

# Nijenhuis geometry of parallel tensors

Andrzej Derdzinski, Paolo Piccione, and Ivo Terek

ABSTRACT. A tensor – meaning here a tensor field  $\Theta$  of any type  $(p, q)$  on a manifold – may be called integrable if it is parallel relative to some torsion-free connection. We provide analytical and geometric characterizations of integrability for differential  $q$ -forms,  $q = 0, 1, 2, n - 1, n$  (in dimension  $n$ ), vectors, bivectors, symmetric  $(2, 0)$  and  $(0, 2)$  tensors, as well as complex-diagonalizable and nilpotent tensors of type  $(1, 1)$ . In most cases, integrability is equivalent to algebraic constancy of  $\Theta$  coupled with the vanishing of one or more suitably defined Nijenhuis-type tensors, depending on  $\Theta$  via a quasilinear first-order differential operator. For  $(p, q) = (1, 1)$ , they include the ordinary Nijenhuis tensor.

## 1. Introduction

We refer to a tensor field  $\Theta$  of any type on a manifold  $M$  as *algebraically constant* when, for any  $x, y \in M$ , some linear isomorphism  $T_x M \rightarrow T_y M$  sends  $\Theta_x$  to  $\Theta_y$ . The algebraic constancy amounts to being constant for functions, to vanishing nowhere or everywhere in the case of vector fields and 1-forms, and to having constant rank for symmetric or skew-symmetric  $(0, 2)$  and  $(2, 0)$  tensors.

We call a tensor field  $\Theta$  *integrable* if some torsion-free connection makes it parallel, and *locally constant* if it has constant components in suitable local coordinates around each point. As one sees using a partition of unity, for integrability it suffices that such torsion-free connections exist locally. Thus,

(1.1) the local constancy of  $\Theta$  implies its integrability (but not conversely),

counterexamples to the converse being nonflat pseudo-Riemannian metrics.

Given an algebraically constant tensor  $\Theta$  on a manifold  $M$  and a distribution  $\mathcal{D} \subseteq TM$  naturally associated with it, as  $\mathcal{D}$  is obviously  $\nabla$ -parallel when  $\nabla\Theta = 0$ ,

(1.2) the integrability of  $\Theta$  implies the distribution-integrability of  $\mathcal{D}$ .

The local constancy of an algebraically constant tensor is nothing else than integrability, in the sense of [15, Prop. 1.1], of the corresponding  $G$ -structure (Remark 6.1).

With a  $(1, 1)$  tensor  $\Theta$  on a manifold  $M$  one associates its Nijenhuis tensor  $N$ , introduced by Nijenhuis [18] and studied by many others [4, 5, 7, 9, 10, 12,

---

**14, 17, 23**], which sends vector fields  $v, w$  to the vector field

$$(1.3) \quad N(v, w) = \Theta[\Theta v, w] + \Theta[v, \Theta w] - [\Theta v, \Theta w] - \Theta^2[v, w].$$

As pointed out by several authors [7, Sect. 2.3], [4, Definition 2.2],  $N = 0$  identically whenever  $\Theta$  is integrable since, for any torsion-free connection  $\nabla$  on  $M$ ,

$$(1.4) \quad N(v, w) = [\Theta \nabla_v \Theta - \nabla_{\Theta v} \Theta]w + [\nabla_{\Theta w} \Theta - \Theta \nabla_w \Theta]v.$$

Various generalizations of the Nijenhuis tensor have been proposed [3, 16, 20, 21, 22]. Below, after stating Proposition G, we elaborate on such generalizations that are of interest to us and have therefore been introduced in this paper.

Complex-diagonalizability of a linear endomorphism of a finite-dimensional real vector space  $V$  means, as usual, diagonalizability of its complex-linear extension to the complexification of  $V$ . Since any endomorphism of  $V$  is, uniquely, the sum of a complex-diagonalizable and a nilpotent one [13, Sect. 4.2], it is natural to deal with these two cases separately.

In Sect. 5, 8–9, 11, 13, 14 and 15–16 we prove our seven main results, stated below. We begin with a fact due to Kurita [17, Theorem 9], which also easily follows (see Sect. 3) from a theorem of Bolsinov, Konyaev and Matveev [4, Theorem 3.2].

REMARK A. For an algebraically constant complex-diagonalizable (1,1) tensor  $\Theta$  on a manifold  $M$  of dimension  $n \geq 1$ , the vanishing of  $N$  is equivalent to the integrability of  $\Theta$ , as well as to its local constancy.

Algebraically constant tensors  $\Theta$  of type (1,1) give rise to the vector subbundles  $\mathcal{Z}^i = \text{Ker } \Theta^i$  and  $\mathcal{B}^i = \text{Im } \Theta^i$  of  $TM$ , for integers  $i \geq 0$ .

THEOREM B. *Given an algebraically constant nilpotent (1,1) tensor  $\Theta$  on a manifold  $M$  of dimension  $n \geq 1$ , the following four conditions are equivalent.*

- (i)  $N = 0$  and  $\mathcal{Z}^i = \text{Ker } \Theta^i$  is integrable for every  $i = 1, \dots, n$ .
- (ii) In some commuting local frame  $e_1, \dots, e_n$  around each point,  $\Theta$  has the Jordan normal form, with  $\Theta e_1 = 0$  and  $\Theta e_i = 0$  or  $\Theta e_i = e_{i-1}$  if  $i > 1$ .
- (iii)  $\Theta$  is locally constant.
- (iv)  $\Theta$  is integrable.

The Jordan normal form of an algebraically constant nilpotent (1,1) tensor  $\Theta$  may be represented by

$$(1.5) \quad \text{a weakly decreasing string } d_1 \dots d_m \text{ of positive integers,}$$

each  $d_q$  standing for a  $d_q \times d_q$  Jordan block matrix with ones immediately above the diagonal and zeros everywhere else. Of interest to us are the Jordan normal forms  $d_1 \dots d_m$  such that  $d_1 = \dots = d_{m-1}$ . In other words,

$$(1.6) \quad \begin{array}{l} \text{either all blocks have the same length, or they represent exactly} \\ \text{two different lengths, with the shorter one occurring just once.} \end{array}$$

We say that a given algebraic type of an algebraically constant nilpotent (1,1) tensor  $\Theta$  is *controlled by the Nijenhuis tensor* if the vanishing of  $N$  implies, on any underlying manifold, the local constancy of  $\Theta$ .

THEOREM C. *Condition (1.6) imposed on the Jordan normal form of an algebraically constant nilpotent (1,1) tensor  $\Theta$  on a manifold  $M$  of dimension  $n \geq 1$  is necessary and sufficient for the algebraic type of  $\Theta$  to be controlled by its Nijenhuis tensor.*

For nilpotent  $(1, 1)$  tensors  $\Theta$  which are *generic*, that is,  $\dim \text{Ker } \Theta = 1$  or, equivalently, the Jordan normal form of  $\Theta$  is the one-term string  $n$  (a single Jordan block), the sufficiency of (1.6) in Theorem C is a result of Kobayashi [14, Sect. 3]. See also [10, Cor. 2.4], [23, Theorem 1], [5, Theorem 1.3, Cor. 1.5], [4, Theorem 4.6]. Kobayashi [14, Sect. 5] further illustrated the necessity of (1.6) by an example, with  $n = 4$  and the Jordan normal form 211, cited in [4, Example 2.1].

Sect. 10 exhibits a special case of Theorem C by means of an affine-bundle construction, resulting in *generalized almost-tangent structures*: nonzero algebraically constant nilpotent  $(1, 1)$  tensors  $\Theta$  with  $\Theta^2 = 0$ , that is, having the Jordan normal form  $2 \dots 2$  or  $2 \dots 21 \dots 1$ . The normal form  $2 \dots 2$ , also characterized by the condition  $\text{Ker } \Theta = \text{Im } \Theta$ , represents the *almost-tangent structures* [25], for which the assertion of Theorem C is due to Goel [9, Theorem 2.4].

We justify the following observation in Sect. 11.

PROPOSITION D. *The closedness of an algebraically constant differential  $q$ -form on an  $n$ -manifold,  $q = 0, 1, 2, n - 1, n$ , implies its local constancy.*

The converse implication (closedness from integrability, and hence also from local constancy) is obviously true for forms of all degrees.

Even weakened by the replacement of local constancy with integrability – cf. (1.1) – Proposition D fails to hold for differential forms of other degrees: as we verify in Sect. 12, for any dimension  $n \geq 5$  and any  $q \in \{3, \dots, n - 2\}$ , in local coordinates  $x^1, \dots, x^n$ , the following formula defines a differential  $q$ -form  $\zeta$  which is algebraically constant and closed, but not integrable:

$$(1.7) \quad \zeta = (dx^1 \wedge dx^2 + dx^3 \wedge dx^4) \wedge (dx^5 + x^1 dx^2 - x^3 dx^4) \wedge dx^6 \wedge \dots \wedge dx^{q+2}.$$

Constant-rank (skew)symmetric  $(0, 2)$  and  $(2, 0)$  tensors, being bundle morphisms  $TM \rightarrow T^*M$  or  $T^*M \rightarrow TM$ , have well-defined kernels and images. The next proposition uses the natural concept of projectability, presented in Sect. 2.

PROPOSITION E. *Let  $g$  be a constant-rank symmetric  $(0, 2)$  tensor on a manifold. For the integrability of  $g$  it is then necessary and sufficient that the distribution  $\text{Ker } g$  be integrable, and  $g$  projectable along  $\text{Ker } g$ .*

The sweeping recent result of Bandyopadhyay, Dacorogna, Matveev and Troyanov [1, Theorem 4.4] provides a characterization of local constancy for  $(0, 2)$  tensors *without any symmetry/skew-symmetry assumptions*. Our Proposition E, much more modest in scope, focuses on the symmetric case and integrability (as opposed to local constancy); what we gain is simplicity of the resulting conditions.

In contrast with 1-forms (Proposition D), the local constancy of a vector field obviously follows just from its algebraic constancy. An analogous difference occurs between symmetric  $(2, 0)$  tensors and symmetric  $(0, 2)$  tensors: the former – unlike the latter – require no projectability condition to guarantee integrability.

PROPOSITION F. *The integrability of a constant-rank symmetric  $(2, 0)$  tensor  $\Theta$  on a manifold is equivalent to the integrability of  $\text{Im } \Theta$ .*

Such tensors  $\Theta$  can be naturally identified (see Remark 2.3) with *sub-pseudo-Riemannian metrics* [11], which include the sub-Riemannian ones [2].

For a bivector, that is, a skew-symmetric  $(2, 0)$  tensor  $\Theta$ , assumed to have constant rank, formula (2.7) defines the *restriction* of  $\Theta$  to  $\mathcal{B} = \text{Im } \Theta$ , which is a nondegenerate section of  $\mathcal{B}^{\wedge 2}$ , thus giving rise to its inverse, a section of  $[\mathcal{B}^*]^{\wedge 2}$ .

PROPOSITION G. *A constant-rank bivector  $\Theta$  on a manifold is locally constant or – equivalently – integrable if and only if the distribution  $\text{Im } \Theta$  is integrable and the inverse of the restriction of  $\Theta$  to  $\text{Im } \Theta$  is closed along each leaf of  $\text{Im } \Theta$ .*

The generalizations of the Nijenhuis tensor which are of interest to us are motivated by Remark A, Theorem C and Proposition D: we want to associate with a given tensor  $\Theta$  one (or more) Nijenhuis-type tensor(s), each depending on  $\Theta$  via a quasilinear first-order differential operator, in such a way that, if  $\Theta$  algebraically constant, the vanishing of these tensors is equivalent to the integrability of  $\Theta$ .

As an example,  $N$  given by (1.3) serves in this capacity for complex-diagonalizable  $(1, 1)$  tensors and nilpotent  $(1, 1)$  tensors with the property (1.6); its quasi-linearity is immediate from (1.4). In the case of differential  $q$ -forms  $\zeta$  in dimension  $n$ , where  $q \in \{0, 1, 2, n-1, n\}$  (but not – see (1.7) – for other degrees), the exterior derivative  $d\zeta$  is a Nijenhuis-type tensor in our sense, while an analogous role for vector fields is played by the zero tensor.

For any symmetric  $(0, 2)$  tensor  $g$  of constant rank  $r$  on a manifold  $M$ , we introduce two Nijenhuis-type tensors  $N'$  and  $N''$ , both of type  $(0, 2r+3)$ , defined as follows:  $N'$  (or,  $N''$ ) sends vector fields  $v, v_1, \dots, v_r$  (or,  $w, u, v_1, \dots, v_r$ ) to the  $(r+2)$ -form, or  $(r+1)$ -form

$$(1.8) \quad \begin{aligned} \text{a) } & N'(v, v_1, \dots, v_r) = d[g(v, \cdot)] \wedge g(v_1, \cdot) \wedge \dots \wedge g(v_r, \cdot), \\ \text{b) } & N''(w, u, v_1, \dots, v_r) = \{[\mathcal{L}g](w, u)\} \wedge g(v_1, \cdot) \wedge \dots \wedge g(v_r, \cdot), \end{aligned}$$

$[\mathcal{L}g](w, u)$  being treated here, formally, as a 1-form sending any vector field  $v$  to the function  $[\mathcal{L}_v g](w, u)$ . The word ‘formally’ reflects the fact that  $[\mathcal{L}g](w, u)$  is not tensorial in  $v$ . Nevertheless, in Sect. 15–16 we point out that  $N'$  and  $N''$  are well-defined tensors, and prove the following result.

THEOREM H. *The vanishing of both  $N'$  and  $N''$  is necessary and sufficient for the integrability of the given symmetric  $(0, 2)$  tensor  $g$  of constant rank  $r$ .*

The lines following formula (15.3) in Sect. 15 provide a set of  $d_1$  Nijenhuis-type tensors for an algebraically constant nilpotent  $(1, 1)$  tensor  $\Theta$  with the Jordan normal form  $d_1 \dots d_m$ . This set consists of  $N$  – see (1.3) – and  $d_1 - 1$  additional tensors responsible for integrability of  $\text{Ker } \Theta^i$ ,  $1 \leq i < d_1$  (which makes them redundant in the case (1.6), due to Theorem C).

Finally, formulae (15.4) – (15.5) in Sect. 15 define, for (skew)symmetric  $(2, 0)$  tensors  $\Theta$  of constant rank  $r$ , a Nijenhuis-type  $(2r+3, 0)$  tensor  $\widehat{N}$  such that  $\widehat{N} = 0$  if and only if  $\text{Im } \Theta$  is integrable. When  $\Theta$  is symmetric, the vanishing of  $\widehat{N}$  thus amounts, by Proposition F, to integrability of  $\Theta$ . However, for a rank  $r$  bivector  $\Theta$ , the condition  $\widehat{N} = 0$ , despite still being necessary, is not sufficient in order that  $\Theta$  be integrable. Obvious examples illustrating the last claim arise, cf. Proposition G, on a product manifold  $M = \Sigma \times \Sigma'$ , with  $\Theta$  obtained as the trivial extension to  $M$  of the inverse of a nonclosed nondegenerate 2-form on  $\Sigma$ .

## 2. Preliminaries

Manifolds (by definition connected) and mappings, including sections of bundles, are always assumed to be smooth. Tensor fields will usually be referred to as *tensors*. All vector spaces are real (except in Sect. 3) and finite-dimensional.

Given a manifold  $M$  and vector subbundles  $\mathcal{D}, \mathcal{D}', \mathcal{D}''$  of  $TM$ , we write

$$(2.1) \quad [\mathcal{D}, \mathcal{D}'] \subseteq \mathcal{D}''$$

when  $[w, w']$  is a local section of  $\mathcal{D}''$  for any local sections  $w$  of  $\mathcal{D}$  and  $w'$  of  $\mathcal{D}'$ .

LEMMA 2.1. *For  $M, \mathcal{D}, \mathcal{D}'$  as above, suppose that  $\mathcal{D}$  contains  $\mathcal{D}'$  with codimension one, and  $[\mathcal{D}, \mathcal{D}'] \subseteq \mathcal{D}$ . Then  $\mathcal{D}$  is integrable.*

PROOF. As  $[\mathcal{D}', \mathcal{D}'] \subseteq \mathcal{D}$ , the relation  $[\mathcal{D}, \mathcal{D}] \subseteq \mathcal{D}$  follows if we note that, locally, sections of  $\mathcal{D}$  have the form  $v + \phi w$  for various sections  $v$  of  $\mathcal{D}'$ , functions  $\phi$ , and one fixed section  $w$  of  $\mathcal{D}$ .  $\square$

Let  $\pi : M \rightarrow \Sigma$  be a mapping between manifolds. We say that a vector field  $w$  (or, a distribution  $\mathcal{Z}$ ) on  $M$  is  $\pi$ -projectable if  $d\pi_x w_x = u_{\pi(x)}$  or, respectively,  $d\pi_x(\mathcal{Z}_x) = \mathcal{W}_{\pi(x)}$  for all  $x \in M$  and some vector field  $u$  (or, distribution  $\mathcal{W}$ ) on  $\Sigma$ . If this is the case,

$$(2.2) \quad \text{the integrability of } \mathcal{Z} \text{ implies that of } \mathcal{W},$$

since  $\pi$  restricted to any leaf of  $\mathcal{Z}$  is, locally, a submersion onto an integral manifold of  $\mathcal{W}$ . We also define  $\pi$ -projectability of a  $(0, q)$  tensor field  $\Theta$  on  $M$  by requiring  $\Theta$  to be the  $\pi$ -pullback of a  $(0, q)$  tensor field on  $\Sigma$ .

Given an integrable distribution  $\mathcal{V}$  on a manifold  $M$ , every point of  $M$  has a neighborhood  $U$  such that, for some manifold  $\Sigma$ , the leaves of  $\mathcal{V}$  restricted to  $U$  are the fibres of a bundle projection  $\pi : U \rightarrow \Sigma$ .

Let  $\mathcal{V}$  be an integrable distribution on a manifold  $M$ . By  $\mathcal{V}$ -projectability of a vector field on an open set  $U' \subseteq M$  (or, of a distribution on  $U'$ , or of a  $(0, q)$  tensor field on  $U'$ ) we mean its  $\pi$ -projectability for any  $\pi, U, \Sigma$  as in the last paragraph such that  $U \subseteq U'$ . Then, for a vector field  $w$  on  $M$ ,

$$(2.3) \quad \begin{aligned} w \text{ is } \mathcal{V}\text{-projectable if and only if, for every section} \\ v \text{ of } \mathcal{V}, \text{ the Lie bracket } [v, w] \text{ is also a section of } \mathcal{V}. \end{aligned}$$

(This is obvious in local coordinates for  $M$  turning  $\pi$  as above into a Cartesian-product projection.) It is also clear that, given a  $(0, q)$  tensor field  $\Theta$ ,

$$(2.4) \quad \begin{aligned} \Theta \text{ is } \mathcal{V}\text{-projectable if and only if } d_v[\Theta(w_1, \dots, w_q)] = 0 \text{ for all sec-} \\ \text{tions } v \text{ of } \mathcal{V} \text{ and all } \mathcal{V}\text{-projectable local vector fields } w_1, \dots, w_q. \end{aligned}$$

LEMMA 2.2. *For an integrable distribution  $\mathcal{V}$  and any distribution  $\mathcal{Z}$  on an  $n$ -dimensional manifold  $M$ , the following two conditions are equivalent.*

- (a)  $\mathcal{Z}$  is  $\mathcal{V}$ -projectable,
- (b)  $\mathcal{Z} \cap \mathcal{V}$  has a constant dimension and  $[\mathcal{V}, \mathcal{Z}] \subseteq \mathcal{V} + \mathcal{Z}$ .

Under the additional assumption that  $\mathcal{V} \subseteq \mathcal{Z}$ ,

- (c)  $\mathcal{Z}$  is  $\mathcal{V}$ -projectable if and only if  $[\mathcal{V}, \mathcal{Z}] \subseteq \mathcal{Z}$ .

PROOF. The equivalence of (a) and (b), once established, trivially implies (c) when  $\mathcal{V} \subseteq \mathcal{Z}$ . We proceed, however, by first proving (c), in the case where  $\mathcal{V} \subseteq \mathcal{Z}$ . It will then clearly follow from (c) that (a) and (b) are equivalent, since  $\mathcal{V}$ -projectability of  $\mathcal{Z}$  amounts to  $\mathcal{V}$ -projectability of  $\mathcal{V} + \mathcal{Z}$ , and  $\mathcal{V} \subseteq \mathcal{V} + \mathcal{Z}$ .

If  $\mathcal{V} \subseteq \mathcal{Z}$  and  $\mathcal{Z}$  is  $\mathcal{V}$ -projectable, onto some distribution  $\mathcal{W}$  on a local leaf space of  $\mathcal{V}$ , then  $\mathcal{Z}$  is spanned by  $\mathcal{V}$ -projectable sections obtained as lifts of sections of  $\mathcal{W}$  (including sections of  $\mathcal{V}$ , which are lifts of 0). As any section of  $\mathcal{Z}$  is a functional combination of  $\mathcal{V}$ -projectable ones, (2.3) yields  $[\mathcal{V}, \mathcal{Z}] \subseteq \mathcal{Z}$ .

Conversely, let  $\mathcal{V} \subseteq \mathcal{Z}$  and  $[\mathcal{V}, \mathcal{Z}] \subseteq \mathcal{Z}$ . We choose local coordinates  $x^1, \dots, x^n$  such that  $\mathcal{V}$  is spanned by the coordinate vector fields  $\partial_i$ ,  $i = 1, \dots, m$ , and a local

trivialization of the subbundle  $\mathcal{Z}$  of  $TM$  having the form  $\partial_1, \dots, \partial_m, w_{m+1}, \dots, w_s$ . Using the index ranges  $1 \leq i, j, k \leq m < a, b, c \leq s$ , we obtain, since  $[\mathcal{V}, \mathcal{Z}] \subseteq \mathcal{Z}$ ,

$$(2.5) \quad [\partial_i, w_a] = \Gamma_{ia}^j \partial_j + \Gamma_{ia}^b w_b$$

for some functions  $\Gamma_{ia}^j, \Gamma_{ia}^b$ . The  $w_b$ -component of the Jacobi identity  $[\partial_i, [\partial_j, w_a]] = [\partial_j, [\partial_i, w_a]]$ , with  $[\partial_i, \partial_j] = 0$ , now implies *symmetry of  $\partial_i \Gamma_{ja}^b + \Gamma_{ic}^b \Gamma_{ja}^c$  in  $i, j$* . This symmetry amounts to the vanishing of the curvature, that is, flatness, for the linear connection with the components  $\Gamma_{ia}^b$  in a rank  $s - m$  vector bundle over a manifold with the coordinates  $x^i, i = 1, \dots, m$ . The equations  $\partial_i \psi^b + \Gamma_{ic}^b \psi^c = 0$ , stating that  $\psi^a$ , with  $m < a \leq s$ , are the components of a parallel section  $\psi$ , is thus locally solvable with any prescribed initial value at a given point  $z$ . Let us choose such a section  $\psi_a$ , for  $a = m + 1, \dots, s$ , with the initial value  $(\delta_a^1, \dots, \delta_a^m)$  at  $z$ , so that

$$(2.6) \quad \partial_i \psi_a^b + \Gamma_{ic}^b \psi_a^c = 0, \quad \psi_a^b(z) = \delta_a^b.$$

Setting  $u_a = \psi_a^b w_b$ , we obtain a new local trivialization  $\partial_1, \dots, \partial_m, u_{m+1}, \dots, u_s$  of  $\mathcal{Z}$  while, by (2.5) and (2.6),  $[\partial_i, u_a]$  are sections of  $\mathcal{Z}$ . Therefore, due to (2.3), our new local trivialization of  $\mathcal{Z}$  consists of  $\mathcal{V}$ -projectable sections, which makes  $\mathcal{Z}$  itself  $\mathcal{V}$ -projectable.  $\square$

Given a symmetric or skew-symmetric  $(2, 0)$  tensor  $\Theta$  in a vector space  $V$ , let  $\text{Ker } \Theta$  and  $\text{Im } \Theta$  be the kernel and image of  $V^* \ni \xi \mapsto \Theta(\xi, \cdot) \in V$ . By the *restriction* of  $\Theta$  to  $W = \text{Im } \Theta$  we mean the  $(2, 0)$  tensor  $\Theta_W$  in  $W$  given by

$$(2.7) \quad \begin{aligned} \Theta_W(\eta, \eta') &= \Theta(\xi, \xi') \text{ for any } \eta, \eta' \in W^* \text{ and} \\ &\text{any extensions } \xi, \xi' : V \rightarrow \mathbb{R} \text{ of } \eta, \eta' \text{ to } V. \end{aligned}$$

As  $\xi$  and  $\xi'$  are unique up to adding elements of  $W' = \text{Ker } \Theta \subseteq V^*$ , the polar space of  $W$ , the restriction is well defined. In other words, since  $W' = \text{Ker } \Theta$ , the bilinear form  $\Theta$  on  $V^*$  descends to one on  $V^*/W' = W^*$ , which is our  $\Theta_W$ . (The natural identification of  $W^*$  with  $V^*/W'$  sends  $\eta \in W^*$  to the  $W'$ -coset of any extension of  $\eta$  to  $V$ .) In addition,  $\Theta$  is the image of  $\Theta_W$  under the linear operator  $W^{\odot 2} \rightarrow V^{\odot 2}$  or  $W^{\wedge 2} \rightarrow V^{\wedge 2}$  induced by the inclusion  $W \rightarrow V$ . Finally,

$$(2.8) \quad \text{the restriction } \Theta_W \text{ is nondegenerate,}$$

as any  $\eta \in W \setminus \{0\}$  has an extension  $\xi$  to  $V$  not lying in  $W' = \text{Ker } \Theta$ , and hence  $\Theta(\xi, \xi') \neq 0$  for some  $\xi' \in V^*$ .

**REMARK 2.3.** Constant-rank symmetric  $(2, 0)$  tensors  $\Theta$  on a manifold  $M$  are naturally identified with sub-pseudo-Riemannian metrics on  $M$ , that is, pseudo-Riemannian fibre metrics  $h$  on vector subbundles  $\mathcal{B}$  of  $TM$ . In fact, one may set  $\mathcal{B} = \text{Im } \Theta$  and, using (2.7) – (2.8), declare  $h$  to be the inverse of the restriction of  $\Theta$  to  $\mathcal{B}$ . Thus, cf. the lines preceding (2.8),  $\Theta$  is the image of the inverse of  $h$  under the bundle morphism  $\mathcal{B}^{\odot 2} \rightarrow [TM]^{\odot 2}$  induced by the inclusion  $\mathcal{B} \rightarrow TM$ .

The  $(r - 1)$ -fold contraction of two  $(r, 0)$ -tensors  $\Theta, \Pi$  on a manifold with a fixed Riemannian metric  $g$ , appearing in (i) below, is

$$(2.9) \quad \text{the } (2, 0) \text{ tensor } \beta \text{ given by } \beta^{ij} = \Theta^{i i_2 \dots i_r} \Pi^{j j_2 \dots j_r} g_{i_2 j_2} \dots g_{i_r j_r}.$$

**REMARK 2.4.** Let  $V$  be a Euclidean  $n$ -space with the inner product  $\langle \cdot, \cdot \rangle$ .

- (i) The  $(r-1)$ -fold contraction (2.9) against itself of a nonzero decomposable  $r$ -vector  $v_1 \wedge \dots \wedge v_r \in V^{\wedge r}$  yields a  $(2, 0)$  tensor which, viewed with the aid of  $\langle \cdot, \cdot \rangle$  as an endomorphism of  $V$ , equals a nonzero multiple of the orthogonal projection onto the span of  $v_1, \dots, v_r$ . (To see this, we are free to assume that  $v_1, \dots, v_r$  are orthonormal.)
- (ii) If  $V$  is oriented,  $*(e_1 \wedge \dots \wedge e_r) = e_{r+1} \wedge \dots \wedge e_n$  for the Hodge star  $* : V^{\wedge r} \rightarrow V^{\wedge(n-r)}$  and any positive orthonormal basis  $e_1, \dots, e_n$  of  $V$ .

REMARK 2.5. In an  $s \times (n-s)$  product  $n$ -dimensional manifold  $M$  with global product coordinates  $x^i, x^a$  (index ranges  $1 \leq i \leq s < a \leq n$ ), let the component functions  $g_{ij}, \Theta^{ij}$  and  $\Gamma_{ij}^k = \Gamma_{ji}^k$  represent families of  $(0, 2)$  tensors,  $(2, 0)$  tensors and torsion-free connections on the leaves of the integrable distribution spanned by the coordinate vector fields  $\partial_i$ . Suppose that each tensor is parallel relative to the corresponding connection on the leaf:  $\partial_i g_{jk} = \Gamma_{ij}^l g_{lk} + \Gamma_{ik}^l g_{jl}$  and  $\partial_i \Theta^{jk} = -\Gamma_{il}^j \Theta^{lk} - \Gamma_{il}^k \Theta^{jl}$ . Setting  $g_{\lambda\mu} = \Theta^{\lambda\mu} = \Gamma_{\lambda\mu}^\nu = 0$  whenever at least one of the indices  $\lambda, \mu, \nu \in \{1, \dots, n\}$  is in the  $a$  range, we extend the above data to their analogs defined on  $M$ , namely, a  $(0, 2)$  tensor  $g$ , a  $(2, 0)$  tensor  $\Theta$  and a torsion-free connection  $\nabla$ , in such a way that, obviously,  $\nabla g = \nabla \Theta = 0$ .

### 3. The complex-diagonalizable case

By (1.3), for a  $(1, 1)$  tensor field  $\Theta$  and any  $a \in \mathbb{R}$ ,

$$(3.1) \quad \Theta \quad \text{and} \quad \Theta - a\text{Id} \quad \text{have the same Nijenhuis tensor.}$$

To justify Remark A, we invoke a result of Bolsinov, Konyaev and Matveev [4, Theorem 3.2]. It states that, if a  $(1, 1)$  tensor  $\Theta$  with  $N = 0$  on a manifold  $M$  has complex characteristic roots of constant (algebraic) multiplicities, then  $M$  and  $\Theta$  are, locally, decomposed into Cartesian products of factor manifolds/tensors with  $N = 0$ , where each factor corresponds to (and realizes) a real eigenvalue function of  $\Theta$ , or a conjugate pair of its (nonreal) complex characteristic-root functions.

Under the assumption made in Remark A, the complex characteristic roots of  $\Theta$  are all constant. Let the symbols  $M$  and  $\Theta$  now stand for one of of factor manifolds/tensors with  $N = 0$ , mentioned above.

If the (constant) eigenvalue realized by this  $\Theta$  is real, our claim follows:  $\Theta$  equals a constant multiple of  $\text{Id}$ .

Otherwise, the characteristic roots realized by  $\Theta$  are  $a \pm bi$ , with  $a, b \in \mathbb{R}$  and  $b \neq 0$ . Let  $J = b^{-1}(\Theta - a\text{Id})$ . By (3.1),  $J$  still has  $N = 0$ , while the characteristic roots of  $J$  (and hence those of its complexification  $\hat{J}$ ) are  $i$  and  $-i$ . As  $\hat{J}$  is diagonalizable – due to our assumption – we get  $\hat{J}^2 = -\text{Id}$ . Thus,  $J^2 = -\text{Id}$ , and the local constancy of  $\Theta$  follows from the Newlander-Nirenberg theorem.

The more modest goal of establishing a weaker version of Remark A, with integrability of  $\Theta$  replacing its local constancy, is easily achieved as follows. Rather than invoking the Newlander-Nirenberg theorem, one shows that an almost-complex structure  $J$  or, more generally, a  $(1, 1)$  tensor  $J$  with  $N = 0$  and  $J^2 = c\text{Id}$ , where  $c \in \mathbb{R} \setminus \{0\}$ , has  $\hat{\nabla}J = 0$  for some torsion-free connection  $\hat{\nabla}$ .

We start from any torsion-free connection  $\nabla$ . By (1.4),  $4c[B_v w - B_w v] = N(v, w)$  for  $B_v w$  given by  $4cB_v w = 2J[\nabla_v J]w + J[\nabla_w J]v + [\nabla_{Jw} J]v$ , that is,  $4cB_v w = (J[\nabla_v J]w + J[\nabla_w J]v) + (J[\nabla_v J]w + [\nabla_{Jw} J]v)$ . Thus, the vanishing of  $N$  for  $J$  amounts to symmetry of  $B_v w$  in  $v, w$ , while  $[J, B_v] = \nabla_v J$  since,  $J^2$

being parallel,  $\nabla_v J$  anticommutes with  $J$ . This is precisely the relation  $\hat{\nabla}J = 0$  for the torsion-free connection  $\hat{\nabla}$  characterized by  $\hat{\nabla}_v = \nabla_v + B_v$ .

The assignment  $\nabla \mapsto \hat{\nabla} = \nabla + B$  appearing above is a natural projection of the affine space of all torsion-free connections on the manifold in question onto the affine subspace formed by those connections which make  $J$  parallel.

The above conclusion is due to Clark and Bruckheimer [7, Theorem 6]. Our argument is a concise version of one used, in a more general situation, by Hernando, Reyes and Gadea [12, Theorems 3.4 and 7.1].

#### 4. Tensors of type (1, 1)

For the reader's convenience, we repeat here the definition, due to Nijenhuis [18], of the Nijenhuis tensor (1.3) associated with a (1, 1) tensor  $\Theta$  on a manifold:

$$(4.1) \quad N(v, w) = \Theta[\Theta v, w] + \Theta[v, \Theta w] - [\Theta v, \Theta w] - \Theta^2[v, w].$$

Applying  $\Theta^i$  to both sides, with any integer  $i \geq 0$ , one obviously obtains

$$(4.2) \quad \Theta^{i+1}(\Theta[v, w] - [v, \Theta w]) = \Theta^i(\Theta[\Theta v, w] - [\Theta v, \Theta w]) - \Theta^i[N(v, w)].$$

Let  $N = 0$ . For any vector fields  $v, w$  and integers  $i, j \geq 0$ ,

$$(4.3) \quad \text{if } \Theta^i v = 0, \text{ then } \Theta^i \text{ also annihilates } \Theta^j[v, w] - [v, \Theta^j w].$$

Namely, let  $R(i, j)$  be the assertion (4.3), and  $R(j)$  the claim that  $R(i, j)$  holds for all  $i \geq 1$ . Now  $R(1, 1)$  is immediate from (4.1), while, assuming  $R(i, 1)$ , and choosing any  $v$  with  $0 = \Theta^{i+1}v = \Theta^i\Theta v$ , we get, from  $R(i, 1)$  for  $\Theta v$  (not  $v$ ), zero on the right-hand side of (4.2), and hence also on the left-hand side, which yields  $R(i+1, 1)$  and, by induction on  $i$ , establishes  $R(i, 1)$  for all  $i \geq 1$ , that is  $R(1)$ . If we now assume  $R(j)$ , and use any  $i \geq 1$ , we see that  $\Theta^i[v, \Theta^{j+1}w] = \Theta^{i+1}[v, \Theta^j w]$  when  $\Theta^i v = 0$  (from  $R(i, 1)$  applied to  $\Theta^j w$  rather than  $w$ ), which in turn equals  $\Theta^{i+j+1}[v, w]$  (due to  $R(i+1, j)$ , a consequence of  $R(j)$ ). One thus has  $R(j+1)$ , which completes the proof of (4.3).

When, again,  $N = 0$  in (4.1) and  $i, j, k$  are nonnegative integers,

$$(4.4) \quad \begin{array}{l} \text{a) } [\mathcal{B}^i, \mathcal{B}^i] \subseteq \mathcal{B}^i, \quad \text{b) } [\mathcal{Z}^i, \mathcal{B}^j] \subseteq \mathcal{Z}^i + \mathcal{B}^j, \quad \text{c) } [\mathcal{Z}^i, \mathcal{Z}^j] \subseteq \mathcal{Z}^{i+j}, \\ \text{d) } [\mathcal{Z}^i, \mathcal{Z}^k] \subseteq \mathcal{Z}^k \text{ if } \mathcal{Z}^i \text{ is integrable and } k \geq i \end{array}$$

– notation of (2.1) – with  $\Theta$  assumed algebraically constant. In fact, (4.4-a), that is, the integrability of each  $\mathcal{B}^i$ , follows via induction on  $i$ , from (4.1) with  $N = 0$  and with  $v, w$  replaced by  $\Theta^i v, \Theta^i w$ . (The third Lie bracket in (4.1) then is a section of  $\mathcal{B}^{i+1}$ , once we assume that  $[\mathcal{B}^i, \mathcal{B}^i] \subseteq \mathcal{B}^i$ .) For (4.4-b), note that the Lie bracket of sections  $v$  of  $\mathcal{Z}^i$  and  $\Theta^j w$  of  $\mathcal{B}^j$  equals, by (4.3),  $\Theta^j[v, w]$  plus a section of  $\mathcal{Z}^i$ . Finally, (4.4-c) and (4.4-d) are further consequences of (4.3): given sections  $v$  of  $\mathcal{Z}^i$  and  $w$  of  $\mathcal{Z}^j$ , (4.3) reads  $\Theta^{i+j}[v, w] = 0$ , while (4.3) with  $j = k - i$ , for sections  $v$  of  $\mathcal{Z}^i$  and  $w$  of  $\mathcal{Z}^k$  (which makes  $\Theta^j w$  and  $[v, \Theta^j w]$  sections of  $\mathcal{Z}^i$  – the latter due to the assumed integrability of  $\mathcal{Z}^i$ ), yields  $\Theta^k[v, w] = 0$ .

The conclusion (4.4-a) is due to Bolsinov, Konyaev and Matveev [4, Cor. 2.5].

#### 5. Proof of Theorem B

We use induction on the dimension, with the following induction step.

LEMMA 5.1. *Let  $\Theta$  be an algebraically constant (1, 1) tensor with  $N = 0$  in (1.3) on a manifold  $M$  such that the distribution  $\mathcal{Z} = \text{Ker } \Theta$  is integrable.*

- (a)  $\Theta$ -images of  $\mathcal{Z}$ -projectable local vector fields in  $M$  are themselves  $\mathcal{Z}$ -projectable, so that  $\Theta$  naturally descends to a  $(1,1)$  tensor  $\widehat{\Theta}$  on any local leaf space  $\Sigma$  of  $\mathcal{Z}$ , and  $\widehat{\Theta}$  also has  $N=0$ .
- (b) If local vector fields  $v, w$ , and hence also  $\Theta v, \Theta w$ , are  $\mathcal{Z}$ -projectable and the projected images of  $v, w, \Theta v, \Theta w$  all commute, then  $[\Theta v, \Theta w] = 0$ .
- (c) Nilpotency of  $\Theta$ , or integrability of the distributions  $\text{Ker } \Theta^i$  for all  $i \geq 1$ , implies the same property for  $\widehat{\Theta}$ .

PROOF. Applying (1.3) to  $v$  with  $\Theta v = 0$  and  $w$  projectable along  $\mathcal{Z}$ , we obtain  $\Theta[v, \Theta w] = 0$ , as  $\Theta[v, w]$ , and hence  $\Theta^2[v, w]$ , vanishes due to projectability of  $w$  and (2.3). By (2.3), this proves the first part of (a), with an obvious definition of  $\widehat{\Theta}$ . Evaluating (1.3) on projectable vector fields, or applying  $\Theta$  to them, we get  $N=0$  for  $\widehat{\Theta}$  or, respectively, the claim about nilpotency in (c).

Under the assumptions of (b),  $[\Theta v, w], [v, \Theta w]$  and  $\Theta[v, w]$  are – by (a) – projectable onto 0, which makes them sections of  $\mathcal{Z} = \text{Ker } \Theta$ , so that (1.3) with  $N=0$  yields  $[\Theta v, \Theta w] = \Theta([\Theta v, w] + [v, \Theta w] - \Theta[v, w]) = 0$ .

If the distributions  $\mathcal{Z}^i = \text{Ker } \Theta^i$  are all integrable, projectable vector fields that project onto sections of  $\text{Ker } \widehat{\Theta}^i$  fill the distribution  $\mathcal{Z}^{i+1}$  (the  $\Theta^i$ -preimage of the vertical distribution  $\mathcal{Z}$ ). Projectability of each  $\mathcal{Z}^{i+1}$ , immediate from that of  $\Theta$ , or from (4.4-d) and Lemma 2.2(c), combined with (2.2), proves (c).  $\square$

The assertion  $N=0$  in (a) is also a special case of [4, Prop. 2.4].

PROOF OF THEOREM B. As the implications (ii)  $\implies$  (iii)  $\implies$  (iv)  $\implies$  (i) are obvious – the last two from (1.1), (1.2) and (1.4) – we now just proceed to show that (ii) holds whenever (i) does, using induction on  $n \geq 1$ . The case  $n=1$  being trivial, we now fix  $n > 1$  and assume that (i) implies (ii) in dimensions less than  $n$ , while (i) is satisfied on an  $n$ -manifold  $M$ , with  $\Theta \neq 0$ . Using  $\widehat{\Theta}$  and a local leaf space  $\Sigma$  arising from Lemma 5.1(a), and replacing  $M$  by a suitable neighborhood of a given point, we get a bundle projection  $\pi : M \rightarrow \Sigma$  with the vertical distribution  $\mathcal{Z} = \text{Ker } \Theta$ , while (i), and hence (ii), holds for  $\widehat{\Theta}$ , on  $\Sigma$ , since  $\dim \Sigma < n$ . The resulting commuting Jordan-form frame for  $\widehat{\Theta}$  is split into  $\widehat{\Theta}$ -orbits  $u_1, \dots, u_d$  of various lengths  $d \geq 1$ , with the initial vector (field)  $u_1$  lying in  $\text{Ker } \widehat{\Theta}$ , the final vector  $u_d$  outside of  $\text{Im } \widehat{\Theta}$ , and  $u_i = \widehat{\Theta}^{d-i} u_d$  for  $i = 1, \dots, d$ .

We now associate with every given  $\widehat{\Theta}$ -orbit  $u_1, \dots, u_d$  the corresponding  $\Theta$ -orbit  $v_0, v_1, \dots, v_d$  of length  $d+1$  in  $M$ . First, we choose each final vector field  $v_d$ , on  $M$ , so that it projects onto  $u_d$  under  $\pi$ , and set  $v_i = \Theta^{d-i} v_d$ ,  $i = 0, \dots, d-1$ . We call  $v_0$  the pre-initial vector. Our  $v_d$  is only unique up to adding sections of  $\mathcal{Z} = \text{Ker } \Theta$  (and will be modified later); this is also the obvious reason why the nonfinal vectors  $v_0, v_1, \dots, v_{d-1}$  are uniquely determined. Due to  $\pi$ -projectability of  $\Theta$  onto  $\widehat{\Theta}$  in Lemma 5.1(a), the resulting  $\Theta$ -orbit, with the pre-initial vector removed, projects onto the original  $\widehat{\Theta}$ -orbit, while the pre-initial vectors are sections of  $\mathcal{Z} \cap \text{Im } \Theta$ , projecting onto zero. Also, by Lemma 5.1(b), the nonfinal vectors from the union of all the  $\Theta$ -orbits commute with one another (which includes the pre-initial ones). Denoting by  $k$  the total number of these commuting vectors, we see that they generate

$$(5.1) \quad \text{a free local action of } \mathbb{R}^k \text{ in } M.$$

The union of all the  $\Theta$ -orbits forms a linearly independent system at every point: the non-pre-initial ones project onto a frame in  $\Sigma$ , which makes them linearly independent over  $\mathcal{Z} = \text{Ker } \Theta$  (meaning linear independence of their images in  $TM/\mathcal{Z}$ ), while the pre-initial ones, lying in  $\mathcal{Z}$ , are linearly independent, being the  $\Theta$ -images of the initial vectors, linearly independent over  $\mathcal{Z}$ .

Next, we modify – as announced above – the final vectors  $e_a$  chosen in  $M$ , and augment the union of all the  $\Theta$ -orbits with some sections  $e_\lambda$ , so as to obtain a commuting frame in  $M$  which, automatically, will be a Jordan-form frame for  $\widehat{\Theta}$ . (The indices  $a, \lambda$  have some appropriate ranges.) To this end, we identify  $M$ , locally, with a Cartesian product of a horizontal factor (our leaf space  $\Sigma$ ) and a vertical factor, tangent to  $\mathcal{Z}$ . Our  $e_a$  and  $e_\lambda$  are suitable systems of commuting vector fields on the factor manifolds, trivially extended to vector fields in  $M$  (which causes  $e_a$  to commute with  $e_\lambda$ ). In a first step, for  $e_a$  we choose the final vectors of our Jordan-form frame for  $\widehat{\Theta}$ , and for  $e_\lambda$  some vertical coordinate vector fields chosen, locally, so as to be linearly independent over  $\mathcal{Z} \cap \text{Im } \Theta$  and represent, under the quotient-bundle projection, a local trivialization of  $\mathcal{Z}/(\mathcal{Z} \cap \text{Im } \Theta)$ . Let  $Q$  now be one leaf of the integrable distribution spanned by all  $e_a$  and  $e_\lambda$ . Thus,  $Q$  has codimension  $k$  in  $M$  and is transverse to the orbits of the local free action (5.1). We now modify all  $e_a$  and  $e_\lambda$  further, by using the action (5.1) to spread their restrictions to  $Q$  from  $Q$  to a neighborhood of  $Q$  in  $M$ . Due to equivariance of  $\pi$  relative to the action (5.1) and the analogous free action in  $\Sigma$  generated by the nonfinal vectors from the union of all the  $\widehat{\Theta}$ -orbits, and the invariance of the final vectors in  $\Sigma$  under the latter action, the modified  $e_a$  still project onto the final vectors (and  $e_\lambda$  onto 0, as the action leaves  $\mathcal{Z}$  invariant). Finally,  $e_a$  and  $e_\lambda$  commute both with the nonfinal vectors from the union of the  $\Theta$ -orbits, and with one another: the former follows from their  $\mathbb{R}^k$ -invariance, the latter since their restrictions to  $Q$  commute. This completes the proof.  $\square$

## 6. Algebraic constancy and connections

Given a real vector bundle  $E$  of rank  $k$  over a manifold  $M$  and integers  $p, q \geq 0$ , we say that a smooth section  $\Theta$  of  $E^{\otimes p} \otimes [E^*]^{\otimes q}$  is *algebraically constant* when, for any  $x, y \in M$ , some linear isomorphism  $E_x \rightarrow E_y$  sends  $\Theta_x$  to  $\Theta_y$ . In this case, let fix  $z \in M$  and an ordered basis  $\mathbf{e} = (e_1, \dots, e_k)$  of  $E_z$ , and

$$(6.1) \quad \text{denote by } \mathbf{e}\Theta_z \text{ the system of components of } \Theta_z \text{ in the basis } \mathbf{e},$$

that is, the  $(p, q)$  tensor in  $\mathbb{R}^k$  arising as the image of  $\Theta_z$  under the linear isomorphism  $E_z \rightarrow \mathbb{R}^k$  associated with  $\mathbf{e}$ . We now define two objects, the first being the matrix group  $G \subseteq \text{GL}(k, \mathbb{R})$  formed by all transition matrices between  $\mathbf{e}$  and all ordered bases  $\bar{\mathbf{e}}$  of  $E_z$  such that  $\bar{\mathbf{e}}\Theta_z = \mathbf{e}\Theta_z$ . In other words,  $G$  is the isotropy group of  $\mathbf{e}\Theta_z$  for the obvious action of  $\text{GL}(k, \mathbb{R})$  on  $(p, q)$  tensors in  $\mathbb{R}^k$ .

The second one, a  $G$ -principal bundle  $P$  over  $M$ , is contained in the  $\text{GL}(k, \mathbb{R})$ -principal bundle  $Q$  over  $M$  naturally associated with  $E$ , and the fibre of  $P$  over any  $x \in M$  consists of the ordered bases  $\bar{\mathbf{e}}$  of  $E_x$  having  $\bar{\mathbf{e}}\Theta_x = \mathbf{e}\Theta_z$ .

Smoothness of  $P$  follows since  $P$  is the preimage of the point  $\mathbf{e}\Theta_z$  under the submersion  $\Phi : Q \rightarrow \Sigma$  sending any ordered basis  $\bar{\mathbf{e}}$  of  $E_x$ , at any  $x \in M$ , to  $\bar{\mathbf{e}}\Theta_x$ , with  $\Sigma$  denoting the  $\text{GL}(k, \mathbb{R})$ -orbit of  $\mathbf{e}\Theta_z$  viewed, again, as a  $(p, q)$  tensor in  $\mathbb{R}^k$ . The submersion property of  $\Phi$  is obvious: even the restriction of  $\Phi$  to

any fibre  $Q_x$  of  $Q$  is a submersion, diffeomorphically equivalent to the projection  $\mathrm{GL}(k, \mathbb{R}) \rightarrow \mathrm{GL}(k, \mathbb{R})/P$ .

Thus, a smooth section  $\Theta$  of  $E^{\otimes p} \otimes [E^*]^{\otimes q}$  is parallel relative to some linear connection  $\nabla$  in  $E$  if and only if it is algebraically constant [17, Theorems 1-2], the ‘only if’ (or, ‘if’) claim being obvious since  $M$  is assumed connected or, respectively, since  $\nabla$  induced by any principal  $G$ -connection in  $P$  clearly makes  $\Theta$  parallel. Such connections are precisely the linear connections in  $E$  with characterized vanishing *inner torsion* in the sense of [19, Sect. 5].

REMARK 6.1. Our construction depends on the choice of  $z \in M$  and an ordered basis  $\mathbf{e}$  of  $E_z$ . However, different choices lead to equivariantly equivalent objects. The case of importance to us is  $E = TM$ , where  $P$  is the  $G$ -structure associated with the given algebraically constant  $(p, q)$  tensor  $\Theta$ . When  $(p, q) = (1, 1)$  and  $\Theta$  is nilpotent, *we will always use  $z$  and  $\mathbf{e}$  realizing the Jordan normal form  $d_1 \dots d_m$  of  $\Theta$ , defined as in (1.5).*

## 7. The Lie brackets of a local Jordan frame

Recall our convention (1.5) about representing the Jordan normal forms of nilpotent  $(1, 1)$  tensors in dimension  $n$  as weakly decreasing strings  $d_1 \dots d_m$  of positive integers, so that  $d_1 + \dots + d_m = n$ , and  $\Theta = 0$  has the Jordan normal form  $1 \dots 1$ , each 1 being the  $1 \times 1$  block matrix  $[0]$ , while  $n$  is the single-block Jordan normal form of a *generic* nilpotent  $(1, 1)$  tensor in dimension  $n$ , cf. [8, Sect. 5]. The Jordan normal form  $2 \dots 2$  characterizes the case  $\mathrm{Ker} \Theta = \mathrm{Im} \Theta$ .

If an algebraically constant nilpotent  $(1, 1)$  tensor  $\Theta$  on an  $n$ -manifold has the Jordan normal form  $d_1 \dots d_m$ , then each subbundle  $\mathrm{Ker} \Theta^i$  clearly has the fibre dimension  $\min(i, d_1) + \dots + \min(i, d_m)$ , and hence

$$(7.1) \quad \mathrm{rank} \Theta^i = n - \min(i, d_1) - \dots - \min(i, d_m).$$

Let us fix an algebraically constant nilpotent  $(1, 1)$  tensor  $\Theta$  on an  $n$ -manifold  $M$  and a local frame field realizing the Jordan normal form  $d_1 \dots d_m$  of  $\Theta$ . (See Remark 6.1.) We focus on three (not necessarily distinct)  $\Theta$ -orbits

$$(7.2) \quad (e_1, \dots, e_p), (\tilde{e}_1, \dots, \tilde{e}_q), (\hat{e}_1, \dots, \hat{e}_r),$$

by which we mean portions of our frame field corresponding to three of the entries  $d_1, \dots, d_m$ . Setting  $e_i = \tilde{e}_j = \hat{e}_k = 0$  for nonpositive integers  $i, j, k$ , we obtain  $(\Theta e_i, \Theta \tilde{e}_j, \Theta \hat{e}_k) = (e_{i-1}, \tilde{e}_{j-1}, \hat{e}_{k-1})$  for all integers  $i, j, k$  not exceeding, respectively,  $p, q$  or  $r$ . Finally, we denote by  $C_{i,j}^k$  the coefficient of  $\hat{e}_k$  in the expansion of the Lie bracket  $[e_i, \tilde{e}_j]$  as a (functional) combination of our fixed frame, and also set  $C_{i,j}^k = 0$  if  $k > r$  or one of  $i, j, k$  is nonpositive; thus  $C_{i,j}^k$  is well defined for integers  $i, j, k$  with  $i \leq p$  and  $j \leq q$ . Now  $N = 0$  in (1.3) if and only if

$$(7.3) \quad C_{i,j}^k + C_{i-1,j-1}^{k-2} = C_{i-1,j}^{k-1} + C_{i,j-1}^{k-1} \quad \text{whenever } k \geq 3, i \leq p \text{ and } j \leq q,$$

where  $C_{i,j}^k = 0$  for  $k > r$ . Namely,  $N(e_i, \tilde{e}_j)$  in (1.3), projected onto the span of  $(\hat{e}_1, \dots, \hat{e}_r)$ , equals  $(C_{i-1,j}^k + C_{i,j-1}^k) \hat{e}_{k-1} - C_{i-1,j-1}^k \hat{e}_k - C_{i,j}^k \hat{e}_{k-2}$  summed over all  $k \leq r$ . The vanishing of the terms involving  $\hat{e}_r$  (or  $\hat{e}_{r-1}$ , if  $r \geq 2$ ) means that  $C_{i-1,j-1}^r = 0$  (or, respectively,  $C_{i-1,j-1}^{r-1} = C_{i-1,j}^r + C_{i,j-1}^r$ ), both of which are special cases of (7.3), with  $k \in \{r+1, r+2\}$ . Leaving these terms aside, we see that the equality in (7.3) multiplied by  $\hat{e}_{k-2}$  follows if we shift the summation

index from  $k$  or  $k-1$  to  $k-2$  as needed, which yields (7.3) as  $\hat{e}_{k-2} = 0$  unless  $k \geq 3$ . In terms of  $E_{i,j}^s = C_{i,j}^{i+j-s-1}$ , or  $C_{i,j}^k = E_{i,j}^{i+j-k+1}$ , (7.3) can be rewritten as

$$(7.4) \quad E_{i,j}^s + E_{i-1,j-1}^s = E_{i-1,j}^s + E_{i,j-1}^s \text{ if } i+j \geq s+2, i \leq p \text{ and } j \leq q,$$

while  $E_{i,j}^s = 0$  whenever  $i+j \geq s+r$ . The reason why we prefer to switch from the integer variables  $i, j, k$  to  $i, j, s$  with  $s = i+j-k+1$ , or  $k = i+j-s-1$ , is that (7.4) uses a fixed value of  $s$ , allowing us to treat different values of  $s$  as completely unrelated. Our conclusions may be summarized as follows.

LEMMA 7.1. *Given  $\Theta$  and the frame field as above, the Nijenhuis tensor (1.3) vanishes if and only if, for any ordered triple of not necessarily distinct  $\Theta$ -orbits (7.2), one has (7.4) along with*

$$(7.5) \quad \begin{aligned} E_{i,j}^s &= 0 \text{ if } i+j < s, \text{ or } i+j \geq s+r, \text{ or } i \leq 0, \text{ or } j \leq 0, \text{ and} \\ &\text{our } E_{i,j}^s \text{ are defined for all } i, j, s \in \mathbb{Z} \text{ such that } i \leq p \text{ and } j \leq q. \end{aligned}$$

PROOF. We already saw that (7.4) is equivalent to (7.3), while (7.5) is clearly nothing else than the obvious boundary conditions ( $C_{i,j}^k = 0$  if  $k \leq 0$ , or  $k > r$ , or  $i \leq 0$ , or  $j \leq 0$ ) coupled with our convention about when  $C_{i,j}^k$  makes sense.  $\square$

Next,  $\mathcal{Z}^l = \text{Ker } \Theta^l$  is integrable (which may or may not be the case) if and only if  $C_{i,j}^k = 0$  whenever  $i, j \leq l < k$ , that is

$$(7.6) \quad E_{i,j}^s = 0 \text{ for all } i, j, s \text{ with } i, j \leq l \text{ and } i+j \geq s+l,$$

and for all ordered triples of (not necessarily distinct)  $\Theta$ -orbits (7.2). With the last clause repeated, the integrability of  $\mathcal{Z}^l = \text{Ker } \Theta^l$  for all  $l \geq 0$  clearly amounts to

$$(7.7) \quad E_{i,j}^s = 0 \text{ whenever } i, j \geq s,$$

since the condition  $i, j \leq i+j-s$  is nothing else than  $i, j \geq s$ .

REMARK 7.2. The equality in (7.4) obviously holds, for all  $i, j, s \in \mathbb{Z}$ , if  $E_{i,j}^s$  is a function of  $i$  alone, or of  $j$  alone, or equals  $i+j$  plus a function of  $s$ .

## 8. Proof of Theorem C: the necessity of (1.6)

For the Jordan normal form of an algebraically constant nilpotent  $(1, 1)$  tensor, *not* being of type (1.6) clearly means that it

$$(8.1) \quad \text{contains three different Jordan blocks of lengths } p, q, r \text{ with } p \leq q < r,$$

PROPOSITION 8.8. *In any dimension  $n \geq 1$ , condition (8.1), imposed on the Jordan normal form of an algebraically constant nilpotent  $(1, 1)$  tensor  $\Theta$ , implies that the algebraic type of  $\Theta$  is not controlled by the Nijenhuis tensor (1.3). More precisely,  $\Theta$  can be realized as a left-invariant  $(1, 1)$  tensor on a Lie group, in such a way that  $N = 0$ , but  $\text{Ker } \Theta^p$  is nonintegrable for some integer  $p \geq 1$ . One may choose  $p$  to be the shortest block length in the Jordan normal form of  $\Theta$ .*

PROOF. We identify local frame field for  $\Theta$ , chosen as in Sect. 7, with a basis of a Lie algebra  $\mathfrak{g}$  formed by left-invariant vector fields on a Lie group  $G$ . This is achieved by requiring (7.3) and the boundary conditions ( $C_{i,j}^k = 0$  if  $k \leq 0$ , or  $k > r$ , or  $i \leq 0$ , or  $j \leq 0$ ) to be satisfied by *constants*  $C_{i,j}^k$  or, equivalently, finding constants  $E_{i,j}^s$  with (7.4) – (7.5). (Our choice will cause all brackets to lie in the center, thus implying the Jacobi identity.) Our  $\Theta$  then becomes a left-invariant  $(1, 1)$  tensor field on  $G$  acting as an endomorphism of the tangent bundle

which sends each frame vector field either to the preceding one, or to zero. As a consequence of (8.1), our local frame contains

(8.2) three different  $\Theta$ -orbits of lengths  $p, q, r$  with  $p \leq q < r$ .

Fixing such  $\Theta$ -orbits (7.2), we now set, in the discussion of Sect. 7,  $E_{i,j}^s = 0$  for all integers  $i, j, s$ , with the exception of  $s = p$ , and  $(i, j)$  from the range  $[1, p] \times [1, q]$  corresponding to the first two of the fixed three  $\Theta$ -orbits (7.2).

FIGURE 1. Values of  $E = E_{i,j}^p$

Given integers  $i \leq p$  and  $j \leq q$ , we define  $E_{i,j}^p$  by

$$(8.3) \quad E_{i,j}^p = \max(0, i + \min(0, j - p)).$$

Speaking below of rectangles, triangles, lines and line segments, we always mean their intersections with  $\mathbb{Z}^2$ , while (sub)rectangles are occasionally reduced to segment or single points. Restricted to  $(i, j)$  ranging over the rectangle  $[1, p] \times [1, q]$ , our  $E_{i,j}^p$  equals 0 on the triangle with vertices  $(1, 1)$ ,  $(1, p-1)$ ,  $(p-1, 1)$  (treated as the empty set, of the single point  $(1, 1)$  when  $p = 1$  or, respectively,  $p = 2$ ), and  $E_{i,j}^p = p$  on the segment  $\{p\} \times [p, q]$  (a point when  $p = q$ ). If  $p > 1$ , then, for any integer  $l$  with  $1 \leq l < p$ , we have  $E_{i,j}^p = l$  on the two-segment broken line joining the points  $(l, q)$ ,  $(l, p)$ ,  $(p, l)$  (reduced to a segment when  $p = q > 1$ ). (This is particularly simple in the case where  $p = q = 1$ , with  $E_{1,1}^1 = 1$ .)

The corresponding Nijenhuis tensor (1.3) vanishes identically, by Lemma 7.1, since – as we now proceed to show – our  $E_{i,j}^p$  satisfy (7.4) and (7.5).

First, (7.5) holds, as nonpositivity of  $i, j$  or  $i + j - s = i + j - p$  in (8.3) yields  $E_{i,j}^p = 0$ , and the remaining implication is vacuous:  $i + j \leq p + q = s + q < s + r$ .

Next, (7.4) “essentially” follows from Remark 7.2:  $E_{i,j}^p = \min(i, p)$ , which is a function of  $i$ , on the subrectangle  $[1, p] \times [p, q]$  (a segment when  $p = q$ ). On

$[1, p] \times [1, p]$ , (8.3) in turn gives  $E_{i,j}^p = \max(0, i + j - p)$ , which coincides with  $i + j - p$  on the subtriangle given by  $i + j \geq s + 2 = p + 2$ .

To dispel any doubts, we now establish (7.4) rigorously, for  $s = p$ . Of interest to us are integers  $i, j$  with  $i + j \geq p + 2$ ,  $i \leq p$  and  $j \leq q$ . We are also free to assume that  $i, j \geq 1$ , since otherwise, by (7.5), all four terms in (7.4) equal 0. If  $j > p$ , (8.3) gives  $E_{i,j}^p = E_{i,j-1}^p = i$  for all  $i \geq 0$ . Now the four terms in (7.4) are  $i, i - 1, i - 1, i$  (whether or not  $i > 1$ ), and the required equality follows. When  $j \leq p$  (and hence  $j - 1 < p$ ), whenever  $i \in \mathbb{Z}$ , (8.3) reads  $E_{i,j}^p = \max(0, i + j - p)$  and, similarly,  $E_{i,j-1}^p = \max(0, i + j - p - 1)$  with  $j$  replaced by  $j - 1$ . In the case of interest to us,  $i + j \geq p + 2$  (see the beginning of this paragraph), so that  $E_{i,j}^p = i + j - p$  and  $E_{i,j-1}^p = i + j - p - 1$ , for all  $i$ , and we get the equality in (7.4):  $(i + j - p) + (i - 1 + j - 1 - p) = (i - 1 + j - p) + (i + j - 1 - p)$ , which proves our claim.

Finally, since  $E_{p,p}^p = p \neq 0$ , (7.6) applied to  $i = j = s = l = p$  shows that  $\text{Ker } \Theta^p$  is not integrable.  $\square$

### 9. Proof of Theorem C: the sufficiency of (1.6)

We now show that, given an algebraically constant nilpotent  $(1, 1)$  tensor  $\Theta$  on a manifold  $M$  of dimension  $n \geq 1$ , with  $N = 0$ , and with the Jordan normal form  $d_1 \dots d_m$  satisfying condition (1.6),  $\Theta$  must also have the property (i) in Theorem B, and hence be locally constant. Note that

$$(9.1) \quad \mathcal{B}^i = \text{Im } \Theta^i \text{ are all integrable due to (4.4-a).}$$

We choose a local frame field realizing the Jordan normal form of  $\Theta$ , that is, a local section of the  $G$ -principal bundle  $P$  over  $M$  associated with  $\Theta$  as in Sect. 6.

In the first case of (1.6),  $d_1 = \dots = d_m = d$  for some  $d \geq 1$ , and our local frame field splits into disjoint  $\Theta$ -orbits of the form  $v_1, \dots, v_d$ , all of length  $d$ , while  $v_i = \Theta^{d-i} v_d$  for  $i = 1, \dots, d - 1$ , and the final vector  $v_d$  lies outside of  $\text{Im } \Theta$ . Thus,  $\mathcal{Z}^i$ ,  $i \geq 0$ , is equal to either  $TM$  (when  $i \geq d$ ), or to  $\mathcal{B}^{d-i}$  (if  $1 \leq i < d$ ), and (9.1) yields our claim.

Consider now the second case of (1.6):  $d_1 = \dots = d_{m-1} = d > d' = d_m$  for some  $d, d' \geq 1$ , with  $m > 1$ , leading to  $\Theta$ -orbits  $v_1, \dots, v_d$  of length  $d$ , of which there are  $m - 1$ , and to one  $\Theta$ -orbit of length  $d'$ .

We first prove the integrability of  $\mathcal{Z}^i$  when  $1 \leq i \leq d'$ , using induction on  $i$ . As  $\mathcal{Z}^1$  is spanned by the  $m$  initial vectors from all  $\Theta$ -orbits, and  $\mathcal{B}^{d-1}$  by the  $m - 1$  initial vectors from all  $\Theta$ -orbits of length  $d$ , the latter subbundle of  $TM$  is contained in the former with codimension one. Thus, (9.1) combined with (4.4-b) and Lemma 2.1 yields the integrability of  $\mathcal{Z}^1$ . For the induction step, if  $1 \leq i < d'$  and  $\mathcal{Z}^i$  is integrable,  $\mathcal{Z}^{i+1}$  is spanned by  $m(i + 1)$  vectors:  $v_1, \dots, v_{i+1}$  from all the  $\Theta$ -orbits combined (if one writes the  $\Theta$ -orbits as  $v_1, \dots, v_d$  or  $v_1, \dots, v_{d'}$ ), and so  $\mathcal{Z}^{i+1}$  contains, with codimension one, the span  $\mathcal{Z}^i + \mathcal{B}^{d-i-1}$  of  $\mathcal{Z}^i$  and  $\mathcal{B}^{d-i-1}$ . the integrability of  $\mathcal{Z}^i + \mathcal{B}^{d-i-1}$  now follows from (4.4-a) – (4.4-b), and we complete the induction step by invoking Lemma 2.1 and (4.4-d).

Finally, let  $d' < i < d$  and  $k = d' - 1$ . This time  $\mathcal{Z}^i$  contains  $\mathcal{Z}^k + \mathcal{B}^{d-i}$  with codimension one: the former is spanned by  $(m - 1)i + d'$  vectors (the initial  $i$  ones from all  $\Theta$ -orbits of length  $d$ , plus the whole  $\Theta$ -orbit of length  $d'$ ), the latter – by the same vectors except the last one in the length  $d'$  orbit. Again, Lemma 2.1 and (4.4-d) prove that  $\mathcal{Z}^i$  is integrable.

## 10. Generalized almost-tangent structures

The following construction provides – as shown below – a local description of all (1,1) tensors  $\Theta$  such that  $\Theta^2 = 0$  and the Nijenhuis tensor (1.3) vanishes identically. They are all algebraically constant.

Given a distribution  $\mathcal{D}$  on a manifold  $\Sigma$ , let  $M$  be the total space of an affine bundle over  $\Sigma$  associated with the quotient vector bundle  $T\Sigma/\mathcal{D}$ . Using the bundle projection  $\pi : M \rightarrow \Sigma$  and the quotient-bundle projection morphism  $T\Sigma \ni v \mapsto [v] \in T\Sigma/\mathcal{D}$ , we define a (1,1) tensor  $\Theta$  on  $M$  by

$$(10.1) \quad \Theta_x v = [d\pi_x v] \in T_y \Sigma / \mathcal{D}_y = T_x M_y, \text{ for } x \in M_y = \pi^{-1}(y),$$

whenever  $x \in M$  and  $v \in T_x M$ . Then  $\Theta^2 = 0$ , since all  $\Theta$ -images are vertical. Also,  $N = 0$  in (1.3). In fact,  $\text{Im } \Theta$  is the vertical distribution  $\mathcal{V} = \text{Ker } d\pi$ . Evaluating (1.3), without loss of generality, on  $\pi$ -projectable vector fields, we see that, by (2.3), the first, second and fourth terms on the right-hand side of vanish as  $\Theta^2 = 0$ . So does the third term:  $\Theta v, \Theta w$  restricted to each fibre are affine-space translations, and consequently commute.

**THEOREM 10.1.** *Every (1,1) tensor  $\Theta$  with  $\Theta^2 = 0$  and vanishing Nijenhuis tensor (1.3) arises, locally, from the above construction, and  $\Theta$  is integrable if and only if so is the distribution  $\mathcal{D}$ , while the fibre dimension of  $\mathcal{D}$  equals the codimension of  $\text{Im } \Theta$  in  $\text{Ker } \Theta$ .*

**PROOF.** Suppose that  $\Theta^2 = 0$  and  $N = 0$  in (1.3). By (4.4-a),  $\text{Im } \Theta$  is an integrable distribution, while  $\text{Im } \Theta \subseteq \text{Ker } \Theta$ . Due to (2.3) and (1.3) with  $\Theta^2 = 0$ ,

$$(10.2) \quad \text{any two projectable vector fields have commuting } \Theta\text{-images,}$$

where we mean  $(\text{Im } \Theta)$ -projectability. By (4.4-b) for  $i = j = 1$  and Lemma 2.2(c), on an open set  $M' \subseteq M$  with a bundle projection  $\pi : M' \rightarrow \Sigma$  having  $\text{Im } \Theta$  as the vertical distribution,  $\text{Ker } \Theta$  is  $\pi$ -projectable onto a distribution  $\mathcal{D}$  on  $\Sigma$ . Any  $\pi$ -projectable lift, along the fibre  $\pi^{-1}(y)$ , of any vector  $w$  tangent to  $\Sigma$  at  $y \in \Sigma$ , is mapped by  $\Theta$  onto the “vertical lift” of  $w$ , a vector field tangent to  $\pi^{-1}(y)$ , which vanishes precisely when  $w$  is tangent to  $\mathcal{D}$ . According to (10.2) the vertical lifts of any  $w, w' \in T_y \Sigma$  commute. This turns  $\pi^{-1}(y)$ , locally, into an affine space having the translation vector space  $T_y \Sigma / \mathcal{D}_y$ , while  $\Theta$  is given by (10.1).  $\square$

Theorem 10.1 illustrates a special case of Theorem C: the condition  $\Theta^2 = 0$  corresponds to the Jordan normal forms  $2 \dots 2$  and  $2 \dots 21 \dots 1$  (plus  $1 \dots 1$ , for  $\Theta = 0$ ). Of these, only  $2 \dots 2$ ,  $2 \dots 21$  and  $1 \dots 1$  satisfy (1.6), reflecting the fact that  $\mathcal{D}$  is necessarily integrable only if it has the fibre dimension 0, 1 or  $\dim \Sigma$ .

When  $\text{Ker } \Theta = \text{Im } \Theta$ , that is,  $\mathcal{D}$  is the zero distribution, our construction gives rise to the *almost-tangent structures* [25, 9].

## 11. Differential $q$ -forms on an $n$ -manifold, $q = 0, 1, 2, n - 1, n$

We now prove Proposition D. Let  $\zeta$  be an algebraically constant differential  $q$ -form on an  $n$ -dimensional manifold,  $q = 0, 1, 2, n - 1, n$ , with  $d\zeta = 0$  (the last condition being obviously redundant if  $q = n$  or, due to the constancy of  $\zeta$ , if  $q = 0$ ).

The cases  $q = 0$  and  $q = 1$  are obvious: the 1-form  $\zeta$ , being locally exact, equals  $dx^1$  in suitable local coordinates  $x^1, \dots, x^n$ .

When  $q = 2$ , algebraic constancy amounts to constant rank, and our claim follows as Darboux's theorem [6, p. 40] gives  $\zeta = dx^1 \wedge dx^2 + \dots + dx^{2r-1} \wedge dx^{2r}$  in some local coordinates  $x^1, \dots, x^n$ , with  $2r = \text{rank } \zeta$ .

If  $q = n$ , we have, in suitable local coordinates  $x^1, \dots, x^n$ ,

$$(11.1) \quad \zeta = dx^1 \wedge dx^2 \wedge \dots \wedge dx^n, \text{ where } x^2, \dots, x^n \text{ can be arbitrary,}$$

as long as  $dx^2 \wedge \dots \wedge dx^n \neq 0$ . In fact, starting from  $\zeta = \phi dx^1 \wedge dx^2 \wedge \dots \wedge dx^n$  for a function  $\phi$  without zeros, and choosing  $\psi$  with  $\partial_1 \psi = \phi$ , we see that  $d\psi$  equals  $\phi dx^1$  plus a functional combination of  $dx^2, \dots, dx^n$  and so  $\zeta = d\psi \wedge dx^2 \wedge \dots \wedge dx^n$ .

Finally, let  $q = n - 1$ . Assuming  $\zeta$  to be nonzero, and fixing a nonzero  $n$ -form  $\omega$ , we get  $\zeta = \omega(v, \cdot, \dots, \cdot)$ , for a unique (nonzero) vector field  $v$ . Then, by (11.1),  $\omega = dx^1 \wedge dx^2 \wedge \dots \wedge dx^n$  in some local coordinates  $x^1, \dots, x^n$ , with  $x^2, \dots, x^n$  chosen so that  $dx^2(v) = \dots = dx^n(v) = 0$ . Now  $\zeta = \chi dx^2 \wedge \dots \wedge dx^n$  for  $\chi = dx^1(v)$ , and  $\partial_1 \chi = 0$  as  $d\zeta = 0$ . Our  $\zeta$ , being thus a top-degree form in  $n - 1$  variables, equals, by (11.1),  $dy^2 \wedge \dots \wedge dy^n$  in suitable coordinates  $y^1, \dots, y^n$ .

## 12. Differential forms of other degrees

We now proceed to verify the statement preceding formula (1.7). The algebraic constancy of  $\zeta$  is clear as  $\zeta = (\xi^1 \wedge \xi^2 + \xi^3 \wedge \xi^4) \wedge \xi^5 \wedge \dots \wedge \xi^{q+2}$ , with linearly independent 1-forms  $\xi^1, \dots, \xi^{q+2}$ , and its closedness since  $d\zeta$  is the exterior product of  $(dx^1 \wedge dx^2 + dx^3 \wedge dx^4) \wedge (dx^1 \wedge dx^2 - dx^3 \wedge dx^4)$  (obviously equal to 0) and  $dx^6 \wedge \dots \wedge dx^{q+2}$ . Being algebraically constant,  $\zeta$  gives rise to the vector subbundle  $\mathcal{F}$  of  $T^*M$  such that the sections of  $\mathcal{F}$  are those 1-forms  $\xi$  for which  $\xi \wedge \zeta = 0$ . The sections of  $\mathcal{F}$  also coincide with functional combinations of the 1-forms

$$(12.1) \quad \eta, dx^6, \dots, dx^{q+2}, \text{ where } \eta = dx^5 + x^1 dx^2 - x^3 dx^4.$$

In fact, writing  $\xi = \xi_i dx^i$ , we see that  $\xi \wedge \zeta$  contains no contributions from the terms  $\xi_i dx^i$  (no summation) with  $6 \leq i \leq q + 2$  (making  $\xi_6, \dots, \xi_{q+2}$  completely arbitrary) while for  $\theta = (dx^1 \wedge dx^2 + dx^3 \wedge dx^4) \wedge (dx^5 + x^1 dx^2 - x^3 dx^4)$  one has

$$\theta = dx^1 \wedge dx^2 \wedge dx^5 + dx^3 \wedge dx^4 \wedge dx^5 - x^3 dx^1 \wedge dx^2 \wedge dx^4 + x^1 dx^2 \wedge dx^3 \wedge dx^4.$$

and so each term  $\xi_i dx^i$  (no summation, again) with  $q + 2 < i \leq n$  contributes to  $\xi \wedge \zeta$  the expression  $\xi_i dx^i \wedge \theta \wedge dx^6 \wedge \dots \wedge dx^{q+2}$  (no summation) comprising all the terms in  $\xi \wedge \zeta$  involving the factor  $dx^i$ . Linear independence of the differentials  $dx^1, \dots, dx^n$  now gives  $\xi_i = 0$  whenever  $q + 2 < i \leq n$ . Finally, the exterior products of  $\xi_1 dx^1, \xi_2 dx^2, \xi_3 dx^3, \xi_4 dx^4, \xi_5 dx^5$  with  $\theta$  are

$$(12.2) \quad \begin{aligned} & \xi_1(dx^1 \wedge dx^3 \wedge dx^4 \wedge dx^5 + x^1 dx^1 \wedge dx^2 \wedge dx^3 \wedge dx^4), \\ & \xi_2(dx^2 \wedge dx^3 \wedge dx^4 \wedge dx^5), \\ & \xi_3(dx^1 \wedge dx^2 \wedge dx^3 \wedge dx^5 - x^3 dx^1 \wedge dx^2 \wedge dx^3 \wedge dx^4), \\ & \xi_4(dx^1 \wedge dx^2 \wedge dx^4 \wedge dx^5), \\ & \xi_5(x^3 dx^1 \wedge dx^2 \wedge dx^4 \wedge dx^5 - x^1 dx^2 \wedge dx^3 \wedge dx^4 \wedge dx^5). \end{aligned}$$

The condition  $\xi \wedge \zeta = 0$  means, after the cancellation of  $dx^6 \wedge \dots \wedge dx^{q+2}$ , that the sum of the five lines of (12.2) equals 0. Writing  $[ijkl]$  for  $dx^i \wedge dx^j \wedge dx^k \wedge dx^l$ , we see that  $[1345]$  and  $[1235]$  occur just once each, giving  $\xi_1 = \xi_3 = 0$ , while the sum of the remaining three lines equals  $(\xi_4 + \xi_5 x^3)[1245] + (\xi_2 - \xi_5 x^1)[2345]$ . Thus,  $\xi_4 + \xi_5 x^3 = 0 = \xi_2 - \xi_5 x^1$ , and the sum of  $\xi_i dx^i$  over  $i = 1, \dots, 5$  equals a function times the 1-form  $\eta$  in (12.1), proving our claim about (12.1).

If  $\zeta$  were integrable, so would be – according to (1.2) – the simultaneous kernel of the 1-forms (12.1) (that is, of all sections of  $\mathcal{F}$ ), naturally determined by  $\zeta$ . This is not the case, as  $d\eta \wedge \eta \wedge dx^6 \wedge \dots \wedge dx^{q+2}$  is nonzero, being equal to  $(dx^1 \wedge dx^2 \wedge dx^5 - dx^3 \wedge dx^4 \wedge dx^5 - x^3 dx^1 \wedge dx^2 \wedge dx^4 - x^1 dx^2 \wedge dx^3 \wedge dx^4) \wedge dx^6 \wedge \dots \wedge dx^{q+2}$ .

### 13. Symmetric (0, 2) and (2, 0) tensors

PROOF OF PROPOSITION E. Let  $g$  be integrable, with  $\nabla g = 0$  for a fixed torsion-free connection  $\nabla$ . The integrability of the distribution  $\mathcal{V} = \text{Ker } g$ , due to (1.2), allows us to choose local coordinates and index ranges for  $i, a, \lambda, \mu, \nu$  as in Remark 2.5, so that  $\mathcal{V}$  is spanned by the coordinate vector fields  $\partial_a$ . As  $\mathcal{V}$  is obviously  $\nabla$ -parallel,  $\Gamma_{ia}^k = \Gamma_{ab}^k = 0$ , while  $g_{ia} = g_{ab} = 0$ , so that  $\partial_a g_{ij} = \Gamma_{ai}^k g_{kj} + \Gamma_{aj}^k g_{ik} = 0$ , and projectability of  $g$  along  $\mathcal{V}$  follows.

Conversely, suppose that  $g$  is projectable along the integrable distribution  $\mathcal{V} = \text{Ker } g$ . As before, we invoke Remark 2.5, selecting local coordinates with index ranges for  $i, a, \lambda, \mu, \nu$  so as to make  $\mathcal{V}$  the span of the coordinate fields  $\partial_a$ . As projectability of  $g$  along  $\mathcal{V}$  gives  $\partial_a g_{ij} = 0$ , while  $g_{ia} = g_{ab} = 0$ , the components  $g_{ij}$  represent a pseudo-Riemannian metric in the factor manifold with the coordinates  $x^i$ . Denoting by  $\Gamma_{ij}^k$  the components of its Levi-Civita connection, and setting  $\Gamma_{\lambda\mu}^\nu = 0$  when  $\lambda, \mu, \nu$  are not all in the  $i, j, k$  range, we now obviously define a torsion-free connection  $\nabla$  in the original manifold with  $\nabla g = 0$ .  $\square$

PROOF OF PROPOSITION F. Integrability of the former implies that of the latter by (1.2). Conversely, let the distribution  $\mathcal{B} = \text{Im } \Theta$  be integrable. Using Remark 2.5, we fix local coordinates and index ranges for  $i, a, \lambda, \mu, \nu$  so that  $\mathcal{B}$  is the span of the coordinate fields  $\partial_i$ . Thus,  $\Theta^{ia} = \Theta^{ab} = 0$ , as the 1-forms  $dx^a$  annihilate each  $\partial_i$ , and hence are sections of the subbundle  $\text{Ker } \Theta \subseteq T^*M$ . On each leaf of  $\mathcal{B}$ , the restriction of  $\Theta$  is nondegenerate – see (2.8) – and so it is the reciprocal of a pseudo-Riemannian metric on the leaf. Its Levi-Civita connection, with the components  $\Gamma_{ij}^k$  (possibly depending on the variables  $x^a$ ), makes the restriction of  $\Theta$  parallel. Thus, if we again set  $\Gamma_{\lambda\mu}^\nu = 0$  unless  $\lambda, \mu, \nu$  are all in the  $i$  range, we obtain a torsion-free connection  $\nabla$  in the original manifold such that  $\nabla \Theta = 0$ .  $\square$

### 14. Local constancy of bivector fields

PROOF OF PROPOSITION G. The ‘only if’ part is immediate: for a torsion-free connection  $\nabla$  on the given manifold having  $\nabla \Theta = 0$ , the distribution  $\mathcal{B} = \text{Im } \Theta$  is  $\nabla$ -parallel and hence integrable, cf. (1.2), and the torsion-free connections induced by  $\nabla$  on the leaves of  $\mathcal{B}$  make the restriction of  $\Theta$  to each leaf parallel, which implies the same (and hence also closedness) for their inverses.

Let us now assume that  $\mathcal{B} = \text{Im } \Theta$  is integrable and the inverses of the restrictions of  $\Theta$  to the leaves of  $\mathcal{B}$  are all closed. These inverses are symplectic forms  $\zeta$  on the leaves, and the Darboux theorem with parameters [1, Lemma 3.10] allows us to choose functions  $x^i$  which, restricted to each leaf, form local coordinates with  $\zeta = dx^1 \wedge dx^2 + \dots + dx^{2r-1} \wedge dx^{2r}$ , where  $2r = \text{rank } \zeta = \text{rank } \Theta$ . We may also choose functions  $x^a$ , with the index ranges  $1 \leq i \leq 2r < a \leq \dim M$ , such that the differentials  $dx^a$  form a local trivialization of the subbundle  $\text{Ker } \Theta \subseteq T^*M$ . In the resulting product coordinates  $x^i, x^a$  the components of  $\Theta$  are all constant:  $\Theta^{ia} = \Theta^{ab} = 0$ , while  $\Theta^{ij} = 1$  (or,  $\Theta^{ij} = -1$ ) if  $(j, i)$ , or  $(i, j)$ , is one of the pairs  $(1, 2), (3, 4), \dots, (2r-1, 2r)$ , and  $\Theta^{ij} = 0$  otherwise.  $\square$

### 15. Integrability of the kernels and images

For any vector bundle  $\mathcal{L}$  over a manifold  $M$  and a vector-bundle morphism  $\Theta : TM \rightarrow \mathcal{L}^*$  of constant rank  $r$  into its dual  $\mathcal{L}^*$ , the resulting dual morphism  $\Theta^* : \mathcal{L} \rightarrow T^*M$ , which also has rank  $\Theta^* = r$ , gives rise to a tensor-like object  $\tilde{N}$  (specifically, a section of  $\text{Hom}(\mathcal{L} \otimes \mathcal{L}^{\wedge r}, [T^*M]^{\wedge(r+2)})$ ), sending sections  $v, v_1, \dots, v_r$  of  $\mathcal{L}$  to the  $(r+2)$ -form

$$(15.1) \quad \tilde{N}(v, v_1, \dots, v_r) = [d(\Theta^*v)] \wedge \Theta^*v_1 \wedge \dots \wedge \Theta^*v_r.$$

Here  $d[\Theta^*(fv)] = fd(\Theta^*v) + df \wedge \Theta^*v$  for a function  $f$ . However,  $\tilde{N}$  itself is tensorial: the nontensorial term  $df \wedge \Theta^*v$  in the last equality has zero exterior product with  $\Theta^*v_1 \wedge \dots \wedge \Theta^*v_r$ , since  $\text{rank } \Theta^* = r$ . Furthermore,

$$(15.2) \quad \tilde{N} = 0 \text{ identically if and only if } \text{Ker } \Theta \text{ is integrable.}$$

In fact, as  $\text{Ker } \Theta$  is the simultaneous kernel of the 1-forms  $\Theta^*v$ , for all sections  $v$  of  $\mathcal{L}$ , its integrability amounts to  $d$ -closedness of the ideal generated by all such 1-forms which, as  $\text{rank } \Theta^* = r$ , is nothing else than the vanishing of  $\tilde{N}$ ,

In the case of  $\mathcal{L} = TM$  and a (possibly nonsymmetric)  $(0, 2)$  tensor  $g$  of constant rank  $r$  on  $M$ , treated as a morphism  $\Theta : TM \rightarrow T^*M$  sending a vector field  $w$  to the 1-form  $g(\cdot, w)$ , the dual  $\Theta^*$  acts via  $v \mapsto g(v, \cdot)$ . Then

$$(15.3) \quad \tilde{N} \text{ in (15.1) becomes } N' \text{ in (1.8-a), so that } N' \text{ is tensorial.}$$

Let  $\Theta$  now be an algebraically constant nilpotent  $(1, 1)$  tensor on an  $n$ -manifold with the Jordan normal form  $d_1 \dots d_m$ , cf. (1.5). Integrability of  $\Theta$ , as well as its local constancy, is equivalent, by Theorem B, to the simultaneous vanishing of the Nijenhuis tensor  $N$  in (1.3) along with further  $d_1 - 1$  Nijenhuis-type tensors  $N^i$ , where  $1 \leq i < d_1$ , such that  $N^i = 0$  if and only if  $\mathcal{Z}^i = \text{Ker } \Theta^i$  is integrable. Specifically, we define  $N^i$  to be  $\tilde{N}$  in (15.1) with  $\mathcal{L} = TM$  and  $\Theta$  replaced by  $\Theta^i$ , where  $r$  equals (7.1), and a fixed Riemannian metric on  $M$  has been used to identify  $TM$  with  $T^*M$ , thus turning each  $\Theta^i$  separately into a vector-bundle morphism  $TM \rightarrow T^*M = \mathcal{L}^*$ .

Finally, given a (skew)symmetric  $(2, 0)$  tensor  $\Theta$  of constant rank  $r$  on a manifold  $M$ , we associate with  $\Theta$  a Nijenhuis-type  $(2r + 3, 0)$  tensor  $\hat{N}$ , testing the integrability of the image distribution  $\mathcal{V} = \text{Im } \Theta \subseteq TM$ . (Note that  $\Theta$  is a bundle morphism  $T^*M \rightarrow TM$ .) To define  $\hat{N}$ , we again fix a Riemannian metric on  $M$ , which allows us to use contractions and the Hodge star operator  $*$  (as the latter enters our formula quadratically,  $M$  need not be oriented). With the notational convention  $\Theta\xi = \Theta(\cdot, \xi)$  for 1-forms  $\xi$  on  $M$ , we set

$$(15.4) \quad \hat{N}(\xi, \xi^1, \dots, \xi^r, \eta, \eta^1, \dots, \eta^r) = \Omega[\Theta\xi, \Theta\eta],$$

where  $\xi, \xi^1, \dots, \xi^r, \eta, \eta^1, \dots, \eta^r$  are any 1-forms on  $M$ , and

$$(15.5) \quad \Omega \text{ denotes the result of an } (r-1)\text{-fold contraction (2.9) of } *(\Theta\xi^1 \wedge \dots \wedge \Theta\xi^r) \text{ against } *(\Theta\eta^1 \wedge \dots \wedge \Theta\eta^r).$$

Clearly, at points where the  $r$ -tuples  $\Theta\xi^1, \dots, \Theta\xi^r$  and  $\Theta\eta^1, \dots, \Theta\eta^r$  of vector fields are both linearly independent,  $\Omega$  is, by Remark 2.4, a nonzero functional multiple of the orthogonal projection onto the orthogonal complement of  $\mathcal{V}$  and, applied to the Lie brackets  $[\Theta\xi, \Theta\eta]$ , tests the integrability of  $\mathcal{V}$ .

## 16. Twice-covariant symmetric tensors

The tensoriality of  $N'$  in (1.8-a) was established in (15.3). For  $N''$ , the non-tensorial contribution to (1.8-b) arising from the equality

$$[\mathcal{L}_{\phi v}g](w, u) = \phi[\mathcal{L}_v g](w, u) + (d_w \phi)g(v, u) + (d_u \phi)g(w, v),$$

for any function  $\phi$  on the given manifold  $M$ , equals  $(d_w \phi)g(u, \cdot) + (d_u \phi)g(w, \cdot)$ . Its exterior product with  $g(v_1, \cdot) \wedge \dots \wedge g(v_r, \cdot)$  vanishes, being a sum of  $(r+1)$ -fold exterior products of sections of a rank  $r$  subbundle of  $T^*M$ , namely, the image of the morphism sending each vector field  $v$  to  $g(v, \cdot)$ .

PROOF OF THEOREM H. We derive our conclusion from Proposition E, by showing that the vanishing of  $N'$  (or  $N''$ ), is equivalent to the integrability of the distribution  $\mathcal{V} = \text{Ker } g$  (or, respectively, to projectability of  $g$  along  $\mathcal{V}$ ).

The first of these claims is obvious from (15.2) and (15.3). It thus obviously suffices to show that *the second equivalence holds if  $\mathcal{V}$  is integrable*.

Clearly, with  $\mathcal{V} = \text{Ker } g$  from now on assumed integrable,

$$(16.1) \quad N'' = 0 \text{ if and only if } N''(w, u, v_1, \dots, v_r) = 0 \text{ for all local vector fields } w, u, v_1, \dots, v_r \text{ projectable along } \mathcal{V}.$$

Although  $[\mathcal{L}g](w, u)$  in (1.8-b) is not a genuine 1-form on the manifold  $M$  in question, we now artificially turn it into one, by fixing a local trivialization of  $TM$ , containing a local trivialization of  $\mathcal{V}$ , and declaring  $[\mathcal{L}g](w, u)$  to be 1-form acting by  $v \mapsto [\mathcal{L}_v g](w, u)$  on our selected (finitely many) vector fields  $v$  trivializing  $TM$ . As  $[\mathcal{L}_v g](w, u) = d_v[g(w, u)] - g([v, w], u) - g(w, [v, u])$ , projectability of  $w, u$  and (2.3) imply that

$$(16.2) \quad [\mathcal{L}_v g](w, u) = d_v[g(w, u)] \text{ whenever } v \text{ is a section of } \mathcal{V} = \text{Ker } g.$$

If  $N'' = 0$ , the  $(r+1)$ -form  $\zeta = N''(w, u, v_1, \dots, v_r)$  vanishes, and hence so does  $d_v[g(w, u)]$  in (16.2), as  $\zeta(v, \cdot, \dots, \cdot)$  equals  $d_v[g(w, u)]$  times the the exterior product  $g(v_1, \cdot) \wedge \dots \wedge g(v_r, \cdot)$  (and the latter  $r$ -form may be chosen nonzero since  $\text{rank } g = r$ ). Consequently, by (2.4),  $g$  is projectable along  $\mathcal{V}$ .

Conversely, let us assume projectability of  $g$  along  $\mathcal{V}$ . Now in (16.1) – (16.2)  $d_v[g(w, u)] = 0$ , and hence  $[\mathcal{L}_v g](w, u) = 0$  for all sections  $v$  of  $\mathcal{V}$ . The 1-form  $[\mathcal{L}g](w, u)$  vanishes on  $\mathcal{V} = \text{Ker } g$ , and so obviously do  $g(v_1, \cdot), \dots, g(v_r, \cdot)$  in (16.1). As  $\text{rank } g = r$ , the 1-forms vanishing on  $\mathcal{V}$  fill a vector subbundle of fibre dimension  $r$  in  $T^*M$ . Thus,  $N'' = 0$  by (16.1).  $\square$
