \mathbb{L}) \rightarrow \operatorname{Hom}^{0}(\mathscr{L}, \mathbb{L})$ with respect to ordered bases $\{p, q, r\}$ and $\{s, t, u\}$ yield two $3 \times 3$ matrices $\Phi^{\mathbb{\unrhd}}(\mathscr{L})$ and $\Psi^{\mathbb{\complement}}(\mathscr{L})$, respectively.

Figure 6. Matrix factorization of $x y z$ corresponding to $\mathscr{L}=\mathscr{L}((3,-2,2), \eta, 1)$
Entries come from the following relations:

$$
\left\{\begin{array} { l } 
{ \mathfrak { m } _ { 1 } ^ { 0 , b } ( p ) = z s + y ^ { 2 } t - \eta x ^ { 2 } u } \\
{ \mathfrak { m } _ { 1 } ^ { 0 , b } ( q ) = x t } \\
{ \mathfrak { m } _ { 1 } ^ { 0 , b } ( r ) = } \\
{ - z t + \quad y u }
\end{array} \quad \text { and } \left\{\begin{array}{ll}
\mathfrak{m}_{1}^{0, b}(s)=x y p+\left(-y^{3}+\eta z x^{2}\right) q+\eta x^{3} r \\
\mathfrak{m}_{1}^{0, b}(t)= & y z q \\
\mathfrak{m}_{1}^{0, b}(u)= & z^{2} q+z x r
\end{array}\right.\right.
$$

Note that the $(■, \bullet)$-entry of $\Phi^{\llbracket}(\mathscr{L})$ or $\Psi^{\unrhd}(\mathscr{L})$ is the coefficient of $■$ in $\mathfrak{m}_{1}^{0, b}(\bullet)$ for $\bullet, \llbracket \in\{p, q, r, s, t, u\}$. So it can be computed from the formula (2.6), which in this case is just a single entry (in $S=\mathbb{C}[[x, y, z]]$ )

That is, each deformed strip $u$ bounded by $L$ and $\mathbb{L}$, whose angles consist of $\bullet, X_{1}, \ldots, X_{i}$ and $\boldsymbol{\square}$ in a counterclockwise order, contributes a monomial $x_{1} \cdots x_{i}$. Its coefficient is determined by coincidence of orientations of $L, \mathbb{L}$ with boundary orientation of $\partial u$ and the number of times $\partial u$ passes through the points $\star_{L}$ or $\star_{\mathbb{L}}$. Figure 7 shows some deformed strips that contribute some of the entries above:

[^9]
(a) $(s, p)$-entry of $\Phi^{\mathbb{L}}(L): z$

(c) $(t, p)$-entry of $\Phi^{\mathbb{L}}(L): y^{2}$

(e) $(p, s)$-entry of $\Psi^{\unrhd}(L): x y$

(b) $(t, r)$-entry of $\Phi^{\unrhd}(L):-z$

(d) $(u, p)$-entry of $\Phi^{\llcorner }(L):-\eta x^{2}$

(f) $(q, u)$-entry of $\Psi^{\unrhd}(L): z^{2}$

(g) $(q, s)$-entry of $\Psi^{\llcorner }(L):-y^{3}+\eta z x^{2}$

Figure 7. Some entries of $\Phi^{\llcorner }(L)$ and $\Psi^{\llcorner }(L)$
2.4. Higher rank computation. We can compute the matrix factorizations corresponding to a higher rank local system on a loop easily once we know the result for rank 1 local systems on the same loop.

Consider two local systems on the same loop $L$ in $\Sigma$ that have rank 1 and $\rho$, respectively:

- $\mathscr{L}_{1}(\eta):=\left(L, E_{1}, \nabla_{1}\right)$ : loop with a local system of rank 1 of holonomy $\eta \in \mathbb{C}^{\times}$.
- $\mathscr{L}_{\rho}(H):=\left(L, E_{\rho}, \nabla_{\rho}\right)$ : loop with a local system of $\operatorname{rank} \rho$ of holonomy $H \in \mathrm{GL}_{\rho}(\mathbb{C})$,

Namely, there is a point $\star$ on $L$ and identification $\left.E_{1}\right|_{\star} \cong \mathbb{C}$ and $\left.E_{\rho}\right|_{\star} \cong \mathbb{C}^{\rho}$, so that $\operatorname{hol}_{\star}\left(E_{1}\right)$ is represented by a scalar $\eta \in \mathbb{C}^{\times}$, while $\operatorname{hol}_{\star}\left(E_{\rho}\right)$ is represented by a matrix $H \in \mathrm{GL}_{\rho}(\mathbb{C})$.

For any $p, s \in \chi(L, \mathbb{L})$, the formula (2.7) and (2.6) imply that the $(s, p)$-entry of $\left(\Phi^{\complement}\left(\mathscr{L}_{1}(\eta)\right), \Psi^{\complement}\left(\mathscr{L}_{1}(\eta)\right)\right)$ and the $\left(\left(\left.E_{\rho}\right|_{s}\right)^{*},\left(\left.E_{\rho}\right|_{p}\right)^{*}\right)$-component of $\left(\Phi^{\unrhd}\left(\mathscr{L}_{\rho}(H)\right), \Psi^{\unrhd}\left(\mathscr{L}_{\rho}(H)\right)\right)$ are given in the form

$$
\begin{equation*}
\sum_{k=-\infty}^{\infty} a_{k} \eta^{k} \in \mathbb{C}[[x, y, z]] \quad \text { and } \quad \sum_{k=-\infty}^{\infty} a_{k}\left(H^{T}\right)^{k} \in \mathbb{C}[[x, y, z]]^{\rho \times \rho} \tag{2.8}
\end{equation*}
$$

respectively, for some $a_{k} \in \mathbb{C}[[x, y, z]]$. (See Theorem 3.13 for the convergence issue).
Proposition $2.5\left(\left(\eta, H^{T}\right)\right.$-substitution). The matrix factorizations corresponding to $\mathscr{L}_{1}(\eta)$ and $\mathscr{L}_{\rho}(H)$ are given in the form

$$
\mathscr{F}^{\mathbb{L}}\left(\mathscr{L}_{1}(\eta)\right)=\left(\sum_{k=-\infty}^{\infty} \varphi_{k} \eta^{k}, \sum_{k=-\infty}^{\infty} \psi_{k} \eta^{k}\right) \quad \text { and } \quad \mathscr{F}^{\mathbb{L}}\left(\mathscr{L}_{\rho}(H)\right)=\left(\sum_{k=-\infty}^{\infty} \varphi_{k} \otimes\left(H^{T}\right)^{k}, \sum_{k=-\infty}^{\infty} \psi_{k} \otimes\left(H^{T}\right)^{k}\right) 15,
$$

respectively, for some $\varphi_{k}, \psi_{k} \in \mathbb{C}[[x, y, z]]^{\tau \times \tau}\left(\tau=\frac{1}{2}|L \cap \mathbb{L}|\right)$.
Proof. Let $\varphi_{k}$ be a $\tau \times \tau$ matrix over $S=\mathbb{C}[[x, y, z]]$ whose ( $s, p$ )-entry is $a_{k}$ given in (2.8) (viewed as a map of free $S$-modules from $\operatorname{Span}_{S}\left(\chi^{0}(L, \mathbb{L})\right)$ to $\operatorname{Span}_{S}\left(\chi^{1}(L, \mathbb{L})\right)$ with respect to an appropriate order in each set $\left.\chi^{\bullet}(L, \mathbb{L})\right)$. Then $\sum_{k=-\infty}^{\infty} \varphi_{k} \eta^{k}$ coincides with $\Phi^{\mathbb{\unrhd}}\left(\mathscr{L}_{1}(\eta)\right)$.

Now $\varphi_{k} \otimes\left(H^{T}\right)^{k}$ is a $\tau \rho \times \tau \rho$ matrix over $S$, which can be also viewed as a map of free $S$-modules

$$
\bigoplus_{p \in \chi^{0}(L, \mathbb{L})} \operatorname{Span}_{S}\{p\} \otimes_{\mathbb{C}}\left(\left.E_{\rho}\right|_{p}\right)^{*} \rightarrow \bigoplus_{s \in \chi^{1}(L, \mathbb{L})} \operatorname{Span}_{S}\{s\} \otimes_{\mathbb{C}}\left(\left.E_{\rho}\right|_{S}\right)^{*}
$$

under an order in $\chi \cdot(L, \mathbb{L})$ and identification $\left.\left.E_{\rho}\right|_{p} \cong E_{\rho}\right|_{s} \cong \mathbb{C}^{\rho}$. Its $\left(\left(\left.E_{\rho}\right|_{s}\right)^{*},\left(\left.E_{\rho}\right|_{p}\right)^{*}\right)$-component is $a_{k}\left(H^{T}\right)^{k}$, where $a_{k}$ denotes the $(s, p)$-entry of $\varphi_{k}$. Therefore, the corresponding component of $\sum_{k=-\infty}^{\infty} \varphi_{k} \otimes\left(H^{T}\right)^{k}$ is $\sum_{k=-\infty}^{\infty} a_{k}\left(H^{T}\right)^{k}$, which is that of $\Phi^{\unrhd}\left(\mathscr{L}_{\rho}(H)\right)$ by (2.8). It works the same for $\psi_{k}$ instead of $\varphi_{k}$.

The proposition says that if we know $\varphi_{k}$ and $\psi_{k}$ 's from the rank 1 cases, we immediately get the result for higher rank cases as well, just by 'substituting the matrix $H^{T}$ for the scalar $\eta$ '. See the example:

Example 2.6. Consider the loop with a local system $\mathscr{L}_{\rho}:=\mathscr{L}((3,-2,2), \eta, \rho)$ of rank $\rho \in \mathbb{Z}_{\geq 1}$. It consists of the same underlying loop $L:=L(3,-2,2)$ as in Subsection 2.3 (Figure 6), trivial vector bundle $E_{\rho}$ of rank $\rho$ over the domain $S^{1}$ of $L$, and a flat connection $\nabla_{\rho}$ on $E_{\rho}$ whose holonomy is $J_{\rho}(\eta)$ at the point $\star$. Then, by the result for $\mathscr{L}_{1}$ in Subsection 2.3 and Proposition 2.5, the corresponding matrix factorization is

$$
\left.\begin{array}{c}
\Phi^{\unrhd}\left(\mathscr{L}_{\rho}\right)=\begin{array}{c}
\left(\left.E\right|_{p}\right)^{*} \\
\left(\left.E\right|_{t}\right)^{*} \\
\left(\left.E\right|_{u}\right)^{*}
\end{array}\left(\begin{array}{ccc}
\left(\left.E\right|_{q}\right)^{*}\left(\left.E\right|_{r}\right)^{*} \\
z I_{\rho} & 0 & 0 \\
y^{2} I_{\rho} & x I_{\rho} & -z I_{\rho} \\
-x^{2} J_{\rho}(\eta)^{T} & 0 & y I
\end{array}\right)
\end{array} \begin{array}{ccc}
\left(\left.E\right|_{s}\right)^{*} & \left(\left.E\right|_{t}\right)^{*}\left(\left.E\right|_{u}\right)^{*} \\
\text { and })^{*}
\end{array} \begin{array}{ccc}
x y I_{\rho} & \Psi^{\unrhd}\left(\mathscr{L}_{\rho}\right) & \left(\left.E\right|_{q}\right)^{*} \\
-y^{3} I_{\rho}+z x^{2} J_{\rho}(\eta)^{T} & y z I_{\rho} & z^{2} I_{\rho} \\
x^{3} J_{\rho}(\eta)^{T} & 0 & z x I_{\rho}
\end{array}\right) .
$$

[^10]
## 3. Matrix Factorizations from Loops with a Local System

In this section, we first define the canonical form of immersed loops in $\Sigma$ and local systems on them, parameterized by normal loop words ( $\$ 3.1$ ) and loop data ( $\$ 3.2$ ), respectively. Then we compute their mirror image under the localized mirror functor, which provides the canonical form of matrix factorizations of $x y z(\$ 3.3)$. The matrix factorizations corresponding to periodic loop words are decomposable, which implies that non-primitive loops (with a local system) are decomposable in the Fukaya category (\$3.4). Meanwhile, an exceptional case is handled separately (\$3.5).
3.1. Loop words and canonical form of immersed loops. We first recall from [CJKR22] the concept of loop words, which parameterize free homotopy classes of loops in $\Sigma$. They were introduced in order to pick a specific representative in each (hyperbolic) free homotopy class, motivated by the observation that two freely homotopic loops correspond to homotopically equivalent matrix factorizations under the localized mirror functor (Theorem 3.13).

Note that the fundamental group of $\Sigma$ can be presented as $\pi_{1}(\Sigma)=\langle\alpha, \beta, \gamma \mid \alpha \beta \gamma=1\rangle$ with the based loops $\alpha, \beta$ and $\gamma$ in $\Sigma$ shown in Figure 8a. Also recall that there is a one-to-one correspondence between the free homotopy classes of loops in $\Sigma$ and the conjugacy classes in $\pi_{1}(\Sigma)$.

(a) Generators $\alpha, \beta, \gamma$ of $\pi_{1}(\Sigma)$

(b) Canonical form $L\left(w^{\prime}, \eta, \rho\right)$ of loops a local system

Figure 8. Fundamental group and loop data

Definition 3.1. A loop word of length $3 \tau$ is

$$
w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, l_{2}^{\prime}, m_{2}^{\prime}, n_{2}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}
$$

$\left(\tau \in \mathbb{Z}_{\geq 1}\right)$. The associated loop, denoted as

$$
L\left(w^{\prime}\right)
$$

is illustrated in Figure 8b. It visits three holes A, B, and C in turn, winding them around the number of times specified in $w^{\prime}$. Namely, starting from the point $\star$ marked in the figure, it winds hole $A l_{1}^{\prime}$-times, hole $B m_{1}^{\prime}$ times, hole C $n_{1}^{\prime}$-times, hole A $l_{2}^{\prime}$-times, hole B $m_{2}^{\prime}-$ times, and so on. After finally it winds hole $C n_{\tau}^{\prime}$-times, it returns to the point $\star$ to form a closed loop. We perturb it if it is necessary to put them together into a transversal set.

Note that its free homotopy class in $\left[S^{1}, \Sigma\right]=\pi_{1}(\Sigma) / \sim_{\text {conjugation }}$ is

$$
\left[L\left(w^{\prime}\right)\right]=\left[\alpha^{l_{1}^{\prime}} \beta^{m_{1}^{\prime}} \gamma^{n_{1}^{\prime}} \alpha^{l_{2}^{\prime}} \beta^{m_{2}^{\prime}} \gamma^{n_{2}^{\prime}} \ldots \alpha^{l_{\tau}^{\prime}} \beta^{m_{\tau}^{\prime}} \gamma^{n_{\tau}^{\prime}}\right] .
$$

Two loop words $w^{\prime}$ and $\tilde{w}^{\prime}$ are regarded as equivalent if $\left[L\left(w^{\prime}\right)\right]=\left[L\left(\tilde{w}^{\prime}\right)\right]$.
Example 3.2. The loop described in Figure 21 and Figure 6 is (a perturbation of) $L(3,-2,2)$.

We denote the $j$-th value of a loop word $w^{\prime}$ as $w_{j}^{\prime}$ so that

$$
w^{\prime}=\left(w_{1}^{\prime}, w_{2}^{\prime}, w_{3}^{\prime}, \ldots, w_{3 \tau-1}^{\prime}, w_{3 \tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau} .
$$

Then any tuple ( $w_{k}^{\prime}, w_{k+1}^{\prime}, \ldots, w_{l}^{\prime}$ ) for some distinct $k, l \in \mathbb{Z}_{3 \tau}$ is called a subword in $w^{\prime}$. We regard the index $i$ of $l_{i}^{\prime}, m_{i}^{\prime}$ and $n_{i}^{\prime}$ to be in $\mathbb{Z}_{\tau}$ (hence $3 i \in \mathbb{Z}_{3 \tau}$ ) and the index $j$ of $w_{j}^{\prime}$ to be in $\mathbb{Z}_{3 \tau}$. Therefore, for example, ( $w_{3 \tau-1}^{\prime}, w_{3 \tau}^{\prime}, w_{1}^{\prime}$ ) is a subword. We define the 1 -shift of a loop word $w^{\prime}$ to be

$$
w^{\prime(1)}=\left(l_{2}^{\prime}, m_{2}^{\prime}, n_{2}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}, l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}\right) \in \mathbb{Z}^{3 \tau}
$$

and $k$-shift to be $w^{\prime(k)}$ which is obtained from $w^{\prime}$ by applying the 1 -shift $k$-times $(k \in \mathbb{Z})$.
For a loop word $w^{\prime}$, we define its $N$-concatenation $\left(w^{\prime}\right)^{N}$ as the $N$ repetitions of $w^{\prime}$. It is called periodic if it is $N$-concatenation of another loop word for some $N \in \mathbb{Z}_{\geq 2}$. For an immersed loop $L: S^{1} \rightarrow \Sigma$, we define its $N$-concatenation by the immersed loop

$$
L^{N}: S^{1} \rightarrow \Sigma, \quad e^{2 \pi i t} \mapsto L\left(e^{2 N \pi i t}\right) .
$$

A loop $L$ or its free homotopy class [ $L$ ] are called non-primitive if $L$ is freely homotopic to an $N$-concatenation of another loop for some $N \in \mathbb{Z}_{\geq 2}$. Otherwise, they are called primitive.

Note that if a loop word $w^{\prime}$ is periodic, then the associated loop $L\left(w^{\prime}\right)$ and its free homotopy class [ $L\left(w^{\prime}\right)$ ] are non-primitive. But the converse is not true in general as a non-periodic loop word $w^{\prime}$ can be equivalent to a periodic one. It will be fixed when we will regard only normal loop words (Corollary 3.7).

The following lemma is easy to check.
Lemma 3.3. The following operations on a loop word $w^{\prime}$ do not change the equivalence class of $w^{\prime}$ :

- (inserting 0s) insert the subword $(0,0,0)$ somewhere in $w^{\prime}$,
- (removing 0 s) remove a subword $(0,0,0)$ in $w^{\prime}$ if it exists,
- (adding 1 s around 0$)$ add $(1,1,1)$ to the subword $\left(w_{j-1}^{\prime}, 0, w_{j+1}^{\prime}\right)$ in $w^{\prime}$ where $w_{j}^{\prime}=0$, and
- (subtracting 1 s around 1$) \operatorname{subtract}(1,1,1)$ from the subword $\left(w_{j-1}^{\prime}, 1, w_{j+1}^{\prime}\right)$ in $w^{\prime}$ where $w_{j}^{\prime}=1$,
- (shifting) take $k$-shift of $w^{\prime}$ for some $k \in \mathbb{Z}$.

The converse statement is also true, but its proof involves a non-trivial word problem.
Proposition 3.4. [CJKR22] Two loop words $w^{\prime}$ and $\tilde{w}^{\prime}$ are equivalent if and only if $\tilde{w}^{\prime}$ can be obtained from $w^{\prime}$ by performing the above five operations finitely many times.

Note that several equivalent loop words can represent the same free homotopy class. To find a unique representative in each class, we introduce the following normal form of loop words. It will play an important role in the conversion formula between loop data and band data.

Definition 3.5. A loop word $w^{\prime}$ is said to be normal if it satisfies the following conditions:

- any subword of the form $(a, 1, b)$ in $w^{\prime}$ satisfies $a, b \leq 0$,
- any subword of the form $(a, 0, b)$ in $w^{\prime}$ satisfies $a \leq-1, b \geq 1$ or $a \geq 1, b \leq-1$ or $a, b \geq 1$,
- $w^{\prime}$ has no subword of the form $(0,-1,-1, \ldots,-1,0)$, and
- $w^{\prime}$ does not consist only of -1 , that is, $w^{\prime} \neq(-1,-1, \ldots,-1)$.

We say that a loop $L$ or its free homotopy class [ $L$ ] are elliptic if $L$ is null-homotopic, parabolic if $L$ is freely homotopic to some concatenation of a boundary loop, and hyperbolic otherwise ${ }^{16}$. An elliptic loop is obstructed, and a parabolic loop $L$ can always be deformed so that it doesn't meet the reference $\mathbb{L}$ at all, which means that the corresponding matrix factorization $\mathscr{F}^{\llcorner }(L)$ is null-homotopic. Therefore, elliptic and parabolic loops will be excluded from our consideration.

According to Definition 3.1, each elliptic or parabolic loop is produced by a loop word equivalent to one of $\left(l^{\prime}, 0,0\right),\left(0, m^{\prime}, 0\right)$ or $\left(0,0, n^{\prime}\right)$ for some $l^{\prime}, m^{\prime}, n^{\prime} \in \mathbb{Z}$. Loop words in those forms are called nonhyperbolic, while the others are called hyperbolic. Therefore, hyperbolic loop words produce hyperbolic loops. Interestingly, the above normality condition automatically rules out non-hyperbolic loop words. Moreover, the normal form up to shifting gives exactly one representative among equivalent hyperbolic loop words.

Proposition 3.6. [CJKR22] Any normal loop word is hyperbolic. Conversely, any hyperbolic loop word is equivalent to a unique normal loop word up to shifting.

This also implies that two normal loop words $w^{\prime}$ and $\tilde{w}^{\prime}$ are equivalent if and only if they coincide up to shifting, that is, $\tilde{w}^{\prime}=w^{\prime(k)}$ for some $k \in \mathbb{Z}$.

Corollary 3.7. A normal loop word $w^{\prime}$ is periodic if and only if the associated loop $L\left(w^{\prime}\right)$ and its free homotopy class $\left[L\left(w^{\prime}\right)\right]$ are non-primitive.

Now we give $\Sigma$ a hyperbolic metric with three cusps. It can be achieved by considering the Poincaré disk as the universal cover of $\Sigma$ as shown in Figure 9. In fact, such a metric is unique up to isometry (Theorem 9.8 .8 in [RAR94]). It is well-known in hyperbolic geometry that there is exactly one (immersed) closed geodesic in each primitive hyperbolic free homotopy class of loops in $\Sigma$ (Theorem 9.6.4 in [RAR94]). This provides another description of normal loop words.

Proposition 3.8. There is a one-to-one correspondence
\{closed geodesics in $\Sigma\} \stackrel{\text { l:1 }}{\leftrightarrow}$ \{non-periodic normal loop words\} $/ \sim_{\text {shifting }}$.

Figure 9. Fundamental domain of $\Sigma$ in its universal cover (Poincaré disk)

[^11]
### 3.2. Loop data and canonical form of loops with a local system.

Definition 3.9. A loop datum $\left(w^{\prime}, \eta, \rho\right)$ consists of the following:

- (normal loop word) $w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, l_{2}^{\prime}, m_{2}^{\prime}, n_{2}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}$ for some $\tau \in \mathbb{Z}_{\geq 1}$,
- (holonomy parameter) $\eta \in \mathbb{C}^{\times}$,
- ((geometric) rank) $\rho \in \mathbb{Z}_{\geq 1}$.

It represents an object $(L, E, \nabla)$ of $\operatorname{Fuk}(\Sigma)$, denoted as

$$
\mathscr{L}\left(w^{\prime}, \eta, \rho\right),
$$

that consists of the loop $L:=L\left(w^{\prime}\right)$ defined in Definition 3.1, a trivial $\mathbb{C}$-vector bundle $E$ of rank $\rho$ over the domain $S^{1}$ of $L$, and a flat connection $\nabla$ on $E$ whose holonomy is $J_{\rho}(\eta)$ at the point $\star$ on $L$ (marked in Figure 8b). We refer to it as the canonical form of loops with a local system corresponding to the loop datum ( $w^{\prime}, \eta, \rho$ ).
Proposition 3.10. Let $(L, E, \nabla)$ be a loop with a local system with $L=L\left(w^{\prime}\right)$ for some normal loop word $w^{\prime}$. Then there are finitely many pairs $\left(\eta_{1}, \rho_{1}\right), \ldots,\left(\eta_{d}, \rho_{d}\right) \in \mathbb{C}^{\times} \times \mathbb{Z}_{\geq 1}\left(d \in \mathbb{Z}_{\geq 1}\right)$ such that $(E, \nabla)$ is gauge equivalent to the direct sum

$$
\left(E_{1}, \nabla_{1}\right) \oplus \cdots \oplus\left(E_{d}, \nabla_{d}\right),
$$

where $\left(L, E_{i}, \nabla_{i}\right)(i \in\{1, \ldots, d\})$ is the canonical form $\mathscr{L}\left(w^{\prime}, \eta_{i}, \rho_{i}\right)$ corresponding to the loop datum $\left(w^{\prime}, \eta_{i}, \rho_{i}\right)$. Moreover, the choice of the pairs is unique up to the order.

Proof. Note that every $\mathbb{C}$-vector bundle over $S^{1}$ is trivial. At a fixed point $\star$ on $L$, the holonomy hol ${ }_{\star}(E)$ of $(E, \nabla)$ along $L$ at $\star$ is represented by some matrix $H \in \mathrm{GL}_{\rho}(\mathbb{C})$. Then the Jordan canonical form of $H$ has Jordan blocks $J_{\rho_{1}}\left(\eta_{1}\right), \ldots, J_{\rho_{d}}\left(\eta_{d}\right)\left(d \in \mathbb{Z}_{\geq 1}\right)$ for some pairs $\left(\eta_{1}, \rho_{1}\right), \ldots,\left(\eta_{d}, \rho_{d}\right) \in \mathbb{C}^{\times} \times \mathbb{Z}_{\geq 1}$, which yields the desired decomposition.

This shows that any indecomposable local system on a fixed loop $L=L\left(w^{\prime}\right)$ is gauge equivalent to a unique canonical form $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$. Combining this with Proposition 3.8, we get the following:
Corollary 3.11. There is a one-to-one correspondence
\{closed geodesics in $\Sigma$ with an indecomposable local system\}/ ~gauge equivalence

$$
\stackrel{1: 1}{\leftrightarrow} \text { \{non-periodic loop data }\} / \sim_{\text {shifting }}{ }^{17} \text {. }
$$

3.3. Matrix factorizations from canonical form of loops with a local system. To get a matrix factorization defined over $\mathbb{C}$ from the loop with a local system $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ constructed in Definition 3.9, we first need to ensure that the underlying loop $L\left(w^{\prime}\right)$ doesn't bound an immersed cylinder with the reference loop $\mathbb{Z}$ (Seidel Lagrangian). We briefly summarize the discussion in [CJKR22] here:
Definition 3.12. A loop $L$ in $\Sigma$ is said to be cylinder-free with $\mathbb{L}$ if there is no immersion $j: S^{1} \times[0,1] \rightarrow \Sigma$ that satisfies $j\left(e^{2 \pi i t}, 0\right)=L(\imath(t))$ and $j\left(e^{2 \pi i t}, 1\right)=\mathbb{\square}(\jmath(t))$ for some immersions $\imath, j: S^{1} \rightarrow S^{1}$.
Theorem 3.13. [CJKR22] For an object $\mathscr{L}:=(L, E, \nabla)$ in Fuk $(\Sigma)$ whose underlying loop $L$ is cylinder-free with $\mathbb{L}$, its mirror matrix factorization $\mathscr{F}^{\natural}(\mathscr{L})=\left(\Phi^{\mathbb{L}}(\mathscr{L}), \Psi^{\mathbb{L}}(\mathscr{L})\right)$ is well-defined over $\mathbb{C}$. More precisely, this means that the moduli spaces involved in formula 2.5 are finite.

Moreover, the homotopy class of $\mathscr{F}^{\mathbb{L}}(\mathscr{L})$ is invariant under free homotopy of the underlying curve $L$ and gauge equivalence of the flat vector bundle $(E, \nabla)^{18}$.
Proposition 3.14. [CJKR22] For a normal loop word $w^{\prime}$ other than of the form $(2,2,2)^{\tau}$, the corresponding loop $L\left(w^{\prime}\right)$ is cylinder-free with $\mathbb{L}$.

[^12]Now we compute the matrix factorization corresponding to the canonical form $(L, E, \nabla):=\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ for a loop datum $\left(w^{\prime}, \eta, \rho\right)$ with $w^{\prime} \neq(2,2,2)^{\tau}$. For a loop word of length $3 \tau$

$$
w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, l_{2}^{\prime}, m_{2}^{\prime}, n_{2}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right),
$$

the corresponding loop $L=L\left(w^{\prime}\right)$ has $6 \tau$ intersections with $\mathbb{L}$. We name even-degree angles from $L$ to $\mathbb{L}$ by $p_{1}, q_{1}, r_{1}, \ldots, p_{\tau}, q_{\tau}, r_{\tau} \in \operatorname{hom}^{0}(L, \mathbb{L})$ and odd-degree angles from $L$ to $\mathbb{L}$ by $s_{1}, t_{1}, u_{1}, \ldots, s_{\tau}, t_{\tau}, u_{\tau} \in$ $\operatorname{hom}^{1}(L, \mathbb{L})$ in the order along the orientation of $L$.

Figure 10. Canonical form $(L, E, \nabla)=\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ and Seidel Lagrangian $\mathbb{L}$
Proposition 3.15. For a loop datum $\left(w^{\prime}, \eta, \rho\right)$ with $w^{\prime} \neq(2,2,2)^{\tau}{ }^{19}$, the corresponding loop with a local system $(L, E, \nabla):=\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ is converted under the localized mirror functor into the matrix factor $\Phi^{\complement}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)$ given by
where $x^{a}, y^{a}, z^{a}$ are regarded as 0 if $a<0$.
Proof. For $\rho=1$ case, the computation is essentially the same as what we did for $\Phi^{\mathbb{L}}(\mathscr{L}((3,-2,2), \eta, 1))$ in Subsection 2.3. A rigorous proof can be found in [CJRR22]. For $\rho \geq 2$, we use Proposition 2.5 to 'substitute the matrix $J_{\rho}(\eta)^{T}$ for the scalar $\eta^{\prime}$, as we did in Example 2.6.

[^13]Inspired by this observation, we propose the following definition:
Definition 3.16. For a loop datum $\left(w^{\prime}, \lambda, \rho\right)$ with $\left(w^{\prime}, \lambda\right) \neq\left((2,2,2)^{\tau}, 1\right)$, consider the matrix

$$
\varphi\left(w^{\prime}, \lambda, \rho\right):=\left(\begin{array}{ccccccc}
z I_{\rho} & -y^{m_{1}^{\prime}-1} I_{\rho} & 0 & 0 & \cdots & 0 & -x^{-l_{1}^{\prime}} J_{\rho}(\lambda)^{-1} \\
-y^{-m_{1}^{\prime}} I_{\rho} & x I_{\rho} & -z^{n_{1}^{\prime}-1} I_{\rho} & 0 & \cdots & 0 & 0 \\
0 & -z^{-n_{1}^{\prime}} I_{\rho} & y I_{\rho} & -x^{l_{2}^{\prime}-1} I_{\rho} & \cdots & 0 & 0 \\
0 & 0 & -x^{-l_{2}^{\prime}} I_{\rho} & z I_{\rho} & \ddots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \ddots & \ddots & -y^{m_{\tau}^{\prime}-1} I_{\rho} & 0 \\
0 & 0 & 0 & \cdots & -y^{-m_{\tau}^{\prime}} I_{\rho} & x I_{\rho} & -z^{n_{\tau}^{\prime}-1} I_{\rho} \\
-x^{l_{1}^{\prime}-1} J_{\rho}(\lambda) & 0 & 0 & \cdots & 0 & -z^{-n_{\tau}^{\prime}} I_{\rho} & y I_{\rho}
\end{array}\right)_{3 \tau \rho \times 3 \tau \rho}
$$

where $x^{a}, y^{a}, z^{a}$ are regarded as 0 if $a<0$. Then it is a matrix factor of $x y z$ with the opposite factor denoted by $\psi\left(w^{\prime}, \lambda, \rho\right)^{20}$. We refer to the pair $\left(\varphi\left(w^{\prime}, \boldsymbol{\lambda}, \rho\right), \psi\left(w^{\prime}, \boldsymbol{\lambda}, \rho\right)\right)$ the canonical form of matrix factorizations of $x y z$ corresponding to the loop datum $\left(w^{\prime}, \lambda, \rho\right)$.

We can transform the matrix $\Phi^{\complement}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)$ obtained in Proposition 3.15 into $\varphi\left(w^{\prime}, \lambda, \rho\right)$ by some bases change and prove the following theorem:

Theorem 3.17. For a loop datum $\left(w^{\prime}, \eta, \rho\right)$ with $w^{\prime} \neq(2,2,2)^{\tau}$, there is an isomorphism

$$
\mathscr{F}^{\mathbb{L}}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right) \cong\left(\varphi\left(w^{\prime}, \lambda, \rho\right), \psi\left(w^{\prime}, \lambda, \rho\right)\right)
$$

in $\mathrm{MF}(x y z)$, where

$$
\lambda:=(-1)^{l_{1}+\cdots+l_{\tau}+\tau} \eta
$$

for $l_{i}:=l_{i}^{\prime}+1-\mathbb{1}_{n_{i-1}^{\prime} \geq 1}-\mathbb{1}_{l_{i}^{\prime} \geq 1}-\mathbb{1}_{m_{i}^{\prime} \geq 1}\left(i \in \mathbb{Z}_{\tau}\right)^{21}$.
Proof. Note that exactly one of block components $-y^{m_{1}^{\prime}-1} I_{\rho}$ and $y^{-m_{1}^{\prime}} I_{\rho}$ survives in $\Phi^{\llcorner }\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)$, for example, as $y^{a}$ is regarded as 0 if $a<0$. By changing the sign of some basis elements, we can replace its block components
$y^{-m_{1}^{\prime}} I_{\rho}, \quad z^{-n_{1}^{\prime}} I_{\rho}, \quad-(-x)^{l_{2}^{\prime}-1} I_{\rho}, \quad-(-x)^{-l_{2}^{\prime}} I_{\rho}, \ldots \quad y^{-m_{\tau}^{\prime}} I_{\rho}, \quad z^{-n_{\tau}^{\prime}} I_{\rho}, \quad-(-x)^{l_{1}^{\prime}-1} J_{\rho}(\eta)^{T},-(-x)^{-l_{1}^{\prime}}\left(J_{\rho}(\eta)^{T}\right)^{-1}$
with

$$
-y^{-m_{1}^{\prime}} I_{\rho}, \quad-z^{-n_{1}^{\prime}} I_{\rho},-x^{l_{2}^{\prime}-1} I_{\rho},-x^{-l_{2}^{\prime}} I_{\rho}, \ldots-y^{-m_{\tau}^{\prime}} I_{\rho},-z^{-n_{\tau}^{\prime}} I_{\rho},-x^{l_{1}^{\prime}-1}(-1)^{\dagger} J_{\rho}(\eta)^{T},-x^{-l_{1}^{\prime}}(-1)^{\dagger}\left(J_{\rho}(\eta)^{T}\right)^{-1}
$$

in order, where $(-1)^{\dagger}$ is the total sign change given by

$$
(-1)^{\dagger}:=(-1)^{\left(l_{1}^{\prime}-1\right) \eta_{l_{1}^{\prime} \geq 1}-l_{1}^{\prime} l_{l_{1}^{\prime} \leq 0} \leq 0_{m_{1}^{\prime} \leq 0}^{\prime}+0_{n_{1}^{\prime} \leq 0}+\left(l_{2}^{\prime}-1\right) 0_{l_{2}^{\prime} \geq 1}-l_{2}^{\prime} l_{l_{2}^{\prime} \leq 0}+0_{m_{2}^{\prime} \leq 0}+\cdots+0_{m_{\tau}^{\prime} \leq 0}+0_{n_{\tau}^{\prime} \leq 0}}=(-1)^{l_{1}+\cdots+l_{\tau}+\tau} .
$$

The last two can be again replaced by $-x^{l_{1}^{\prime}-1} J_{\rho}(\lambda)$ and $-x^{-l_{1}^{\prime}} J_{\rho}(\lambda)^{-1}$ for $\lambda:=(-1)^{\dagger} \eta$, respectively, by some bases change using the fact that the matrix $(-1)^{\dagger} J_{\rho}(\eta)^{T}$ is similar to $J_{\rho}(\lambda)$ from the relation

$$
\left(\begin{array}{ccccc}
0 & \cdots & 0 & 0 & 1 \\
0 & \cdots & 0 & (-1)^{\dagger} & 0 \\
0 & \cdots & 1 & 0 & 0 \\
\vdots & . & \vdots & \vdots & \vdots \\
\pm 1 & \cdots & 0 & 0 & 0
\end{array}\right)(-1)^{\dagger}\left(\begin{array}{ccccc}
\eta & 0 & 0 & \cdots & 0 \\
1 & \eta & 0 & \cdots & 0 \\
0 & 1 & \eta & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & \cdots & 1 & \eta
\end{array}\right)\left(\begin{array}{ccccc}
0 & 0 & 0 & \cdots & \pm 1 \\
\vdots & \vdots & \vdots & . & \vdots \\
0 & 0 & 1 & \cdots & 0 \\
0 & (-1)^{\dagger} & 0 & \cdots & 0 \\
1 & 0 & 0 & \cdots & 0
\end{array}\right)=\left(\begin{array}{ccccc}
\lambda & 1 & 0 & \cdots & 0 \\
0 & \lambda & 1 & \cdots & 0 \\
0 & 0 & \lambda & \ddots & \vdots \\
\vdots & \vdots & \vdots & \ddots & 1 \\
0 & 0 & 0 & \cdots & \lambda
\end{array}\right)
$$

[^14]To manipulate and analyze the canonical form of matrix factorizations, it is convenient to introduce notations on some special matrices.

Notation 3.18. Denote the $N \times N$ Jordan block of eigenvalue 0 and its transpose as

$$
J_{N}:=\left(\begin{array}{ccccc}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
0 & 0 & 0 & \ddots \\
\vdots & \vdots & \vdots & \ddots & \ddots \\
0 & 0 & 0 & \cdots & 0
\end{array}\right)_{N \times N} \quad \text { and } \quad K_{N}:=J_{N}^{T}=\left(\begin{array}{cccccc}
0 & 0 & 0 & \cdots & 0 \\
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots \\
0 & 0 & \cdots & 1 & 0
\end{array}\right)_{N \times N} .
$$

Note that the $n \times n$ Jordan block of eigenvalue $\lambda \in \mathbb{C}$ is $J_{n}(\lambda)=\lambda I_{n}+J_{n}$. We will also frequently use

$$
R_{N}(\lambda):=J_{N}+\lambda K_{N}^{N-1}=\left(\begin{array}{ccccc}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
0 & 0 & 0 & \ddots \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\lambda & 0 & 0 & \cdots & 0
\end{array}\right)_{N \times N} \quad \text { and } \quad R_{N}^{T}(\lambda)=K_{N}+\lambda J_{N}^{N-1}=\left(\begin{array}{cccccc}
0 & 0 & 0 & \cdots & \lambda \\
1 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & \cdots & 1 & 0
\end{array}\right)_{N \times N},
$$

and their enlargement by replacing $\lambda$ with $J_{\rho}(\lambda)^{ \pm 1}$

$$
\begin{gathered}
R_{N}\left(J_{\rho}(\lambda)\right)=J_{N} \otimes I_{\rho}+K_{N}^{N-1} \otimes J_{\rho}(\lambda)=\left(\begin{array}{ccccc}
0 & I_{\rho} & 0 & \cdots & 0 \\
0 & 0 & I_{\rho} & \cdots & 0 \\
0 & 0 & 0 & \ddots & \vdots \\
\vdots & \vdots & \vdots & \ddots & I_{\rho} \\
J_{\rho}(\lambda) & 0 & 0 & \cdots & 0
\end{array}\right)_{N \rho \times N \rho}, \\
R_{N}^{T}\left(J_{\rho}(\lambda)^{-1}\right)=K_{N} \otimes I_{\rho}+J_{N}^{N-1} \otimes J_{\rho}(\lambda)^{-1}=\left(\begin{array}{ccccc}
0 & 0 & 0 & \cdots & J_{\rho}(\lambda)^{-1} \\
I_{\rho} & 0 & 0 & \cdots & 0 \\
0 & I_{\rho} & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & \cdots & I_{\rho} & 0
\end{array}\right)_{N \rho \times N \rho} .
\end{gathered}
$$

For square matrices $A_{1}, \ldots, A_{\tau}$, we denote the block diagonal matrix made from them as

$$
\bigoplus_{i=1}^{\tau} A_{i}:=\left(\begin{array}{ccccc}
A_{1} & 0 & 0 & \cdots & 0  \tag{3.1}\\
0 & A_{2} & 0 & \cdots & 0 \\
0 & 0 & A_{3} & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & A_{\tau}
\end{array}\right) .
$$

Using these new notations, we can write the canonical form given in Definition 3.16 for $\rho=1$ as

$$
\varphi\left(w^{\prime}, \lambda, 1\right)=\varphi\left(w^{\prime}, 0,1\right)-\lambda x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1}-\lambda^{-1} x^{-l_{1}^{\prime}} J_{3 \tau}^{3 \tau-1}
$$

where $\varphi\left(w^{\prime}, 0,1\right)$ is obtained by putting $\lambda=\lambda^{-1}=0$ in the expression of $\varphi\left(w^{\prime}, \lambda, 1\right)$. Then the general expression for arbitrary $\rho$ is obtained from it by 'substituting the matrix $J_{\rho}(\lambda)$ for the scalar $\lambda$ ', that is,

$$
\begin{equation*}
\varphi\left(w^{\prime}, \lambda, \rho\right)=\varphi\left(w^{\prime}, 0,1\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)-x^{-l_{1}^{\prime}} J_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)^{-1} \tag{3.2}
\end{equation*}
$$

It can be also viewed as a consequence of Proposition 2.5.
By reordering rows and columns of the canonical form $\varphi\left(w^{\prime}, \lambda, \rho\right)$, we obtain an alternative canonical form

$$
\varphi_{\mathrm{alt}}\left(w^{\prime}, \lambda, \rho\right):=\left(\begin{array}{ccc}
z I_{\tau \rho} & -\bigoplus_{i=1}^{\tau} y^{m_{i}^{\prime}-1} I_{\rho} & -\left(\bigoplus_{i=1}^{\tau} x^{-l_{i}^{\prime}} I_{\rho}\right) R_{N}^{T}\left(J_{\rho}(\lambda)^{-1}\right)  \tag{3.3}\\
-\bigoplus_{i=1}^{\tau} y^{-m_{i}^{\prime}} I_{\rho} & x I_{\tau \rho} & -\bigoplus_{i=1}^{\tau} z^{n_{i}^{\prime}-1} I_{\rho} \\
-R_{N}\left(J_{\rho}(\lambda)\right)\left(\bigoplus_{i=1}^{\tau} x^{l_{i}^{\prime}-1} I_{\rho}\right) & -\bigoplus_{i=1}^{\tau} z^{-n_{i}^{\prime}} I_{\rho} & y I_{\tau \rho}
\end{array}\right)_{3 \tau \rho \times 3 \tau \rho}
$$

Sometimes it is more convenient to work with this alternative version than with the original one.

[^15]3.4. Periodic case. In this subsection, we show that objects corresponding to the periodic normal loop words are decomposable. The core of the decomposition lies in the following linear algebra problem:

Lemma 3.19. The Jordan canonical form of $R_{N}\left(J_{\rho}(\lambda)\right)$ and $R_{N}^{T}\left(J_{\rho}(\lambda)^{-1}\right)$ are $\bigoplus_{k=0}^{N-1} J_{\rho}\left(\lambda_{k}\right)$ and $\bigoplus_{k=0}^{N-1} J_{\rho}\left(\lambda_{k}^{-1}\right)^{23}$, respectively, where $\lambda_{0}, \ldots, \lambda_{N-1} \in \mathbb{C}^{\times}$are the $N$-th roots of $\lambda \in \mathbb{C}^{\times}$(i.e., distinct solutions of $x^{N}=\lambda$ ).

Proof. By the following Lemma 3.20, the matrix $R_{N}\left(J_{\rho}(\lambda)\right)=J_{N} \otimes I_{\rho}+K_{N}^{N-1} \otimes J_{\rho}(\lambda)$ is similar to $I_{\rho} \otimes J_{N}+J_{\rho}(\lambda) \otimes K_{N}^{N-1}=\left(\begin{array}{ccccc}J_{N}+\lambda K_{N}^{N-1} & K_{N}^{N-1} & 0 & \cdots & 0 \\ 0 & J_{N}+\lambda K_{N}^{N-1} & K_{N}^{N-1} & \cdots & 0 \\ 0 & 0 & J_{N}+\lambda K_{N}^{N-1} & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & K_{N}^{N-1} \\ 0 & 0 & 0 & \cdots & J_{N}+\lambda K_{N}^{N-1}\end{array}\right)_{\rho N \times \rho N} \quad=\left(\begin{array}{ccccc}R_{N}(\lambda) & K_{N}^{N-1} & 0 & \cdots & 0 \\ 0 & R_{N}(\lambda) & K_{N}^{N-1} & \cdots & 0 \\ 0 & 0 & R_{N}(\lambda) & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & K_{N}^{N-1} \\ 0 & 0 & 0 & \cdots & R_{N}(\lambda)\end{array}\right)_{\rho N \times \rho N}$, whose characteristic polynomial (in $t$ ) is

$$
\left(\operatorname{det}\left(t I_{N}-R_{N}(\lambda)\right)\right)^{\rho}=\left|\begin{array}{ccccc}
t & -1 & 0 & \cdots & 0 \\
0 & t & -1 & \cdots & 0 \\
0 & 0 & t & \ddots & \vdots \\
\vdots & \vdots & \vdots & \ddots & -1 \\
-\lambda & 0 & 0 & \cdots & t
\end{array}\right|_{N \times N}^{\rho}=\left(t^{N}-\lambda\right)^{\rho}=\left(t-\lambda_{0}\right)^{\rho} \cdots\left(t-\lambda_{N-1}\right)^{\rho} .
$$

It is straightforward to check that the eigenspace for each eigenvalue $t=\lambda_{k}(k \in\{0, \ldots, N-1\})$ has dimension only 1 , which completes the proof for $R_{N}\left(J_{\rho}(\lambda)\right)$. The proof for $R_{N}^{T}\left(J_{\rho}(\lambda)^{-1}\right)$ is similar.
Lemma 3.20. For two matrices $A \in \mathbb{C}^{m_{1} \times n_{1}}$ and $B \in \mathbb{C}^{m_{2} \times n_{2}}$, their Kronecker products $A \otimes B \in \mathbb{C}^{m_{1} m_{2} \times n_{1} n_{2}}$ and $B \otimes A \in \mathbb{C}^{m_{2} m_{1} \times n_{2} n_{1}}$ are permutation equivalent. More specifically, there is a perfect shuffle matrix $S_{p, q} \in O(p q)$ for each $(p, q) \in \mathbb{Z}_{\geq 1} \times \mathbb{Z}_{\geq 1}$ whose entries are 0 or 1 , such that $S_{p, q}^{T}=S_{p, q}^{-1}=S_{q, p}$ and

$$
S_{m_{1}, m_{2}}(A \otimes B) S_{n_{2}, n_{1}}=B \otimes A
$$

for any $A \in \mathbb{C}^{m_{1} \times n_{1}}$ and $B \in \mathbb{C}^{m_{2} \times n_{2}}$.
In particular, if $A$ and $B$ are square matrices, $A \otimes B$ and $B \otimes A$ are similar.
Proof. One can get $B \otimes A$ from $A \otimes B$ (and vice versa) just by reordering rows and columns. It is straightforward to check the detail (see [Wik24]).

Theorem 3.21. Let $\left(w^{\prime}, \lambda, \rho\right)$ be a loop datum with $\left(w^{\prime}, \lambda\right) \neq\left((2,2,2)^{\tau}, 1\right)$. If the normal loop word $w^{\prime}$ is periodic, i.e., $w^{\prime}=\left(\tilde{w}^{\prime}\right)^{N} \in \mathbb{Z}^{3 \tau}$ for another normal loop word $\tilde{w}^{\prime} \in \mathbb{Z}^{3 \tilde{\tau}}(\tau=N \tilde{\tau})$, there is an invertible matrix $V \in \mathrm{GL}_{3 \tau \rho}(\mathbb{C})$ such that

$$
\varphi\left(w^{\prime}, \lambda, \rho\right)=V^{-1}\left(\begin{array}{cccc}
\varphi\left(\tilde{w}^{\prime}, \lambda_{0}, \rho\right) & 0 & \cdots & 0 \\
0 & \varphi\left(\tilde{w}^{\prime}, \lambda_{1}, \rho\right) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \varphi\left(\tilde{w}^{\prime}, \lambda_{N-1}, \rho\right)
\end{array}\right) V
$$

where $\lambda_{0}, \ldots, \lambda_{N-1} \in \mathbb{C}^{\times}$are the $N$-th roots of $\lambda$. This yields a decomposition in $\mathrm{MF}(x y z)$

$$
\varphi\left(w^{\prime}, \lambda, \rho\right) \cong \bigoplus_{k=0}^{N-1} \varphi\left(\tilde{w}^{\prime}, \lambda_{k}, \rho\right)
$$

Proof. Recall the formula (3.2)

$$
\varphi\left(w^{\prime}, \lambda, \rho\right)=\varphi\left(w^{\prime}, 0,1\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)-x^{-l_{1}^{\prime}} J_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)^{-1}
$$

Here we have

$$
\varphi\left(w^{\prime}, 0,1\right)=I_{N} \otimes \varphi\left(\tilde{w}^{\prime}, 0,1\right)-x_{1}^{l_{1}^{\prime}-1} J_{N} \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}-x_{1}^{-l_{1}^{\prime}} K_{N} \otimes J_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}
$$

${ }^{23}$ If $\rho=1$, they are diagonalizable via a transition matrix given by the Vandermonde matrix $\left(\lambda_{j}^{i}\right)_{0 \leq i, j \leq N-1}$.
for a periodic word $w^{\prime}=\left(\tilde{w}^{\prime}\right)^{N}$. Denoting by $\tilde{\varphi}:=\varphi\left(\tilde{w}^{\prime}, 0,1\right)$, we can rewrite $\varphi\left(w^{\prime}, \lambda, \rho\right)$ as
$\left(I_{N} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1} J_{N} \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}-x_{1}^{-l_{1}^{\prime}} K_{N} \otimes J_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{N}^{N-1} \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1} \otimes J_{\rho}(\lambda)-x^{-l_{1}^{\prime}} J_{N}^{N-1} \otimes J_{3 \tilde{\tau}}^{3 \tilde{\tau}-1} \otimes J_{\rho}(\lambda)^{-1}$, where we also used trivial identities $K_{3 \tau}^{3 \tau-1}=K_{N}^{N-1} \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}$ and $J_{3 \tau}^{3 \tau-1}=J_{N}^{N-1} \otimes J_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}$.

By Lemma 3.20, we can switch the order in the Kronecker product $A \otimes B \otimes C$ above into $A \otimes C \otimes B$ to get a similar matrix. That is, $\varphi\left(w^{\prime}, \lambda, \rho\right)$ is similar to

$$
\begin{align*}
& I_{N} \otimes I_{\rho} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1}\left(J_{N} \otimes I_{\rho}+K_{N}^{N-1} \otimes J_{\rho}(\lambda)\right) \otimes K_{3}^{3 \tilde{\tilde{\tau}}-1}-x_{1}^{-l_{1}^{\prime}}\left(K_{N} \otimes I_{\rho}+J_{N}^{N-1} \otimes J_{\rho}(\lambda)^{-1}\right) \otimes J_{3}^{3 \tilde{\tilde{\tau}}-1}  \tag{3.4}\\
& =I_{N \rho} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1} R_{N}\left(J_{\rho}(\lambda)\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}-x_{1}^{-l_{1}^{\prime}} R_{N}^{T}\left(J_{\rho}(\lambda)^{-1}\right) \otimes J_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}
\end{align*}
$$

via transition matrices given by $I_{N} \otimes S_{3 \tilde{\tau}, \rho}$ and $I_{N} \otimes S_{\rho, 3 \tilde{\tau}}$. In other words, (3.4) is another expression for

$$
\left(I_{N} \otimes S_{3 \tilde{\tau}, \rho}\right) \varphi\left(w^{\prime}, \lambda, \rho\right)\left(I_{N} \otimes S_{\rho, 3 \tilde{\tau}}\right) .
$$

Now we may assume $l_{1}^{\prime} \geq 1$. (The other case is handled in the same way.) Then we can drop the third term in (3.4). Lemma 3.19 implies that there is an invertible matrix $P \in \mathrm{GL}_{N \rho}(\mathbb{C})$ satisfying

$$
R_{N}\left(J_{\rho}(\lambda)\right) P=P\left(\bigoplus_{k=0}^{N-1} J_{\rho}\left(\lambda_{k}\right)\right)
$$

Multiplying $P \otimes I_{3 \tilde{\tau}}$ to (3.4) on the right yields

$$
\begin{aligned}
\left(I_{N} \otimes S_{3 \tilde{\tau}, \rho}\right) \varphi\left(w^{\prime}, \lambda, \rho\right)\left(I_{N} \otimes S_{\rho, 3 \tilde{\tau}}\right)\left(P \otimes I_{3 \tilde{\tau}}\right) & =P \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1}\left(R_{N}\left(J_{\rho}(\lambda)\right) P\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1} \\
& =P \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1} P\left(\bigoplus_{k=0}^{N-1} J_{\rho}\left(\lambda_{k}\right)\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1} \\
& =\left(P \otimes I_{3 \tilde{\tau})}\left(I_{N \rho} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1}\left(\bigoplus_{k=0}^{N-1} J_{\rho}\left(\lambda_{k}\right)\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}\right)\right. \\
& =\left(P \otimes I_{3 \tilde{\tau}}\right) \bigoplus_{k=0}^{N-1}\left(I_{\rho} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1} J_{\rho}\left(\lambda_{k}\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tau}-1}\right) .
\end{aligned}
$$

Lemma 3.20 says that each direct summand $I_{\rho} \otimes \tilde{\varphi}-x_{1}^{l_{1}^{\prime}-1} J_{\rho}\left(\lambda_{k}\right) \otimes K_{3 \tilde{\tau}}^{3 \tilde{\tilde{\tau}}-1}$ is similar to

$$
\varphi\left(\tilde{w}^{\prime}, \lambda_{k}, \rho\right)=\tilde{\varphi} \otimes I_{\rho}-x_{1}^{l_{1}^{\prime}-1} K_{3 \tilde{\tau}}^{3 \tilde{-}-1} \otimes J_{\rho}\left(\lambda_{k}\right)
$$

via transition matrices $S_{\rho, 3 \tilde{\tau}}$ and $S_{3 \tilde{\tau}, \rho}$, and hence their direct sum is similar to $\oplus_{k=0}^{N-1} \varphi\left(\tilde{w}^{\prime}, \lambda_{k}, \rho\right)$ via transition matrices $\bigoplus_{k=0}^{N-1} S_{\rho, 3 \tilde{\tau}}=I_{N} \otimes S_{\rho, 3 \tilde{\tau}}$ and $\bigoplus_{k=0}^{N-1} S_{3 \tilde{\tau}, \rho}=I_{N} \otimes S_{3 \tilde{\tau}, \rho}$. Therefore, we can write

$$
\left(I_{N} \otimes S_{\rho, 3 \tilde{\tau}}\right)\left(P^{-1} \otimes I_{3 \tilde{\tau}}\right)\left(I_{N} \otimes S_{3 \tilde{\tau}, \rho}\right) \varphi\left(w^{\prime}, \lambda, \rho\right)\left(I_{N} \otimes S_{\rho, 3 \tilde{\tau}}\right)\left(P \otimes I_{3 \tilde{\tau}}\right)\left(I_{N} \otimes S_{3 \tilde{\tau}, \rho}\right)=\bigoplus_{k=0}^{N-1} \varphi\left(\tilde{w}^{\prime}, \lambda_{k}, \rho\right),
$$

which shows the claim with $V:=\left(I_{N} \otimes S_{\rho, 3 \tilde{\tau}}\right)\left(P \otimes I_{3 \tilde{\tau}}\right)\left(I_{N} \otimes S_{3 \tilde{\tau}, \rho}\right) \in \mathrm{GL}_{3 \tau \rho}(\mathbb{C})$.
Corollary 3.22. Let $\left(w^{\prime}, \eta, \rho\right)$ be a loop datum with $w^{\prime} \neq(2,2,2)^{\tau}$. If the normal loop word $w^{\prime}$ is periodic, i.e., $w^{\prime}=\left(\tilde{w}^{\prime}\right)^{N} \in \mathbb{Z}^{3 \tau}$ for another normal loop word $\tilde{w}^{\prime} \in \mathbb{Z}^{3 \tilde{\tau}}(\tau=N \tilde{\tau})$, there is a decomposition in $\operatorname{Fuk}(\Sigma)$

$$
\mathscr{L}\left(w^{\prime}, \eta, \rho\right) \cong \bigoplus_{k=0}^{N-1} \mathscr{L}\left(\tilde{w}^{\prime}, \eta_{k}, \rho\right),
$$

where $\eta_{0}, \ldots, \eta_{N-1} \in \mathbb{C}^{\times}$are the $N$-th roots of $\eta$.
Remark 3.23. This shows that non-primitive loops (with a local system) are decomposable in the Fukaya category, which is not intuitively obvious. In following up works, we will see that this is indeed a general and intrinsic feature of the Fukaya category of hyperbolic Riemann surfaces.
3.5. Non-cylinder-free case $w^{\prime}=(2,2,2)^{\tau}$. Note that a loop $L$ in $\Sigma$ is not cylinder-free with $\mathbb{L}$ only if it is freely homotopic to $\mathbb{L}^{\tau}$ for some $\tau \in \mathbb{Z}$. Only in cases of $w^{\prime}=(1,0,1,0,1,0)^{\tau}$ or $(2,2,2)^{\tau}$ for some $\tau \in \mathbb{Z} \geq 1$, the corresponding loop $L\left(w^{\prime}\right)$ has the same free homotopy type with $\mathbb{L}^{\tau}$ and $\mathbb{L}^{-\tau}$, respectively. Then it has a chance to bound an immersed cylinder with $\mathbb{L}$. In the former case, $i t$ is not the case for our canonical form given in Definition 3.1. In the latter case, however, our canonical form bounds an immersed cylinder with $\mathbb{\_}$, which indeed produces some infinite moduli spaces involved in the formula 2.5 for the matrix factor $\Psi^{\complement}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)^{24}$.

To prevent this, we take a very specific perturbed version of the loop for the case $w^{\prime}=(2,2,2)^{\tau}$. We first define the loop $L:=L(2,2,2)$ as shown in Figure 11. Then let $L\left((2,2,2)^{\tau}\right)$ be the $\tau$-concatenation (with $\star$ as a starting point) of it. For a loop datum $\left((2,2,2)^{\tau}, \eta, \rho\right)$, we define the loop with a local system $\mathscr{L}\left((2,2,2)^{\tau}, \eta, \rho\right)$ as in Definition 3.9 so that it has holonomy $J_{\rho}(\eta)$ at $\star$, using the modified underlying loop $L\left((2,2,2)^{\tau}\right)$.

Figure 11. Loop with a local system $\mathscr{L}:=\mathscr{L}((2,2,2), \eta, \rho)$ and the corresponding matrix factorization

Definition 3.24. The degenerate canonical form of matrix factorizations of $x y z$ corresponding to a loop datum $\left((2,2,2)^{\tau}, \lambda, \rho\right)$ is defined as

$$
\begin{aligned}
& \left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right)\right) \\
& :=\left(\left(\begin{array}{cccc}
-z x I_{\tau \rho} & 0 & 0 & 0 \\
z I_{\tau \rho} & -y I_{\tau \rho} & 0 & 0 \\
0 & x I_{\tau \rho} & -z I_{\tau \rho} & 0 \\
-x R_{\tau, \rho}(\lambda) & 0 & y I_{\tau \rho} & -x y I_{\tau \rho}
\end{array}\right)_{4 \tau \rho \times 4 \tau \rho},\left(\begin{array}{cccc}
-y I_{\tau \rho} & 0 & 0 & 0 \\
-z I_{\tau \rho} & -z x I_{\tau \rho} & 0 & 0 \\
-x I_{\tau \rho} & -x^{2} I_{\tau \rho} & -x y I_{\tau \rho} & 0 \\
-I_{\tau \rho}+R_{\tau, \rho}(\lambda) & -x I_{\tau \rho} & -y I_{\tau \rho} & -z I_{\tau \rho}
\end{array}\right)_{4 \tau \rho \times 4 \tau \rho}\right) .
\end{aligned}
$$

Theorem 3.25. For a loop datum $\left((2,2,2)^{\tau}, \eta, \rho\right)$, there is an isomorphism

$$
\mathscr{F}^{\llcorner }\left(\mathscr{L}\left((2,2,2)^{\tau}, \eta, \rho\right)\right) \cong\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right)\right)
$$

in MF $(x y z)$, where $\lambda:=(-1)^{\tau} \eta$.

[^16]Proof. For $\tau=1$ case, the matrix factorization $\mathscr{F}^{\complement}(\mathscr{L}((2,2,2), \eta, \rho))$ is computed in Figure 11, using the same method as in Proposition 3.15. It can be transformed to $\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right)\right)$ by changing the sign of some basis elements. The case of $\tau \geq 2$ is handled similarly.

For $\lambda \neq 1$, we can reduce the degenerate canonical form into the original version using the following 'matrix reduction':

Lemma 3.26. [CJKR22] Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{n}\right]\right]$ of $n$ variables and $f \in S$ its nonzero element. Assume that the pair $\left(\left(\begin{array}{cc}C & D \\ E^{T} & u\end{array}\right),\left(\begin{array}{cc}F & G \\ H^{T} & v\end{array}\right)\right)$ is a matrix factorization of $f$ in $S$, for some matrices $C$, $F \in S^{k \times k}, D, E, G, H \in S^{k \times 1}$ and $u, v \in S$. If $u$ or $v$ is a unit in $S$, there is an isomorphism

$$
\left(\left(\begin{array}{cc}
C & D \\
E^{T} & u
\end{array}\right),\left(\begin{array}{cc}
F & G \\
H^{T} & v
\end{array}\right)\right) \cong\left(C-D u^{-1} E^{T}, F\right) \oplus(1, f) \quad \text { or } \quad\left(C, F-G v^{-1} H^{T}\right) \oplus(f, 1)
$$

respectively, in $\mathrm{MF}(f)$. Therefore, the pair is isomorphic to the reduced pair $\left(C-D u^{-1} E^{T}, F\right)$ or $\left(C, F-G v^{-1} H^{T}\right)$, respectively, in the homotopy category $\mathrm{MF}(f)$.

Proof. Assume that $u$ is a unit in $S$, and consider the following diagram:

The commutativity of the diagram is immediate from some matrix calculations using the fact that the original pair is a matrix factorization of $f$. Also, note that the vertical maps are all isomorphisms. This yields an isomorphism $\left(\left(\begin{array}{cc}C & D \\ E^{T} & u\end{array}\right),\left(\begin{array}{rr}F & G \\ H^{T} & v\end{array}\right)\right) \cong\left(C-D u^{-1} E^{T}, F\right) \oplus(1, f)$ in $\operatorname{MF}(f)$.

One can construct an explicit homotopy between $(1, f)$ or $(f, 1)$ and the zero object $0 \rightleftarrows 0$ in $\operatorname{MF}(f)$, which shows that it is a zero object in the homotopy category $\mathrm{MF}(f)$. (It is also a consequence of Proposition A.15.) This means that we can drop the direct summand $(1, f)$ or $(f, 1)$ in $\underline{\mathrm{MF}}(f)$.

Proposition 3.27. If $\lambda \neq 1$, the degenerate canonical form $\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right)\right)(\tau, \rho \in$ $\left.\mathbb{Z}_{\geq 1}\right)$ is isomorphic to the original version $\left(\varphi\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi\left((2,2,2)^{\tau}, \lambda, \rho\right)\right)$ in $\underline{\mathrm{MF}}(x y z)$.

Proof. In the simplest case $\tau=\rho=1$, the reducing process in Lemma 3.26 along a unit $-1+\lambda$ in $\psi_{\operatorname{deg}}((2,2,2), \lambda, 1)$ yields a commutative diagram, which proves the claim:

In general case, we 'substitute the matrix $R_{\tau, \rho}(\lambda)$ for the scalar $\lambda$ ' to get a commutative diagram:

Therefore, the degenerate canonical form is isomorphic to the alternative canonical form (3.3) in $\underline{\mathrm{MF}}(x y z)$, which is again isomorphic to the original canonical form in $\operatorname{MF}(x y z)$.

This shows that even if the normal loop word is $w^{\prime}=(2,2,2)^{\tau}$ (and hence we use the perturbed loop for $\left.\mathscr{L}\left((2,2,2)^{\tau}, \eta, \rho\right)\right)$, we can still define and use the original canonical form of matrix factorizations $\left(\varphi\left((2,2,2)^{\tau}, \lambda, \rho\right), \psi\left((2,2,2)^{\tau}, \lambda, \rho\right)\right)$ unless $\lambda=1$ (or equivalently $\left.\eta=(-1)^{\tau}\right)$. Therefore, we would not call them all degenerate cases.

Definition 3.28. A normal loop word is called non-cylinder-free if it is $w^{\prime}=(2,2,2)^{\tau}$ for some $\tau \in \mathbb{Z}_{\geq 1}$, and a loop datum is called degenerate if it is
(1) $\left(w^{\prime}=(2,2,2)^{\tau}, \eta=(-1)^{\tau}, \rho\right)$ and parameterizes loops with a local system $\mathscr{L}\left((2,2,2)^{\tau},(-1)^{\tau}, \rho\right)$,
(2) $\left(w^{\prime}=(2,2,2)^{\tau}, \lambda=1, \rho\right)$ and parameterizes matrix factorizations $\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right)\right)$.

Now Theorem 3.17, Theorem 3.25, and Proposition 3.27 complete the proof of Theorem 1.3 in the introduction.

For $\tau \geq 2$, the non-cylinder-free loop word $(2,2,2)^{\tau}$ is periodic, and the corresponding objects are decomposable as in the general case (Theorem 3.21):

Proposition 3.29. For a loop datum $\left((2,2,2)^{\tau}, \lambda, \rho\right)$, there is a decomposition

$$
\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, \lambda, \rho\right) \cong \bigoplus_{k=0}^{\tau-1} \varphi_{\operatorname{deg}}\left((2,2,2), \lambda_{\tau, k}, \rho\right)
$$

in $\operatorname{MF}(x y z)$, where $\lambda_{\tau, 0}, \ldots, \lambda_{\tau, \tau-1} \in \mathbb{C}$ are the $\tau$-th roots of $\lambda$.
Proof. It is proven in the same way as Theorem 3.21.
Combining Proposition 3.29 and Proposition 3.27, we get a decomposition of the matrix factorization for periodic degenerate cases $\left(w^{\prime}=(2,2,2)^{\tau}, \lambda=1\right)$ as

$$
\begin{align*}
\varphi_{\mathrm{deg}}\left((2,2,2)^{\tau}, 1, \rho\right) & \cong \bigoplus_{k=0}^{\tau-1} \varphi_{\operatorname{deg}}\left((2,2,2), e^{2 \pi i \cdot \frac{k}{\tau}}, \rho\right) \quad \text { in MF}(x y z) \\
& \cong \varphi_{\operatorname{deg}}((2,2,2), 1, \rho) \oplus \bigoplus_{k=1}^{\tau-1} \varphi\left((2,2,2), e^{2 \pi i \cdot \frac{k}{\tau}}, \rho\right) \quad \text { in } \underline{\operatorname{MF}}(x y z) \tag{3.5}
\end{align*}
$$

This also implies the decomposition of the loop with a local system for periodic degenerate cases $\left(w^{\prime}=\right.$ $\left.(2,2,2)^{\tau}, \eta=(-1)^{\tau}\right)$ as

$$
\begin{equation*}
\mathscr{L}\left((2,2,2)^{\tau},(-1)^{\tau}, \rho\right) \cong \bigoplus_{k=0}^{\tau-1} \mathscr{L}\left((2,2,2),-e^{2 \pi i \cdot \frac{k}{\tau}}, \rho\right) \quad \text { in } \operatorname{Fuk}(\Sigma) \tag{3.6}
\end{equation*}
$$

extending the result of Corollary 3.22 to any periodic normal loop words.

## 4. Matrix Factorizations from Maximal Cohen-Macaulay Modules

In this section, we first recall some general concepts on maximal Cohen-Macaulay modules which we will need in the rest of the section, including the Macaulayfication and its computation (§4.1). Then we recall Burban-Drozd's classification [BD17a] of band-type indecomposable maximal Cohen-Macaulay modules over $A:=\mathbb{C}[[x, y, z]] /(x y z)$. Their canonical form is provided as a submodule of a free module $A^{\tau \mu}$, whose generators are given in terms of band data ( $\$ 4.2$ ). Those band data are in one-to-one correspondence with loop data by the conversion formula given in [CJKR22] (§4.3). Using this correspondence, we prove the main theorem in this section that the canonical form of matrix factorizations corresponding to loop data is related to the canonical form of band-type maximal Cohen-Macaulay modules corresponding to band data under Eisenbud's equivalence (\$4.4). The degenerate case will be treated separately (§4.5).
4.1. Maximal Cohen-Macaulay modules and Macaulayfication. Let $(A, \mathfrak{m})$ be a Noetherian local ring, $\mathbb{k}:=A / \mathfrak{m}$ its residue field, and $d:=\operatorname{kr}$. $\operatorname{dim}(A)$ its Krull dimension.

Definition 4.1. A Noetherian $A$-module $M$ is called maximal Cohen-Macaulay if

$$
\operatorname{Ext}_{A}^{i}(\mathbb{k}, M)=0 \quad \text { for } i \in\{0, \ldots, d-1\} .
$$

We denote by $\mathrm{CM}(A)$ the category of maximal Cohen-Macaulay modules over $A$, which is a full subcategory of the category $A-\bmod$ of Noetherian (i.e. finitely generated) $A$-modules.

We refer readers, for example, to [Yos90] for general properties and representations of maximal CohenMacaulay modules, and [BH98] for (not necessarily maximal) Cohen-Macaulay modules. However, note that many authors, including [Yos90], refer to maximal Cohen-Macaulay modules simply as Cohen-Macaulay modules.
4.1.1. Macaulayfication. Now let us focus on our specific case where $A$ is given by $\mathbb{C}[[x, y, z]] /(x y z)$. It is an example of surface singularities (i.e. $d=2$ ), and many technics and representation-theoretic aspects for them were developed and studied in [BD08, BD17a]. We will especially use the following Macaulayfying process, which naturally associates any Noetherian $A$-module a maximal Cohen-Macaulay $A$-module:
Definition 4.2. [BD08] The Macaulayfication of a Noetherian A-module $\tilde{M}$ is defined by

$$
\tilde{M}^{\dagger}:=\operatorname{Hom}_{A}\left(\operatorname{Hom}_{A}(\tilde{M}, A), A\right)^{25}
$$

It is indeed a maximal Cohen-Macaulay $A$-module ${ }^{26}$. This defines a functor $\dagger: A-\bmod \rightarrow \mathrm{CM}(A)$, which is called the Macaulayfication functor.

We will use a combinatorial tool to compute the Macaulayfication of a given $A$-module in practice:
Definition 4.3. Let $\tilde{M}$ be an $A$-submodule of a free module $A^{r}$. If there is an element $F \in A^{r} \backslash \tilde{M}$ such that $x F, y F, z F \in \tilde{M}$, we call it a Macaulayfying element of $\tilde{M}$ in $A^{r}$.
Proposition 4.4. [BD17a] For an A-submodule $\tilde{M}$ of a free module $A^{r}$, the following hold:
(1) $\tilde{M}$ is maximal Cohen-Macaulay if and only if there is no Macaulayfying element of $\tilde{M}$ in $A^{r}$. We have $\tilde{M}^{\dagger}=\tilde{M}$ in this case.
(2) $\tilde{M}^{\dagger} \cong\langle\tilde{M}, F\rangle_{A}^{\dagger}$ holds for any Macaulayfying element $F$ of $\tilde{M}$ in $A^{r}$.

Proof. See Proposition 4.2 in [CJKR22] for the proof of (1), and Lemma 1.5 in [BD17a] for (2).

[^17]4.2. Band data and canonical form of maximal Cohen-Macaulay modules. We recall the concept of the band data from [BD17a], which parameterize band-type indecomposable maximal Cohen Macaulay modules over $A=\mathbb{C}[[x, y, z]] /(x y z)$. Here we use a slightly modified version of band words given in [CJKR22] for our specific singularity $A$, in order to match them with the loop data in the next subsection.
Definition 4.5. $A$ band datum $(w, \lambda, \mu)$ consists of the following:

- (band word) $w=\left(l_{1}, m_{1}, n_{1}, l_{2}, m_{2}, n_{2}, \ldots, l_{\tau}, m_{\tau}, n_{\tau}\right) \in \mathbb{Z}^{3 \tau}$ for some $\tau \in \mathbb{Z}_{\geq 1}$,
- (eigenvalue) $\lambda \in \mathbb{C}^{\times}$,
- ((algebraic) multiplicity) $\mu \in \mathbb{Z}_{\geq 1}$.

It defines an A-module, denoted by

$$
\tilde{M}(w, \lambda, \mu)
$$

as an $A$-submodule of $A^{\tau \mu}$ generated by all columns of the 6 matrices

$$
\begin{aligned}
& x^{2} y^{2} I_{\tau \mu}, \quad y^{2} z^{2} I_{\tau \mu}, \quad z^{2} x^{2} I_{\tau \mu}, \quad \pi_{x}(w, \lambda, \mu):=\left(\begin{array}{cccc}
x^{l_{1}^{-}+2} y I_{\mu} & z x_{2}^{l_{2}^{+}+2} I_{\mu} & \cdots & 0 \\
0 & x^{l_{2}^{-}+2} y I_{\mu} & \ddots & \vdots \\
\vdots & \vdots & \ddots & z x^{l_{\tau}^{+}+2} I_{\mu} \\
z x_{1}^{++2} J_{\mu}(\lambda) & 0 & \cdots & x^{l_{\tau}^{-}+2} y I_{\mu}
\end{array}\right)_{\tau \mu \times \tau \mu}, \\
& \pi_{y}(w, \lambda, \mu):=\left(\begin{array}{cccc}
\left(x y^{m_{1}^{+}+2}+y^{m_{1}^{-}+2} z\right) I_{\mu} & 0 & \cdots & 0 \\
0 & \left(x y^{m_{2}^{+}+2}+y^{m_{2}^{-}+2} z\right) I_{\mu} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \left(x y^{m_{\tau}^{+}+2}+y^{m_{\tau}^{-}+2} z\right) I_{\mu}
\end{array}\right)_{\tau \mu \times \tau \mu}, \\
& \pi_{z}(w, \lambda, \mu):=\left(\begin{array}{cccc}
\left(y z^{n_{1}^{+}+2}+z^{n_{1}^{-}+2} x\right) I_{\mu} & 0 & \cdots & 0 \\
0 & \left(y z^{n_{2}^{+}+2}+z^{n_{2}^{-}+2} x\right) I_{\mu} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \left(y z^{n_{\tau}^{+}+2}+z^{n_{\tau}^{-}+2} x\right) I_{\mu}
\end{array}\right)_{\tau \mu \times \tau \mu}
\end{aligned}
$$

where $a^{+}:=\max \{0, a\}$ and $a^{-}:=\max \{0,-a\}$ for $a \in \mathbb{Z}$.
The notion of shift, subword, concatenation and periodicity of a band word can be defined similarly following those of a loop word. Two band words $w$ and $\tilde{w}$ are considered equivalent if they coincide up to shifting, that is, $\tilde{w}=w^{(k)}$ for some $k \in \mathbb{Z}$.

In general, however, the $A$-module $\tilde{M}(w, \lambda, \mu)$ fails to be maximal Cohen-Macaulay. So we need to Macaulayfy it to get an object in $\mathrm{CM}(A)$ from a band datum.
Definition 4.6. Given a band datum $(w, \lambda, \mu)$, we define the corresponding maximal Cohen-Macaulay $A-$ module

$$
M(w, \lambda, \mu):=\tilde{M}(w, \lambda, \mu)^{\dagger}
$$

as the Macaulayfication of $\tilde{M}(w, \lambda, \mu)$. We refer to it as the canonical form of band-type maximal CohenMacaulay modules over A corresponding to the band datum $(w, \lambda, \mu)$.

The maximal Cohen-Macaulay module $M(w, \lambda, \mu)$ constructed from any band datum is locally free on the punctured spectrum of $A$, that is, for any $\mathfrak{p} \in \operatorname{Spec}(A) \backslash\{\mathfrak{m}\}$ the localization $M_{\mathfrak{p}}$ is a free $A_{\mathfrak{p}}$-module, where $\mathfrak{m}$ is the maximal ideal of $A$. The converse also holds, which is the following classification theorem:

Theorem 4.7. [BD17a] Any indecomposable maximal Cohen-Macaulay module over A that is locally free on the punctured spectrum is isomorphic to the canonical form $M(w, \lambda, \mu)$ for some unique non-periodic band datum $(w, \lambda, \mu)$ up to shifting of the band word $w$.

The proof of the theorem actually follows from a highly non-trivial representation-theoretic study of the category $\mathrm{CM}(A)$, which is applicable to much broader class (i.e. degenerate cusp) of non-isolated surface singularities. To be more specific, they created its equivalent category $\operatorname{Tri}(A)$, called the category of triples (or Burban-Drozd's triple category in some literature), and a natural equivalence functor $\mathbb{F}_{\mathrm{BD}}: \mathrm{CM}(A) \stackrel{\simeq}{\rightrightarrows} \operatorname{Tri}(A)^{27}$. Its object consists of two modules and a 'linearized morphism' between them, and the indecomposable objects can be classified via a matrix problem on the linear map. As a result, they fall into the following two types: band-type and string-type. The canonical form $\Theta(w, \lambda, \mu)$ of bandtype indecomposable objects in $\operatorname{Tri}(A)$ is given in Figure 12, which are parameterized by the band data $(w, \lambda, \mu)$. Then they determine the corresponding objects $M(w, \lambda, \mu)$ in $\operatorname{CM}(A)$ under the equivalence, which we take as presented in Definition 4.6.

Figure 12. Canonical form of band-type indecomposable objects in $\operatorname{Tri}(A)$
Remark 4.8. One can also consider a direct functor $\underline{\mathrm{MF}}(x y z) \rightarrow \underline{\operatorname{Tri}}(A)$ by composing the Eisenbud's cokernel functor and Burban-Drozd's functor $⿷_{B D}$. Then we have an alternative way to compute objects in $\underline{\operatorname{Tri}(A)}$ corresponding to the canonical form of objects in $\underline{\mathrm{MF}}(x y z)$. This gives another proof for Theorem 4.14 without going through the Macaulayfication process. However, since it involves additional algebro-geometric consideration for the category $\operatorname{Tri}(A)$ ([Rho23, Chapter 5]), we defer it to a separate future work.

Remark 4.9. Indecomposable maximal Cohen-Macaulay modules over A that are not locally free on the punctured spectrum were also classified in [BD17a] by using string data instead of band data. On the mirror side, they correspond to arcs starting and ending at boundaries of $\Sigma$. Most statements and proofs in the present paper apply to these cases without significant modifications, while one should take care on some technical details when proving homotopy invariance of matrix factorizations to establish a one-to-one correspondence of them with open geodesics. There we have to consider wrapped morphisms between arcs (non-compact Lagrangian submanifolds), and a discussion on the wrapped Fukaya category of immersed non-exact Lagrangians should precede this. Here we present only some correspondence between basic objects as in Figure 13, which also correspond to $z \cdot x y, x \cdot y z$ and $y \cdot z x$ in $\underline{\mathrm{MF}}(x y z)$, respectively.

Figure 13. Mirror symmetry of generating objects

[^18]4.3. Conversion formula between loop/band data. We define the conversion formula, which underlies the correspondence between the canonical form of matrix factorizations of $x y z$ (in loop data) and the canonical form of band-type indecomposable maximal Cohen-Macaulay modules over $A$ (in band data). It was first introduced in [CJKR22], and now we reformulate and extend it for higher rank/multiplicity.

Definition 4.10 (Conversion from loop data to band data). A loop datum ( $w^{\prime}, \eta, \rho$ ) with a normal loop word $w^{\prime}=\left(w_{1}^{\prime}, w_{2}^{\prime}, w_{3}^{\prime}, w_{4}^{\prime}, w_{5}^{\prime}, w_{6}^{\prime}, \ldots, w_{3 \tau-2}^{\prime}, w_{3 \tau-1}^{\prime}, w_{3 \tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}$ is converted to a band datum $(w, \lambda, \mu)$ as follows:

- The normal loop word $w^{\prime}$ is converted to the band word $w \in \mathbb{Z}^{3 \tau}$, defined as

$$
w_{j}:=w_{j}^{\prime}+1-\mathbb{1}_{w_{j-1}^{\prime} \geq 1}-\mathbb{1}_{w_{j}^{\prime} \geq 1}-\mathbb{1}_{w_{j+1}^{\prime} \geq 1} \quad\left(j \in \mathbb{Z}_{3 \tau}\right)
$$

- The holonomy parameter $\eta \in \mathbb{C}^{\times}$is converted to the eigenvalue

$$
\lambda:=(-1)^{l_{1}+\cdots+l_{\tau}+\tau} \eta \quad \text { where } l_{i}:=w_{3 i-2} \text { for } i \in \mathbb{Z}_{\tau}
$$

- The geometric rank $\rho$ is converted to the algebraic multiplicity ${ }^{28}$

$$
\mu:= \begin{cases}\rho & \text { in non-degenerate cases, } \\ \rho+1 & \text { in the non-periodic degenerate case }\left(w^{\prime}=(2,2,2), \eta=-1\right) .\end{cases}
$$

We call a band datum degenerate if it is $\left(w=(0,0,0)^{\tau}, \lambda=1, \mu\right)$ for some $\tau, \mu \in \mathbb{Z}_{\geq 1}$. Note that it corresponds to a degenerate loop datum $\left(w^{\prime}=(2,2,2)^{\tau}, \eta=(-1)^{\tau}, \rho\right)$ under above the conversion formula above (while ignoring the relation between $\mu$ and $\rho$ which is not defined if $\tau \geq 2$ ).

Definition 4.11 (Conversion from band data to loop data). A band datum ( $w, \lambda, \mu$ ) with a band word $w=\left(w_{1}, w_{2}, w_{3}, w_{4}, w_{5}, w_{6}, \ldots, w_{3 \tau-2}, w_{3 \tau-1}, w_{3 \tau}\right) \in \mathbb{Z}^{3 \tau}$ is converted to a loop datum $\left(w^{\prime}, \eta, \rho\right)$ as follows:

- The band word $w$ is converted to the normal loop word $w^{\prime} \in \mathbb{Z}^{3 \tau}$, defined as

$$
w_{j}^{\prime}:=w_{j}-1+\delta_{j-1}+\delta_{j}+\delta_{j+1} \quad\left(j \in \mathbb{Z}_{3 \tau}\right)
$$

where $\delta=\delta(w) \in\{0,1\}^{3 \tau}$ is given by

$$
\delta_{j}:= \begin{cases}0 & \text { if } \quad\left\{\begin{array}{l}
w_{j}<0, \text { or } \\
w_{j}=0 \text { and at least one of the first non-zero entries adjacent to the } \\
\text { string of Os containing } w_{j} \text { (exists and) is negative, }
\end{array}\right. \\
\begin{array}{ll}
1 & \text { otherwise }
\end{array} \quad\left(j \in \mathbb{Z}_{3 \tau}\right) .\end{cases}
$$

- The eigenvalue $\lambda \in \mathbb{C}^{\times}$is converted to the holonomy parameter

$$
\eta:=(-1)^{l_{1}+\cdots+l_{\tau}+\tau} \lambda \quad \text { where } l_{i}:=w_{3 i-2} \text { for } i \in \mathbb{Z}_{\tau}
$$

- The algebraic multiplicity $\mu$ is converted to the geometric rank ${ }^{29}$

$$
\rho:= \begin{cases}\mu & \text { in non-degenerate cases, } \\ \mu-1 \quad \text { in the non-periodic degenerate case }(w=(0,0,0), \lambda=1) .\end{cases}
$$

Proposition 4.12. [CJKR22] (1) The loop word $w^{\prime}$ converted from a band word $w$ is indeed normal.

## (2) Two conversion formula above are inverse to each other.

[^19]CANONICAL FORM OF MATRIX FACTORIZATIONS FROM FUKAYA CATEGORY OF SURFACE
Example 4.13. The following shows the conversion between a normal loop word $w^{\prime}$ and a band word $w$ :

$$
\begin{aligned}
w^{\prime} & =\left(\frac{8,2,3,-1,-1,-4,-1,0,5,0,-2,1,0,4,6}{1}-\frac{4}{1,0}\right) \\
\mathbb{1}_{w^{\prime} \geq 1}=\delta(w) & =(1,1,1,0,0,0,0,0,1,0,0,1,0,1,1) \\
w & =(6,0,2,-1,0,-3,0,0,5,0,-2,1,-1,3,4)
\end{aligned}
$$

The holonomy parameter $\eta$ and eigenvalue $\lambda$ in this case are related by $\lambda=(-1)^{6-1+0+0-1+5} \eta=-\eta$.
4.4. Matrix Factorizations from canonical form of maximal Cohen-Macaulay modules. Let $S:=\mathbb{C}[[x, y, z]]$ be a power series ring and $A:=\mathbb{C}[[x, y, z]] /(x y z)$ a hypersurface singularity. For a non-degenerate band datum $(w, \lambda, \mu)$, let $w^{\prime}$ be the converted normal loop word from the band word $w$ and $\rho:=\mu$. They define objects in the canonical form as follows:

- the matrix factorization $\left(\varphi\left(w^{\prime}, \lambda, \rho\right), \psi\left(w^{\prime}, \lambda, \rho\right)\right)$ corresponding to the loop datum $\left(w^{\prime}, \boldsymbol{\lambda}, \rho\right)$,
- the maximal Cohen-Macaulay module $M(w, \lambda, \mu)$ corresponding to the band datum $(w, \lambda, \mu)$.

Now we state our main theorem in this section that they are related under Eisenbud's equivalence:
Theorem 4.14. Let $(w, \lambda, \mu)$ be a non-degenerate band datum, $w^{\prime}$ the converted normal loop word from the band word $\omega$ and $\rho:=\mu$. Then there is an isomorphism in $\underline{\mathrm{CM}}(A)$

$$
\operatorname{coker} \underline{\varphi}\left(w^{\prime}, \lambda, \rho\right) \cong M(w, \lambda, \mu)
$$

or equivalently, regarding $M(w, \lambda, \mu)$ as an $S$-module $M_{S}(w, \lambda, \mu)$, it has a free resolution of the form

$$
0 \longrightarrow S^{n} \xrightarrow{\varphi\left(w^{\prime}, \lambda, \rho\right)} S^{n} \xrightarrow{\pi} M_{S}(w, \lambda, \mu) \longrightarrow 0 .
$$

To prove the theorem, we need to compute an explicit Macaulayfication of the module in Definition 4.5 and find its resolution. The case of $\mu=1$ was carried out in [CJKR22]. We have developed our setup so that we can extend the construction of $\mu=1$ to the general case by 'substituting the matrix $J_{\mu}(\lambda)$ for the scalar $\lambda^{\prime}$ in all matrices. (Recall that we did the same operation in the geometric side (Proposition 2.5).) We explain the procedure in detail below:
4.4.1. Preservation of Exactness. Let $R$ be a $\mathbb{C}$-algebra and consider a one-parameter family of matrices in the form

$$
\varphi(\lambda)=\sum_{k=-N}^{N} \varphi_{k} \lambda^{k} \in R^{m \times n}
$$

for some matrices $\varphi_{k} \in R^{m \times n}$. For any $\mathbb{C}$-valued square matrix $\Lambda \in \mathbb{C}^{\mu \times \mu}$, we associate a new matrix by

$$
\varphi(\Lambda):=\sum_{k=-N}^{N} \varphi_{k} \otimes \Lambda^{k} \in R^{m \mu \times n \mu} .
$$

We call the pair $(\varphi(\lambda), \varphi(\Lambda))$ a $(\lambda, \Lambda)$-substitution pair. We have seen many examples:

- $\left(\varphi\left(w^{\prime}, \lambda, 1\right), \varphi\left(w^{\prime}, \lambda, \rho\right)\right)$ (Definition 3.16) forms a $\left(\lambda, J_{\rho}(\lambda)\right)$-substitution pair. We denote them as

$$
\varphi\left(w^{\prime}, \lambda\right):=\varphi\left(w^{\prime}, \lambda, 1\right) \quad \text { and } \quad \varphi\left(w^{\prime}, J_{\rho}(\lambda)\right):=\varphi\left(w^{\prime}, \lambda, \rho\right) .
$$

- $\left(\pi_{\chi}(w, \lambda, 1), \pi_{\chi}(w, \lambda, \mu)\right)$ (Definition 4.5) forms a $\left(\lambda, J_{\mu}(\lambda)\right)$-substitution pair for each $\chi \in\{x, y, z\}$, denoted as

$$
\pi_{\chi}(w, \lambda):=\pi_{\chi}(w, \lambda, 1) \quad \text { and } \quad \pi\left(w, J_{\mu}(\lambda)\right):=\pi(w, \lambda, \mu) .
$$

Such a pair enjoys a nice homological property, namely, $(\lambda, \Lambda)$-substitution preserves the exactness of a sequence as in the following proposition. We thank Kyoungmo Kim for providing us the idea of the proof.

Proposition 4.15. Let

$$
\varphi(\lambda)=\sum_{k=-N}^{N} \varphi_{k} \lambda^{k} \in R^{m \times n} \quad \text { and } \quad \psi(\lambda)=\sum_{k=-N}^{N} \psi_{k} \lambda^{k} \in R^{l \times m}
$$

be one-parameter families of matrices for some $\varphi_{k} \in R^{m \times n}, \psi_{k} \in R^{l \times n}$, which form a sequence

$$
\begin{equation*}
R^{n} \xrightarrow{\varphi(\lambda)} R^{m} \xrightarrow{\psi(\lambda)} R^{l} \tag{4.1}
\end{equation*}
$$

for each $\lambda \in \mathbb{C}$. Given a square matrix $\Lambda \in \mathbb{C}^{\mu \times \mu}$, we have new matrices

$$
\varphi(\Lambda)=\sum_{k=-N}^{N} \varphi_{k} \otimes \Lambda^{k} \in R^{m \mu \times n \mu} \quad \text { and } \quad \psi(\Lambda)=\sum_{k=-N}^{N} \psi_{k} \otimes \Lambda^{k} \in R^{l \mu \times m \mu}
$$

so that $(\varphi(\lambda), \varphi(\Lambda))$ and $(\psi(\lambda), \psi(\Lambda))$ form $(\lambda, \Lambda)$-substitution pairs, which also make a sequence

$$
\begin{equation*}
R^{n} \otimes R^{\mu} \xrightarrow{\varphi(\Lambda)} R^{m} \otimes R^{\mu} \xrightarrow{\psi(\Lambda)} R^{l} \otimes R^{\mu} . \tag{4.2}
\end{equation*}
$$

Now if the sequence (4.1) is exact, more precisely, if we assume
(i) $\psi(\lambda) \varphi(\lambda)=0$ for any $\lambda \in \mathbb{C}$,
(ii) $\operatorname{im} \varphi(\lambda)=\operatorname{ker} \psi(\lambda)$ for any eigenvalue $\lambda$ of $\Lambda$,
then the sequence (4.2) is also exact, i.e., $\operatorname{im} \varphi(\Lambda)=\operatorname{ker} \psi(\Lambda)$.
Proof. The assumption (i) is equivalent to each coefficient of $\lambda^{k}$ in the expansion of $\psi(\lambda) \varphi(\lambda)$ being zero ${ }^{30}$, that is, $\psi(\lambda) \varphi(\lambda)$ is zero as a Laurent polynomial in $\lambda$. This implies $\psi(\Lambda) \varphi(\Lambda)=0$.

The converse is not immediate. First we show that we can replace $\Lambda$ with any similar matrix $J$. Namely, let $J \in \mathbb{C}^{\mu \times \mu}$ be a matrix satisfying $\Lambda=P^{-1} J P$ for some invertible matrix $P \in \mathrm{GL}_{\mu}(\mathbb{C})$. Then the computation

$$
\begin{aligned}
\varphi(\Lambda) & =\sum_{k=-N}^{N} \varphi_{k} \otimes \Lambda^{k}=\sum_{k=-N}^{N} \varphi_{k} \otimes\left(P^{-1} J^{k} P\right)=\sum_{k=-N}^{N}\left(I_{m} \otimes P^{-1}\right)\left(\varphi_{k} \otimes J^{k}\right)\left(I_{n} \otimes P\right) \\
& =\left(I_{m} \otimes P^{-1}\right)\left(\sum_{k=-N}^{N} \varphi_{k} \otimes J^{k}\right)\left(I_{n} \otimes P\right)=\left(I_{m} \otimes P^{-1}\right) \varphi(J)\left(I_{n} \otimes P\right)
\end{aligned}
$$

and the same computation for $\psi(\Lambda)$ show the commutativity of the following diagram:

Since the vertical maps are all isomorphisms, the statement is equivalent to $\operatorname{im} \varphi(J)=\operatorname{ker} \psi(J)$. This enables us to replace $\Lambda$ with its Jordan canonical form.

Furthermore, if $J$ is decomposed into block diagonals $J_{1}, \ldots, J_{k}$ (in the sense of (3.1)), an analogous argument shows that the statement holds for $J$ if and only if it holds for each block $J_{i}$. Therefore, it is enough to prove the statement for a Jordan block $J_{\mu}(\lambda)$, where $\lambda$ is an eigenvalue of $\Lambda$.

We proceed by an induction on $\mu$. For $\mu=1$, the statement is the same as the assumption (ii). Now let $\mu \geq 2$ and assume that the statement is true for $\Lambda=J_{\mu-1}(\lambda)$. We deform $\varphi\left(J_{\mu}(\lambda)\right)$ into its similar matrix $\left(\begin{array}{cc}\varphi\left(J_{\mu-1}(\lambda)\right) & * \\ 0 & \varphi(\lambda)\end{array}\right)$ by the following computation:

[^20]\[

$$
\begin{aligned}
& \varphi\left(J_{\mu}(\lambda)\right)=\sum_{k=-N}^{N} \varphi_{k} \otimes J_{\mu}(\lambda)^{k}=\sum_{k=-N}^{N} \varphi_{k} \otimes\left(\begin{array}{cc}
J_{\mu-1}(\lambda) & \stackrel{*}{2} \\
0 & \lambda
\end{array}\right)^{k}=\sum_{k=-N}^{N} \varphi_{k} \otimes\left(\begin{array}{cc}
J_{\mu-1}(\lambda)^{k} & * \\
0 & \lambda^{k}
\end{array}\right) \\
& =\sum_{k=-N}^{N} S_{\mu, m}\left(\left(\begin{array}{cc}
J_{\mu-1}(\lambda)^{k} & * \\
0 & \lambda^{k}
\end{array}\right) \otimes \varphi_{k}\right) S_{n, \mu}=S_{\mu, m}\left(\sum_{k=-N}^{N}\left(\begin{array}{cc}
J_{\mu-1}(\lambda)^{k} \otimes \varphi_{k} & * \\
0 & \lambda^{k} \varphi_{k}
\end{array}\right)\right) S_{n, \mu} \\
& =S_{\mu, m}\left(\sum_{k=-N}^{N}\left(\begin{array}{cc}
S_{m, \mu-1}\left(\varphi_{k} \otimes J_{\mu-1}(\lambda)^{k}\right) S_{\mu-1, n} & * \\
0 & \lambda^{k} \varphi_{k}
\end{array}\right) S_{n, \mu}\right. \\
& =S_{\mu, m}\left(S_{m, \mu-1} \oplus 1\right)\left(\begin{array}{cc}
\underset{\left(J_{\mu-1}(\lambda)\right)}{0} & \stackrel{*}{\varphi(\lambda)}
\end{array}\right)\left(S_{\mu-1, n} \oplus 1\right) S_{n, \mu} .
\end{aligned}
$$
\]

The same computation also works for $\psi\left(J_{\mu}(\lambda)\right)$, which yields the following commutative diagram:

Note that the vertical maps are natural isomorphisms. As we know $\psi\left(J_{\mu}(\lambda)\right) \varphi\left(J_{\mu}(\lambda)\right)=0$ from our first discussion, the composition in the bottom row also vanishes. The exactness of the bottom row easily follows from the induction hypothesis and the assumption (ii), also implying that the top row is exact.
4.4.2. Proof of the theorem. Now recall that we have $\tilde{M}(w, \lambda, \mu)=\operatorname{im} \tilde{\pi}(w, \lambda, \mu) \subset A^{\tau \mu}$, where

$$
\tilde{\pi}(w, \lambda, \mu):=\left(x^{2} y^{2} I_{\tau \mu}\left|y^{2} z^{2} I_{\tau \mu}\right| z^{2} x^{2} I_{\tau \mu}\left|\pi_{x}\left(w, J_{\mu}(\lambda)\right)\right| \pi_{y}\left(w, J_{\mu}(\lambda)\right) \mid \pi_{z}\left(w, J_{\mu}(\lambda)\right)\right)_{\tau \mu \times 6 \tau \mu}
$$

is an $A$-valued matrix, or an $A$-module map $A^{6 \tau \mu} \rightarrow A^{\tau \mu}$. Because it does not directly become maximal Cohen-Macaulay, we will find its Macaulayfying elements in $A^{\tau \mu}$ to Macaulayfy it. Here we briefly recall our previous discussion in [CJKR22] for $\mu=1$ case:

For a fixed band word $w$, consider a one-parameter family of elements in $A^{\tau}$ of the form

$$
\begin{equation*}
F(\lambda)=F_{-} \lambda^{-1}+F_{0}+F_{+} \lambda \text { where } F_{-}, F_{0}, F_{+} \in A^{\tau} \text { and } \lambda \in \mathbb{C}^{\times} \tag{4.3}
\end{equation*}
$$

(see (9.8) in [CJKR22]) that satisfies

$$
\begin{equation*}
\chi F(\lambda)=\tilde{\pi}(w, \lambda, 1) a_{\chi}(\lambda) \text { for each } \chi \in\{x, y, z\} \text { and } \lambda \in \mathbb{C}^{\times} \tag{4.4}
\end{equation*}
$$

for some $a_{\chi}(\lambda)=a_{\chi,-} \lambda^{-1}+a_{\chi, 0}+a_{\chi, 1} \lambda$ where $a_{\chi,-}, a_{\chi, 0}, a_{\chi,+} \in A^{6 \tau \mu}$ (see (9.10) in [CJKR22]). Then we have $\chi F(\lambda) \in \tilde{M}(w, \lambda, 1)$ for each $\chi \in\{x, y, z\}$ and $\lambda \in \mathbb{C}^{\times}$, which means that $F(\lambda)$ is a Macaulayfying element of $\tilde{M}(w, \lambda, 1)$ in $A^{\tau}$ for each $\lambda \in \mathbb{C}^{\times}$.

Theorem 4.16 (Theorem 9.1 in [CJKR22]). Let $(w, \lambda, 1)$ be a non-degenerate band datum and $w^{\prime}$ the converted normal loop word from the band word $w$. Then there are Macaulayfying elements $F_{1}(\lambda), \ldots, F_{\xi}(\lambda)$ of $\tilde{M}(w, \lambda, 1)$ in $A^{\tau}$ of the form (4.3), realizing the Macaulayfication of $\tilde{M}(w, \lambda, 1)$ as

$$
M(w, \lambda, 1)=\tilde{M}(w, \lambda, 1)^{\dagger}=\left\langle\tilde{M}(w, \lambda, 1), F_{1}(\lambda), \ldots, F_{\xi}(\lambda)\right\rangle^{31} .
$$

Moreover, denoting the right side as $\operatorname{im} \pi(w, \lambda, 1)$ for some matrix $\pi(w, \lambda, 1) \in A^{\tau \times 3 \tau}$, it fits into the free resolution of $M_{S}(w, \lambda, 1)$, which is $M(w, \lambda, 1)$ viewed as an S-module:

$$
\begin{equation*}
0 \longrightarrow S^{n} \xrightarrow{\varphi\left(w^{\prime}, \lambda, 1\right)} S^{n} \xrightarrow{\pi(w, \lambda, 1)} M_{S}(w, \lambda, 1) \longrightarrow 0 \tag{4.5}
\end{equation*}
$$

[^21]Now we 'substitute $J_{\mu}(\lambda)$ for $\lambda$ ' in all matrices to accomplish the same result for $\mu \geq 2$ :
Proof of Theorem 4.14. For each Macaulayfying element $F(\lambda)=F_{-} \lambda^{-1}+F_{0}+F_{+} \lambda \in A^{\tau}$ of $\tilde{M}(w, \lambda, 1)$ in $A^{\tau}$ given in Theorem 4.16, we associate a matrix $F\left(J_{\mu}(\lambda)\right):=F_{-} \otimes J_{\mu}(\lambda)^{-1}+F_{0} \otimes I_{\mu}+F_{+} \otimes J_{\mu}(\lambda) \in A^{\tau \mu \times \mu}$ to get a $\left(\lambda, J_{\mu}(\lambda)\right)$-substitution pair $\left(F(\lambda), F\left(J_{\mu}(\lambda)\right)\right)$. Then relation (4.4) implies

$$
\chi F\left(J_{\mu}(\lambda)\right)=\tilde{\pi}(w, \lambda, \mu) a_{\chi}\left(J_{\mu}(\lambda)\right) \text { for each } \chi \in\{x, y, z\},
$$

which shows that each column of $F\left(J_{\mu}(\lambda)\right)$ is a Macaulayfying element of $\tilde{M}(w, \lambda, \mu)$ in $A^{\tau \mu}$. Therefore,

$$
M(w, \lambda, \mu)=\tilde{M}(w, \lambda, \mu)^{\dagger}=\left\langle\tilde{M}(w, \lambda, \mu), F_{1}\left(J_{\mu}(\lambda)\right), \ldots, F_{\xi}\left(J_{\mu}(\lambda)\right)\right\rangle^{\dagger} .
$$

Theorem 4.16 also implies that

$$
\left\langle\tilde{M}(w, \lambda, \mu), F_{1}\left(J_{\mu}(\lambda)\right), \ldots, F_{\xi}\left(J_{\mu}(\lambda)\right)\right\rangle=\operatorname{im} \pi\left(w, J_{\mu}(\lambda)\right) \subset A^{\tau \mu}
$$

On the other hand, applying Proposition 4.15 to the above resolution (4.5), we have a free resolution

$$
0 \longrightarrow S^{3 \tau \mu} \xrightarrow{\varphi\left(w^{\prime}, J_{\mu}(\lambda)\right)} S^{3 \tau \mu} \xrightarrow{\pi\left(w, J_{\mu}(\lambda)\right)} \operatorname{im} \pi\left(w, J_{\mu}(\lambda)\right)_{S} \longrightarrow 0
$$

of $\operatorname{im} \pi\left(w, J_{\mu}(\lambda)\right)$ as an $S$-module. Finally, we know that $\varphi\left(w^{\prime}, J_{\mu}(\lambda)\right)$ is a matrix factor of $x y z$, namely,

$$
\varphi\left(w^{\prime}, J_{\mu}(\lambda)\right) \psi\left(w^{\prime}, J_{\mu}(\lambda)\right)=x y z I_{3 \tau \mu},
$$

which implies that $\operatorname{im} \pi\left(w, J_{\mu}(\lambda)\right)$ is already maximal Cohen-Macaulay and hence equals $M(w, \lambda, \mu)$.
4.5. Degenerate case. Under the conversion formula, the degenerate band data (without multiplicity) $\left(w=(0,0,0)^{\tau}, \lambda=1\right)$ and the degenerate loop data (without rank) $\left(w^{\prime}=(2,2,2)^{\tau}, \lambda=1\right)$ are converted to each other. Recall that we have the degenerate canonical form of matrix factorizations (Definition 3.24)

$$
\left(\varphi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right), \psi_{\operatorname{deg}}\left((2,2,2)^{\tau}, 1, \rho\right)\right) .
$$

For $\tau \geq 2$, the normal loop word $(2,2,2)^{\tau}$ is periodic and the matrix factorization is decomposed into $\tau$ pieces, each of which corresponds to the non-periodic normal loop word (2,2,2) (Proposition 3.29). Among them, only one piece still has eigenvalue $\lambda=1$. We compare it with the maximal Cohen-Macaulay module corresponding to the non-periodic degenerate band data $(w=(0,0,0), \lambda=1, \mu)$ :

- the matrix factorization $\left(\varphi_{\operatorname{deg}}((2,2,2), 1, \rho), \psi_{\operatorname{deg}}((2,2,2), 1, \rho)\right)$,
- the maximal Cohen-Macaulay module $M((0,0,0), 1, \mu)$.

It turns out that they correspond to each other under the relation $\rho=\mu-1$ :
Theorem 4.17. For a geometric rank $\rho \in \mathbb{Z}_{\geq 1}$ and algebraic multiplicity $\mu \in \mathbb{Z}_{\geq 2}$ with $\rho=\mu-1$, we have

$$
\operatorname{coker} \varphi_{\operatorname{deg}}((2,2,2), 1, \rho) \cong M((0,0,0), 1, \mu)
$$

in $\underline{\mathrm{CM}}(A)$. For $\mu=1$, the right side $M((0,0,0), 1,1) \cong A^{32}$ is a zero object in $\underline{\mathrm{CM}}(A)$.
Theorem 4.14 and Theorem 4.17 are combined to give Theorem 1.4 in the introduction. To prove Theorem 4.17, it is convenient to introduce a reduced form of our matrix factorization: We define

$$
\left.\begin{array}{l}
\left.\widehat{\varphi_{\operatorname{deg}}}((2,2,2), 1, \rho), \widetilde{\psi_{\operatorname{deg}}}((2,2,2), 1, \rho)\right) \\
\quad:=\left(\left(\begin{array}{cccc}
-z x \mathbf{e}_{1}^{T} & 0 & 0 & 0 \\
z I_{\rho} & -y I_{\rho} & 0 & 0 \\
0 & x I_{\rho} & -z I_{\rho} & 0 \\
-x J_{\rho}(1) & 0 & y I_{\rho} & -x y \mathbf{e}_{\rho}
\end{array}\right)_{(3 \rho+1) \times(3 \rho+1)},\left(\begin{array}{ccc}
-y \mathbf{e}_{1}-x y J_{\rho}(0)^{T} & -y^{2} J_{\rho}(0)^{T} & -y z J_{\rho}(0)^{T} \\
-z \mathbf{e}_{1}-z x J_{\rho}(1)^{T} & -y z J_{\rho}(0)^{T} & -z^{2} J_{\rho}(0)^{T} \\
-x \mathbf{e}_{1}-x^{2} J_{\rho}(1)^{T} & -x y J_{\rho}(1)^{T} & -z x J_{\rho}(0)^{T} \\
0 & -x \mathbf{e}_{\rho}^{T} & -y \mathbf{e}_{\rho}^{T} \\
-z \mathbf{e}_{\rho}^{T}
\end{array}\right)_{(3 \rho+1) \times(3 \rho+1)}\right.
\end{array}\right) .
$$

[^22]for $\rho \in \mathbb{Z}_{\geq 1}$, and
$$
\left(\widetilde{\varphi_{\operatorname{deg}}}((2,2,2), 1,0), \widetilde{\psi_{\operatorname{deg}}}((2,2,2), 1,0)\right):=(-x y z,-1)
$$
for $\rho=0$.
Lemma 4.18. For $\rho \in \mathbb{Z}_{\geq 1}$, the degenerate canonical form $\left(\varphi_{\operatorname{deg}}((2,2,2), 1, \rho), \psi_{\operatorname{deg}}((2,2,2), 1, \rho)\right)$ is isomorphic to its reduced form $\left(\widetilde{\varphi_{\operatorname{deg}}}((2,2,2), 1, \rho), \widetilde{\psi_{\operatorname{deg}}}((2,2,2), 1, \rho)\right)$ in MF $(x y z)$.

Proof. The submatrix $-I_{\tau \rho}+R_{\tau, \rho}(\lambda)=-I_{\rho}+J_{\rho}(1)$ of $\psi_{\operatorname{deg}}((2,2,2), 1, \rho)$ has $(\rho-1)$ units. So we can use Lemma $3.26(\rho-1)$-times to reduce it to $(3 \rho+1) \times(3 \rho+1)$ size, the computation is straightforward.

Proof of Theorem 4.17. Let $\mu \in \mathbb{Z}_{\geq 1}$. We will find a free resolution

$$
\begin{equation*}
0 \longrightarrow S^{3 \mu-2} \xrightarrow{\left.\widetilde{\varphi_{\operatorname{deg}}}(2,2,2), 1, \mu-1\right)} S^{3 \mu-2} \xrightarrow{\pi} M_{S}((0,0,0), 1, \mu) \longrightarrow 0 . \tag{4.6}
\end{equation*}
$$

Then Eisenbud's equivalence and Lemma 4.18 complete the proof.
Note that

$$
\tilde{M}((0,0,0), \lambda, \mu)=\operatorname{im} \tilde{\pi}((0,0,0), \lambda, \mu)=\operatorname{im}\left(z x^{2} J_{\mu}(\lambda)+x^{2} y I_{\mu}\left|\left(x y^{2}+y^{2} z\right) I_{\mu}\right|\left(y z^{2}+z^{2} x\right) I_{\mu}\right)_{A} \subset A^{\mu}
$$

for any $\lambda \in \mathbb{C}^{\times}$and $\mu \in \mathbb{Z}_{\geq 1}$. It is easy to check that the sequence

$$
S^{4} \xrightarrow{\left(\begin{array}{cccc}
z & -y & 0 & 0 \\
0 & x & -z & 0 \\
-\lambda x & 0 & y & -x y
\end{array}\right)} S^{3} \xrightarrow{\left(\lambda z x^{2}+x^{2} y\left|x y^{2}+y^{2} z\right| y z^{2}+z^{2} x\right)} \tilde{M}((0,0,0), \lambda, 1) S \longrightarrow 0
$$

is exact for any $\lambda \in \mathbb{C}^{\times}$. Then by Proposition 4.15,

$$
S^{4 \mu} \xrightarrow{\left(\begin{array}{cccc}
z I_{\mu} & -y I_{\mu} & 0 & 0 \\
0 & x I_{\mu} & -z I_{\mu} & 0 \\
-x J_{\mu}(1) & 0 & y I_{\mu} & -x y I_{\mu}
\end{array}\right)} S^{3 \mu} \xrightarrow{\left(z x^{2} J_{\mu}(1)+x^{2} y I_{\mu}\left|\left(x y^{2}+y^{2} z\right) I_{\mu}\right|\left(y z^{2}+z^{2} x\right) I_{\mu}\right)} \tilde{M}((0,0,0), 1, \mu)_{S} \longrightarrow 0
$$

is also exact. Using

$$
\left(\begin{array}{ccc}
z I_{\mu} & -y I_{\mu} & 0 \\
0 & x I_{\mu} & -z I_{\mu} \\
-x J_{\mu}(1) & 0 & y I_{\mu}
\end{array}\right)\left(\begin{array}{c}
y I_{\mu} \\
z I_{\mu} \\
x I_{\mu}
\end{array}\right)=\left(\begin{array}{c}
0 \\
0 \\
-x y J_{\mu}(0)
\end{array}\right),
$$

we can reduce it to the following, which is still exact:

$$
S^{3 \mu+1} \xrightarrow{\left(\begin{array}{cccc}
z I_{\mu} & -y I_{\mu} & 0 & 0 \\
0 & x I_{\mu} & -z I_{\mu} & 0 \\
-x J_{\mu}(1) & 0 & y I_{\mu} & -x y \mathbf{e}_{\mu}
\end{array}\right)} S^{3 \mu} \xrightarrow{\left(z x^{2} J_{\mu}(1)+x^{2} y I_{\mu}\left|\left(x y^{2}+y^{2} z\right) I_{\mu}\right|\left(y z^{2}+z^{2} x\right) I_{\mu}\right)} \tilde{M}((0,0,0), 1, \mu)_{S} \longrightarrow 0 .
$$

There is a Macaulayfying element $F:=(x y+y z+z x) \mathbf{e}_{1}:=(x y+y z+z x, 0, \ldots, 0) \in A^{\tau}$ of $\tilde{M}((0,0,0), 1, \mu)$ in $A^{\tau}$. So we enlarge it as $M_{0}((0,0,0), 1, \mu):=\langle F, \tilde{M}((0,0,0), 1, \mu)\rangle_{A} \subset A^{\tau}$, then

$$
S^{3 \mu+4} \xrightarrow{\left(\begin{array}{ccccccc}
x & y & z & 0 & 0 & 0 & 0 \\
-\mathbf{e}_{1} & 0 & 0 & z I_{\mu} & -y I_{\mu} & 0 & 0 \\
0 & -\mathbf{e}_{1} & 0 & 0 & x I_{\mu} & -z I_{\mu} & 0 \\
0 & 0 & -\mathbf{e}_{1}-x J_{\mu}(1) & 0 & y I_{\mu}-x y \mathbf{e}_{\mu}
\end{array}\right)} \underbrace{3 \mu+1}_{\left((x y+y z+z x) \mathbf{e}_{1}\left|z x^{2} J_{\mu}(1)+x^{2} y I_{\mu}\right|\left(x y^{2}+y^{2} z\right) I_{\mu} \mid\left(y z^{2}+z^{2} x\right) I_{\mu}\right)} M_{0}((0,0,0), 1, \mu)_{S} \longrightarrow 0
$$

is exact. (One can check it using Lemma 9.7 in [CJKR22].)

We can reduce matrices along three unit entries of the first matrix. (See Lemma Lemma 9.8 in [CJKR22].) As a result, for $\mu=1$, we get a free resolution

$$
0 \longrightarrow S \xrightarrow{-x y z} S \xrightarrow{x y+y z+z x} M_{0}((0,0,0), 1,1)_{S} \longrightarrow 0
$$

and for $\mu \geq 2$, we have

$$
0 \longrightarrow S^{3 \mu-2} \xrightarrow{\left(\begin{array}{cccc}
-z x \mathbf{e}_{1}^{T} & 0 & 0 & 0 \\
z I_{\mu-1} & -y I_{\mu-1} & 0 & 0 \\
0 & x I_{\mu-1} & -z I_{\mu-1} & 0 \\
-x J_{\mu-1}(1) & 0 & y I_{\mu-1} & -x y \mathbf{e}_{\mu-1}
\end{array}\right)} S^{\left(\begin{array}{cc}
x y+y z+z x & z x^{2} \mathbf{e}_{1}^{T} \\
0 & z x^{2} J_{\mu-1}(1)+x^{2} y I_{\mu-1} \\
\left(x y^{2}+y^{2} z\right) I_{\mu-1} & 0 \\
\left(y z^{2}+z^{2} x\right) I_{\mu-1}
\end{array}\right)} S_{0}((0,0,0), 1, \mu)_{S} \longrightarrow 0 .
$$

Note that the left matrix is $\widetilde{\varphi_{\operatorname{deg}}}((2,2,2), 1, \mu-1)$. As it is a matrix factor of $x y z$, the induced map $S^{3 \mu-2} \rightarrow$ $S^{3 \mu-2}$ is injective and $M_{0}((0,0,0), 1, \mu)$ is maximal Cohen-Macaulay, implying that it is the same as the Macaulayfication $M((0,0,0), 1, \mu)=\tilde{M}((0,0,0), 1, \mu)^{\dagger}$. So we achieved the desired free resolution (4.6) of $M((0,0,0), 1, \mu)_{S}$ for any $\mu \geq 1$.

We finish this section with a remark on the periodic cases: We showed that the matrix factorizations corresponding to periodic loop data are decomposable (Theorem 3.21 for cylinder-free case and Proposition 3.29 for non-cylinder-free case). In non-degenerate cases, they are mapped to maximal CohenMacaulay modules corresponding to periodic band data (Theorem 4.14). It yields the decomposition

$$
\begin{equation*}
M(w, \lambda, \mu) \cong \bigoplus_{k=0}^{N-1} M\left(\tilde{w}, \lambda_{k}, \mu\right) \tag{4.7}
\end{equation*}
$$

in $\underline{\mathrm{CM}}(A)$, where $(w, \lambda, \mu)$ is a non-degenerate band datum with a periodic band word $w=\tilde{w}^{N}$ for another band word $\tilde{w}$, and $\lambda_{0}, \ldots, \lambda_{N-1} \in \mathbb{C}^{\times}$are the $N$-th roots of $\lambda$. In fact, an investigation in the category $\operatorname{Tri}(A)$ proves that the decomposition (4.7) is still valid in $\mathrm{CM}(A)$, even for non-degenerate band data.

Now something tricky happens in periodic degenerate cases: For a band datum $\left(w=(0,0,0)^{\tau}, \boldsymbol{\lambda}=1, \mu\right)$, the corresponding maximal Cohen-Macaulay module is decomposed as

$$
M\left((0,0,0)^{\tau}, 1, \mu\right) \cong \bigoplus_{k=0}^{\tau-1} M\left((0,0,0), e^{2 \pi i \cdot \frac{k}{\tau}}, \mu\right)
$$

Note that only the first direct summand is still degenerate, and the rank of its converted loop datum is shifted only in that piece. Namely, the corresponding matrix factorization and loop with a local system is (4.8)

$$
\varphi_{\mathrm{deg}}((2,2,2), 1, \mu-1) \oplus \bigoplus_{k=1}^{\tau-1} \varphi\left((2,2,2), e^{2 \pi i \cdot \frac{k}{\tau}}, \mu\right) \quad \text { and } \quad \mathscr{L}((2,2,2),-1, \mu-1) \oplus \bigoplus_{k=1}^{\tau-1} \mathscr{L}\left((2,2,2),-e^{2 \pi i \cdot \frac{k}{\tau}}, \mu\right)
$$

Therefore, the object in $\underline{\mathrm{CM}}(A)$ corresponding to a periodic degenerate band datum is mapped to objects in MF $(x y z)$ or Fuk ( $\Sigma$ ) that are decomposed into pieces having different geometric ranks.

Conversely, for a loop datum $\left(w^{\prime}=(2,2,2)^{\tau}, \eta=-1, \rho\right)$ or $\left(w^{\prime}=(2,2,2)^{\tau}, \lambda=1, \rho\right)$, we observed in (3.6) and (3.5) the decomposition of the corresponding loop with a local system and matrix factorization. Now we know that they correspond to the decomposition of maximal Cohen-Macaulay module

$$
\begin{equation*}
M((0,0,0), 1, \rho+1) \oplus \bigoplus_{k=1}^{\tau-1} M\left((0,0,0), e^{2 \pi i \cdot \frac{k}{\tau}}, \rho\right) \tag{4.9}
\end{equation*}
$$

where only the first direct summand has a shifted multiplicity.

## 5. Applications

5.1. Flip of loops and dual of modules. Generally speaking, a symplectomorphism (diffeomorphism preserving the symplectic form) between symplectic manifolds induces an equivalence on their Fukaya categories. There are some obvious symmetries in our pair-of-pants surface $\Sigma$, each of which induces a corresponding auto-equivalence on $\operatorname{Fuk}(\Sigma)$, and hence on $\underline{\mathrm{MF}}(x y z)$ and $\underline{\mathrm{CM}}(A)$.

In this subsection, we take a look at the $\mathbb{Z}_{2}$-symmetry given by flipping $\Sigma$ back-and-forth, which is described in Example 5.7. It is given by an orientation-reversing diffeomorphism $l: \Sigma \rightarrow \Sigma$, which is an antisymplectomorphism $\left(\imath^{*} \omega=-\omega\right)$. Such a map defines a natural contravariant $A_{\infty}$-functor $l: \operatorname{Fuk}(\Sigma) \rightarrow$ $\operatorname{Fuk}(\Sigma)(\S 5.1 .1)$. We also define the transpose functor in $\mathrm{MF}_{A_{\infty}}(f)$ as a contravariant $A_{\infty}$-functor (§5.1.2), and show that, in our situation, two $A_{\infty}$-functors are related under the localized mirror functor (§5.1.3). It is also related with the duality functor $\operatorname{Hom}_{A}(-, A)$ in $\underline{\mathrm{CM}}(A)$ under Eisenbud's equivalence (§5.1.4). We also give a description of these operations in terms of loop/band data (§5.1.5).
5.1.1. Anti-symplectomorphism and contravariant $A_{\infty}$-functor on Fukaya categories. We first recall some general algebraic notions following [Sei08]:

Definition 5.1. Given a $\mathbb{Z}_{2}$-graded $A_{\infty}$-category $\mathscr{A}$, the opposite $A_{\infty}$-category $\mathscr{A}^{\text {op }}$ consists of the same class of objects $\mathrm{Ob}\left(\mathscr{A}^{\mathrm{op}}\right):=\mathrm{Ob}(\mathscr{A})$, switched morphism spaces $\operatorname{hom}_{\mathscr{A}^{\circ} \mathrm{pp}}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right):=\operatorname{hom}_{\mathscr{A}}^{\bullet}\left(\mathscr{L}_{1}, \mathscr{L}_{0}\right)(\bullet \in$ $\mathbb{Z}_{2}$ ), and $A_{\infty}$-operations $\left\{\mathfrak{m}_{k}^{\mathrm{op}}\right\}_{k \geq 1}$ defined as

$$
\mathfrak{m}_{k}^{\mathrm{op}}\left(g_{1}, \ldots, g_{k}\right):=(-1)^{\left|g_{1}\right|+\cdots+\left|g_{k}\right|-k_{1}} \mathfrak{m}_{k}\left(g_{k}, \ldots, g_{1}\right)
$$

for $g_{i} \in \operatorname{hom}_{\mathscr{A}^{\text {op }}}^{\bullet}\left(\mathscr{L}_{i-1}, \mathscr{L}_{i}\right)=\operatorname{hom}_{\mathscr{A}}^{\bullet}\left(\mathscr{L}_{i}, \mathscr{L}_{i-1}\right)\left(i \in\{1, \ldots, k\}, \bullet \in \mathbb{Z}_{2}\right)$.
A straightforward calculation shows that $\mathscr{A}^{\mathrm{op}}$ is indeed an $A_{\infty}$-category.
Definition 5.2. A contravariant $A_{\infty}$-functor $\mathscr{G}:=\left\{\mathscr{G}_{k}\right\}_{k \geq 0}$ between two $A_{\infty}$-categories $\mathscr{A}$ and $\mathscr{B}$ is an $A_{\infty}$ functor from $\mathscr{A}^{\mathrm{op}}$ to $\mathscr{B}$. Equivalently, it can be defined by giving a mapping

$$
\mathscr{G}_{0}: \mathrm{Ob}(\mathscr{A}) \rightarrow \mathrm{Ob}(\mathscr{B})
$$

and $\mathbb{k}$-linear maps $(k \geq 1)$

$$
\mathscr{G}_{k}: \operatorname{hom}_{\mathscr{A}}\left(\mathscr{L}_{1}, \mathscr{L}_{0}\right) \otimes \cdots \otimes \operatorname{hom}_{\mathscr{A}}\left(\mathscr{L}_{k}, \mathscr{L}_{k-1}\right) \rightarrow \operatorname{hom}_{\mathscr{B}}\left(\mathscr{G}_{0}\left(\mathscr{L}_{0}\right), \mathscr{G}_{0}\left(\mathscr{L}_{k}\right)\right)
$$

of degree $1-k$, satisfying $A_{\infty}$-relations

$$
\begin{align*}
\sum_{1 \leq k \leq n} & \sum_{1 \leq i_{1}<\cdots<i_{k}=n} \mathfrak{m}_{k}^{\mathscr{B}}\left(\mathscr{G}_{i_{1}}\left(g_{1}, \ldots, g_{i_{1}}\right), \ldots, \mathscr{G}_{i_{k}}\left(g_{i_{k-1}+1}, \ldots, g_{n}\right)\right) \\
& =\sum_{0 \leq i<j \leq n}(-1)^{\left|g_{1}\right|+\cdots+\left|g_{j}\right|-j} \mathscr{G}_{n-j+i+1}\left(g_{1}, \ldots, g_{i}, \mathfrak{m}_{j-i}^{\mathscr{A}}\left(g_{j}, \ldots, g_{i+1}\right), g_{j+1}, \ldots, g_{n}\right) \tag{5.1}
\end{align*}
$$

for any fixed $n \in \mathbb{Z}_{\geq 1}$ and morphisms $g_{i} \in \operatorname{hom}_{\mathscr{A}}^{\bullet}\left(\mathscr{L}_{i}, \mathscr{L}_{i-1}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$.
It induces an ordinary contravariant functor $H^{0}(\mathscr{G}): H^{0}(\mathscr{A}) \rightarrow H^{0}(\mathscr{B})$, whose mapping on objects is $\mathscr{G}_{0}$ and action on morphisms is given by $[g] \mapsto\left[\mathscr{G}_{1}(g)\right]$.

Now let $(\Sigma, \omega)$ and $\left(\Sigma^{\prime}, \omega^{\prime}\right)$ be 2-dimensional symplectic manifolds (possibly with boundary) of finite type (as in §A.2) and $l: \Sigma \rightarrow \Sigma^{\prime}$ an anti-symplectomorphism $\left(\imath^{*} \omega^{\prime}=-\omega\right)$. We will define a contravariant $A_{\infty}$-functor $l:=\left\{\iota_{k}\right\}_{k \geq 0}: \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{Fuk}\left(\Sigma^{\prime}\right)$ as follows:

Any object $\mathscr{L}:=(L, E, \nabla)$ of $\operatorname{Fuk}(\Sigma)$ consists of a loop $L: S^{1} \rightarrow \Sigma$, a finite-rank $\mathbb{C}$-vector bundle $E$ over $S^{1}$, and a flat connection $\nabla$ on $E$. We define its image under the functor $l$ as the triple

$$
l_{0}(\mathscr{L}):=\left(\imath(L), E^{*}, \nabla^{*}\right)
$$

where $l(L):=\imath \circ L: S^{1} \rightarrow \Sigma^{\prime}$ is the image of $L$ under $l, E^{*}$ is the dual vector bundle of $E$ over $S^{1}$, and $\nabla^{*}$ is the dual connection of $\nabla$.

For two objects $\mathscr{L}_{i}:=\left(L_{i}, E_{i}, \nabla_{i}\right)(i \in\{0,1\})$, note that there are bijections

$$
\chi^{\bullet}\left(L_{1}, L_{0}\right) \stackrel{1: 1}{\longleftrightarrow} \chi^{\bullet}\left(\imath\left(L_{0}\right), l\left(L_{1}\right)\right), \quad q \leftrightarrow \imath(q) \quad\left(\bullet \in \mathbb{Z}_{2}\right)
$$

as shown in Figure 14 for $\bullet=0$ case. Therefore, we have

$$
\begin{aligned}
\operatorname{hom}^{\bullet}\left(l\left(\mathscr{L}_{0}\right), l\left(\mathscr{L}_{1}\right)\right) & =\bigoplus_{q^{\prime} \in \chi} \bigoplus_{\left(l\left(L_{0}\right), l\left(L_{1}\right)\right)} \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}^{*}\right|_{q^{\prime}},\left.E_{1}^{*}\right|_{q^{\prime}}\right) \\
& =\bigoplus_{q \in \chi \cdot\left(L_{1}, L_{0}\right)} \operatorname{Hom}_{\mathbb{C}}\left(\left(\left.E_{0}\right|_{q}\right)^{*},\left(\left.E_{1}\right|_{q}\right)^{*}\right) \quad\left(\bullet \in \mathbb{Z}_{2}\right)
\end{aligned}
$$

We define $l_{1}: \operatorname{hom}\left(\mathscr{L}_{1}, \mathscr{L}_{0}\right) \rightarrow \operatorname{hom}\left(\imath\left(\mathscr{L}_{0}\right), l\left(\mathscr{L}_{1}\right)\right)$ by

$$
\begin{equation*}
g \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{1}\right|_{q},\left.E_{0}\right|_{q}\right) \mapsto(-1)^{|g|} g^{*} \in \operatorname{Hom}_{\mathbb{C}}\left(\left(\left.E_{0}\right|_{q}\right)^{*},\left(\left.E_{1}\right|_{q}\right)^{*}\right) \tag{5.2}
\end{equation*}
$$

for a base morphism $g$ over $q \in \chi^{\bullet}\left(L_{1}, L_{0}\right)\left(\bullet \in \mathbb{Z}_{2}\right)$, and then linearly extend it to any morphisms. Higher components $l_{k \geq 2}$ are defined to be zero.

Figure 14. $q \in \chi^{0}\left(L_{1}, L_{0}\right), \imath(q) \in \chi^{0}\left(\imath\left(L_{0}\right), \imath\left(L_{1}\right)\right)$

Figure 15. A polygon and its image under $l$

Proposition 5.3. The functor $\imath: \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{Fuk}\left(\Sigma^{\prime}\right)$ defined above is indeed a contravariant $A_{\infty}$-functor.
Proof. As $l_{k \geq 2}=0$, the required $A_{\infty}$-relations (5.1) simplify to

$$
\begin{equation*}
\mathfrak{m}_{n}\left(\iota_{1}\left(g_{1}\right), \ldots, \iota_{1}\left(g_{n}\right)\right)=(-1)^{\left|g_{1}\right|+\cdots+\left|g_{n}\right|-n} \iota_{1}\left(\mathfrak{m}_{n}\left(g_{n}, \ldots, g_{1}\right)\right) \tag{5.3}
\end{equation*}
$$

for $n \in \mathbb{Z}_{\geq 1}$ and $g_{i} \in \operatorname{hom}_{\operatorname{Fuk}(\Sigma)}^{\bullet}\left(\mathscr{L}_{i}, \mathscr{L}_{i-1}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$.
For $q_{i} \in \chi^{\bullet}\left(L_{i}, L_{i-1}\right)$ and $g_{i} \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{i}\right|_{q_{i}},\left.E_{i-1}\right|_{q_{i}}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$, the left side is
$\mathfrak{m}_{n}\left((-1)^{\left|g_{1}\right|} g_{1}^{*}, \ldots,(-1)^{\left|g_{n}\right|} g_{n}^{*}\right)=\sum_{r^{\prime} \in \chi\left(\imath\left(L_{0}\right), l\left(L_{n}\right)\right)} \sum_{u^{\prime} \in \mathscr{M}\left(\imath\left(q_{1}\right), \ldots, l\left(q_{n}\right), \overline{r^{\prime}}\right)}(-1)^{\left|q_{1}\right|+\cdots+\left|q_{n}\right|} \operatorname{sign}\left(u^{\prime}\right) \operatorname{hol}_{r^{\prime}}\left(\partial u^{\prime}\right)\left(g_{1}^{*}, \ldots, g_{n}^{*}\right)$.
Note that there is a bijection between angles

$$
\chi\left(L_{n}, L_{0}\right) \stackrel{1: 1}{\longleftrightarrow} \chi\left(\imath\left(L_{0}\right), \imath\left(L_{n}\right)\right), \quad r \leftrightarrow \imath(r)
$$

and between immersed polygons

$$
\mathscr{M}\left(q_{n}, \ldots, q_{1}, \bar{r}\right) \stackrel{1: 1}{\longleftrightarrow} \mathcal{M}\left(\imath\left(q_{1}\right), \ldots, \imath\left(q_{n}\right), \imath(\bar{r})\right), \quad u \leftrightarrow \imath(u):=\imath \circ u
$$

as shown in Figure 19, for each $r \in \chi\left(L_{n}, L_{0}\right)$. Therefore, the right side of (5.4) is replaced by

$$
\begin{equation*}
\sum_{r \in \chi\left(L_{n}, L_{0}\right)} \sum_{u \in \mathscr{M}\left(q_{n}, \ldots, q_{1}, \bar{r}\right)}(-1)^{\left|q_{1}\right|+\cdots+\left|q_{n}\right|} \operatorname{sign}(\imath(u)) \operatorname{hol}_{l(r)}(\partial(\imath(u)))\left(g_{1}^{*}, \ldots, g_{n}^{*}\right) . \tag{5.5}
\end{equation*}
$$

For each pair of $u$ and $l(u)$ in those sets, from the sign rule (A.6), we have

$$
\begin{align*}
& \operatorname{sign}(u) \operatorname{sign}(\imath(u))=(-1)^{\wedge}\left(\sum_{i=1}^{n}\left|q_{i}\right| \mathbb{1}_{\mathbf{o}\left(L_{i-1}\right) \neq \mathbf{o}(\partial u)}+|r| \mathbb{1}_{\mathrm{o}\left(L_{0}\right) \neq \mathbf{o}(\partial u)}+\sum_{i=1}^{n}\left|\imath\left(q_{i}\right)\right| \mathbb{1}_{\mathrm{o}\left(\imath\left(L_{i}\right)\right) \neq \mathrm{o}(\partial u)}+|\imath(r)| \mathbb{1}_{\mathrm{o}\left(\imath\left(L_{n}\right)\right) \neq \mathrm{o}(\partial u)}\right)  \tag{5.6}\\
& =(-1)^{\wedge}\left(\sum_{i=1}^{n}\left|q_{i}\right|\left(\mathbb{T}_{\mathbf{o}\left(L_{i-1}\right) \neq \mathbf{o}(\partial u)}-\mathbb{1}_{\mathbf{o}\left(L_{i}\right) \neq \mathbf{o}(\partial u)}+1\right)+|r|\left(\mathbb{T}_{\mathbf{o}\left(L_{0}\right) \neq \mathbf{o}(\partial u)}-\mathbb{1}_{\mathbf{o}\left(L_{n}\right) \neq \mathbf{o}(\partial u)}+1\right)\right),
\end{align*}
$$

where we used the fact that $\left|q_{i}\right|=\left|\imath\left(q_{i}\right)\right|,|r|=|\imath(r)|(i \in\{1, \ldots, n\})$ and that the orientation of $L_{i}$ coincides with that of $\partial u$ if and only if the orientation of $l\left(L_{i}\right)$ differs from that of $\partial(l(u))$. Note also that

$$
\left(\left|q_{i}\right|=1 \quad \Leftrightarrow \quad \mathbb{T}_{\mathbf{o}\left(L_{i-1}\right) \neq \mathbf{o}(\partial u)}=\mathbb{T}_{\mathbf{o}\left(L_{i}\right) \neq \mathbf{o}(\partial u)}\right) \quad \text { and } \quad\left(|r|=1 \quad \Leftrightarrow \quad \mathbb{1}_{\mathbf{o}\left(L_{0}\right) \neq \mathbf{o}(\partial u)} \neq \mathbb{T}_{\mathbf{o}\left(L_{n}\right) \neq \mathbf{o}(\partial u)}\right),
$$

which reduce (5.6) to $(-1)^{\sum_{i=1}^{n}\left|q_{i}\right|}$.
On the other hand, $\operatorname{hol}_{l(r)}(\partial(l(u)))\left(g_{1}^{*}, \ldots, g_{n}^{*}\right)$ is by definition given as

$$
P\left((\partial(l(u)))_{0}\right) \circ g_{n}^{*} \circ P\left((\partial(\imath(u)))_{1}\right) \circ g_{n-1}^{*} \circ \cdots \circ g_{2}^{*} \circ P\left((\partial(\imath(u)))_{n-1}\right) \circ g_{1}^{*} \circ P\left((\partial(l(u)))_{n}\right),
$$

where each $P\left((\partial(\imath(u)))_{i}\right)$ is the parallel transport with respect to $\nabla_{i}^{*}$ from $\left.E_{i}^{*}\right|_{l\left(q_{i}\right)}$ to $\left.E_{i}^{*}\right|_{l\left(q_{i+1}\right)}$, which is the dual $P\left((\partial u)_{i}\right)^{*}$ of the parallel transport $P\left((\partial u)_{i}\right)$ with respect to $\nabla_{i}$ from $\left.E_{i}\right|_{q_{i+1}}$ to $\left.E_{i}\right|_{q_{i}}$. Therefore, we can replace the total composition by $\left(\operatorname{hol}_{r}(\partial u)\left(g_{n}, \ldots, g_{1}\right)\right)^{*}$.

Summing up, we can rewrite (5.5) as

$$
\sum_{r \in \chi\left(L_{n}, L_{0}\right)} \sum_{u \in \mathscr{M}\left(q_{n}, \ldots, q_{1}, \bar{r}\right)} \operatorname{sign}(u)\left(\operatorname{hol}_{r}(\partial u)\left(g_{n}, \ldots, g_{1}\right)\right)^{*},
$$

whose degree is $|r|=2-n+\left|q_{1}\right|+\cdots+\left|q_{n}\right|$. Therefore, it is the same as $(-1)^{\left|g_{1}\right|+\cdots+\left|g_{n}\right|-n} l_{1}\left(\mathfrak{m}_{n}\left(g_{n}, \ldots, g_{1}\right)\right)$, or the right side of (5.3).
5.1.2. Transpose functor on $\mathrm{MF}_{A_{\infty}}(f)$. Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, and $f \in S$ its nonzero element. Taking transpose of matrix factorizations of $f$ gives rise to a contravariant $A_{\infty}$-functor - $\operatorname{Tr}: \mathrm{MF}_{A_{\infty}}(f) \rightarrow \mathrm{MF}_{A_{\infty}}(f)$, called the (minus) transpose functor ${ }^{33}$, which we now define:

For an object $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ with free $S$-modules $P^{0}, P^{1}$, we define its image as $\left(P^{1}\right)^{*} \underset{-\psi^{*}}{\stackrel{-\varphi^{*}}{\rightleftarrows}}\left(P^{0}\right)^{*}$, where $P^{*}$ denotes the $S$-dual $\operatorname{Hom}_{S}(P, S)$ of an $S$-module $P$ and $\varphi^{*}, \psi^{*}$ denote the natural pull-back maps. It defines the functor $-\operatorname{Tr}:=\left\{-\operatorname{Tr}_{k}\right\}_{k \geq 0}$ on the object level as

$$
-\operatorname{Tr}_{0}: \operatorname{Ob}\left(\operatorname{MF}_{A_{\infty}}(f)\right) \rightarrow \mathrm{Ob}\left(\operatorname{MF}_{A_{\infty}}(f)\right), \quad(\varphi, \psi) \rightarrow\left(-\varphi^{*},-\psi^{*}\right)
$$

Given two matrix factorizations $P_{0}^{0} \underset{\psi_{0}}{\stackrel{\varphi_{0}}{\rightleftarrows}} P_{0}^{1}$ and $P_{1}^{0} \underset{\psi_{1}}{\stackrel{\varphi_{1}}{\rightleftarrows}} P_{1}^{1}$ of $f$ and an even-degree morphism $\left(\alpha: P_{0}^{0} \rightarrow P_{1}^{0}, \beta: P_{0}^{1} \rightarrow P_{1}^{1}\right)$ (resp. an odd-degree morphism $\left(\gamma: P_{0}^{0} \rightarrow P_{1}^{1}, \delta: P_{0}^{1} \rightarrow P_{1}^{0}\right)$ ) (see diagrams in (A.9)), we take dual of the maps to define its image under $-\operatorname{Tr}_{1}$ :
$-\operatorname{Tr}_{1}: \operatorname{hom}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) \rightarrow \operatorname{hom}\left(\left(\varphi_{1}^{*}, \psi_{1}^{*}\right),\left(\varphi_{0}^{*}, \psi_{0}^{*}\right)\right), \quad(\alpha, \beta) \mapsto\left(\beta^{*}, \alpha^{*}\right) \quad\left(\operatorname{resp} .(\gamma, \delta) \mapsto\left(\delta^{*}, \gamma^{*}\right)\right)$.
The higher components $\operatorname{Tr}_{k \geq 2}$ are defined to be zero. It is straightforward to check that Tr is a contravariant $A_{\infty}$-functor.

[^23]5.1.3. Flip of loops and transpose of matrix factorizations. Coming back to our specific situation, the antisymplectomorphism $t: \Sigma \rightarrow \Sigma$ described in Example 5.7 and the discussion so far yield the diagram:

In this subsection, we will show that the diagram commutes, in the sense that two $A_{\infty}$-functors $\mathscr{F}^{\mathbb{L}} \circ l$ and $-\operatorname{Tr} \circ \mathscr{F}^{\mathrm{L}}$ are quasi-isomorphic ${ }^{34}$ to each other.

It is based on the fact that our reference object $\mathbb{L}$ (Seidel Lagrangian) is invariant under the flipping functor $l$. Namely, Figure 16 shows that $l(\mathbb{L})$ consists of the same underlying loop with $\mathbb{L}$ and its local system is gauge equivalent to that of $\mathbb{L}$. Moreover, one can easily check (as we did in Proposition 2.1) that

$$
-\imath(b)=-x \imath(X)-y l(Y)-z \imath(Z) \in \operatorname{hom}^{1}(\imath(\mathbb{L}), l(\mathbb{L}))
$$

is a weak bounding cochain with the disk potential $W^{\prime(\mathbb{L})}=x y z$. Therefore, the pair $(\imath(\mathbb{L}),-\imath(b))$ defines a localized mirror functor $\mathscr{F}^{l(\mathbb{L})}: \operatorname{Fuk}(\Sigma) \rightarrow \mathrm{MF}_{A_{\infty}}(x y z)$.

Figure 16. Seidel Lagrangian and its image under $l$

Figure 17. A deformed strip and its image under $l$

Now we have two localized mirror functors $\mathscr{F}^{\mathbb{L}}$ and $\mathscr{F}^{\imath(\mathbb{L})}$, but there is a trivial isomorphism between $(\mathbb{L}, b)$ and $(\imath(\mathbb{L}),-\imath(b))$, and it has been already proven (with much greater generality) in [CHL18] that such isomorphic weak bounding cochains induce quasi-isomorphic $A_{\infty}$-functors:

Proposition 5.4. [CHL18, Theorem 4.7.(2)] Two localized mirror functors $\mathscr{F}^{\natural}$ and $\mathscr{F}^{\prime(\mathbb{L})}$ are quasi-isomorphic.
To show that the diagram (5.7) commutes, therefore, it is enough to check the following alternative:
Proposition 5.5. Two $A_{\infty}$-functors $\mathscr{F}^{\imath(\mathbb{L})} \circ\left\llcorner\right.$ and $-\operatorname{Tr} \circ \mathscr{F}^{\mathbb{L}}$ are the same.
Proof. Recall from $\$ 2.2$ that $\mathscr{F}^{\complement}(\mathscr{L})=\left(\Phi^{\mathbb{L}}(\mathscr{L}), \Psi^{\complement}(\mathscr{L})\right)$ is given as maps
whose $\left(\left(\left.E\right|_{s}\right)^{*},\left(\left.E\right|_{p}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0, b}:\left(\left.E\right|_{p}\right)^{*} \rightarrow\left(\left.E\right|_{s}\right)^{*}$ for each $p, s \in \chi(L, \mathbb{L})$ is

$$
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots\left(x_{i}, X_{i}\right) \\ \epsilon\{(x, x),(y, Y),(z, z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)}(-1)^{(i+1))_{0(L)}(1) \neq(\partial u)+\#\left(\partial u \cap \star_{\mathrm{L}}\right)} P\left((\partial u)_{0}\right)^{*},
$$

[^24]where $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{s},\left.E\right|_{p}\right)$ is the parallel transport from $\left.E\right|_{s}$ to $\left.E\right|_{p}$ along the side of $u$ lying in $L$.
Taking its dual yields the map $-\operatorname{Tr}\left(\mathscr{F}^{\llcorner }(\mathscr{L})\right)=\left(-\Phi^{\mathbb{L}}\left(\mathscr{L}^{*},-\Psi^{\mathbb{L}}\left(\mathscr{L}^{*}\right)\right.\right.$ given by
$$
\left(\operatorname{hom}^{1}(\mathscr{L}, \mathbb{L})\right)^{*}=\left.\left.\bigoplus_{s \in \chi^{1}(L, \mathbb{L})} E\right|_{s} \stackrel{-\Phi^{\mathrm{L}}(\mathscr{L})^{*}}{-^{\mathrm{L}}(\mathscr{L})^{*}} \underset{p \in \chi^{0}(L, \mathbb{L})}{ } E\right|_{p}=\left(\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L})\right)^{*},
$$
whose $\left(\left.E\right|_{p},\left.E\right|_{s}\right)$-component $\left.\left.E\right|_{s} \rightarrow E\right|_{p}$ for each $p, s \in \chi(L, \mathbb{L})$ is

On the other hand, the opposite side $\mathscr{F}^{l(\mathbb{L})}(l(\mathscr{L}))=\left(\Phi^{l(\mathbb{L})}(\imath(\mathscr{L})), \Psi^{l(\mathbb{L})}(l(\mathscr{L}))\right)$ is given by (5.8)

$$
\operatorname{hom}^{0}(l(\mathscr{L}), l(\mathbb{\mathbb { L }}))=\bigoplus_{p^{\prime} \in \chi^{0}(l(L), l(\mathbb{L}))}\left(\left.E^{*}\right|_{p^{\prime}}\right)^{*} \stackrel{\Phi^{L_{(L)}}(l(\mathscr{L}))=\mathbf{m}_{1}^{0,-l(b)}}{\rightleftarrows} \bigoplus_{\Psi^{(\mathbb{L})}(l(\mathscr{L}))=\mathbf{m}_{1}^{0,-l(b)}}^{\longrightarrow} \underset{s^{\prime} \in \chi^{1}(l(L), l(\mathbb{L}))}{ }\left(\left.E^{*}\right|_{s^{\prime}}\right)^{*}=\operatorname{hom}^{1}(l(\mathscr{L}), l(\mathbb{L})),
$$

whose $\left(\left(E^{*}| |_{s^{\prime}}\right)^{*},\left(E^{*} \mid p_{p^{\prime}}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0,-\imath(b)}:\left(\left.E^{*}\right|_{p^{\prime}}\right)^{*} \rightarrow\left(\left.E^{*}\right|_{s^{\prime}}\right)^{*}$ for each $p^{\prime}, s^{\prime} \in \chi(l(L), l(\mathbb{L}))$ is

Under the bijection between angles

$$
\chi^{\bullet}(L, \mathbb{L}) \stackrel{1: 1}{\longleftrightarrow} \chi^{\bullet+1}(l(L), l(\mathbb{L})), \quad p \leftrightarrow l(\bar{p}) \quad\left(\bullet \in \mathbb{Z}_{2}\right),
$$

we can put $p^{\prime}=l(\bar{s})$ and $s^{\prime}=l(\bar{p})$ for some $p, s \in \chi(L, \mathbb{L})$. Each $X_{i}^{\prime}$ is $l\left(X_{i}\right)$ for some $X_{i} \in\{X, Y, Z\}$. There is also a bijection between deformed strips

$$
\mathscr{M}\left(p, X_{i}, \ldots, X_{1}, \bar{s}\right) \stackrel{1: 1}{\longleftrightarrow} \mathcal{M}\left(\imath(\bar{s}), \imath\left(X_{1}\right), \ldots, \imath\left(X_{i}\right), \iota(p)\right), \quad u \leftrightarrow \imath(u):=\imath \circ u
$$

as shown in Figure 17. Also using the identifications $\left(\left.E^{*}\right|_{l(\bar{s})}\right)^{*}=\left.E\right|_{s}$ and $\left(\left.E^{*}\right|_{l(\bar{p})}\right)^{*}=\left.E\right|_{p}$, we can rewrite (5.16) and (5.9) as

$$
\left.\left.\bigoplus_{s \in \chi^{1}(L, L)} E\right|_{s} \underset{\Phi^{\ell(L)}(l(\mathscr{L}))=\mathfrak{m}_{1}^{0,-l(b)}}{\stackrel{\Phi^{\ell(L)}(l(\mathscr{L}))=\mathfrak{m}_{1}^{0,-(t(b)}}{\rightleftarrows}} \bigoplus_{p \in \chi^{0}(L, L)} E\right|_{p}
$$

where the $\left(\left.E\right|_{p},\left.E\right|_{s}\right)$-component $\left.\left.E\right|_{s} \rightarrow E\right|_{p}$ is

$$
\begin{equation*}
\sum_{\substack{\left(x_{1}, x_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \epsilon\{\{(x, x),(y, y),(z, z)\}}}\left(-x_{1}\right) \cdots\left(-x_{i}\right) \sum_{u \in \mathcal{M}\left(p, X_{i}, \ldots, X_{1}, \bar{s}\right)}(-1)^{\left.\left.\left.(i+1) 0_{0(u(L))) \neq v(\partial u}(u)\right)\right)+\#\left(\partial(\imath(u)) \cap \iota\left(\star_{L}\right)\right)\right)} P\left((\partial(\imath(u)))_{0}\right)^{*} \tag{5.10}
\end{equation*}
$$

The obvious relations

$$
\mathbb{1}_{\mathbf{o}(\mathbb{L}) \neq 0}(\partial u)+\mathbb{1}_{\mathrm{o}(l(\mathbb{L})) \neq 0}(\partial(l(u)))=1 \quad \text { and } \quad \#\left(\partial u \cap \star_{\mathbb{L}}\right)=\#\left(\partial(l(u)) \cap u\left(\star_{\mathbb{L}}\right)\right)
$$

and the fact that $P\left((\partial(\imath(u)))_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E^{*}\right|_{p},\left.E^{*}\right|_{s}\right)$ is the dual of $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{s},\left.E\right|_{p}\right)$ replace (5.10) again into

$$
-\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots\left(x_{i}, X_{i}\right) \\ \in\{\{(x, X),(y, Y),(z, z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathcal{M}\left(p, X_{i}, \ldots, X_{1}, \bar{s}\right)}(-1)^{\left.(i+1) \eta_{0(L l}\right) \neq 0(\partial u)+\#\left(\partial u \cap \star_{\llcorner }\right)} P\left((\partial u)_{0}\right) .
$$

This shows that two functors are the same on the object level. It is also straightforward to check that they coincide on the morphism level.
5.1.4. Flip of loops and dual of modules. The commutativity of diagram (5.7) induces the commutativity of the left square in the following diagram of ordinary categories and functors:

We check the commutativity of the right square in the general setting:
Proposition 5.6. Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, $f \in S$ its nonzero element and $A:=S /(f)$ the quotient ring. Then the following diagram is commutative, that is, two compositions of functors are naturally isomorphic to each other:

Proof. Recall that under Eisenbud's equivalence (Theorem A.16), a matrix factorization $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ of $f$ corresponds to a maximal Cohen-Macaulay $A$-module $M:=\operatorname{coker} \underline{\varphi}$, which admits a 2-periodic free resolution given by

$$
\cdots \longrightarrow P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \xrightarrow{\underline{\psi}} P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \longrightarrow M \longrightarrow 0 .
$$

Taking $\operatorname{Hom}_{A}(-, A)$ yields a 2-periodic free resolution of $\operatorname{Hom}_{A}(M, A)$ as

$$
0 \longrightarrow \operatorname{Hom}_{A}(M, A) \longrightarrow \operatorname{Hom}_{S}\left(P^{1}, A\right) \xrightarrow{\stackrel{\varphi^{*}}{\longrightarrow} \operatorname{Hom}_{A}\left(P^{0}, A\right) \xrightarrow{\psi^{*}} \operatorname{Hom}_{A}\left(P^{1}, A\right) \longrightarrow, ~}
$$

where $\varphi^{*}=\varphi^{*} \otimes \operatorname{id}_{A}:\left(P^{1}\right)^{*} \otimes_{S} A \rightarrow\left(P^{0}\right)^{*} \otimes_{S} A$ is induced from $\varphi^{*}:\left(P^{1}\right)^{*} \rightarrow\left(P^{0}\right)^{*}$. It gives natural isomorphisms
$\operatorname{Hom}_{A}(M, A) \cong \operatorname{ker} \underline{\varphi^{*}}=\operatorname{im} \underline{\psi^{*}} \cong \operatorname{Hom}_{A}\left(P^{0}, A\right) / \operatorname{ker} \underline{\psi^{*}}=\operatorname{Hom}_{A}\left(P^{0}, A\right) / \operatorname{im} \underline{\varphi^{*}}=\operatorname{coker} \underline{\varphi^{*}}=\operatorname{coker}\left(\underline{-\varphi^{*}}\right)$.
5.1.5. Correspondence of canonical forms. Flipping a loop with a local system, taking transpose of a matrix factorization, and taking dual of a maximal Cohen-Macaulay modules can all be given explicitly in terms of loop/band data.

- In $\operatorname{Fuk}(\Sigma)$, let $(L, E, \nabla):=\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ be the loop with a local system corresponding to a loop datum $\left(w^{\prime}, \eta, \rho\right)$. Its flip is given by $\left(\imath(L), E^{*}, \nabla^{*}\right)$. Recall that the free homotopy class of the loop $L\left(w^{\prime}\right)$ corresponding to the given normal loop word $w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}$ is given by

$$
\left[L\left(w^{\prime}\right)\right]=\left[\alpha^{l_{1}^{\prime}} \beta^{m_{1}^{\prime}} \gamma^{n_{1}^{\prime}} \cdots \alpha^{l_{\tau}^{\prime}} \beta^{m_{\tau}^{\prime}} \gamma^{n_{\tau}^{\prime}}\right]
$$

where $\alpha, \beta, \gamma$ are generators of $\pi_{1}(\Sigma)$ (Figure 8a). It is easy to see that the free homotopy class of the flipped loop $l\left(L\left(w^{\prime}\right)\right)$ is

$$
\left[\iota\left(L\left(w^{\prime}\right)\right)\right]=\left[\alpha^{1-l_{1}^{\prime}} \beta^{1-m_{1}^{\prime}} \gamma^{1-n_{1}^{\prime}} \cdots \alpha^{1-l_{\tau}^{\prime}} \beta^{1-m_{\tau}^{\prime}} \gamma^{1-n_{\tau}^{\prime}}\right]
$$

Defining a new normal loop word $1-w^{\prime}$ as the normal form of the loop word ${ }^{35}$

$$
\left(1-l_{1}^{\prime}, 1-m_{1}^{\prime}, 1-n_{1}^{\prime}, \ldots, 1-l_{\tau}^{\prime}, 1-m_{\tau}^{\prime}, 1-n_{\tau}^{\prime}\right) \in \mathbb{Z}^{3 \tau}
$$

two loops $l\left(L\left(w^{\prime}\right)\right)$ and $L\left(1-w^{\prime}\right)$ are freely homotopic to each other.
The holonomy of ( $E, \nabla$ ) at some point is represented by a matrix $J_{\rho}(\eta)$ (up to conjugacy). It changes to $\left(J_{\rho}(\eta)^{T}\right)^{-1}$ (which is similar to $J_{\rho}(\eta)^{-1}$ by discussion in the proof of Theorem 3.17) for the dual local system ( $E^{*}, \nabla^{*}$ ). This is because the parallel transport from $\left.E^{*}\right|_{p}$ to $\left.E^{*}\right|_{q}$ is $\left(P\left(L_{p \rightarrow q}\right)^{*}\right)^{-1}$, where $P\left(L_{p \rightarrow q}\right)$ is the parallel transport in $(E, \nabla)$ from $\left.E\right|_{p}$ to $\left.E\right|_{q}$.

Thus, the flipped loop with a local system $\left(l(L), E^{*}, \nabla^{*}\right)$ is isomorphic to the canonical form $\mathscr{L}\left(1-w^{\prime}, \eta^{-1}, \rho\right)$, that is, they give isomorphic matrix factorizations in $\underline{\mathrm{MF}}(x y z)$ by Theorem 3.13.

- In MF $(x y z)$ (or MF $(x y z)$ ), consider the canonical form $\varphi\left(w^{\prime}, \lambda, \rho\right)$ corresponding to a loop datum ( $w^{\prime}, \lambda, \rho$ ). Its transpose still remains in the canonical form up to equivalence of loop words and bases change $J_{\rho}\left(\lambda^{-1}\right)^{T} \sim J_{\rho}\left(\lambda^{-1}\right) \sim J_{\rho}(\lambda)^{-1}$, which results in the canonical form $\varphi\left(1-w^{\prime}, \lambda^{-1}, \rho\right)$.
- In $\underline{\mathrm{CM}}(A)$ (or $\mathrm{CM}(A)$ ), the canonical form given in terms of Definition 4.6 does not directly show the relation with taking dual. However, in $\operatorname{Tri}(A)$, one can handle it in an algebraic way and see that the dual of the canonical form $M(w, \lambda, \mu)$ corresponding to a band datum $(w, \lambda, \mu)$ is isomorphic to $M\left(-w, \lambda^{-1}, \mu\right)$, where $-w$ is the band word given by multiplying -1 to every entry of $w$.

The above discussions summarize to the following mappings (up to isomorphism) under the diagram (5.11), while two rows are consistent with our main correspondence (1.5):

Example 5.7. The following shows the correspondence of loops with a local system $\mathscr{L}((3,-2,2), \eta, 1) \leftrightarrow$ $\mathscr{L}\left((-2,3,-1), \eta^{-1}, 1\right)$, matrix factorizations $\varphi((3,-2,2), \lambda, 1) \leftrightarrow \varphi\left((-2,3,-1), \lambda^{-1}, 1\right)$, and maximal CohenMacaulay modules $M((2,-3,1), \lambda, 1) \leftrightarrow M\left((-2,3,-1), \lambda^{-1}, 1\right)$ (in $\left.\operatorname{Tri}(A)\right)$ up to isomorphism, where $\lambda=-\eta$.

 maximal Cohen-Macaulay modules

[^25]5.2. Reverse of loops and shift of modules. Orientation-reversing of loops induces another auto-equivalence on $\operatorname{Fuk}(\Sigma)(\S 5.2 .1)$. We also define the switching functor in $\mathrm{MF}_{A_{\infty}}(f)(\$ 5.2 .2)$, and show that, in our situation, two $A_{\infty}$-functors are related under the localized mirror functor (§5.2.3). They boil down to shift functors of triangulated categories, and therefore, are also related with the shift functor of $\underline{C M}(A)(\$ 5.2 .4)$. We give an algorithm to compute them in terms of loop/band data (§5.2.5).
5.2.1. Orientation-reversing ofloops and auto-equivalence on the Fukaya category. Let ( $\Sigma, \omega$ ) be a 2-dimensional symplectic manifolds (possibly with boundary) of finite type (as in §A.2). There is an obvious symmetry of objects in $\operatorname{Fuk}(\Sigma)$, namely, we can reverse the orientation of the underlying loop of every object. It results in an auto-equivalence on $\operatorname{Fuk}(\Sigma)$ given by a (covariant) $A_{\infty}$-functor $j:=\left\{J_{k}\right\}_{k \geq 0}: \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{Fuk}(\Sigma)$ we define now:

Any object $\mathscr{L}:=(L, E, \nabla)$ of $\operatorname{Fuk}(\Sigma)$ consists of a loop $L: S^{1} \rightarrow \Sigma$, a finite-rank $\mathbb{C}$-vector bundle $E \rightarrow S^{1}$, and a flat connection $\nabla$ on $E$. We define its image under the functor $J$ as the triple

$$
J_{0}(\mathscr{L}):=\left(\jmath(L):=L \circ \kappa, \kappa^{*} E, \kappa^{*} \nabla\right)
$$

where $\kappa: S^{1} \rightarrow S^{1}, e^{2 \pi i t} \mapsto e^{-2 \pi i t}$ denotes the orientation-reversing map.
Note that reversing the orientation of loops doesn't affect their (self-)intersections. Therefore, for two objects $\mathscr{L}_{i}:=\left(L_{i}, E_{i}, \nabla_{i}\right)(i \in\{0,1\})$, the sets $\chi^{\bullet}\left(L_{0}, L_{1}\right)$ and $\chi^{\bullet}\left(J\left(L_{0}\right), j\left(L_{1}\right)\right)\left(\bullet \in \mathbb{Z}_{2}\right)$ are identified, as shown in Figure 18. The fibers $\left.E_{i}\right|_{p}$ and $\left.\kappa^{*} E_{i}\right|_{p}$ over the preimages (in $S^{1}$ ) of the point $p \in \Sigma$ under $L_{i}$ and $J\left(L_{i}\right)$, respectively, are also naturally identified. So there is also a natural identification between

$$
\bigoplus_{p \in \chi^{*}\left(L_{0}, L_{1}\right)} \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p},\left.E_{1}\right|_{p}\right) \quad \text { and } \quad \bigoplus_{p \in \chi^{\bullet}\left(J\left(L_{0}\right), j\left(L_{1}\right)\right)} \operatorname{Hom}_{\mathbb{C}}\left(\left.\kappa^{*} E_{0}\right|_{p},\left.\kappa^{*} E_{1}\right|_{p}\right)
$$

We define $j_{1}: \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \rightarrow \operatorname{hom}\left(\jmath\left(\mathscr{L}_{0}\right), j\left(\mathscr{L}_{1}\right)\right)$ by

$$
\begin{equation*}
f \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p},\left.E_{1}\right|_{p}\right) \mapsto(-1)^{|f|} f \in \operatorname{Hom}_{\mathbb{C}}\left(\left.\kappa^{*} E_{0}\right|_{p},\left.\kappa^{*} E_{1}\right|_{p}\right) \tag{5.12}
\end{equation*}
$$

for a base morphism $f$ over $p \in \chi^{\bullet}\left(L_{0}, L_{1}\right)\left(\bullet \in \mathbb{Z}_{2}\right)$, and then linearly extend it to any morphisms. Higher components $J_{k \geq 2}$ are defined to be zero.

Figure 18. $p, \bar{p} \in \chi\left(L_{0}, L_{1}\right)=\chi\left(J\left(\mathscr{L}_{0}\right), \jmath\left(\mathscr{L}_{1}\right)\right)$

Figure 19. A polygon $u \in \mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)$

Proposition 5.8. The functor $J: \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{Fuk}(\Sigma)$ defined above is indeed a covariant $A_{\infty}$-functor.
Proof. As $J_{k \geq 2}=0$, the required $A_{\infty}$-relations (A.3) simplify to

$$
\begin{equation*}
\mathfrak{m}_{n}\left(J_{1}\left(f_{1}\right), \ldots, J_{1}\left(f_{n}\right)\right)=J_{1}\left(\mathfrak{m}_{n}\left(f_{1}, \ldots, f_{n}\right)\right) \tag{5.13}
\end{equation*}
$$

for $n \in \mathbb{Z}_{\geq 1}$ and $f_{i} \in \operatorname{hom}^{\bullet}\left(\mathscr{L}_{i-1}, \mathscr{L}_{i}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$. For $p_{i} \in \chi^{\bullet}\left(L_{i-1}, L_{i}\right)$ and $f_{i} \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{i-1}\right|_{p_{i}},\left.E_{i}\right|_{p_{i}}\right)$ ( $i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}$ ), recalling the definition of $\mathfrak{m}_{n}$ in (A.5), both the left and right sides are contributed by the same polygons $u \in \mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)$ for $q \in \chi\left(L_{0}, L_{k}\right)$. But for each polygon $u$, its bounding loops have different orientations in both sides. It plays a role only when we compute sign $(u)$, whose quotient in both sides is given by $(-1)^{\sum_{i=1}^{k}\left|p_{i}\right|+|q|}$ following the sign rule (A.6). It cancels all the signs that occur when taking $J_{1}$, which confirms (5.13).
5.2.2. Switching functor on $\mathrm{MF}_{A_{\infty}}(f)$. Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, and $f \in S$ its nonzero element. Switching two factors in matrix factorizations of $f$ gives rise to a covariant $A_{\infty}$-functor [1]: $\mathrm{MF}_{A_{\infty}}(f) \rightarrow \mathrm{MF}_{A_{\infty}}(f)$, called the switching functor ${ }^{36}$, which we now define:

For an object $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ with free $S$-modules $P^{0}, P^{1}$, we define its image as $P^{1} \underset{\varphi}{\stackrel{\psi}{\rightleftarrows}} P^{0}$. It defines the functor $[1]:=\left\{[1]_{k}\right\}_{k \geq 0}$ on the object level as

$$
[1]_{0}: \mathrm{Ob}\left(\mathrm{MF}_{A_{\infty}}(f)\right) \rightarrow \mathrm{Ob}\left(\mathrm{MF}_{A_{\infty}}(f)\right), \quad(\varphi, \psi) \rightarrow(\psi, \varphi) .
$$

Given two matrix factorizations $P_{1}^{0} \underset{\psi_{1}}{\stackrel{\varphi 1}{\rightleftarrows}} P_{1}^{1}$ and $P_{0}^{0} \underset{\psi_{0}}{\stackrel{\varphi_{0}}{\leftrightarrows}} P_{0}^{1}$ of $f$ and an even-degree morphism $\left(\alpha: P_{1}^{0} \rightarrow P_{0}^{0}, \beta: P_{1}^{1} \rightarrow P_{0}^{1}\right)$ (resp. an odd-degree morphism $\left(\gamma: P_{1}^{0} \rightarrow P_{0}^{1}, \delta: P_{1}^{1} \rightarrow P_{0}^{0}\right)$ ), we define its image under [1] ${ }_{1}$ as

$$
[1]_{1}: \operatorname{hom}\left(\left(\varphi_{1}, \psi_{1}\right),\left(\varphi_{0}, \psi_{0}\right)\right) \rightarrow \operatorname{hom}\left(\left(\psi_{1}, \varphi_{1}\right),\left(\psi_{0}, \varphi_{0}\right)\right), \quad(\alpha, \beta) \mapsto(\beta, \alpha) \quad(\text { resp. }(\gamma, \delta) \mapsto(\delta, \gamma)) .
$$

The higher components [1] ${ }_{k \geq 2}$ are defined to be zero. Then it is straightforward to check that [1] is a covariant $A_{\infty}$-functor.
5.2.3. Orientation-reversing of loops and switching of matrix factorizations. Now in our situation, we have the diagram of $A_{\infty}$-categories and functors:

In this subsection, we will show that the diagram commutes, more precisely:
Proposition 5.9. Two $A_{\infty}$-functors $\mathscr{F}^{\llcorner } \circ \mathrm{J}$ and $[1] \circ \mathscr{F}^{\mathrm{L}}$ are the same.
Proof. Recall from $\$ 2.2$ that $\mathscr{F}^{\mathbb{L}}(\mathscr{L})=\left(\Phi^{\mathbb{L}}(\mathscr{L}), \Psi^{\mathbb{L}}(\mathscr{L})\right)$ is given as maps

$$
\begin{equation*}
\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L})=\bigoplus_{p \in \chi^{0}(L, \mathbb{L})}\left(\left.E\right|_{p}\right)^{*} \underset{\Psi^{\mathbb{L}}(\mathscr{L})=\mathfrak{m}_{1}^{0, b}}{\stackrel{\Phi^{\mathrm{L}}(\mathscr{L})=\mathfrak{m}_{1}^{0, b}}{\rightleftarrows}} \bigoplus_{S \in \chi^{1}(L, \mathbb{L})}\left(\left.E\right|_{s}\right)^{*}=\operatorname{hom}^{1}(\mathscr{L}, \mathbb{L}), \tag{5.15}
\end{equation*}
$$

whose $\left(\left(\left.E\right|_{s}\right)^{*},\left(\left.E\right|_{p}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0, b}:\left(\left.E\right|_{p}\right)^{*} \rightarrow\left(\left.E\right|_{s}\right)^{*}$ for each $p, s \in \chi(L, \mathbb{L})$ is

$$
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots\left(x_{i}, X_{i}\right) \\ \in\{\{(x, X),(, y, Y),(z, z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathcal{M}\left(p, X_{1}, \ldots, X_{i}, \bar{s}\right)}(-1)^{(i+1) 0_{0(1) \nmid)}(\partial u)+\#\left(\partial u \cap \star_{\llcorner }\right)} P\left((\partial u)_{0}\right)^{*},
$$

where $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{s},\left.E\right|_{p}\right)$ is the parallel transport from $\left.E\right|_{s}$ to $\left.E\right|_{p}$ along the side of $u$ lying in $L$.
Switching positions of the left and right sides in (5.15), $\mathscr{F}^{\mathbb{L}}(\mathscr{L})[1]$ is given by maps

$$
\operatorname{hom}^{1}(\mathscr{L}, \mathbb{L})=\bigoplus_{s \in \chi^{1}(L, \mathbb{L})}\left(\left.E\right|_{s}\right)^{*} \underset{\Phi^{\mathbb{L}}(\mathscr{L})=\mathbf{m}_{1}^{0, b}}{\stackrel{\psi^{\mathbb{L}}(\mathscr{L})=\mathbf{m}_{1}^{0, b}}{\rightleftarrows}} \bigoplus_{p \in \chi^{0}(L, \mathbb{L})}\left(\left.E\right|_{p}\right)^{*}=\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L}),
$$

whose $\left(\left(\left.E\right|_{p}\right)^{*},\left(\left.E\right|_{s}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0, b}:\left(\left.E\right|_{s}\right)^{*} \rightarrow\left(\left.E\right|_{p}\right)^{*}$ for each $s, p \in \chi(L, \mathbb{L})$ is

$$
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots\left(x_{i}, X_{i}\right) \\ \epsilon\{(x, X),(y, y),(z, z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(s, X_{1}, \ldots, X_{i}, \bar{p}\right)}(-1)^{\left.(i+1))_{0(1) \nmid) \neq(\partial u)+\#(\partial u \cap \star\llcorner }\right)} P\left((\partial u)_{0}\right)^{*},
$$

[^26]where $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{p},\left.E\right|_{s}\right)$ is the parallel transport from $\left.E\right|_{p}$ to $\left.E\right|_{s}$ along the side of $u$ lying in $L$.
On the other hand, the opposite side $\mathscr{F}^{\complement}(J(\mathscr{L}))=\left(\Phi^{\complement}(J(\mathscr{L})), \Psi^{\complement}(J(\mathscr{L}))\right)$ is given by
whose $\left(\left(\left.E^{*}\right|_{s^{\prime}}\right)^{*},\left(\left.E^{*}\right|_{p^{\prime}}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0, b}:\left(\left.\kappa^{*} E\right|_{p^{\prime}}\right)^{*} \rightarrow\left(\left.\kappa^{*} E\right|_{s^{\prime}}\right)^{*}$ for each $p^{\prime}, s^{\prime} \in \chi(J(L), \mathbb{L})$ is
\[

$$
\begin{equation*}
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \epsilon\{(x, X),(y, Y),(z, Z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(p^{\prime}, X_{1}, \ldots, X_{i}, \overline{s^{\prime}}\right)}(-1)^{(i+1) \mathbb{1}_{0(\mathbb{L}) \neq 0}(\partial u)+\#\left(\partial u \cap \star_{\mathbb{L}}\right)} P\left((\partial u)_{0}\right)^{*} \tag{5.17}
\end{equation*}
$$

\]

where $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.\kappa^{*} E\right|_{s^{\prime}},\left.\kappa^{*} E\right|_{p^{\prime}}\right)$ is the parallel transport from $\left.\kappa^{*} E\right|_{s^{\prime}}$ to $\left.\kappa^{*} E\right|_{p^{\prime}}$ along the side of $u$ lying in $L$.

Note that reversing the orientation of $L$ doesn't affect its intersection with $\mathbb{L}$, but their degree changes. Therefore, we can replace $p^{\prime} \in \chi^{0}(J(L), \mathbb{L})$ and $s^{\prime} \in \chi^{1}(J(L), \mathbb{L})$ with $s \in \chi^{1}(L, \mathbb{L})$ and $p \in \chi^{0}(L, \mathbb{L})$, respectively. The fibers $\left.\kappa^{*} E\right|_{p^{\prime}}$ and $\left.\kappa^{*} E\right|_{s^{\prime}}$ are also identified with $\left.E\right|_{s}$ and $\left.E\right|_{p}$, respectively. So we can rewrite (5.16) and (5.17) as

$$
\bigoplus_{s \in \chi^{1}(L, \mathbb{L})}\left(\left.E\right|_{s}\right)^{*} \frac{\Phi^{\mathbb{L}}(J(\mathscr{L}))=\mathfrak{m}_{1}^{0, b}}{\Psi^{\mathbb{L}}(J(\mathscr{L}))=\mathfrak{m}_{1}^{0, b}} \bigoplus_{p \in \chi^{0}(L, \mathbb{L})}\left(\left.E\right|_{p}\right)^{*}
$$

whose $\left(\left(\left.E\right|_{p}\right)^{*},\left(\left.E\right|_{s}\right)^{*}\right)$-component $\mathfrak{m}_{1}^{0, b}:\left(\left.E\right|_{s}\right)^{*} \rightarrow\left(\left.E\right|_{p}\right)^{*}$ is

$$
\sum_{\substack{\left(x_{1}, X_{1}\right), \ldots,\left(x_{i}, X_{i}\right) \\ \in\{(x, X),(y, Y),(z, Z)\}}} x_{1} \cdots x_{i} \sum_{u \in \mathscr{M}\left(s, X_{1}, \ldots, X_{i}, \bar{p}\right)}(-1)^{(i+1) \mathbb{1}_{\mathrm{o}(\mathbb{1}) \neq \mathrm{o}(\partial u)}+\#\left(\partial u \cap \star_{\mathrm{L}}\right)} P\left((\partial u)_{0}\right)^{*},
$$

where $P\left((\partial u)_{0}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{p},\left.E\right|_{s}\right)$ is the parallel transport from $\left.E\right|_{p}$ to $\left.E\right|_{s}$ along the side of $u$ lying in $L$.
Notice that it is the same expression with $\mathscr{F}^{\text {L }}(\mathscr{L})$ [1], especially because $\operatorname{sign}(u)$ is not relevant to the orientation of $L$. This shows that two functors are the same on the object level. It is also straightforward to check that they coincide on the morphism level.
5.2.4. Orientation-reversing of loops and shift of modules. The commutativity of diagram (5.14) induces the commutativity of the left square in the following diagram of ordinary categories and functors:

We explain the commutativity of the right square in the general setting:
Definition 5.10. [Buc21] Let $(A, \mathfrak{m})$ be a Noetherian local ring and $M \in \underline{\mathrm{CM}}(A)$ be a maximal CohenMacaulay module over A. Choose an injection $i: M \rightarrow Q$ of $M$ into a finitely generated projective $A$-module $Q$ such that its cokernel is still maximal Cohen-Macaulay. We define the shift ${ }^{37}$ of $M$ as

$$
M[1]:=\operatorname{coker}(i)
$$

[^27]In the case of hypersurface singularities, it can be explicitly given in terms of matrix factorizations under Eisenbud's equivalence:

Proposition 5.11. Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, $f \in S$ its nonzero element and $A:=S /(f)$ the quotient ring. Then the following diagram is commutative, that is, two compositions of functors are naturally isomorphic to each other:

Proof. Recall that under Eisenbud's equivalence (Theorem A.16), a matrix factorization $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ of $f$ corresponds to a maximal Cohen-Macaulay $A$-module $M:=\operatorname{coker} \underline{\varphi}$, which admits a 2-periodic free resolution given by

$$
\cdots \longrightarrow P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \xrightarrow{\underline{\psi}} P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \longrightarrow M \longrightarrow 0 .
$$

From this we have natural isomorphisms

$$
M=\operatorname{coker} \underline{\varphi}=\left(P^{1} \otimes_{S} A\right) / \operatorname{im} \underline{\varphi}=\left(P^{1} \otimes_{S} A\right) / \operatorname{ker} \underline{\psi} \cong \operatorname{im} \underline{\psi}=\operatorname{ker} \underline{\varphi},
$$

and hence there is a natural embedding of $M$ into a finitely generated free $A$-module $P^{0} \otimes_{S} A$ :

$$
i: M \cong \operatorname{ker} \underline{\varphi} \rightarrow P^{0} \otimes_{S} A .
$$

Taking its cokernel gives

$$
M[1]=\operatorname{coker}(i)=\left(P^{0} \otimes_{S} A\right) / \operatorname{ker} \underline{\varphi} \cong\left(P^{0} \otimes_{S} A\right) / \operatorname{im} \underline{\psi}=\operatorname{coker} \underline{\psi},
$$

which is also maximal Cohen-Macaulay, being the image of the switched matrix factorization $(\psi, \varphi)$ under Eisenbud's equivalence.
5.2.5. Correspondence of canonical forms. Orientation-reversing of a loop with a local system, switching two factors of a matrix factorization, and the shift of a maximal Cohen-Macaulay modules can all be given explicitly in terms of loop/band data.

- In $\operatorname{Fuk}(\Sigma)$, let $(L, E, \nabla):=\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ be the loop with a local system corresponding to a loop datum $\left(w^{\prime}, \eta, \rho\right)$. Its orientation-reverse is given by $\left(J(L), \kappa^{*} E, \kappa^{*} \nabla\right)$. Recall that the free homotopy class of the loop $L\left(w^{\prime}\right)$ corresponding to the given normal loop word $w^{\prime}=\left(l_{1}^{\prime}, m_{1}^{\prime}, n_{1}^{\prime}, \ldots, l_{\tau}^{\prime}, m_{\tau}^{\prime}, n_{\tau}^{\prime}\right) \in$ $\mathbb{Z}^{3 \tau}$ is given by

$$
\left[L\left(w^{\prime}\right)\right]=\left[\alpha^{l_{1}^{\prime}} \beta^{m_{1}^{\prime}} \gamma^{n_{1}^{\prime}} \ldots \alpha^{l_{\tau}^{\prime}} \beta^{m_{\tau}^{\prime}} \gamma^{n_{\tau}^{\prime}}\right],
$$

where $\alpha, \beta, \gamma$ are generators of $\pi_{1}(\Sigma)$ (Figure 8a). The free homotopy class of the orientationreversed loop $J\left(L\left(w^{\prime}\right)\right)$ is

$$
\begin{aligned}
{\left[J\left(L\left(w^{\prime}\right)\right)\right] } & =\left[\gamma^{-n_{\tau}^{\prime}} \beta^{-m_{\tau}^{\prime}} \alpha^{-l_{\tau}^{\prime}} \cdots \gamma^{-n_{1}^{\prime}} \beta^{-m_{1}^{\prime}} \alpha^{-l_{1}^{\prime}}\right] . \\
& =\left[\alpha^{-l_{1}^{\prime}} \beta^{0} \gamma^{-n_{\tau}^{\prime}} \alpha^{0} \beta^{-m_{\tau}^{\prime}} \gamma^{0} \alpha^{-l_{\tau}^{\prime}} \beta^{0} \cdots \gamma^{-n_{1}^{\prime}} \alpha^{0} \beta^{-m_{1}^{\prime}} \gamma^{0}\right] .
\end{aligned}
$$

Define a new normal loop word $w^{\prime}[1]$, the reverse of $w^{\prime}$, as the normal form of the loop word ${ }^{38}$

$$
\begin{equation*}
\left(-l_{1}^{\prime}, 0,-n_{\tau}^{\prime}, 0,-m_{\tau}^{\prime}, 0,-l_{\tau}^{\prime}, 0, \ldots,-n_{1}^{\prime}, 0,-m_{1}^{\prime}, 0\right) \in \mathbb{Z}^{6 \tau} \tag{5.19}
\end{equation*}
$$

then two loops $J\left(L\left(w^{\prime}\right)\right)$ and $L\left(w^{\prime}[1]\right)$ are freely homotopic to each other.
The holonomy of $(E, \nabla)$ at some point is represented by a matrix $J_{\rho}(\eta)$ (up to conjugacy). It changes to $J_{\rho}(\eta)^{-1}$ for the pull-back local system ( $\kappa^{*}, \kappa^{*} \nabla$ ).

Thus, the orientation-reversed loop with a local system $\left(J(L), \kappa^{*} E, \kappa^{*} \nabla\right)$ is isomorphic to the canonical form $\mathscr{L}\left(w^{\prime}[1], \eta^{-1}, \rho\right)$, that is, they give isomorphic matrix factorizations in $\underline{\mathrm{MF}}(x y z)$ by Theorem 3.13.

- In MF $(x y z)$, it is just easy to switch two factors of canonical form $\left(\varphi\left(w^{\prime}, \lambda, \rho\right), \psi\left(w^{\prime}, \lambda, \rho\right)\right)$ corresponding to a loop datum $\left(w^{\prime}, \lambda, \rho\right)$, but then $\psi\left(w^{\prime}, \lambda, \rho\right)$ no longer appears in the canonical form. Even worse, it is never obvious how to change it into the canonical form $\varphi\left(\tilde{w}^{\prime}, \tilde{\lambda}, \tilde{\rho}\right)$ for some another loop datum $\left(\tilde{w}^{\prime}, \tilde{\lambda}, \tilde{\rho}\right)$. Example 5.14 shows that the length $3 \tau$ of the word $w^{\prime}$ can be also changed. (In general, we have $\frac{1}{2} \tau \leq \tilde{\tau} \leq 2 \tau$, where $3 \tilde{\tau}$ is the length of $\tilde{w}^{\prime}$.)
- In $\underline{\mathrm{CM}}(A)$ or $\underline{\operatorname{Tri}}(A)$, there is no easy way or formula to compute the shift of modules.

The above discussions say that so far the only way to compute the canonical form of the shift of maximal Cohen-Macaulay modules is to make a detour to use the geometric operation in the Fukaya category. We summarize the procedure as follows:
Proposition 5.12 (Shift algorithm). Let $M(w, \lambda, \mu) \in \underline{\mathrm{CM}}(A)$ be the maximal Cohen-Macaulay module over A corresponding to a band datum $(w, \lambda, \mu)$. Its shift is given by

$$
M(w, \lambda, \mu)[1]=M\left(w[1], \pm \lambda^{-1}, \mu\right)
$$

where the band datum $\left(w[1], \pm \lambda^{-1}, \mu\right)$ is computed in the following manner:
(1) Convert the band datum $(w, \lambda, \mu)$ into a loop datum $\left(w^{\prime}, \eta, \rho\right)$, following Definition 4.11.
(2) Compute the reverse $w^{\prime}[1]$ of the loop word $w^{\prime}$ (i.e. find the normal form of the loop word (5.19)).
(3) Convert the loop datum $\left(w^{\prime}[1], \eta^{-1}, \rho\right)$ again into a band datum $\left(w[1], \pm \lambda^{-1}, \mu\right)$, following Definition 4.10.

We have the following mappings (up to isomorphism) under the diagram (5.18), while two rows are consistent with our main correspondence (1.5):

Example 5.13. The following shows the computation of $w[1]$ from the band word $w$ in Example 4.13:

$$
\begin{aligned}
w & =(6,0,2,-1,0,-3,0,0,5,0,-2,1,-1,3,4) \\
w^{\prime} & =(8,2,3,-1,-1,-4,-1,0,5,0,-2,1,0,4,6) \\
w^{\prime}[1] & =(-8,0,-6,0,-4,0,0,0,-1,0,2,0,0,0,-5,0,0,0,1,0,4,0,1,0,1,0,-3,0,-2,0) \\
& \sim(-6,1,-4,1,-3,-1,0,2,-5,1,0,4,0,1,0,1,0,-2,1,0,1) \\
w[1] & =(-7,1,-5,1,-3,0,0,2,-6,1,-1,4,-1,1,-1,1,0,-2,1,-1,1)
\end{aligned}
$$

[^28]Example 5.14. The following shows the correspondence of loops with a local system $\mathscr{L}((3,-2,2), \eta, 1) \leftrightarrow$ $\mathscr{L}\left((-2,1,-1,0,2,0), \eta^{-1}, 1\right)$, matrix factorizations $\varphi((3,-2,2), \lambda, 1) \leftrightarrow \varphi\left((-2,1,-1,0,2,0),-\lambda^{-1}, 1\right)$, and maximal Cohen-Macaulay modules $M((2,-3,1), \lambda, 1) \leftrightarrow M\left((-2,1,-1,0,2,0),-\lambda^{-1}, 1\right)$ (in $\left.\operatorname{Tri}(A)\right)$ up to isomorphism, where $\lambda=-\eta$. (First two in the bottom row are not presented in the canonical forms.)

Reverse orientation of Switch two factors of loops with a local system $\quad \leftrightarrow$ matrix factorizations $\leftrightarrow$ maximal Cohen-Macaulay modules

5.3. Higher rank/multiplicity and twisted complexes. In this subsection, we first recall the concept of twisted complexes in an $A_{\infty}$-category and related notions, based on [Sei08, Boc21] (\$5.3.1). Then we associate any twisted complex in $\mathrm{MF}_{A_{\infty}}(f)$ an equivalent matrix factorization (\$5.3.2). We derive a formula for extending the localized mirror functor to twisted complexes ( $\$ 5.3 .3$ ). Finally, we show that our canonical objects in MF $(x y z)$ as well as Fuk $(\Sigma)$ of higher rank are isomorphic to twisted complexes of lower rank objects (\$5.3.4, §5.3.5).

### 5.3.1. Twisted complexes and twisted completion.

Definition 5.15. Let $\mathscr{A}$ be a $\mathbb{Z}_{2}$-graded $A_{\infty}$-category over a field $\mathbb{k}$. An abstract twisted complex ${ }^{39}$ in $\mathscr{A}$ is a pair $(\mathscr{L}, \delta)$, which consists of

- $a$ direct sum of shifted objects, which is a formal expression of the form

$$
\mathscr{L}:=\bigoplus_{i=1}^{N} \mathscr{L}_{i}\left[k_{i}\right]
$$

for some $N \in \mathbb{Z}_{\geq 1}, \mathscr{L}_{i} \in \mathrm{Ob}(\mathscr{A})$ and $k_{i} \in \mathbb{Z}_{2}(i \in\{1, \ldots, N\})$,

- a collection of morphisms

$$
\delta:=\left(\delta_{i j} \in \operatorname{hom}_{\mathscr{A}}^{1}\left(\mathscr{L}_{i}, \mathscr{L}_{j}\right)\left[-k_{i}+k_{j}\right]^{40}\right)_{1 \leq i<j \leq N}
$$

satisfying the Maurer-Cartan equation

$$
\begin{equation*}
\mathfrak{m}_{0}^{\delta}(\mathscr{L}):=\sum_{n=1}^{\infty} \mathfrak{m}_{n}(\delta, \ldots, \delta)^{41}=0, \tag{5.20}
\end{equation*}
$$

[^29]where $\mathfrak{m}_{n}(\delta, \ldots, \delta)$ is an element of $\bigoplus_{1 \leq i, j \leq N} \operatorname{hom}_{\mathscr{A}}^{2}\left(\mathscr{L}_{i}, \mathscr{L}_{j}\right)\left[-k_{i}+k_{j}\right]$ with components given by
\[

$$
\begin{equation*}
\left(\mathfrak{m}_{n}(\delta, \ldots, \delta)\right)_{i j}:=\sum_{\substack{1 \leq n \leq j-i \\ i<i_{1}<\cdots<i_{n-1}<j}} \mathfrak{m}_{n}\left(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j}\right) \in \operatorname{hom}_{\mathscr{A}}^{2}\left(\mathscr{L}_{i}, \mathscr{L}_{j}\right)\left[-k_{i}+k_{j}\right] \tag{5.21}
\end{equation*}
$$

\]

Definition 5.16. Given a $\mathbb{Z}_{2}$-graded $A_{\infty}$-category $\mathscr{A}$, its twisted completion $\operatorname{Tw~} \mathscr{A}$ is a $\mathbb{Z}_{2}$-graded $A_{\infty}$ category defined as follows:

- Its objects are the abstract twisted complexes in $\mathscr{A}$,
- The morphism space between $\left(\mathscr{L}_{0}=\bigoplus_{i=1}^{N_{0}} \mathscr{L}_{0 i}\left[k_{0 i}\right], \delta_{0}\right)$ and $\left(\mathscr{L}_{1}=\bigoplus_{i=1}^{N_{1}} \mathscr{L}_{1 i}\left[k_{1 i}\right], \delta_{1}\right)$ is

$$
\operatorname{hom}_{\operatorname{Tw} \mathscr{A}}^{\cdot}\left(\bigoplus_{i=1}^{N_{0}} \mathscr{L}_{0 i}\left[k_{0 i}\right], \bigoplus_{j=1}^{N_{1}} \mathscr{L}_{1 j}\left[k_{1 j}\right]\right):=\bigoplus_{i=1}^{N_{0}} \bigoplus_{j=1}^{N_{1}} \operatorname{hom}_{\mathscr{A}}^{\bullet}\left(\mathscr{L}_{0 i}, \mathscr{L}_{1 j}\right)\left[-k_{0 i}+k_{1 j}\right] \quad\left(\bullet \in \mathbb{Z}_{2}\right)
$$

- The $A_{\infty}$-operations $\left\{\mathfrak{m}_{k}^{\mathrm{Tw} \mathscr{A}}\right\}_{k \geq 1}$ are defined as
$\mathfrak{m}_{k}^{\mathrm{Tw} \mathscr{A}}: \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{0}, \delta_{0}\right),\left(\mathscr{L}_{1}, \delta_{1}\right)\right) \otimes \cdots \otimes \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{k-1}, \delta_{k-1}\right),\left(\mathscr{L}_{k}, \delta_{k}\right)\right) \rightarrow \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{0}, \delta_{0}\right),\left(\mathscr{L}_{k}, \delta_{k}\right)\right)$,
$\left(f_{1}, \ldots, f_{k}\right) \mapsto \mathfrak{m}_{k}^{\delta_{0}, \ldots, \delta_{k}}\left(f_{1}, \ldots, f_{k}\right):=\sum_{m_{0}, \ldots, m_{k} \geq 0} \mathfrak{m}_{k+m_{0}+\cdots+m_{k}}^{\mathscr{A}}(\underbrace{\delta_{0}, \ldots, \delta_{0}}_{m_{0}}, f_{1}, \underbrace{\delta_{1}, \ldots, \delta_{1}}_{m_{1}}, f_{2}, \ldots, f_{k}, \underbrace{\delta_{k}, \ldots, \delta_{k}}_{m_{k}})^{42}$.
for $f_{i} \in \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{i-1}, \delta_{i-1}\right),\left(\mathscr{L}_{i}, \delta_{i}\right)\right)(i \in\{1, \ldots, k\})$.
It is a triangulated $A_{\infty}$-category, and its cohomological category $H^{0}(\mathrm{Tw} \mathscr{A})$ becomes a triangulated category in the classical sense ([Sei08, §I.3]).

Note that there is a natural embedding $\mathscr{A} \hookrightarrow \operatorname{Tw\mathscr {A}\text {of}A_{\infty }\text {-categoriessendingeachobject}\mathscr {L}\in \operatorname {Ob}(\mathscr {A})~}$ to the trivial abstract twisted complex ( $\mathscr{L}[0], 0)$.

Taking the twisted completion of $A_{\infty}$-categories is functorial in the following sense:
Proposition 5.17. An $A_{\infty}$-functor $\mathscr{F}:=\left\{\mathscr{F}_{k}\right\}_{k \geq 0}: \mathscr{A} \rightarrow \mathscr{B}$ between $A_{\infty}$-categories induces an $A_{\infty}$-functor $\operatorname{Tw} \mathscr{F}:=\left\{(\mathrm{Tw} \mathscr{F})_{k}\right\}_{k \geq 0}: \operatorname{Tw} \mathscr{A} \rightarrow \operatorname{Tw} \mathscr{B}$ between their twisted completions defined as follows:

- An abstract twisted complex $\left(\bigoplus_{i=1}^{N} \mathscr{L}_{i}\left[k_{i}\right], \delta\right)$ in $\mathscr{A}$ is mapped to the abstract twisted complex in $\mathscr{B}$ given by

$$
\left(\bigoplus_{i=1}^{N} \mathscr{F}_{0}\left(\mathscr{L}_{i}\right)\left[k_{i}\right], \sum_{n=1}^{\infty} \mathscr{F}_{n}(\delta, \ldots, \delta)\right)
$$

where $\mathscr{F}_{n}(\delta, \ldots, \delta)$ is an element of $\bigoplus_{1 \leq i, j \leq N} \operatorname{hom}_{\mathscr{B}}^{1}\left(\mathscr{F}_{0}\left(\mathscr{L}_{i}\right), \mathscr{F}_{0}\left(\mathscr{L}_{j}\right)\right)\left[-k_{i}+k_{j}\right]$ with components

$$
\left(\mathscr{F}_{n}(\delta, \ldots, \delta)\right)_{i j}:=\sum_{\substack{1 \leq n \leq j-i \\ i<i_{1}<\cdots<i_{n-1}<j}} \mathscr{F}_{n}\left(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j}\right) \in \operatorname{hom}_{\mathscr{B}}^{1}\left(\mathscr{F}_{0}\left(\mathscr{L}_{i}\right), \mathscr{F}_{0}\left(\mathscr{L}_{j}\right)\right)\left[-k_{i}+k_{j}\right]
$$

- Higher components $\left\{(\mathrm{Tw} \mathscr{F})_{k}\right\}_{k \geq 1}$ are given by

$$
\begin{aligned}
&(\operatorname{Tw} \mathscr{F})_{k}: \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{0}, \delta_{0}\right),\left(\mathscr{L}_{1}, \delta_{1}\right)\right) \otimes \cdots \otimes \operatorname{hom}_{\mathrm{Tw} \mathscr{A}}\left(\left(\mathscr{L}_{k-1}, \delta_{k-1}\right),\left(\mathscr{L}_{k}, \delta_{k}\right)\right) \\
& \rightarrow \operatorname{hom}_{\mathrm{Tw} \mathscr{B}}\left(\left(\operatorname{Tw} \mathscr{F}_{0}\left(\left(\mathscr{L}_{0}, \delta_{0}\right)\right),(\operatorname{Tw} \mathscr{F})_{0}\left(\left(\mathscr{L}_{k}, \delta_{k}\right)\right)\right),\right. \\
&\left(f_{1}, \ldots, f_{k}\right) \mapsto \sum_{m_{0}, \ldots, m_{k} \geq 0} \mathscr{F}_{k+m_{0}+\cdots+m_{k}}(\underbrace{\delta_{0}, \ldots, \delta_{0}}_{m_{0}}, f_{1}, \underbrace{\delta_{1}, \ldots, \delta_{1}}_{m_{1}}, f_{2}, \ldots, f_{k}, \underbrace{\delta_{k}, \ldots, \delta_{k}}_{m_{k}}) .
\end{aligned}
$$

The induced $A_{\infty}$-functor $\operatorname{Tw} \mathscr{F}: \operatorname{Tw} \mathscr{A} \rightarrow \operatorname{Tw} \mathscr{B}$ also boils down to an exact functor $H^{0}(\operatorname{Tw} \mathscr{F}): H^{0}(\operatorname{Tw} \mathscr{A}) \rightarrow$ $H^{0}(\mathrm{Tw} \mathscr{B})$ between classical triangulated categories.

[^30]5.3.2. Twisted complexes of matrix factorizations. Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, and $f \in S$ its nonzero element. We will demonstrate that the $A_{\infty}$-category of matrix factorizations $\mathrm{MF}_{A_{\infty}}(f)$ has an intrinsic notion of twisted complexes, by constructing them as actual objects in it.

In $\S 5.2$.2, we already defined the shift functor $[1]: \mathrm{MF}_{A_{\infty}}(f) \rightarrow \mathrm{MF}_{A_{\infty}}(f)$, which simply switches the position of two matrices in a given matrix factorization. More precisely, given a matrix factorization $P^{0} \underset{\psi}{\varphi} P^{1}$, we define its $k$-shift $\left(k \in \mathbb{Z}_{2}\right)$ as $P[k]^{0} \underset{\psi[k]}{\stackrel{\varphi[k]}{\leftrightarrows}} P[k]^{1}$, where $P[k]^{i}:=P^{i+k}$ and

$$
(\varphi, \psi)[k]:=(\varphi[k], \psi[k]):= \begin{cases}(\varphi, \psi) & \text { if } k=0, \\ (\psi, \varphi) & \text { if } k=1 .\end{cases}
$$

Now we associate any abstract twisted complex given in Definition 5.15 an object in $\mathrm{MF}_{A_{\infty}}(f)$. Suppose that we have finitely many shifted matrix factorizations $P_{i}\left[k_{i}\right]^{0} \underset{\psi_{i}\left[k_{i}\right]}{\stackrel{\varphi_{i}\left[k_{i}\right]}{\leftrightarrows}} P_{i}\left[k_{i}\right]^{1} \quad\left(N \in \mathbb{Z}_{\geq 1}, i \in\{1, \ldots, N\}\right)$ and morphisms between them

$$
\left(\gamma_{i j}, \delta_{i j}\right) \in \operatorname{hom}^{1}\left(\left(\varphi_{j}, \psi_{j}\right),\left(\varphi_{i}, \psi_{i}\right)\right)\left[-k_{j}+k_{i}\right]=\operatorname{Hom}_{S}\left(P_{j}\left[k_{j}\right]^{0}, P_{i}\left[k_{i}\right]^{1}\right) \times \operatorname{Hom}_{S}\left(P_{j}\left[k_{j}\right]^{1}, P_{i}\left[k_{i}\right]^{0}\right)
$$

for $1 \leq i<j \leq N$, which form the following left diagram (not necessarily commutative):

We can arrange them into the block matrix form as follows:

$$
\begin{aligned}
& (\varphi, \psi):=\left(\bigoplus_{i=1}^{N} \varphi_{i}\left[k_{i}\right], \bigoplus_{i=1}^{N} \psi_{i}\left[k_{i}\right]\right)
\end{aligned}
$$

$$
\begin{aligned}
& (\gamma, \delta):=\left(\left(\gamma_{i j}, \delta_{i j}\right) \in \operatorname{hom}^{1}\left(\left(\varphi_{j}, \psi_{j}\right),\left(\varphi_{i}, \psi_{i}\right)\right)\left[-k_{j}+k_{i}\right]\right)_{1 \leq i<j \leq N} \\
& =\left(\begin{array}{c}
\begin{array}{cccc}
P_{1}\left[k_{1}\right]^{0} & P_{2}\left[k_{2}\right]^{0} & \cdots & P_{N}\left[k_{N}\right]^{0}
\end{array} \\
P_{1}\left[k_{1}\right]^{1} \\
P_{2}\left[k_{2}\right]^{1} \\
\vdots \\
P_{N}\left[k_{N}\right]^{1}
\end{array}\left(\begin{array}{cccc}
0 & \gamma_{12} & \cdots & \gamma_{1 N} \\
0 & 0 & \ddots & \vdots \\
\vdots & \vdots & \ddots & \gamma_{(N-1) N} \\
0 & 0 & \cdots & 0
\end{array}\right), \begin{array}{c}
\left.P_{1}\left[k_{1}\right]_{1}\right]^{1} \\
P_{2}\left[k_{2}\right]^{0}\left[k_{2}\right]^{1} \\
\vdots \\
P_{N}\left[k_{N}\right]^{0}
\end{array}\left(\begin{array}{ccc}
0 & P_{N}\left[k_{N}\right]^{1} \\
0 & 0 & \ddots \\
\hline
\end{array}\right)\right.
\end{aligned}
$$

Observe that $(\varphi, \psi)$ forms a new matrix factorization $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$, where $P^{\bullet}:=\oplus_{i=1}^{N} P_{i}\left[k_{i}\right]^{\bullet}\left(\bullet \in \mathbb{Z}_{2}\right)$, and $(\gamma, \delta)$ defines a morphism $(\gamma, \delta) \in \operatorname{hom}^{1}((\varphi, \psi),(\varphi, \psi))$, which form the right diagram in (5.22) (not necessarily commutative).

The $A_{\infty}$-operations between them are computed as

$$
\mathfrak{m}_{1}((\gamma, \delta))=(\psi \gamma+\delta \varphi, \varphi \delta+\gamma \psi), \quad \mathfrak{m}_{2}((\gamma, \delta),(\gamma, \delta))=(\delta \gamma, \gamma \delta) \quad \text { and } \quad \mathfrak{m}_{k \geq 3}((\delta, \gamma), \ldots,(\delta, \gamma))=0
$$

following (A.10). It is easy to check that their components are also compatible with the abstract definition in (5.21). Therefore, the Maurer-Cartan equation (5.20) is phrased as

$$
\begin{equation*}
0=\mathfrak{m}_{1}((\gamma, \delta))+\mathfrak{m}_{2}((\gamma, \delta),(\gamma, \delta))=(\psi \gamma+\delta \varphi+\delta \gamma, \varphi \delta+\gamma \psi+\gamma \delta) \tag{5.23}
\end{equation*}
$$

and an abstract twisted complex in $\mathrm{MF}_{A_{\infty}}(f)$ is equivalent to a pair $((\varphi, \psi),(\gamma, \delta))$ satisfying (5.23) ${ }^{43}$.
We define the rigid twisted complex in $\mathrm{MF}_{A_{\infty}}(f)$ associated to such a pair as $P^{0} \underset{\psi+\delta}{\stackrel{\varphi+\gamma}{\rightleftarrows}} P^{1}$. More precisely, it is given as

$$
\begin{aligned}
& \operatorname{Tw}((\varphi, \psi),(\gamma, \delta)):=(\varphi+\gamma, \psi+\delta)
\end{aligned}
$$

It is indeed a matrix factorization of $f$, as a direct consequence of the equation (5.23).
Proposition 5.18. The embedding $i: \operatorname{MF}_{A_{\infty}}(f) \hookrightarrow \operatorname{Tw}_{M_{\infty}}(f)$ of $A_{\infty}$-categories is a quasi-equivalence.
Proof. The natural embedding $i$ sends each matrix factorization $(\varphi, \psi)$ to the abstract twisted complex $((\varphi, \psi)[0], 0)$. The morphism space between such two complexes $\left(\left(\varphi_{0}, \psi_{0}\right)[0], 0\right)$ and $\left(\left(\varphi_{1}, \psi_{1}\right)[0], 0\right)$ is identified with the original hom space $\operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{1}, \psi_{1}\right),\left(\varphi_{0}, \psi_{0}\right)\right)$. On the morphism level, the first component $i_{1}$ is the identity map on that space, and the higher components $i_{k \geq 2}$ are defined to be zero.

We define its quasi-inverse $\pi: \operatorname{TwMF}_{A_{\infty}}(f) \rightarrow \mathrm{MF}_{A_{\infty}}(f)$ by sending each abstract twisted complex

$$
\left((\varphi, \psi):=\left(\bigoplus_{i=1}^{N} \varphi_{i}\left[k_{i}\right], \bigoplus_{i=1}^{N} \psi_{i}\left[k_{i}\right]\right),(\gamma, \delta):=\left(\left(\gamma_{i j}, \delta_{i j}\right) \in \operatorname{hom}^{1}\left(\left(\varphi_{j}, \psi_{j}\right),\left(\varphi_{i}, \psi_{i}\right)\right)\left[-k_{j}+k_{i}\right]\right)_{1 \leq i<j \leq N}\right)
$$

to the rigid twisted complex $\operatorname{Tw}((\varphi, \psi),(\gamma, \delta))$. Given two abstract twisted complexes $\left(\left(\varphi_{0}, \psi_{0}\right),\left(\gamma_{0}, \delta_{0}\right)\right)$ and $\left(\left(\varphi_{1}, \psi_{1}\right),\left(\gamma_{1}, \delta_{1}\right)\right)$, their hom space

$$
\begin{aligned}
& \operatorname{hom}_{\operatorname{TwMF}_{A_{\infty}}(f)}^{\bullet}\left(\left(\left(\varphi_{0}, \psi_{0}\right),\left(\gamma_{0}, \delta_{0}\right)\right),\left(\left(\varphi_{1}, \psi_{1}\right),\left(\gamma_{1}, \delta_{1}\right)\right)\right)=\bigoplus_{i=1}^{N_{0}} \bigoplus_{j=1}^{N_{1}} \operatorname{hom} \\
&=\bigoplus_{i=1}^{N_{0}} \bigoplus_{j=1}^{N_{1}}\left(\left(\varphi_{1 j}, \psi_{1 j}\right),\left(\varphi_{0 i}, \psi_{0 i}\right)\right)\left[-k_{0 i}+k_{1 j}\right]
\end{aligned}
$$

is naturally identified with the hom space between rigid twisted complexes
$\operatorname{hom}_{\mathrm{MF}_{A_{\infty}}(f)}\left(\operatorname{Tw}\left(\left(\varphi_{0}, \psi_{0}\right)\left(\gamma_{0}, \delta_{0}\right)\right), \operatorname{Tw}\left(\left(\varphi_{1}, \psi_{1}\right),\left(\gamma_{1}, \delta_{1}\right)\right)\right)$

$$
=\operatorname{Hom}_{S}\left(\bigoplus_{i=1}^{N_{1}} P_{1 j}\left[k_{1 j}\right]^{0}, \bigoplus_{j=1}^{N_{0}} P_{0 i}\left[k_{0 i}\right]^{\bullet}\right) \times \operatorname{Hom}_{S}\left(\bigoplus_{i=1}^{N_{1}} P_{1 j}\left[k_{1 j}\right]^{1}, \bigoplus_{j=1}^{N_{0}} P_{0 i}\left[k_{0 i}\right]^{1+\bullet}\right) \quad\left(\bullet \in \mathbb{Z}_{2}\right) .
$$

Therefore, we can define the first component $\pi_{1}$ of the $A_{\infty}$-functor $\pi$ as the identity map on that space, and the higher components $\pi_{k \geq 2}$ as zero. It is straightforward to check that $i$ and $\pi$ are indeed quasiinverse to each other.

[^31]5.3.3. Twisted complexes under localized mirror functor. Combining above discussions, we derive a formula for extending the localized mirror functor to twisted complexes.

Proposition 5.19. The image of an abstract twisted complex $\left(\mathscr{L}:=\bigoplus_{i=1}^{N} \mathscr{L}_{i}, \delta\right)$ in $W$ Fuk $(\Sigma)$ under the induced localized mirror functor $\operatorname{Tw} \mathscr{F}^{\mathbb{L}}: \operatorname{Tw} W \operatorname{Fuk}(\Sigma) \rightarrow \mathrm{MF}_{A_{\infty}}(x y z)$ is the rigid twisted complex

$$
\bigoplus_{i=1}^{N} \operatorname{hom}^{0}\left(\mathscr{L}_{i}, \mathbb{L}\right) \stackrel{\Phi^{\mathbb{L}}((\mathscr{L}, \delta))=\mathfrak{m}_{1}^{\delta, b}}{\stackrel{\Psi^{\llcorner }((\mathscr{L}, \delta))=\mathfrak{m}_{1}^{\delta, b}}{\rightleftarrows}} \bigoplus_{j=1}^{N} \operatorname{hom}^{1}\left(\mathscr{L}_{j}, \mathbb{L}\right),
$$

with components given by
(5.25)

$$
\left(\mathfrak{m}_{1}^{\delta, b}\right)_{i j}:=\sum_{\substack{0 \leq n \leq j-i \\ i<i_{1}<\cdots<i_{n-1}<j}} \sum_{k=0}^{\infty} \mathfrak{m}_{n+1+k}(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j},-, \underbrace{b, \ldots, b}_{k})^{44}: \operatorname{hom}^{\bullet}\left(\mathscr{L}_{j}, \mathbb{L}\right) \rightarrow \operatorname{hom}^{\bullet+1}\left(\mathscr{L}_{i}, \mathbb{L}\right)
$$

for $1 \leq i \leq j \leq N$ and $\bullet \in \mathbb{Z}_{2}$.
In particular, its diagonal components are given by the original mirror $\left(\Phi^{\mathbb{L}}\left(\mathscr{L}_{i}\right), \Psi^{\natural}\left(\mathscr{L}_{i}\right)\right)$ (2.3) of $\mathscr{L}_{i}$, and its strictly upper triangular components are determined by inserting ( $j-i$ )-times of the twisting $\delta$.

Proof. Recall from Proposition 5.17 that the induced functor $\operatorname{Tw} \mathscr{F}^{\mathbb{L}}: \operatorname{Tw} W \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{TwMF} A_{A_{\infty}}(x y z)$ maps the given abstract twisted complex to the abstract twisted complex in $\mathrm{MF}_{A_{\infty}}(x y z)$ given by

$$
\begin{equation*}
\left(\bigoplus_{i=1}^{N} \mathscr{F}_{0}^{\mathrm{L}}\left(\mathscr{L}_{i}\right), \sum_{n=1}^{\infty} \mathscr{F}_{n}^{\mathrm{\complement}}(\delta, \ldots, \delta)\right), \tag{5.26}
\end{equation*}
$$

where $\mathscr{F}_{n}^{\mathbb{L}}(\delta, \ldots, \delta)$ is an element of $\bigoplus_{1 \leq i, j \leq N} \operatorname{hom}_{\mathrm{MF}_{A_{\infty}}(x y z)}^{1}\left(\mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{i}\right), \mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{j}\right)\right)$ with components

$$
\left(\mathscr{F}_{n}^{\mathbb{L}}(\delta, \ldots, \delta)\right)_{i j}:=\sum_{\substack{1 \leq n \leq j-i \\ i<i_{1}<\cdots<i_{n-1}<j}} \mathscr{F}_{n}^{\mathbb{L}}\left(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j}\right) \in \operatorname{hom}_{\mathrm{MF}_{A_{\infty}}(x y z)}^{1}\left(\mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{i}\right), \mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{j}\right)\right) .
$$

The definition of $\mathscr{F}^{\mathbb{L}}$ in Theorem 2.3 identifies those with

$$
\begin{aligned}
\mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{i}\right) & =\mathfrak{m}_{1}^{0, b}: \operatorname{hom}^{\bullet}\left(\mathscr{L}_{i}, \mathbb{L}\right) \rightarrow \operatorname{hom}^{\bullet+1}\left(\mathscr{L}_{i}, \mathbb{L}\right) \quad \text { and } \\
\mathscr{F}_{n}^{\mathbb{L}}\left(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j}\right) & =\mathfrak{m}_{n+1}^{0, \ldots, 0, b}\left(\delta_{i i_{1}}, \delta_{i_{1} i_{2}}, \ldots, \delta_{i_{n-1} j},-\right): \operatorname{hom}^{\bullet}\left(\mathscr{L}_{j}, \mathbb{L}\right) \rightarrow \operatorname{hom}^{\bullet+1}\left(\mathscr{L}_{i}, \mathbb{L}\right) .
\end{aligned}
$$

Finally, under (5.24), the rigid twist complex in $\mathrm{MF}_{A_{\infty}}(x y z)$ corresponding to (5.26) is given by

$$
\bigoplus_{i=1}^{N} \mathscr{F}_{0}^{\mathbb{L}}\left(\mathscr{L}_{i}\right)+\sum_{n=1}^{\infty} \mathscr{F}_{n}^{\mathbb{\unrhd}}(\delta, \ldots, \delta)=\mathfrak{m}_{1}^{0, b}(-)+\sum_{n=1}^{\infty} \mathfrak{m}_{n+1}^{0, \ldots, 0, b}(\underbrace{\delta, \ldots, \delta}_{n},-)=\sum_{n=0}^{\infty} \mathfrak{m}_{n+1}^{0, \ldots, 0, b}(\underbrace{\delta, \ldots, \delta}_{n},-),
$$

which is the map $\mathfrak{m}_{1}^{\delta, b}: \bigoplus_{i=1}^{N} \operatorname{hom}^{\bullet}\left(\mathscr{L}_{i}, \mathbb{L}\right) \rightarrow \bigoplus_{i=1}^{N} \operatorname{hom}^{\bullet+1}\left(\mathscr{L}_{i}, \mathbb{L}\right)$ with the same components as given in (5.25).

Remark 5.20. One can also directly define the localized mirror functor $\mathscr{F}^{\mathbb{L}}: \operatorname{Tw} W \operatorname{Fuk}(\Sigma) \rightarrow \operatorname{MF}_{A_{\infty}}(x y z)$ based on the above formula, not passing through Proposition 5.17. For instance, the identity $\left(\mathfrak{m}_{1}^{\delta, b}\right)^{2}=W^{\mathbb{L}}$. $\mathrm{id}_{\mathrm{hom}(\mathscr{L}, \mathbb{L})}$ for any twisted complex (as well as bounding cochain) $\left(\mathscr{L}:=\bigoplus_{i=1}^{N} \mathscr{L}_{i}, \delta\right)$ in $W$ Fuk ( $\Sigma$ ) follows from the same line of proof as in Lemma 2.2. Then one can extend the definition given in Theorem 2.3 by using $\mathfrak{m}_{1}^{\delta, b}$ and $\mathfrak{m}_{k+1}^{\delta, \ldots, \delta, b}$ instead of $\mathfrak{m}_{1}^{0, b}$ and $\mathfrak{m}_{k+1}^{0, \ldots, 0, b}$, respectively.

[^32]5.3.4. Canonical form of matrix factorizations viewed as twisted complexes. Now we show that our canonical form of matrix factorizations of $x y z$ defined in Definition 3.16 with a higher rank is expressed as a twisted complex consisting of several copies of the corresponding object with rank 1.

Proposition 5.21. The canonical form $\left(\varphi\left(w^{\prime}, \lambda, \rho\right), \psi\left(w^{\prime}, \lambda, \rho\right)\right)$ of matrix factorizations of xyz corresponding to a non-degenerate loop datum is quasi-isomorphic in $\mathrm{MF}_{A_{\infty}}(x y z)$ (and isomorphic in $\mathrm{MF}(x y z)$ ) to the rigid twisted complex

$$
\operatorname{Tw}\left(\left(\varphi\left(w^{\prime}, \lambda, 1\right)^{\oplus \rho}, \psi\left(w^{\prime}, \lambda, 1\right)^{\oplus \rho}\right),(\gamma, \delta)\right)
$$

for some morphisms

$$
(\gamma, \delta):=\left(\left(\gamma_{i j}, \delta_{i j}\right) \in \operatorname{hom}^{1}\left(\left(\varphi\left(w^{\prime}, \lambda, 1\right), \psi\left(w^{\prime}, \lambda, 1\right)\right),\left(\varphi\left(w^{\prime}, \lambda, 1\right), \psi\left(w^{\prime}, \lambda, 1\right)\right)\right)\right)_{1 \leq i<j \leq \rho} .
$$

Proof. Recall from (3.2) that the canonical form of matrix factorizations of $x y z$ corresponding to a nondegenerate loop datum $\left(w^{\prime}, \lambda, \rho\right)$ is written as

$$
\begin{aligned}
\varphi\left(w^{\prime}, \lambda, \rho\right) & =\varphi\left(w^{\prime}, 0,1\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)-x^{-l_{1}^{\prime}} J_{3 \tau}^{3 \tau-1} \otimes J_{\rho}(\lambda)^{-1} \\
& =\varphi\left(w^{\prime}, \lambda, 1\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1} \otimes\left(J_{\rho}(\lambda)-\lambda I_{\rho}\right)-x^{-l_{1}^{\prime}} J_{3 \tau}^{3 \tau-1} \otimes\left(J_{\rho}(\lambda)^{-1}-\lambda^{-1} I_{\rho}\right) \\
& =\varphi\left(w^{\prime}, \lambda, 1\right) \otimes I_{\rho}-x^{l_{1}^{\prime}-1} K_{3 \tau}^{3 \tau-1} \otimes J_{\rho}-x^{-l_{1}^{\prime}} \int_{3 \tau}^{3 \tau-1} \otimes\left(-\lambda^{-2} J_{\rho}+\lambda^{-3} J_{\rho}^{2}-\cdots-(-\lambda)^{-\rho} J_{\rho}^{\rho-1}\right) .
\end{aligned}
$$

Using Lemma 3.20, we know that it is similar to

$$
I_{\rho} \otimes \varphi\left(w^{\prime}, \lambda, 1\right)-x^{l_{1}^{\prime}-1} J_{\rho} \otimes K_{3 \tau}^{3 \tau-1}+x^{-l_{1}^{\prime}}\left(\lambda^{-2} J_{\rho}-\lambda^{-3} J_{\rho}^{2}+\cdots+(-\lambda)^{-\rho} J_{\rho}^{\rho-1}\right) \otimes J_{3 \tau}^{3 \tau-1},
$$

which is expressed as

in the case of $l_{1}^{\prime} \geq 1$ and $l_{1}^{\prime} \leq 0$, respectively. This observation together with the definition (5.24) of rigid twisted complexes prove the proposition.
5.3.5. Canonical form of loops with a local system viewed as twisted complexes. In this subsection, we will realize (5.27) as the image of an abstract twisted complex in Fuk ( $\Sigma$ ) under the induced localized mirror functor $\operatorname{Tw} \mathscr{F}^{\mathbb{L}}: \operatorname{Tw} W \operatorname{Fuk}(\Sigma) \rightarrow \mathrm{MF}_{A_{\infty}}(x y z)$, as a direct consequence of Proposition 5.19.

We first take the loop with a rank 1 local system $\mathscr{L}:=(L, E, \nabla):=\mathscr{L}\left(w^{\prime}, \eta, 1\right)$, where $\left(w^{\prime}, \eta, 1\right)$ is the nondegenerate loop datum corresponding to $\left(w^{\prime}, \lambda, 1\right)$ under Theorem 3.17. Its underlying loop $L=L\left(w^{\prime}\right)$ has a marked point $o_{L} \in \chi^{1}(L, L)$ that we assume is located nearby the point $\star$ as in Figure 20. We denote by $o:=\left.\operatorname{id}\right|_{o_{L}} \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E\right|_{o_{L}},\left.E\right|_{o_{L}}\right) \subseteq \operatorname{hom}^{1}(\mathscr{L}, \mathscr{L})$.

Consider the abstract twisted complex

$$
\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)^{\oplus \rho}, \delta=\left(\begin{array}{cccccc}
0 & O_{12} & 0 & \cdots & 0  \tag{5.28}\\
0 & 0 & 0_{23} & \cdots & 0 \\
0 & 0 & 0 & \ddots & \vdots \\
\vdots & \vdots & \vdots & \ddots & o_{(N-1) N} \\
0 & 0 & 0 & \cdots & 0
\end{array}\right)\right)
$$

that consists of the direct sum of $\rho$-copies of $\mathscr{L}_{i}:=\mathscr{L}=\mathscr{L}\left(w^{\prime}, \eta, 1\right)(i \in\{1, \ldots, \rho\})$ and a collection of morphisms

$$
\delta:=\left(\delta_{i j} \in \operatorname{hom}^{1}\left(\mathscr{L}_{i}, \mathscr{L}_{j}\right)\right)_{1 \leq i<j \leq \rho}
$$

where $\delta_{i j}$ is nontrivial only for $j=i+1$, in which case it is $o_{i(i+1)}:=o \in \operatorname{hom}^{1}\left(\mathscr{L}_{i}, \mathscr{L}_{i+1}\right)=\operatorname{hom}^{1}(\mathscr{L}, \mathscr{L})$.

Proposition 5.22. The mirror image of the abstract twisted complex (5.28) in $\mathrm{Fuk}(\Sigma)$ is quasi-isomorphic in $\mathrm{MF}_{A_{\infty}}(x y z)$ (and isomorphic in $\mathrm{MF}(x y z)$ ) to the rigid twisted complex

$$
J_{\rho}(\eta)^{-1} \otimes \varphi_{-1}+I_{\rho} \otimes \varphi_{0}+J_{\rho}(\eta) \otimes \varphi_{1}=\left(\begin{array}{ccccc}
\Phi^{\mathbb{L}}\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right) & \varphi_{1}-\eta^{-2} \varphi_{-1} & \eta^{-3} \varphi_{-1} & \cdots & -(-\eta)^{-\rho} \varphi_{-1} \\
0 & \Phi^{\llcorner }\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right) & \varphi_{1}-\eta^{-2} \varphi_{-1} & \cdots & -(-\eta)^{-\rho+1} \varphi_{-1} \\
0 & 0 & \Phi^{\mathbb{L}}\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right) & \ddots & \vdots \\
\vdots & \vdots & \vdots & \ddots & \varphi_{1}-\eta^{-2} \varphi_{-1} \\
0 & 0 & 0 & \cdots & \Phi^{\llcorner }\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right)
\end{array}\right)_{\rho 3 \tau \times \rho 3 \tau}
$$

where $\Phi^{\mathbb{L}}\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right)=\eta^{-1} \varphi_{-1}+\varphi_{0}+\eta \varphi_{1}$ for $\varphi_{-1}, \varphi_{0}, \varphi_{1} \in \mathbb{C}[[x, y, z]]^{3 \tau \times 3 \tau}$ (from Proposition 3.15).
In particular, it is also isomorphic to the rigid twisted complex (5.27) given in Proposition 5.21.

Proof. According to Proposition 5.19, the mirror image is given in the form

$$
\operatorname{hom}^{0}(\mathscr{L}, \mathbb{L})^{\oplus \rho} \frac{\Phi^{\mathbb{L}}\left(\left(\mathscr{L}^{\oplus \rho}, \delta\right)\right)=\mathfrak{m}_{1}^{\delta, b}}{\rightleftarrows} \underset{\Psi^{\mathbb{L}}\left(\left(\mathscr{L}^{\oplus \rho}, \delta\right)\right)=\mathfrak{m}_{1}^{\delta, b}}{\rightleftarrows} \operatorname{hom}^{1}(\mathscr{L}, \mathbb{L})^{\oplus \rho} .
$$

Each diagonal component of $\Phi^{\complement}\left(\left(\mathscr{L}^{\oplus \rho}, \delta\right)\right)$ is $\Phi^{\complement}(\mathscr{L})$, and strictly upper triangular components are

$$
\begin{equation*}
\left(\mathfrak{m}_{1}^{\delta, b}\right)_{i j}:=\sum_{k=0}^{\infty} \mathfrak{m}_{j-i+1+k}(o_{i(i+1)}, \ldots, o_{(j-1) j},-, \underbrace{b, \ldots, b}_{k}): \operatorname{hom}^{\bullet}\left(\mathscr{L}_{j}, \mathbb{L}\right) \rightarrow \operatorname{hom}^{\bullet+1}\left(\mathscr{L}_{i}, \mathbb{L}\right) \tag{5.29}
\end{equation*}
$$

for $1 \leq i<j \leq N$ and $\bullet \in \mathbb{Z}_{2}$. Note that it depends only on the difference $j-i$, and hence we assume $i=1$ without loss of generality. Substituting $f=\left.f\right|_{p} \in \operatorname{hom}^{0}\left(\mathscr{L}_{j}, \mathbb{L}\right)$ for some $p \in \chi^{0}\left(L_{j}, \mathbb{L}\right)$ into it becomes
$\sum_{\left(x_{1}, X_{1}\right), \ldots,\left(x_{k}, x_{k}\right)} x_{1} \ldots x_{k} \sum_{s \in \chi^{1}\left(L_{1}, \mathbb{L}\right)} \sum_{u \in \mathscr{M}\left(o_{12}, o_{23} \ldots, o_{(j-1) j}, p, X_{1}, \ldots, X_{k}, \bar{s}\right)} \operatorname{sign}(u) \operatorname{hol}_{s}(\partial u)\left(o_{12}, o_{23}, \ldots, o_{(j-1) j}, f, X_{1}, \ldots, X_{k}\right)$, $\epsilon\{(x, X),(y, Y),(z, Z)\}$
following the same procedure as in $\$ 2.2$.
We will associate each element $u$ in the moduli space

$$
\begin{equation*}
\mathscr{M}\left(o_{12}, o_{23}, \ldots, o_{(j-1) j}, p, X_{1}, \ldots, X_{k}, \bar{s}\right) \tag{5.30}
\end{equation*}
$$

with an element $u^{\prime}$ in $\mathscr{M}\left(p, X_{1}, \ldots, X_{k}, \bar{s}\right)$, by considering recursive perturbations of $\rho$-copies of $L_{i}=L=$ $L\left(w^{\prime}\right)(i \in\{1, \ldots, \rho\})$ as described in Figure 20.

Figure 20. Recursive perturbations of a loop $L$

Case i) The boundary orientation of $u$ coincides with the orientations of $L_{i}$ 's. Such a polygon $u$ cannot have angles at more than one of $o_{12}, o_{23}, \ldots, o_{(j-1) j}$ in a consecutive manner because of their arrangement as in Figure 20. Hence it exists only when $j=2$, and it has an angle at $o_{12}$. Ignoring $o_{12}$ and identifying $L_{1}$ and $L_{2}, u$ has an obvious counterpart $u^{\prime}$ in $\mathscr{M}\left(p, X_{1}, \ldots, X_{k}, \bar{s}\right)$ that passes through the point $\star$ and has the
same boundary orientation with $L_{i}$ 's. In other words, such polygons $u$ are identified with the polygons $u^{\prime}$ in $\mathscr{M}\left(p, X_{1}, \ldots, X_{k}, \bar{s}\right)$ such that the holonomy of $\partial u^{\prime}$ contains one $\eta$-factor.

Under the correspondence, it is easily checked that $\operatorname{sign}(u)$ and $\operatorname{sign}\left(u^{\prime}\right)$ are the same, and the holonomy of $\partial u$ and $\partial u^{\prime}$ contain zero and one $\eta$-factor, respectively, because they pass through the point $\star$ 0 and 1 times, respectively. As those polygons $u^{\prime}$ contribute to the factor $\eta \varphi_{1}$ in the decomposition of $\Phi^{\unrhd}\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right)$, their corresponding polygons $u$ contribute $\varphi_{1}$ to the component (5.29) for $j=i+1$.
Case ii) The boundary orientation of $u$ differs from the orientations of $L_{i}$ 's. Such a polygon $u$ now have angles at $o_{12}, o_{23}, \ldots, o_{(j-1) j}$ consecutively as drawn in yellow in Figure 20. Ignoring those angles and all perturbations, $u$ has an obvious counterpart $u^{\prime}$ in $\mathscr{M}\left(p, X_{1}, \ldots, X_{k}, \bar{s}\right)$ that passes through the point $\star$ and has the opposite boundary orientation with $L_{i}$ 's. In other words, such polygons $u$ are identified with the polygons $u^{\prime}$ in $\mathscr{M}\left(p, X_{1}, \ldots, X_{k}, \bar{s}\right)$ such that the holonomy of $\partial u^{\prime}$ contains one $\eta^{-1}$-factor.

Under the correspondence, the quotient of $\operatorname{sign}(u)$ and $\operatorname{sign}\left(u^{\prime}\right)$ is given by $(-1)^{j-i}$, because $u$ have $j-i$ more angles of odd degree that $u^{\prime}$, where its boundary orientation is different from loops. The holonomy of $\partial u$ and $\partial u^{\prime}$ contain one $\eta^{-(j-i+1)}$ and $\eta^{-1}$ factor, respectively, because they pass through the point $\star$ with the opposite orientation $j-i+1$ and 1 times, respectively. As those polygons $u^{\prime}$ contribute to the factor $\eta^{-1} \varphi_{-1}$ in the decomposition of $\Phi^{\unrhd}\left(\mathscr{L}\left(w^{\prime}, \eta, 1\right)\right)$, their corresponding polygons $u$ contribute $-(-\eta)^{-(j-i+1)} \varphi_{-1}$ to the component (5.29).

To summarize, the polygons in Case i) and Case ii) contribute to $J_{\rho}(\eta) \otimes \varphi_{1}$ and $J_{\rho}(\eta)^{-1} \otimes \varphi_{-1}$ part of the given matrix factorization, respectively (while the $I_{\rho} \otimes \varphi_{0}$ part is not relevant to the twisting $o_{i(i+1)}$ 's).

The second statement follows from bases change as done in Theorem 3.17. (One can also use (3.2).)
Remark 5.23. Proposition 5.22 also reveals that the canonical form $\mathscr{L}\left(w^{\prime}, \eta, \rho\right)$ of loops with a local system corresponding to non-degenerate loop data $\left(w^{\prime}, \eta, \rho\right)$ is quasi-isomorphic in $\operatorname{TwFuk}(\Sigma)$ to the abstract twisted complex (5.28), which is made of $\rho$-copies of $\mathscr{L}\left(w^{\prime}, \eta, 1\right)$ and odd-degree morphism o's between them. In fact, it can be also derived from purely Fukaya-categorical discussions, not appealing to homological mirror symmetry. It has been shown in [Bae17, Theorem 5.8] that every higher rank local system over a loop can be realized as an abstract twisted complex of rank 1 local systems, using de Rham version of Fukaya category.

But our specific realization of recursive perturbations as in Figure 20 still suggests how we should perturb underlying loops when we want to work with the perturbation method instead of de Rham version. Especially when inputs of an $A_{\infty}$-operation involve multiple $e_{L}$ 's and $o_{L}$ 's, its definition becomes more tricky and unsymmetric in some sense, which was not fully explained in Remark A.9. Nevertheless, some systematic recursive perturbations can be made so that the $A_{\infty}$-relations remain valid.

This also gives an example where the mapping cone of two loops at their intersection is not quasiisomorphic to their surgery at that point, contrary to the usual situation which has been explained in many places in the literature including [Abo08, Lemma 5.4], [OPS18, Theorem 4.1] and [Boc21, Theorem 6.68]. This happens because two perturbed loops cannot satisfy the minimality condition, as also remarked in [AS21, Lemma 2.25]. We hope our explicit construction of twisted complexes involving $o_{L}$ 's can be extended to realizing mapping cones of arbitrary morphisms in Fukaya category as geometric objects. We will come back to these points in another future work.

## Appendix A. Relevant Categories

A.1. $A_{\infty}$-category. Let us first recall the definition (and convention) of an $A_{\infty}$-category over a field $k$ and related concepts.

Definition A.1. $A \mathbb{Z}_{2}$-graded $A_{\infty}$-category $\mathscr{A}$ over $\mathbb{k}$ consists of a class of objects $\mathrm{Ob}(\mathscr{A})$, a $\mathbb{Z}_{2}$-graded $\mathbb{k}$ vector space $\operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right)=\operatorname{hom}^{0}\left(\mathscr{L}^{0}, \mathscr{L}^{1}\right) \oplus \operatorname{hom}^{1}\left(\mathscr{L}^{0}, \mathscr{L}^{1}\right)$ for $\mathscr{L}_{0}, \mathscr{L}_{1} \in \operatorname{Ob}(\mathscr{A})$, and $A_{\infty}$-operations $\left\{\mathfrak{m}_{k}\right\}_{k \geq 1}$ given by $\mathbb{k}_{k}$-linear maps

$$
\mathfrak{m}_{k}: \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \otimes \cdots \otimes \operatorname{hom}\left(\mathscr{L}_{k-1}, \mathscr{L}_{k}\right) \rightarrow \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{k}\right)
$$

of degree $2-k^{45}$ satisfying $A_{\infty}$-relations

$$
\begin{equation*}
\sum_{0 \leq i<j \leq n}(-1)^{\left|f_{1}\right|+\cdots+\left|f_{i}\right|-i} \mathfrak{m}_{n-j+i+1}\left(f_{1}, \ldots, f_{i}, \mathfrak{m}_{j-i}\left(f_{i+1}, \ldots, f_{j}\right), f_{j+1}, \ldots, f_{n}\right)=0 \tag{A.1}
\end{equation*}
$$

for any fixed $n \in \mathbb{Z}_{\geq 1}$ and morphisms $f_{i} \in \operatorname{hom}^{\bullet}\left(\mathscr{L}_{i-1}, \mathscr{L}_{i}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$.
It is called (strictly) unital if each object $\mathscr{L}$ has $a$ unit $\operatorname{id}_{\mathscr{L}} \in \operatorname{hom}(\mathscr{L}, \mathscr{L})$ satisfying

$$
\begin{equation*}
\mathfrak{m}_{2}\left(\operatorname{id}_{\mathscr{L}}, f\right)=f, \quad \mathfrak{m}_{2}\left(g, \operatorname{id}_{\mathscr{L}}\right)=(-1)^{|g|} g \quad \text { and } \quad \mathfrak{m}_{k}\left(\ldots, \operatorname{id}_{\mathscr{L}}, \ldots\right)=0 \quad \text { if } k \neq 2 \tag{A.2}
\end{equation*}
$$

for any $\mathscr{L}^{\prime} \in \mathrm{Ob}(\mathscr{A}), f \in \operatorname{hom}\left(\mathscr{L}, \mathscr{L}^{\prime}\right)$ and $g \in \operatorname{hom}^{\bullet}\left(\mathscr{L}^{\prime}, \mathscr{L}\right)\left(\bullet \in \mathbb{Z}_{2}\right)$.
Definition A.2. An $A_{\infty}$-functor $\mathscr{F}:=\left\{\mathscr{F}_{k}\right\}_{k \geq 0}$ between two $A_{\infty}$-categories $\mathscr{A}$ and $\mathscr{B}$ consists of a mapping

$$
\mathscr{F}_{0}: \mathrm{Ob}(\mathscr{A}) \rightarrow \mathrm{Ob}(\mathscr{B})
$$

and $\mathbb{k}$-linear maps $(k \geq 1)$

$$
\mathscr{F}_{k}: \operatorname{hom}_{\mathscr{A}}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \otimes \cdots \otimes \operatorname{hom}_{\mathscr{A}}\left(\mathscr{L}_{k-1}, \mathscr{L}_{k}\right) \rightarrow \operatorname{hom}_{\mathscr{B}}\left(\mathscr{F}_{0}\left(\mathscr{L}_{0}\right), \mathscr{F}_{0}\left(\mathscr{L}_{k}\right)\right)
$$

of degree $1-k$, satisfying $A_{\infty}$-relations

$$
\begin{align*}
\sum_{1 \leq k \leq n} & \sum_{1 \leq i_{1}<\cdots<i_{k}=n} \mathfrak{m}_{k}^{\mathscr{B}}\left(\mathscr{F}_{i_{1}}\left(f_{1}, \ldots, f_{i_{1}}\right), \ldots, \mathscr{F}_{n-i_{k-1}}\left(f_{i_{k-1}+1}, \ldots, f_{n}\right)\right) \\
& =\sum_{0 \leq i<j \leq n}(-1)^{\left|f_{1}\right|+\cdots+\left|f_{i}\right|-i} \mathscr{F}_{n-j+i+1}\left(f_{1}, \ldots, f_{i}, \mathfrak{m}_{j-i}^{\mathscr{A}}\left(f_{i+1}, \ldots, f_{j}\right), f_{j+1}, \ldots, f_{n}\right) \tag{A.3}
\end{align*}
$$

for any fixed $n \in \mathbb{Z}_{\geq 1}$ and morphisms $f_{i} \in \operatorname{hom}_{\mathscr{A}}^{\bullet}\left(\mathscr{L}_{i-1}, \mathscr{L}_{i}\right)\left(i \in\{1, \ldots, n\}, \bullet \in \mathbb{Z}_{2}\right)$.
The composition $\mathscr{G} \circ \mathscr{F}:=\left\{(\mathscr{G} \circ \mathscr{F})_{k}\right\}_{k \geq 0}$ of two $A_{\infty}$-functors $\mathscr{F}: \mathscr{A} \rightarrow \mathscr{B}$ and $\mathscr{G}: \mathscr{B} \rightarrow \mathscr{C}$ is given by

$$
(\mathscr{G} \circ \mathscr{F})_{n}\left(f_{1}, \ldots, f_{n}\right):=\sum_{1 \leq k \leq n} \sum_{1 \leq i_{1}<\cdots<i_{k}=n} \mathscr{G}_{k}\left(\mathscr{F}_{i_{1}}\left(f_{1}, \ldots, f_{i_{1}}\right), \ldots, \mathscr{F}_{n-i_{k-1}}\left(f_{i_{k-1}+1}, \ldots, f_{n}\right)\right) .
$$

An $A_{\infty}$-functor $\mathscr{F}: \mathscr{A} \rightarrow \mathscr{B}$ is called unital if $\mathscr{A}, \mathscr{B}$ are unital and

$$
\mathscr{F}_{1}\left(\mathrm{id}_{\mathscr{L}}\right)=\mathrm{id}_{\mathscr{F}_{0}(\mathscr{L})} \quad \text { and } \quad \mathscr{F}_{k}\left(\ldots, \mathrm{id}_{\mathscr{L}}, \ldots\right)=0 \quad \text { if } k \geq 2
$$

for any $\mathscr{L} \in \mathrm{Ob}(\mathscr{A})$.
The $\mathbb{Z}_{2}$-graded $\mathbb{k}$-vector space hom $\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right)=\operatorname{hom}^{0}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \oplus \operatorname{hom}^{1}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right)$ has a degree 1 map $\mathfrak{m}_{1}$ : $\operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \rightarrow \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right)$ satisfying $\mathfrak{m}_{1}^{2}=0$ by the $A_{\infty}$-relation for $n=1$. Therefore, it becomes a cochain complex equipped with a differential $\mathfrak{m}_{1}$. Taking its cohomology yields an ordinary category:
Definition A.3. For a unital $A_{\infty}$-category $\mathscr{A}$, its cohomological category $H^{0}(\mathscr{A})$ is an ordinary category whose objects are the same as $\mathscr{A}$ and the morphism space between two objects $\mathscr{L}_{0}, \mathscr{L}_{1}$ is given by

$$
\operatorname{Hom}_{H^{0}(\mathscr{A})}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right):=H^{0}\left(\operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right), \mathfrak{m}_{1}\right) .
$$

A unital $A_{\infty}$-functor $\mathscr{F}: \mathscr{A} \rightarrow \mathscr{B}$ induces an ordinary functor $H^{0}(\mathscr{F}): H^{0}(\mathscr{A}) \rightarrow H^{0}(\mathscr{B})$, whose mapping on objects is $\mathscr{F}_{0}$ and action on morphisms is given by $[f] \mapsto\left[\mathscr{F}_{1}(f)\right]$.

[^33]A.2. Compact Fukaya category of a surface. We establish our geometric setup of the Fukaya category. We refer to [FOOO09, Sei08, AJ10] for its general definitions and properties, [Abo08, Sei11] for Fukaya category of surfaces, and [Aur14, Bae17, Kon17] for higher rank vector bundles in Fukaya category.
A.2.1. Objects. Let $(\Sigma, \omega)$ be a 2 -dimensional symplectic manifold (possibly with boundary) of finite type. That is, $\Sigma$ is a connected oriented smooth surface (with boundary) of finite type and $\omega$ is an area form on it. Then any smooth curve $L$ in $\Sigma$ automatically satisfies the Lagrangian conditions ( $\left.\omega\right|_{L}=0, \operatorname{dim} L=\frac{1}{2} \operatorname{dim} \Sigma$ ) and hence is a Lagrangian submanifold in $\Sigma$.

Consider an immersed oriented smooth loop $L: S^{1} \rightarrow \Sigma \backslash \partial \Sigma$ having only transversal self-intersections. We assign two distinct marked points $e_{L}, o_{L}{ }^{46}$ on the image of $L$ away from its self-intersections, and call the triple ( $L, e_{L}, o_{L}$ ) a marked loop in $\Sigma$. When there is no need to specify marked points, we will call a marked loop just a loop, and denote it shortly as $L$.

Definition A.4. A setO consisting of some marked loops in $\Sigma$ is called transversal if it satisfies the following:

- Any two distinct loops in $\mathscr{O}$ meet transversally.
- There are no triple intersections among loops in $\mathscr{O}$.
- Marked points of each loop in $\mathscr{O}$ do not lie on any intersection of itself or any other loop in $\mathfrak{O}$.

Definition A.5. (1) A loop $L: S^{1} \rightarrow \Sigma$ is called obstructed if it bounds an immersed disk or 'fish-tale'. This means that there is an immersion $i: D^{2} \rightarrow \Sigma$ which satisfies $i\left(e^{2 \pi i t}\right)=L(\imath(t))$ for some immersion $\imath:[0,1] \rightarrow$ $S^{1}$. Otherwise, $L$ is called unobstructed. A transversal set $\mathscr{O}$ of marked loops in $\Sigma$ is called unobstructed if all of its elements are unobstructed ${ }^{47}$.
(2) A transversal set $\mathscr{O}$ of marked loops in $\Sigma$ is called full if it contains at least one element in each primitive free homotopy class other than the null-homotopic one.

Given a full unobstructed set $\mathscr{O}$ of marked loops in $\Sigma$, we define a $\mathbb{Z}_{2}$-graded compact Fukaya category $\operatorname{Fuk}(\Sigma)=\operatorname{Fuk}_{\mathbb{C}}^{\mathbb{Z}_{2}}(\Sigma ; \mathscr{O})$ with respect to $\mathscr{O}$ over $\mathbb{C}$.
Definition A.6. An object $o f \operatorname{Fuk}(\Sigma)$ is given by a triple $\mathscr{L}=(L, E, \nabla)$, which consists of the following:

- a marked loop $L: S^{1} \rightarrow \Sigma$ in $\mathscr{O}$,
- a $\mathbb{C}$-vector bundle $E$ of finite rank $\rho$ over the domain of $L$, and
- a flat ${ }^{48}$ connection $\nabla$ on $E$.

Figure 21. Objects in $\operatorname{Fuk}(\Sigma)$ where $\Sigma=S^{2} \backslash\{3$ points $\}$

[^34]For a computational purpose, we want to (not globally) trivialize $E$ so that the parallel transport between two points is trivial away from a special point on $L$. For that, we choose a point $\star$ on (the domain of) $L$ avoiding any intersection points (also with other loops) and denote by

$$
\operatorname{hol}_{\star}(E) \in \operatorname{Hom}\left(\left.E\right|_{\star},\left.E\right|_{\star}\right)
$$

the holonomy of $(E, \nabla)$ along $L$ at $\star{ }^{49}$. We choose an identification $\left.E\right|_{\star} \cong \mathbb{C}^{\rho}$ where $\rho$ is the rank of $E$, then $\operatorname{hol}_{\star}(E)$ is represented by some matrix $H \in \mathrm{GL}_{\rho}(\mathbb{C})$. (We simply say that the object $(L, E, \nabla)$ has a holonomy $H$ (at $\star$ ).)

Proposition A.7. There is a trivialization

$$
\left.E\right|_{S^{1} \backslash \star} \cong\left(S^{1} \backslash \star\right) \times \mathbb{C}^{\rho}
$$

of E over $S^{1} \backslash \star$ satisfying the following: For any two points $p$ and $q$ on (the domain of) L other than $\star$, the parallel transport

$$
P\left(L_{p \rightarrow q}\right) \in \operatorname{Hom}\left(\left.E\right|_{p},\left.E\right|_{q}\right)
$$

from $\left.E\right|_{p}$ to $\left.E\right|_{q}$ along $L$ (in the shortest way from $p$ to $q$ following the orientation of $L$ ) is represented by
(1) $H$ if there is $\star$ in the way from $p$ to $q$, and
(2) $I_{\rho}$ (the identity matrix) otherwise,
with respect to the induced identifications $\left.E\right|_{p} \cong \mathbb{C}^{\rho}$ and $\left.E\right|_{q} \cong \mathbb{C}^{\rho}$.
Proof. Note that the linear isomorphisms $P\left(L_{\star \rightarrow p}\right): E_{\star} \stackrel{\cong}{\rightrightarrows} E_{p}$ for each $p \in S^{1} \backslash \star$ yield the bundle isomorphism

$$
\begin{aligned}
\left(S^{1} \backslash \star\right) \times E_{\star} & \left.\stackrel{\cong}{\rightrightarrows} E\right|_{S^{1} \backslash \star} \\
(p, w) & \mapsto P\left(L_{\star \rightarrow p}\right)(w)
\end{aligned}
$$

In case (1),

$$
P\left(L_{p \rightarrow q}\right)=P\left(L_{\star \rightarrow p}\right)^{-1} \circ \operatorname{hol}_{\star}(E) \circ P\left(L_{\star \rightarrow q}\right): E_{p} \stackrel{\cong}{\rightrightarrows} E_{\star} \rightarrow E_{\star} \xlongequal{\cong} E_{q}
$$

coincides with the map $\operatorname{hol}_{\star}(E): E_{\star} \rightarrow E_{\star}$ under the identifications of $E_{p}$ and $E_{q}$ with $E_{\star}$.
In case (2),

$$
P\left(L_{p \rightarrow q}\right)=P\left(L_{\star \rightarrow p}\right)^{-1} \circ P\left(L_{\star \rightarrow q}\right): E_{p} \xrightarrow{\cong} E_{\star} \stackrel{\cong}{\rightrightarrows} E_{q}
$$

is just the identity on $E_{\star}$ under the same identifications.
A.2.2. Morphisms. Given two objects $\mathscr{L}_{0}=\left(L_{0}, E_{0}, \nabla_{0}\right)$ and $\mathscr{L}_{1}=\left(L_{1}, E_{1}, \nabla_{1}\right)$ in Fuk $(\Sigma)$, roughly speaking, their morphism space hom $\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right)$ is defined as a direct sum of $\mathbb{Z}_{2}$-graded $\mathbb{C}$-vector spaces attached to each (self-)intersection of underlying curves $L_{0}$ and $L_{1}$. We will explain the attached vector spaces below by dividing it into two cases:

In the case $L_{0} \neq L_{1}$, as they are compact, they have finitely many intersection points. We define the set

$$
\chi\left(L_{0}, L_{1}\right):=L_{0} \cap L_{1}
$$

which is divided into an even-part and an odd-part according to orientations of two curves at each element. An element $p \in \chi\left(L_{0}, L_{1}\right)$ has an even-degree if the orientation of $T_{p} L_{1} \oplus T_{p} L_{0}$ agrees with that of $T_{p} \Sigma$, and an odd-degree otherwise. Both situations are compared in Figure 22. We use + or - signs to indicate that $p$ is even or odd, respectively, writing $|p|=0$ or 1 . We denote by $\chi^{0}\left(L_{0}, L_{1}\right)$ (the even-part) and $\chi^{1}\left(L_{0}, L_{1}\right)$ (the odd-part) the subsets of $\chi\left(L_{0}, L_{1}\right)$ consisting of even-degree and odd-degree elements, respectively.

[^35]Each intersection of $L_{0}$ and $L_{1}$ contributes one element to each of $\chi\left(L_{0}, L_{1}\right)$ and $\chi\left(L_{1}, L_{0}\right)$. We distinguish them by denoting one by $p$ and the other by $\bar{p}$. Note that $|p|+|\bar{p}|=1$ always holds. It is convenient to view $p \in \chi\left(L_{0}, L_{1}\right)$ as a pair of clockwise opposite angles from $L_{0}$ to $L_{1}$, and $\bar{p} \in \chi\left(L_{1}, L_{0}\right)$ as the angles from $L_{1}$ to $L_{0}$, as described in Figure 22.

(a) $p \in \chi^{0}\left(L_{0}, L_{1}\right), \bar{p} \in \chi^{1}\left(L_{0}, L_{1}\right)$

(b) $p \in \chi^{1}\left(L_{0}, L_{1}\right), \bar{p} \in \chi^{0}\left(L_{0}, L_{1}\right)$

Figure 22. Angles $p \in \chi\left(L_{0}, L_{1}\right), \bar{p} \in \chi\left(L_{1}, L_{0}\right)$ when $L_{0} \neq L_{1}$

In the case $L:=L_{0}=L_{1}$, it has finitely many self-intersections. In a small neighborhood of such a selfintersection $p$, there are two pieces $\tilde{L}_{a}, \tilde{L}_{b}$ of $L$ meeting at $p$. We may assume that the orientation of $T_{p} \tilde{L}_{b} \oplus T_{p} \tilde{L}_{a}$ agrees with that of $T_{p} \Sigma$. As in Figure 23, the pair of clockwise opposite convex angles from $\tilde{L}_{a}$ to $\tilde{L}_{b}$ is denoted by $p$ and has an even-degree. Its adjacent pair of clockwise opposite convex angles from $\tilde{L}_{b}$ to $\tilde{L}_{a}$ is denoted by $\bar{p}$ and has an odd-degree. Two (pair-of-)angles $p$ and $\bar{p}$ will have different meaning when we count polygons involving them.

We consider the marked points $e_{L}$ and $o_{L}$ to have even and odd degrees, respectively. We define the set

$$
\chi(L, L):=\left\{e_{L}, o_{L}\right\} \cup\{p, \bar{p} \mid p: \text { a self-intersection point of } L\},
$$

which is divided into two subsets $\chi^{0}(L, L)$ and $\chi^{1}(L, L)$ as before.
In both cases, we define the $A_{\infty}$-morphism spaces as

$$
\begin{equation*}
\operatorname{hom}^{\bullet}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right):=\bigoplus_{p \in \chi^{\cdot\left(L_{0}, L_{1}\right)}} \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p},\left.E_{1}\right|_{p}\right) \quad\left(\bullet \in \mathbb{Z}_{2}\right) \tag{A.4}
\end{equation*}
$$

where $\left.E_{0}\right|_{p}$ and $\left.E_{1}\right|_{p}$ are the fibers of $E_{0}$ and $E_{1}$ over the preimages (in $S^{1}$ ) of the point $p \in \Sigma$ under $L_{0}$ and $L_{1}$ (or under different branches $\tilde{L}_{a}$ and $\tilde{L}_{b}$ of $L$ in the case $L:=L_{0}=L_{1}$ ), respectively. They yield a $\mathbb{Z}_{2}$-graded morphism space

$$
\operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right):=\operatorname{hom}^{0}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \oplus \operatorname{hom}^{1}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) .
$$

An element $f \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p},\left.E_{1}\right|_{p}\right)$ for each $p \in \chi\left(L_{0}, L_{1}\right)$ is called a base morphism over $p$, and we denote it by $\left.f\right|_{p}$ to specify that fact.
Remark A.8. According to Proposition A.7, we have identifications $\left.E_{0}\right|_{p} \cong \mathbb{C}^{\rho_{0}}$ and $\left.E_{1}\right|_{p} \cong \mathbb{C}^{\rho_{1}}$, which yield $\operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p},\left.E_{1}\right|_{p}\right) \cong \mathbb{C}^{\rho_{1} \times \rho_{0}}$. Denoting by $p_{\text {ab }}$ the generator corresponding to the $\rho_{1} \times \rho_{0}$ matrix whose the only nonzero entry is 1 in the $(a, b)$-th position, we have

$$
\operatorname{hom} \cdot\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \cong \bigoplus_{p \in \chi \cdot\left(L_{0}, L_{1}\right)} \bigoplus_{\substack{1 \leq a \leq \rho_{1} \\ 1 \leq b \leq \rho_{0}}} \operatorname{Span}_{\mathbb{C}}\left\{p_{a b}\right\} \quad\left(\bullet \in \mathbb{Z}_{2}\right)
$$

In the simplest case $\rho_{0}=\rho_{1}=1$, we just write

$$
\operatorname{hom}^{\bullet}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \cong \bigoplus_{p \in \chi^{*}\left(L_{0}, L_{1}\right)} \operatorname{Span}_{\mathbb{C}}\{p\}=\operatorname{Span}_{\mathbb{C}}\left(\chi^{\bullet}\left(L_{0}, L_{1}\right)\right) \quad\left(\bullet \in \mathbb{Z}_{2}\right) .
$$

A.2.3. $A_{\infty}$-operations. The $A_{\infty}$-operations $\left\{\mathfrak{m}_{k}\right\}_{k \geq 1}$ on base morphisms between objects $\mathscr{L}_{i}=\left(L_{i}, E_{i}, \nabla_{i}\right)$ $(i \in\{0, \ldots, k\}$ ) are defined as

$$
\begin{align*}
\mathfrak{m}_{k}: \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \otimes \cdots \otimes \operatorname{hom}\left(\mathscr{L}_{k-1}, \mathscr{L}_{k}\right) & \rightarrow \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{k}\right) \\
\quad\left(\left.f_{1}\right|_{p_{1}}, \ldots,\left.f_{k}\right|_{p_{k}}\right) & \mapsto \sum_{q \in \chi\left(L_{0}, L_{k}\right)} \sum_{u \in \mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)} \operatorname{sign}(u) \operatorname{hol}_{q}(\partial u)\left(f_{1}, \ldots, f_{k}\right) \tag{A.5}
\end{align*}
$$

for any $p_{i} \in \chi\left(L_{i-1}, L_{i}\right)$ other than $e_{L}$ or $o_{L}{ }^{50}$, such that $p_{i+1} \neq \overline{p_{i}}$, and $f_{i}=\left.f_{i}\right|_{p_{i}} \in \operatorname{Hom}\left(\left.E_{i-1}\right|_{p_{i}},\left.E_{i}\right|_{p_{i}}\right)$. Then it is linearly extended to other morphisms. We will explain the meaning of each component one by one below.

First, the moduli space $\mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)$ is the set of immersed $(k+1)$-gons bounded by $L_{0}, L_{1}, \ldots, L_{k}$ whose angles consist of $p_{1}, \ldots, p_{k}, \bar{q}$ in counter-clockwise order. To be precise, it means a continuous map $u: D^{2} \rightarrow \Sigma$ together with $k+1$ points $z_{1}, \ldots, z_{k}, z_{0} \in \partial D^{2}$ (in counterclockwise order) such that the segment of $\partial D^{2}$ between $z_{i}$ and $z_{i+1}$ is mapped to $L_{i}\left(i \in \mathbb{Z}_{k+1}\right)$, the image of $u$ has a convex corner $p_{i}$ at $u\left(z_{i}\right)=p_{i}$ ( $p_{k+1}:=\bar{q}$ ), and $u$ is an orientation-preserving immersion on $D^{2} \backslash\left\{z_{1}, \ldots, z_{k}, z_{0}\right\}$. We consider such maps up to automorphisms of the domain $D^{2}$, that is, $\left(\left\{z_{1}, \ldots, z_{k}, z_{0}\right\}, u\right)$ and $\left(\left\{z_{1}^{\prime}, \ldots, z_{k}^{\prime}, z_{0}^{\prime}\right\}, u^{\prime}\right)$ define the same element in the moduli space if and only if there is a homeomorphism $\phi: D^{2} \rightarrow D^{2}$ such that $\phi\left(z_{i}\right)=z_{i}^{\prime}$ $\left(i \in \mathbb{Z}_{k+1}\right), u$ is a diffeomorphism on $D^{2} \backslash\left\{z_{1}, \ldots, z_{k}, z_{0}\right\}$, and $u^{\prime}=u \circ \phi$.

Figure 24. An element $u$ of $\mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)$

Second, to determine the sign of $u$, we follow the sign rule established and illustrated in [Sei08, Sei11]: Consider the boundary orientation on $\partial u$ as usual, that is, it is given in such a way that $u$ lies on the left along it. The orientation of $L_{0}$ is irrelevant. For $1 \leq i \leq k$, whenever the orientation of $L_{k}$ does not match the orientation of $\partial u,(-1)^{\left|p_{i}\right|}$ is contributed to $\operatorname{sign}(u)$, which changes the sign only when the angle $p_{i}$ from $L_{i-1}$ to $L_{i}$ has odd-degree. In addition, if the orientation of $L_{k}$ differs from that of $\partial u$, the sign $(-1)^{|q|}$ of the output angle $q$ from $L_{0}$ to $L_{k}$ is also contributed. Summing up, we have

$$
\begin{align*}
\operatorname{sign}(u):= & \prod_{\substack{1 \leq i \leq k, \\
\text { orientation of } L_{i} \\
\neq \text { orientation of } \partial u}}(-1)^{\left|p_{i}\right|} \times \prod_{\substack{\text { if orientation of } L_{k} \\
\neq \text { orientation of } \partial u}}(-1)^{|q|}  \tag{A.6}\\
= & (-1)^{\wedge}\left(\sum_{i=1}^{k}\left|p_{i}\right| \mathbb{1}_{\mathbf{o}\left(L_{i}\right) \neq \mathbf{o}(\partial u)}+|q| \mathbb{1}_{\mathbf{o}\left(L_{k}\right) \neq \mathbf{o}(\partial u)}\right)
\end{align*}
$$

where $o(L)$ denotes the orientation of a curve $L$ and $1_{\text {statement }}$ is 1 if the statement is true and 0 otherwise.

[^36]Third, the holonomy operation of $\partial u$ at $q$ is defined as

$$
\begin{aligned}
& \operatorname{hol}_{q}(\partial u): \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p_{1}},\left.E_{1}\right|_{p_{1}}\right) \otimes \cdots \otimes \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{k-1}\right|_{p_{k}},\left.E_{k}\right|_{p_{k}}\right) \rightarrow \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{0}\right|_{p_{0}},\left.E_{k}\right|_{p_{0}}\right) \\
& \left(f_{1}, \ldots, f_{k}\right) \mapsto P\left((\partial u)_{k}\right) \circ f_{k} \circ P\left((\partial u)_{k-1}\right) \circ f_{k-1} \circ \cdots \circ f_{2} \circ P\left((\partial u)_{1}\right) \circ f_{1} \circ P\left((\partial u)_{0}\right)
\end{aligned}
$$

where

$$
P\left((\partial u)_{i}\right) \in \operatorname{Hom}_{\mathbb{C}}\left(\left.E_{i}\right|_{p_{i}},\left.E_{i}\right|_{p_{i+1}}\right)
$$

is the parallel transport with respect to $\nabla_{i}$ from $\left.E_{i}\right|_{p_{i}}$ to $\left.E_{i}\right|_{p_{i+1}}$ along the side of $u$ (following the boundary orientation) lying in $L_{i}$.

Remark A.9. When $o_{L_{i}}$ or $e_{L_{i}}$ are involved in the moduli space $\mathscr{M}\left(p_{1}, \ldots, p_{k}, p_{k+1}\right)$, an appropriate perturbation scheme can be introduced. Here we follow [Sei11] and explain some special cases where we have only one of them in input or output of the $A_{\infty}$-operations, which will be enough for our purpose ${ }^{51}$.
(1) If $\mathscr{L}_{i-1}=\mathscr{L}_{i}(i \in\{1, \ldots, k\})$ (and hence $L_{i-1}=L_{i}$ is a loop) and an input $p_{i}$ is $o_{L_{i}}$ from $L_{i-1}=L_{i}$ to itself, then elements of $\mathscr{M}\left(p_{1}, \ldots, p_{i-1}, o_{L_{i}}, p_{i+1}, \ldots, p_{k}, \bar{q}\right)$ are polygons which have convex corners at $p_{1}, \ldots, p_{i-1}$, pass through the point $o_{L_{i}}$, and then again have convex corners at $p_{i+1}, \ldots, p_{k}, \bar{q}$ in counterclockwise order.
(2) If $\mathscr{L}_{i-1}=\mathscr{L}_{i}(i \in\{1, \ldots, k\})$ and $p_{i}$ is $e_{L_{i-1}}=e_{L_{i}}$, the set $\mathscr{M}\left(p_{1}, \ldots, e_{L_{i}}, \ldots, p_{k}, \bar{q}\right)$ is empty unless $k=2$, which yields

$$
\begin{equation*}
\mathfrak{m}_{k}\left(\ldots,\left.\mathrm{id}\right|_{e_{L_{i}}}, \ldots\right)=0 \quad \text { if } k \neq 2 \tag{A.7}
\end{equation*}
$$

If $k=2$, given two objects $\mathscr{L}=(L, E, \nabla)$ and $\mathscr{L}^{\prime}=\left(L^{\prime}, E^{\prime}, \nabla^{\prime}\right)$, we regard a segment $\left(\rightarrow \frac{p}{L^{\prime}} \frac{L^{\prime}}{\bar{p}^{\prime}} L\right)$ of $L$ from $e_{L}$ to any point $p \in \chi\left(L, L^{\prime}\right)$ (which doesn't pass through $o_{L}$ ) as an 'infinitesimal triangle' whose angles are $e_{L}, p$ and $\bar{p}$. It provides the unique element of $\mathscr{M}\left(e_{L}, p, \bar{p}\right)$ and $\mathscr{M}\left(\bar{p}, e_{L}, p\right)$, which yields

$$
\begin{equation*}
\mathfrak{m}_{2}\left(\left.\mathrm{id}\right|_{e_{L}},\left.f\right|_{p}\right)=\left.f\right|_{p} \quad \text { and } \quad \mathfrak{m}_{2}\left(\left.g\right|_{\bar{p}},\left.\mathrm{id}\right|_{e_{L}}\right)=\left.(-1)^{|\bar{p}|} g\right|_{\bar{p}} \tag{A.8}
\end{equation*}
$$

for any $\left.f\right|_{p} \in \operatorname{hom}\left(\mathscr{L}, \mathscr{L}^{\prime}\right)$ and $\left.g\right|_{\bar{p}} \in \operatorname{hom}\left(\mathscr{L}^{\prime}, \mathscr{L}\right)$. Equations (A.7) and (A.8) imply that $\mathrm{id} \mathscr{L}:=\left.\operatorname{id}\right|_{e_{L}}$ is a unit of $\mathscr{L}$.
(3) If $\mathscr{L}_{0}=\mathscr{L}_{k}=: \mathscr{L}$ and the output $q$ is $e_{L}$, elements of $\mathscr{M}\left(p_{1}, \ldots, p_{k}, \overline{e_{L}}\right)$ are polygons which have convex corners at $p_{1}, \ldots, p_{k}$ and then pass through the point $e_{L}$ in counterclockwise order.

Remark A.10. In fact, the definition given in (A.5) involves a crucial problem. That is, sometimes there are infinitely many elements in the moduli space $\mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)$. Therefore, a priori, we must work over the Novikov field

$$
\Lambda:=\left\{\sum_{i=0}^{\infty} a_{i} T^{\lambda_{i}} \mid a_{i} \in \mathbb{C}, \lambda_{i} \in \mathbb{R}, \lim _{i \rightarrow \infty} \lambda_{i}=\infty\right\}
$$

instead of the base field $\mathbb{C}$ (which makes the hom spaces $\Lambda$-vector spaces) and define the $A_{\infty}$-operations as

$$
\begin{aligned}
\mathfrak{m}_{k}: \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{1}\right) \otimes \cdots \otimes \operatorname{hom}\left(\mathscr{L}_{k-1}, \mathscr{L}_{k}\right) & \rightarrow \operatorname{hom}\left(\mathscr{L}_{0}, \mathscr{L}_{k}\right) \\
\qquad\left(\left.f_{1}\right|_{p_{1}}, \ldots,\left.f_{k}\right|_{p_{k}}\right) & \mapsto \sum_{q \in \chi\left(L_{0}, L_{k}\right)} \sum_{u \in \mathscr{M}\left(p_{1}, \ldots, p_{k}, \bar{q}\right)} \operatorname{sign}(u) T^{\omega(u)} \operatorname{hol}_{q}(\partial u)\left(f_{1}, \ldots, f_{k}\right)
\end{aligned}
$$

instead of (A.5). But we demonstrated in [CJKR22] that we can evaluate $T=1$ when we compute the matrix factorizations corresponding to cylinder-free loops under the localized mirror functor (See Definition 3.12 and Theorem 3.13.). In this paper, therefore, we still work over $\mathbb{C}$ and use the definition (A.5) when computing the mirror images of cylinder-free loops.

[^37]A.3. Categories of matrix factorizations. Let $S$ be the formal power series $\operatorname{ring} \mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, and $f \in S$ its nonzero element.

Definition A.11. A matrix factorization off (inS) is a pair $(\varphi, \psi)$ ofS-module homomorphisms $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ between two finite-rank free $S$-modules $P^{0}$ and $P^{1}$ that satisfy

$$
\psi \varphi=f \cdot \mathrm{id}_{P^{0}} \quad \text { and } \quad \varphi \psi=f \cdot \mathrm{id}_{P 1}{ }^{52} .
$$

There are several versions of the categories of matrix factorizations of $f$. They all have matrix factorizations of $f$ as objects, but morphism spaces are different, which we will now explain:

Given two matrix factorizations $P_{0}^{0} \underset{\psi_{0}}{\stackrel{\varphi_{0}}{\rightleftarrows}} P_{0}^{1}$ and $P_{1}^{0} \underset{\psi_{1}}{\stackrel{\varphi_{1}}{\rightleftarrows}} P_{1}^{1} \quad$ of $f$, an even-degree or odd-degree morphism between them is a pair of $S$-module maps $\left(\alpha: P_{0}^{0} \rightarrow P_{1}^{0}, \beta: P_{0}^{1} \rightarrow P_{1}^{1}\right)$ or $\left(\gamma: P_{0}^{0} \rightarrow P_{1}^{1}, \delta: P_{0}^{1} \rightarrow\right.$ $\left.P_{1}^{0}\right)$, respectively. They consist the even-part and odd-part of the morphism space defined as

$$
\operatorname{hom}^{\bullet}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right):=\operatorname{Hom}_{S}\left(P_{0}^{0}, P_{1}^{\bullet}\right) \times \operatorname{Hom}_{S}\left(P_{0}^{1}, P_{1}^{1+\bullet}\right) \quad\left(\bullet \in \mathbb{Z}_{2}\right),
$$

and form the following diagram but are not required to commute it:

The $\mathbb{Z}_{2}$-graded morphism space is a $\mathbb{Z}_{2}$-graded $\mathbb{C}$-vector space defined as

$$
\operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right):=\operatorname{hom}^{0}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) \oplus \operatorname{hom}^{1}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) .
$$

We define a $\mathbb{C}$-linear map $d$ of degree 1 on it as $\operatorname{hom}^{0}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) \xrightarrow{d} \operatorname{hom}^{1}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) \quad$ and $\operatorname{hom}^{1}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right) \xrightarrow{d} \operatorname{hom}^{0}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right)$.

$$
(\alpha, \beta) \mapsto\left(\varphi_{1} \circ \alpha-\beta \circ \varphi_{0}, \psi_{1} \circ \beta-\alpha \circ \psi_{0}\right) \quad(\gamma, \delta) \mapsto\left(\psi_{1} \circ \gamma+\delta \circ \varphi_{0}, \varphi_{1} \circ \delta+\gamma \circ \psi_{0}\right)
$$

It satisfies $d^{2}=0$, making the morphism space a 2-periodic cochain complex with a differential $d$.
Definition A.12. We define four different categories of matrix factorizations of $f$. Their objects are matrix factorizations of $f$. The morphism space between two matrix factorizations $\left(\varphi_{0}, \psi_{0}\right)$ and $\left(\varphi_{1}, \psi_{1}\right)$ will be defined, while the composition of morphisms and the identity morphisms are given in the obvious way.
(1) In differential $\mathbb{Z}_{2}$-graded category $\operatorname{MF}_{d g}(f)$, it is given by $\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right), d\right)$, which is a $\mathbb{Z}_{2}$-graded $\mathbb{C}$-vector space equipped with the differential d.
(2) In (ordinary) category $\operatorname{MF}(f)$, it is given by $Z^{0}\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right), d\right)$, which consists of evendegree morphisms $(\alpha, \beta) \in \operatorname{hom}^{0}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right)$ that commute the left diagram in (A.9).
(3) In homotopy category MF $(f)$, it is given by $H^{0}\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{0}, \psi_{0}\right),\left(\varphi_{1}, \psi_{1}\right)\right), d\right)$. This category is the same as the stable category $\underline{\operatorname{MF}(f)}:=\operatorname{MF}(f) /\{(1, f),(f, 1)\}$ (Definition A.14).
(4) In $\mathbb{Z}_{2}$-graded) $A_{\infty}$-category $\mathrm{MF}_{A_{\infty}}(f)$, it is given by the $\mathbb{Z}_{2}$-graded $\mathbb{C}$-vector spacehom ${ }^{\mathbb{Z}_{2}}\left(\left(\varphi_{1}, \psi_{1}\right),\left(\varphi_{0}, \psi_{0}\right)\right)$. (Note that it is reversed.) The $A_{\infty}$-operations $\left\{\mathfrak{m}_{k}\right\}_{k \geq 1}$ are defined as:

$$
\begin{equation*}
\mathfrak{m}_{1}:=d, \quad \mathfrak{m}_{2}\left(\left(\alpha_{0}, \beta_{0}\right),\left(\alpha_{1}, \beta_{1}\right)\right):=(-1)^{\bullet-1}\left(\alpha_{0}, \beta_{0}\right) \circ\left(\alpha_{1}, \beta_{1}\right), \quad \text { and } \quad \mathfrak{m}_{k \geq 3}:=0 \tag{A.10}
\end{equation*}
$$

for $\left(\alpha_{0}, \beta_{0}\right) \in \operatorname{hom}^{\bullet}\left(\left(\varphi_{1}, \psi_{1}\right),\left(\varphi_{0}, \psi_{0}\right)\right)\left(\bullet \in \mathbb{Z}_{2}\right)$ and $\left(\alpha_{1}, \beta_{1}\right) \in \operatorname{hom}^{\mathbb{Z}_{2}}\left(\left(\varphi_{2}, \psi_{2}\right),\left(\varphi_{1}, \psi_{1}\right)\right)$.

[^38]A.4. Stable categories and Eisenbud's equivalence. ${ }^{53}$ Let $S$ be the power series ring $\mathbb{C}\left[\left[x_{1}, \ldots, x_{m}\right]\right]$ of $m$ variables, $f \in S$ its nonzero element and $A:=S /(f)$ the quotient ring. In this case, we can relate the category $\mathrm{CM}(A)$ of maximal Cohen-Macaulay modules over $A$ (Definition 4.1) and the category MF $(f)$ of matrix factorizations of $f$ (Definition A.12(2)) in a stable sense. We need some preparation:

Definition A.13. Let $\mathscr{A}$ be a category whose Hom-sets are abelian groups, and $P$ a set of some objects in $\mathscr{A}$. For any two objects $M, N$ in $\mathscr{A}$, we denote by $I(M, N)$ the subgroup of $\operatorname{Hom}_{\mathscr{A}}(M, N)$ generated by all morphisms from $M$ to $N$ that factor through a direct sum of objects in $P$. We define the quotient of $\mathscr{A}$ by $P$ as the category $\mathscr{A} / P$ whose objects are the same as $\mathscr{A}$, and the morphism spaces are defined as

$$
\operatorname{Hom}_{\mathscr{A} / P}(M, N):=\operatorname{Hom}_{\mathscr{A}}(M, N) / I(M, N) .
$$

Note that any objects in $P$ are zero objects in the category $\mathscr{A} / P$, and it is the largest quotient of $\mathscr{A}$ with this property.

Definition A. 13 enables us to define the stable categories of maximal Cohen-Macaulay modules over $A$ and matrix factorizations of $f^{54}$ :

Definition A.14. (1) The stable category of maximal Cohen-Macaulay modules over $A$ is defined as

$$
\underline{\mathrm{CM}}(A):=\mathrm{CM}(A) /\{A\} .
$$

## (2) The stable category of matrix factorizations of $f$ is defined as

$$
\underline{\operatorname{MF}}(f):=\operatorname{MF}(f) /\{(1, f),(f, 1)\}
$$

The following justifies our use of the same notation as the homotopy category $\underline{M F}(f)$ in Definition A.12:
Proposition A.15. The stable category and the homotopy category of matrix factorizations of $f$ are the same.

Proof. A more general statement and proof for the identification of the stable category and the homotopy category of cochain complexes in an additive category can be found in $\S 4.1$ in [Kra21]. Here we provide an explicit proof for our setting:

We actually show that their Hom-sets are the same. For that, it is enough to show

$$
I\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right)=B^{0}\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right), d\right)
$$

for any matrix factorizations $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows}} P^{1}$ and $P^{\prime 0} \underset{\psi^{\prime}}{\stackrel{\varphi^{\prime}}{\rightleftarrows}} P^{\prime 1}$ of $f$.
First let $\left(\alpha: P^{0} \rightarrow P^{\prime 0}, \beta: P^{1} \rightarrow P^{\prime 1}\right)$ be a generator of $I\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right)$, i.e., it factors through a direct
 of generality. That is, $(\alpha, \beta)$ is a composition $\left(\alpha^{\prime \prime} \circ \alpha^{\prime}, \beta^{\prime \prime} \circ \beta^{\prime}\right)$ of some morphisms that are described in

[^39](and commute the squares in) the following diagram:

Now we know that $(\alpha, \beta)$ is null-homotopic by checking that it is the differential of an odd-degree morphism $\left(\beta_{2}^{\prime \prime} \circ \alpha_{2}^{\prime}: P^{0} \rightarrow P^{\prime 1}, \alpha_{1}^{\prime \prime} \circ \beta_{1}^{\prime}: P^{1} \rightarrow P^{\prime 0}\right)$. This shows $(\alpha, \beta) \in B^{0}\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right), d\right)$.

Conversely, an element of $B^{0}\left(\operatorname{hom}^{\mathbb{Z}_{2}}\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right), d\right)$ is by definition given by the differential of an odd-degree morphism $\left(\gamma: P^{0} \rightarrow P^{\prime 1}, \delta: P^{1} \rightarrow P_{0}^{\prime}\right)$. As the differential is additive, we may assume $\delta=0$ without loss of generality. Now the differential of $(\gamma, 0)$ is $\left(\psi^{\prime} \circ \gamma, \gamma \circ \psi\right)$, and the following commutative diagram shows that it factors through the direct sum of $P^{0} \underset{f \cdot \text { id }}{\stackrel{\text { id }}{\rightleftarrows}} P^{0}$ and $P^{\prime 1} \underset{\text { id }}{\stackrel{f}{\rightleftarrows} \text { id }} P^{\prime 1}$, being an element of $I\left((\varphi, \psi),\left(\varphi^{\prime}, \psi^{\prime}\right)\right)$ :

Now we can state Eisenbud's equivalence between two stable categories:
Theorem A. 16 (Eisenbud's matrix factorization theorem [Eis80, Yos90]). A matrix factorization $P^{0} \underset{\psi}{\stackrel{\varphi}{\rightleftarrows} P^{1}}$ of $f$ defines a 2-periodic acyclic chain complex of $A$-modules

$$
\cdots \longrightarrow P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \xrightarrow{\underline{\psi}} P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \xrightarrow{\underline{\psi}} \cdots,
$$

where $\underline{\varphi}:=\varphi \otimes \mathrm{id}_{A}$ and $\underline{\psi}:=\psi \otimes \mathrm{id}_{A}$. Taking the cokernel of $\underline{\varphi}$ yields a maximal Cohen-Macaulay A-module $M:=\operatorname{coker} \underline{\varphi}^{55}$. It defines a functor coker : $\mathrm{MF}(f) \rightarrow \mathrm{CM}(A)$, which also induces a functor between stable categories

$$
\text { coker : } \underline{\mathrm{MF}}(f) \rightarrow \underline{\mathrm{CM}}(A)
$$

Conversely, a maximal Cohen-Macaulay A-module $M$, regarded as an $S$-module $M_{S}$, admits a (not unique) free resolution

$$
0 \longrightarrow S^{n} \xrightarrow{\varphi} S^{n} \longrightarrow M_{S} \longrightarrow 0
$$

It determines another map $\psi: S^{n} \rightarrow S^{n}$ such that $\varphi \psi=\psi \varphi=f \cdot \mathrm{id}_{S^{n}}$, yielding a matrix factorization $(\varphi, \psi)$ of $f$. This process defines a quasi-inverse to the above induced functor, giving an equivalence of stable categories MF $(f)$ and $\underline{\mathrm{CM}}(A)$.
${ }^{55}$ Note that $M$ admits 2-periodic free resolution $\cdots \rightarrow P^{0} \otimes_{S} A \stackrel{\varphi}{\Longrightarrow} P^{1} \otimes_{S} A \xrightarrow{\underline{\psi}} P^{0} \otimes_{S} A \xrightarrow{\underline{\varphi}} P^{1} \otimes_{S} A \rightarrow M=\operatorname{coker} \underline{\varphi} \rightarrow 0$.

[^0]:    ${ }^{1}$ In our paper, a closed geodesic is always oriented, non-periodic, immersed (i.e., not necessarily simple) and considered up to orientation-preserving reparameterization.

[^1]:    ${ }^{2}$ We place this discussion in the middle of the main text (§3.4) since they are also needed to analyze degenerate cases.
    ${ }^{3}$ But we are not giving a new proof, as classification of objects in the Fukaya category here relies on the B-side result via HMS.

[^2]:    ${ }^{4}$ We denote by $J_{\rho}(\eta) \in \mathrm{GL} \rho(\mathbb{C})$ the $\rho \times \rho$ Jordan block with eigenvalue $\eta \in \mathbb{C}^{\times}$.

[^3]:    ${ }^{5}$ It is also parameterized by loop data $\left(w^{\prime}, \boldsymbol{\lambda}, \rho\right)$, but it is more convenient to distinguish two continuous parameters $\eta$ (for loops with a local system) and $\lambda$ (for matrix factorizations). They are related under the conversion formula in §4.3.

[^4]:    ${ }^{6}$ We regard a matrix factorization $(\varphi, \psi)$ of $x y z$ as a pair of homomorphisms between two free modules over $S:=\mathbb{C}[[x, y, z]]$ (Definition A.11), then define $\varphi:=\varphi \otimes \mathrm{id}_{A}$ as an $A$-module homomorphism (See Theorem A.16).

[^5]:    ${ }^{7}$ Note that if the left side is in a degenerate case, exactly one of direct summands in the right side is in a degenerate case.

[^6]:    ${ }^{8}$ This condition is necessary when we consider the Novikov field $\Lambda$ instead of our field $\mathbb{C}$.
    ${ }^{9}$ Note that although two $E_{\mathbb{L}} \mid$.'s have the same notation, they are actually fibers of $E$ over different preimages (in $S^{1}$ ) of the point

    - $\in \Sigma$ under $L$, as noted in the definition in (A.4).

[^7]:    ${ }^{10}$ For definition of wrapped Fukaya category $W$ Fuk ( $\Sigma$ ), see [AS10] and [Abo12] (also [Aur14] for surfaces). Its objects involve not only loops but also arcs between boundaries, and it contains the compact Fukaya category Fuk ( $\Sigma$ ) as a full subcategory.

[^8]:    ${ }^{11}$ It is obtained from $W$ Fuk $(\Sigma)$ by taking twisted completion (Definition 5.16), idempotent completion and then the cohomological category (Definition A.3). For more details, we refer to [Sei08].
    ${ }^{12}$ We can take the target of the functor as $\mathrm{MF}_{A_{\infty}}[x y z]$ (see Remark 1.5) since every object in $W$ Fuk $(\Sigma)$ is quasi-isomorphic to an object whose image lies in $\mathrm{MF}_{A_{\infty}}[x y z]$. Then $\underline{\mathrm{MF}}[x y z]$ is the same as its cohomological category $H^{0}\left(\mathrm{MF}_{A_{\infty}}[x y z]\right)$.
    ${ }^{13}$ Following the standard natation in matrices, $\left(\left.E\right|_{s}\right)^{*}$ and $\left(\left.E\right|_{p}\right)^{*}$ are subspaces of the codomain and domain, respectively.

[^9]:    ${ }^{14}$ This is the canonical form of loops with a local system corresponding to a loop datum $((3,-2,2), \eta, 1)$. See Definition 3.9.

[^10]:    ${ }^{15}$ Here $\otimes$ for matrices refers to the Kronecker product.

[^11]:    ${ }^{16}$ The terminologies come from hyperbolic geometry. In fact, if we assign a hyperbolic metric to the surface, the elliptic, parabolic, and hyperbolic loops correspond to concepts already in use in hyperbolic geometry. We refer readers to Section 9.6 in [RAR94].

[^12]:    ${ }^{17}$ We say that a loop datum is periodic if its normal loop word is periodic, and define a shift of a loop datum as the shifting of its normal loop word.
    ${ }^{18}$ See also [CHL19, Proposition 5.4] for its invariance under Hamiltonian isotopy of $L$.

[^13]:    ${ }^{19}$ For the case $w^{\prime}=(2,2,2)^{\tau}$, we still get the same form even if we use the loop constructed in Definition 3.1, which is not cylinder-free with $\mathbb{L}$. For $\eta=-1$, however, it fails to be a matrix factor of $x y z$ as its determinant is zero. For $\eta \neq-1$, it is a valid matrix factor of $x y z$ but the opposite matrix factor $\Psi^{\complement}\left(\mathscr{L}\left(w^{\prime}, \eta, \rho\right)\right)$ cannot be directly obtained by counting polygons between $L$ and $\mathbb{L}$, because it involves some moduli spaces having infinitely many elements. To justify it, we will need to develop additional explanation but we won't to do in that way here. We will rather treat them separately in Subsection 3.5.

[^14]:    ${ }^{20}$ Note that it is a consequence of Theorem 3.13, Proposition 3.14 and Theorem 3.17. An algebraic proof is given in the proof of Theorem 4.14. Indeed, the opposite matrix $\psi\left(w^{\prime}, \lambda, \rho\right)$ can be explicitly written, see Corollary 9.6 in [CJKR22].
    ${ }^{21}$ This is a part of the conversion formula from loop data to band data (Definition 4.10).

[^15]:    ${ }^{22}$ Note that both are just $(\lambda)_{1 \times 1}$ if $N=1$.

[^16]:    ${ }^{24}$ Still the matrix factorization can be defined over the Novikov field. Moreover, unless $\eta=-1$, we can use the formula $1-\eta+$ $\eta^{2}-\eta^{3}+\cdots=\frac{1}{1+\eta}$ to evaluate $T=1$ in some infinite series to get a matrix factorization over $\mathbb{C}$, which is isomorphic to the corresponding (original) canonical form. But instead of justifying that formula, we will take a detour using the perturbed loop and showing Proposition 3.27.

[^17]:    ${ }^{25}$ We are using the fact that $A$ is Gorenstein in codimension one and therefore its canonical module is isomorphic to $A$. See [BD08] for general definition when $A$ does not have a such property.
    ${ }^{26}$ Here the fact that the Krull dimension of $A$ is 2 is essential. See Lemma 3.1 in [BD08].

[^18]:    ${ }^{27}$ See also [BZ20] for another elaboration on this equivalence and its applications.

[^19]:    ${ }^{28}$ We do not define it for periodic degenerate cases $\left(w^{\prime}=(2,2,2)^{\tau}, \eta=(-1)^{\tau}\right.$ with $\left.\tau \geq 2\right)$, because the corresponding loop with a local system and matrix factorization are decomposed into $\tau$ pieces ((3.6) and (3.5)) and they are mapped to maximal CohenMacaulay modules having different algebraic multiplicities (4.9).
    ${ }^{29}$ We do not define it for periodic degenerate cases $\left(w=(0,0,0)^{\tau}, \lambda=1\right.$ with $\left.\tau \geq 2\right)$ in the same reason as above.

[^20]:    $\overline{{ }^{30} \text { This is true for }}$ any infinite (e.g. algebraically closed) field, including our field $\mathbb{C}$.

[^21]:    ${ }^{31}$ In degenerate case $\left(w=(0,0,0)^{\tau}, \lambda=1\right)$, we find only one Macaulayfying element (which doesn't belong to a one-parameter family in $\lambda$ ) to acheive the Macaulayfication, because there are no Macaulayfying elements for ( $w=(0,0,0)^{\tau}, \lambda \neq 1$ ).

[^22]:    ${ }^{32}$ See Remark 9.5 in [BD17a]. It also follows from our discussion below.

[^23]:    ${ }^{33}$ We put the minus sign here to match with the flip functor in the next subsection. However, the functor with a minus sign and one without a minus sign are ( $A_{\infty}$-)quasi-isomorphic to each other.

[^24]:    ${ }^{34}$ Two $A_{\infty}$-functors are quasi-isomorphic to each other if there are $A_{\infty}$-natural transformations between them satisfying some homotopy conditions. Any $A_{\infty}$-natural transformation induces an (ordinary) natural transformation between the induced ordinary functors. See [Sei08] for the details.

[^25]:    ${ }^{35}$ It is not normal a priori in general, but Proposition 3.6 ensures that one can deform it to the unique normal loop word by performing five operations in Lemma 3.3 finitely many times.

[^26]:    ${ }^{36}$ It boils down to the shift functor of the triangulated category $\underline{\text { MF }}(f)$.

[^27]:    ${ }^{37}$ It was called translate in [Buc21], and AR translation in [Yos90].

[^28]:    ${ }^{38}$ It is not normal a priori in general, but Proposition 3.6 ensures that one can deform it to the unique normal loop word by performing five operations in Lemma 3.3 finitely many times.

[^29]:    ${ }^{39}$ The terminology is intended to distinguish it from the rigid twisted complex in $\mathrm{MF}_{A_{\infty}}(f)$ below (5.24).
    ${ }^{40}$ For a $\mathbb{Z}_{2}$-graded vector space $V:=V^{0} \oplus V^{1}$ and $k \in \mathbb{Z}_{2}$, we denote by $V[k]$ its $k$-shift, i.e., $V[k]^{\bullet}=V^{\bullet}+k$ for $\bullet \in \mathbb{Z}_{2}$.
    ${ }^{41}$ It is a finite sum because $\mathfrak{m}_{n}(\delta, \ldots, \delta)$ vanishes for $n \geq N$.

[^30]:    

[^31]:    ${ }^{43}$ The pair is also an example of a bounding cochain. Compare it with the weak Maurer-Cartan equation (2.1).

[^32]:    ${ }^{44}$ It is just $\mathfrak{m}_{1+k}(-, b, \ldots, b)$ if $n=0$.

[^33]:    ${ }^{45}$ Here it is just $k$ as we are using the $\mathbb{Z}_{2}$-grading.

[^34]:    ${ }^{46}$ Equivalently, we can assign a Morse function $f_{L}: S^{1} \rightarrow \mathbb{R}$ on the domain of $L$ which has a minimum at $e_{L}$ and a maximum at $o_{L}$ so that they are all critical points of $f_{L}$. Graph of its differential $d f_{L}$ induces a $C^{0}$-small Hamiltonian perturbation $\phi_{H}(L)$ in a neighborhood of $L$ so that they make transversal intersections at $e_{L}$ and $o_{L}$.
    ${ }^{47}$ We need this condition for the $A_{\infty}$-relations (without $\mathfrak{m}_{0}$-terms) to hold. See [Abo08].
    ${ }^{48}$ In fact, every connection is flat in this case because $\operatorname{dim} S^{1}=1$, but we still stick to the terminology to emphasize that it defines a local system.

[^35]:    ${ }^{49}$ It is the only invariant of flat bundles under gauge equivalence. Two gauge equivalent flat bundles $\left(E_{1}, \nabla_{1}\right)$ and $\left(E_{2}, \nabla_{2}\right)$ define quasi-isomorphic objects in the Fukaya category. See, for example, Proposition 4.9 in [Bae17].

[^36]:    ${ }^{50}$ If $e_{L}$ or $o_{L}$ 's are involved as inputs, the definition of $A_{\infty}$-operation becomes much complicated. See Remark A. 9 for some cases.

[^37]:    ${ }^{51}$ But see also Figure 20 for the case where many $o_{L_{i}}$ 's are involved.

[^38]:    ${ }^{52}$ These conditions imply that $P^{0}$ and $P^{1}$ have the same rank. Moreover, $\psi$ is completely determined by $\varphi$ and vice versa.

[^39]:    ${ }^{53}$ All discussions in this section (except for Proposition A.15) can be found in Chapter 7 in [Yos90].
    ${ }^{54}$ In general, one can take the quotient of a Frobenius category by its projective objects to make it a triangulated category, called the stable category. See $\$ 3.3$ in [Kra21].
