

The Honeymoon Oberwolfach Problem: small cases

MARIE ROSE JERADE and MATEJA ŠAJNA*

University of Ottawa

July 2, 2024

Abstract

The Honeymoon Oberwolfach Problem $\text{HOP}(2m_1, 2m_2, \dots, 2m_t)$ asks the following question. Given $n = m_1 + m_2 + \dots + m_t$ newlywed couples at a conference and t round tables of sizes $2m_1, 2m_2, \dots, 2m_t$, is it possible to arrange the $2n$ participants at these tables for $2n - 2$ meals so that each participant sits next to their spouse at every meal, and sits next to every other participant exactly once? A solution to $\text{HOP}(2m_1, 2m_2, \dots, 2m_t)$ is a decomposition of $K_{2n} + (2n - 3)I$, the complete graph K_{2n} with $2n - 3$ additional copies of a fixed 1-factor I , into 2-factors, each consisting of disjoint I -alternating cycles of lengths $2m_1, 2m_2, \dots, 2m_t$.

The Honeymoon Oberwolfach Problem was introduced in a 2019 paper by Lepine and Šajna. The authors conjectured that $\text{HOP}(2m_1, 2m_2, \dots, 2m_t)$ has a solution whenever the obvious necessary conditions are satisfied, and proved the conjecture for several large cases, including the uniform cycle length case $m_1 = \dots = m_t$, and the small cases with $n \leq 9$. In the present paper, we extend the latter result to all cases with $n \leq 20$ using a computer search.

Keywords: Honeymoon Oberwolfach Problem, 2-factorization, semi-uniform 1-factorization, HOP-colouring-orientation.

1 Introduction

The well-known Oberwolfach Problem, denoted $\text{OP}(m_1, \dots, m_t)$, asks whether $n = m_1 + \dots + m_t$ participants can be seated at t tables of sizes m_1, \dots, m_t for several nights in a row so that each participant gets to sit next to every other participant exactly once. Thus, we are asking whether K_n , the complete graph on n vertices, admits a 2-factorization such that each 2-factor is a disjoint union of t cycles of lengths m_1, \dots, m_t . The problem has been solved in many special cases — see [1, 2, 3, 5, 6, 7, 8, 9, 10, 12, 13] — but is in general still open.

In the 2019 paper [11], Lepine and the second author introduced a new variant of the Oberwolfach Problem, called the Honeymoon Oberwolfach Problem. This problem, denoted $\text{HOP}(m_1, \dots, m_t)$, can be described as follows. We have $n = \frac{1}{2}(m_1 + \dots + m_t)$ newlywed

*Corresponding author. Email: msajna@uottawa.ca. Mailing address: Department of Mathematics and Statistics, University of Ottawa, Ottawa, ON, Canada.

couples attending a conference and t tables of sizes m_1, \dots, m_t (where each $m_i \geq 3$). Is it possible to arrange the participants at these t round tables on $2n - 2$ consecutive nights so that each couple sit together every night, and every participant sits next to every other participant exactly once?

In graph-theoretic terms we are asking whether $K_{2n} + (2n - 3)I$, the multigraph obtained from the complete graph K_{2n} by adjoining $2n - 3$ additional copies of a chosen 1-factor I , admits a decomposition into 2-factors, each a vertex-disjoint union of cycles of lengths m_1, \dots, m_t , so that in each of these cycles, every other edge is a copy of an edge of I . A solution to $\text{HOP}(m_1, m_2, \dots, m_t)$ is equivalent to a *semi-uniform 1-factorization of K_{2n} of type (m_1, m_2, \dots, m_t)* ; that is, a 1-factorization $\{F_1, F_2, \dots, F_{2n-1}\}$ such that for all $i \neq 1$, the 2-factor $F_1 \cup F_i$ consists of disjoint cycles of lengths m_1, m_2, \dots, m_t .

If $m_1 = \dots = m_t = m$ and $tm = 2n$, then the symbol $\text{HOP}(m_1, \dots, m_t)$ is abbreviated as $\text{HOP}(2n; m)$. Note that if $\text{HOP}(m_1, \dots, m_t)$ has a solution, then the m_i are all even and at least 4; these are the obvious necessary conditions.

In [11], the authors proposed the following conjecture.

Conjecture 1.1 [11] *The obvious necessary conditions for $\text{HOP}(m_1, \dots, m_t)$ to have a solution are also sufficient.*

They also proved the conjecture in the following cases.

Theorem 1.2 [11] *Let m and n be positive integers, $2 \leq m \leq n$. Then $\text{HOP}(2n; 2m)$ has a solution if and only if $n \equiv 0 \pmod{m}$.*

Theorem 1.3 [11] *Let $2 \leq m_1 \leq \dots \leq m_t$ be integers, and $n = m_1 + \dots + m_t$. Then $\text{HOP}(2m_1, \dots, 2m_t)$ has a solution in each of the following cases.*

- (i) $m_i \equiv 0 \pmod{4}$ for all i .
- (ii) n is odd and $\text{OP}(m_1, \dots, m_t)$ has a solution.
- (iii) n is odd and $t = 2$.
- (iv) n is odd, $n < 40$, and $m_1 \geq 3$.
- (v) $n \leq 9$.

We remark that case (iv) of Theorem 1.3 is extended to $n \leq 60$ by the result of [12]. In this paper, we extend case (v) of Theorem 1.3, thus proving the following result.

Theorem 1.4 *Let m_1, \dots, m_t be integers with $m_i \geq 2$ for all i , and $n = m_1 + \dots + m_t$ such that $n \leq 20$. Then $\text{HOP}(2m_1, \dots, 2m_t)$ has a solution.*

To prove Theorem 1.4, we use the approach described in [11], combined with a computer-assisted search. In Sections 2 and 3, we present the relevant terminology and tools from [11], in Section 4, we give the framework of the proof of Theorem 1.4, while in the appendices, we list the computational results supporting the proof.

2 Terminology

In this paper, graphs may contain parallel edges, but not loops. As usual, K_n and λK_n denote the complete graph and the λ -fold complete graph, respectively, on n vertices. For $m \geq 2$, the symbol C_m denotes the cycle of length m , or m -cycle.

Let G be a graph, and let H_1, \dots, H_t be subgraphs of G . The collection $\{H_1, \dots, H_t\}$ is called a *decomposition* of G if $\{E(H_1), \dots, E(H_t)\}$ is a partition of $E(G)$.

An r -factor in a graph G is an r -regular spanning subgraph of G , and an r -factorization of G is a decomposition of G into r -factors. A 2-factor of G consisting of disjoint cycles of lengths m_1, \dots, m_t , respectively, is called a $(C_{m_1}, \dots, C_{m_t})$ -factor of G , and a decomposition into $(C_{m_1}, \dots, C_{m_t})$ -factors is called a $(C_{m_1}, \dots, C_{m_t})$ -factorization of G .

For a positive integer n and $S \subseteq \mathbb{Z}_n^*$ such that $S = -S$, we define a *circulant* $\text{Circ}(n; S)$ as the graph with vertex set $\{x_i : i \in \mathbb{Z}_n\}$ and edge set $\{x_i x_{i+d} : i \in \mathbb{Z}_n, d \in S\}$. An edge of the form $x_i x_{i+d}$ is said to be of *difference* d . Note that an edge of difference d is also of difference $n - d$, so we may assume that each difference is in $\{1, 2, \dots, \lfloor \frac{n}{2} \rfloor\}$.

In this paper, the complete graph K_n will be viewed as the join of the circulant $\text{Circ}(n - 1; \mathbb{Z}_{n-1}^*)$ and the complete graph K_1 with vertex x_∞ . Thus, $V(K_n) = \{x_i : i \in \mathbb{Z}_{n-1}\} \cup \{x_\infty\}$ and $E(K_n) = \{x_i x_j : i, j \in \mathbb{Z}_{n-1}, i \neq j\} \cup \{x_i x_\infty : i \in \mathbb{Z}_{n-1}\}$. If this is the case, then an edge of the form $x_i x_\infty$ will be called of *difference infinity*.

Let I be a chosen 1-factor in the graph K_{2n} . An edge of K_{2n} is said to be an I -edge if it belongs to $E(I)$, and a *non- I -edge* otherwise. The symbol $K_{2n} + \lambda I$ denotes the graph K_{2n} with λ additional copies of each I -edge, for a total of $\lambda + 1$ copies of each I -edge. (Note that these additional copies of I -edges of K_{2n} are then also considered to be I -edges of $K_{2n} + \lambda I$.) A cycle C of $K_{2n} + \lambda I$, necessarily of even length, is said to be I -alternating if the I -edges and non- I -edges along C alternate. A 2-factor (or 2-factorization) of $K_{2n} + \lambda I$ is said to be I -alternating if each of its cycles is I -alternating.

Thus, a solution to the Honeymoon Oberwolfach Problem $\text{HOP}(m_1, \dots, m_t)$ is an I -alternating $(C_{m_1}, \dots, C_{m_t})$ -factorization of $K_{2n} + (2n - 3)I$ for $2n = m_1 + m_2 + \dots + m_t$.

3 The Tools

As in [11], we use the symbol $4K_n^\bullet$ to denote the 4-fold complete graph with n vertices whose edges are coloured pink, blue, and black, and black edges are oriented so that each 4-set of parallel edges contains one pink edge, one blue edge, and two opposite black arcs.

Definition 3.1 [11] A 2-factorization \mathcal{D} of $4K_n^\bullet$ is said to be *HOP* if each cycle of \mathcal{D} satisfies the following condition:

- (C) any two adjacent (that is, consecutive) edges satisfy one of the following:
- one is blue and the other pink; or
 - both are black and directed in the same way;

- one is blue and the other black, directed towards the blue edge; or
- one is pink and the other black, directed away from the pink edge.

Theorem 3.2 [11] *Let m_1, \dots, m_t be integers greater than 1, and let $n = m_1 + \dots + m_t$. Then $HOP(2m_1, \dots, 2m_t)$ has a solution if and only if $4K_n^\bullet$ admits an $HOP(C_{m_1}, \dots, C_{m_t})$ -factorization.*

In the next proposition, the symbol $2K_n^\circ$ denotes the multigraph $2K_n$ whose edges are coloured pink and black so that each 2-set of parallel edges contains one pink edge and one black edge.

Proposition 3.3 [11] *Assume n is even, and let the vertex set of $2K_n^\circ$ be $\{x_i : i \in \mathbb{Z}_{n-1}\} \cup \{x_\infty\}$. Let ρ be the permutation $\rho = (x_\infty)(x_0 x_1 x_2 \dots x_{n-2})$, and let ρ_\circ denote the permutation on the edge set of $2K_n^\circ$ that is induced by ρ and that preserves the colour of the edges.*

Suppose $2K_n^\circ$ admits a $(C_{m_1}, \dots, C_{m_t})$ -factor F such that

(A1) *each cycle in F of length at least 3 contains an even number of pink edges, and*

(A2) *F contains exactly one edge from each of the orbits of $\langle \rho_\circ \rangle$.*

Then $4K_n^\bullet$ admits an $HOP(C_{m_1}, \dots, C_{m_t})$ -factorization.

Proposition 3.4 [11] *Assume n is even, and let the vertex set of $4K_n^\bullet$ be $\{x_i : i \in \mathbb{Z}_{n-1}\} \cup \{x_\infty\}$. Let ρ be the permutation $\rho = (x_\infty)(x_0 x_1 x_2 \dots x_{n-2})$, and let ρ_\bullet denote the permutation on the edge set of $4K_n^\bullet$ that is induced by ρ and that preserves the colour (and orientation) of the edges.*

Suppose $4K_n^\bullet$ admits edge-disjoint $(C_{m_1}, \dots, C_{m_t})$ -factors F_1 and F_2 such that

(D1) *each cycle in F_1 and F_2 satisfies Condition (C) in Definition 3.1, and*

(D2) *F_1 and F_2 jointly contain exactly one edge from each of the orbits of $\langle \rho_\bullet \rangle$.*

Then $\mathcal{D} = \{\rho_\bullet^i(F_1), \rho_\bullet^i(F_2) : i \in \mathbb{Z}_{n-1}\}$ is an $HOP(C_{m_1}, \dots, C_{m_t})$ -factorization of $4K_n^\bullet$.

Proposition 3.5 [11] *Assume n is odd, and let the vertex set of $4K_n^\bullet$ be $\{x_i : i \in \mathbb{Z}_{n-1}\} \cup \{x_\infty\}$. Let ρ be the permutation $\rho = (x_\infty)(x_0 x_1 x_2 \dots x_{n-2})$, and let ρ_\bullet denote the permutation on the edge set of $4K_n^\bullet$ that is induced by ρ and that preserves the colour (and orientation) of the edges.*

Suppose $4K_n^\bullet$ admits pairwise edge-disjoint $(C_{m_1}, \dots, C_{m_t})$ -factors F_1, F_2 , and F_3 such that

(E1) *each cycle in F_1, F_2 , and F_3 satisfies Condition (C) in Definition 3.1;*

(E2) *each orbit of $\langle \rho_\bullet \rangle$ has edges either in $F_1 \cup F_2$ or in F_3 ;*

(E3) if $e \in E(F_1 \cup F_2)$, then $\rho_{\bullet}^{\frac{n-1}{2}}(e) \in E(F_1 \cup F_2)$; and

(E4) $F_1 \cup F_2$ contains a pink and a blue edge of difference $\frac{n-1}{2}$.

Then $\mathcal{D} = \{\rho_{\bullet}^i(F_1), \rho_{\bullet}^i(F_2) : i = 0, 1, \dots, \frac{n-3}{2}\} \cup \{\rho_{\bullet}^i(F_3) : i \in \mathbb{Z}_{n-1}\}$ is an HOP $(C_{m_1}, \dots, C_{m_t})$ -factorization of $4K_n^{\bullet}$.

The required 2-factors F from Proposition 3.3, F_1 and F_2 from Proposition 3.4, and F_1, F_2 , and F_3 from Proposition 3.5 will be called the *starter 2-factors* (or *starters*) of the resulting 2-factorizations. Thus, we are referring to Propositions 3.3, 3.4, and 3.5 as the one-starter, two-starter, and three-starter approach, respectively.

4 Proof of Theorem 1.4

By the *type* of a $(C_{m_1}, \dots, C_{m_t})$ -factor we mean the multiset $[m_1, \dots, m_t]$.

PROOF. By Theorem 1.3(v), it suffices to consider $10 \leq n \leq 20$. For each value of n , we list all possible 2-factor types $[m_1, \dots, m_t]$, and refer to the result that guarantees existence of a solution to HOP $(2m_1, \dots, 2m_t)$. In cases where we are referring to Proposition 3.3, 3.4, or 3.5, appropriate starter 2-factors are given in the appendices.

A Guide to computational results

In cases where Proposition 3.3, 3.4, or 3.5 is used to prove existence of a solution to HOP($2m_1, \dots, 2m_t$), the remaining sections provide appropriate starter 2-factors.

- Where Proposition 3.3 is used: one starter, namely $F = \{C_0, C_1, \dots, C_{t-1}\}$.
- Where Proposition 3.4 is used: two starters, namely $F_1 = \{C_0, C_1, \dots, C_{t-1}\}$ and $F_2 = \{C'_0, C'_1, \dots, C'_{t-1}\}$.
- Where Proposition 3.5 is used: two starters, namely $F_1 = \{C_0, C_1, \dots, C_{t-1}\}$ and $F_3 = \{C'_0, C'_1, \dots, C'_{t-1}\}$. Note that in all cases, F_1 contains a 2-cycle consisting of a pink and blue edge of difference $\frac{n-1}{2}$. The starter 2-factor F_2 (as denoted in Proposition 3.5) is obtained from F_1 by applying $\rho_{\bullet}^{\frac{n-1}{2}}$ and then replacing the 2-cycle containing a pink and

blue edge of difference $\frac{n-1}{2}$ with a directed 2-cycle (with the same vertices) containing black arcs of length $\frac{n-1}{2}$.

The vertices of $2K_n^\circ$ or $4K_n^\bullet$ are labelled $0, 1, \dots, n-1$; label $n-1$ represents vertex x_∞ . Edge orbits are given in the form $[d, c]$ where $d \in \{1, 2, \dots, \lfloor \frac{n-1}{2} \rfloor\} \cup \{n-1\}$ is the difference (with $n-1$ representing the infinity difference), and c is the colour-orientation: 0 for pink, 2 for blue, 1 for black (single starter cases) or black orientated forward (two- and three-starter cases), and -1 for black oriented backward. We consider an arc $(u, u+d)$, for $u, d \in \mathbb{Z}_{n-1}$, oriented forward if $d < \frac{n-1}{2}$, and oriented backward if $d > \frac{n-1}{2}$. The case $d = \frac{n-1}{2}$ can occur only in the three-starter approach (that is, for odd n); however, in this case, black arcs of difference $\frac{n-1}{2}$ appear only in the starter 2-factor F_2 , which is not specified below.

Each t -cycle in a starter 2-factor is presented in the form

$$C = [v_0, [d_0, c_0], v_1, [d_1, c_1], v_2, \dots, v_{t-2}, [d_{t-2}, c_{t-2}], v_{t-1}, [d_{t-1}, c_{t-1}]],$$

where v_0, v_1, \dots, v_{t-1} are the consecutive vertices of the cycle, and $[d_i, c_i]$ represents the orbit of the edge $v_i v_{i+1}$, for $i \in \mathbb{Z}_t$, as explained above.

B Computational results for $n = 10$

- 2-factor type $[4, 2, 2, 2]$: one starter
