# A PARALLEL BATCH GREEDY ALGORITHM IN REDUCED BASIS METHODS: CONVERGENCE RATES AND NUMERICAL RESULTS 

NIKLAS REICH, KARSTEN URBAN, AND JÜRGEN VORLOEPER

#### Abstract

The "classical" (weak) greedy algorithm is widely used within model order reduction in order to compute a reduced basis in the offline training phase: An a posteriori error estimator is maximized and the snapshot corresponding to the maximizer is added to the basis. Since these snapshots are determined by a sufficiently detailed discretization, the offline phase is often computationally extremely costly.

We suggest to replace the serial determination of one snapshot after the other by a parallel approach. In order to do so, we introduce a batch size $b$ and add $b$ snapshots to the current basis in every greedy iteration. These snapshots are computed in parallel.

We prove convergence rates for this new batch greedy algorithm and compare them to those of the classical (weak) greedy algorithm in the Hilbert and Banach space case. Then, we present numerical results where we apply a (parallel) implementation of the proposed algorithm to the linear elliptic thermal block problem. We analyze the convergence rate as well as the offline and online wall-clock times for different batch sizes. We show that the proposed variant can significantly speed-up the offline phase while the size of the reduced problem is only moderately increased. The benefit of the parallel batch greedy increases for more complicated problems.

## 1. InTRODUCTION

Model order reduction of parameterized partial differential equations (PPDEs) by the reduced basis method (RBM) has been a very active research field over the last at least 15 years, see [7, $9,15,18]$ for surveys. The reduced model is determined in an offline training phase by determining certain samples of the parameter and using sufficiently detailed numerical solutions to compute approximations of the solution of the PPDE (called snapshots) for those samples. These snapshots then form the reduced basis. Since the snapshots need to be sufficiently detailed, their computation might be computationally costly. Parallel computing can of course be used for each snapshot.

However, since the sample values of the parameter are determined by maximizing an a posteriori error over a training set of parameters in a (weak) greedy algorithm, one snapshot is selected in each greedy iteration, which is a serial process. In order to fully benefit from a potential gain of computational power in the offline phase, we suggest in this paper to chose $b \geq 2$ samples at once and to compute all such $b$ snapshots in parallel. We call this a parallel batch greedy algorithm.

[^0]The convergence properties of the (standard) greedy algorithm are very well understood, $[1,5]$. In fact, it has been proven in these papers that the convergence rate of the weak greedy method is optimal as compared to the rate of the best possible linear approximation, which is given by the Kolmogorov $n$-width. We analyze the effect of the batch variant both theoretically and numerically. It turns out that the theoretical results and the proofs in $[1,5]$ only need to be modified in a minor manner to obtain corresponding results for the batch greedy case (see Theorem 3.4 below). As expected, the convergence rate of the weak greedy (slightly) suffers for larger values of $b$, which means that the size of the reduced model increases (the offline speedup comes at the cost of additional online cost). Since this effect is based upon the sizes of involved constants, we performed numerical experiments comparing the batch greedy with the standard, "classical" greedy method.

This paper is organized as follows. In Section 2, we introduce the classical greedy method in strong and weak form. We also introduce the batch version of the weak greedy scheme. The convergence analysis is described in Section 3 and the results of our numerical experiments are presented in Section 4. The error analysis in Banach spaces as a straightforward generalization of [5, Sec. 4] is presented in Appendix A.

## 2. GREEDY ALGORITHMS

We start by recalling known facts on greedy algorithms from $[1,5]$ and introduce the idea of a batch greedy algorithm. We restrict ourselves to the case where $X$ is a Hilbert space with a norm induced by an inner product, i.e. $\|\cdot\| \equiv\|\cdot\|_{X} \equiv \sqrt{\langle\cdot, \cdot\rangle},\langle\cdot, \cdot \cdot\rangle \equiv\langle\cdot, \cdot\rangle_{X}$; the Banach space case is described in Appendix A. Let $\mathcal{F} \subseteq X$ be compact and (for notational convenience only and without loss of generality) we shall assume that the elements $f$ of $\mathcal{F}$ satisfy $\|f\|_{X} \leq 1$, i.e., $\mathcal{F} \subseteq \mathcal{B}_{1}(0)$, the unit ball in $X$.
2.1. The classical strong greedy algorithm. Before formulating the algorithm, we introduce some notation. Let $V_{n} \subset X$ be some subspace of dimension $n \in \mathbb{N}$. Then,

$$
\begin{equation*}
\sigma_{n}(f):=\operatorname{dist}\left(f, V_{n}\right):=\inf _{g_{n} \in V_{n}}\left\|f-g_{n}\right\|, \quad \sigma_{n}(\mathcal{F}):=\max _{f \in \mathcal{F}} \operatorname{dist}\left(f, V_{n}\right) \tag{2.1}
\end{equation*}
$$

This means in particular that $\sigma_{0}(f):=\|f\|$ and therefore $\sigma_{0}(\mathcal{F}):=\max _{f \in \mathcal{F}}\|f\| \leq 1$, since $\operatorname{dim} V_{0}=0$. The strong greedy method is shown in Algorithm 1.

```
Algorithm 1 Strong Greedy Algorithm
Require: \(V_{0}:=\emptyset\).
    for \(n=0,1,2, \ldots\) do
        Choose \(f_{n} \in \mathcal{F}\) such that \(f_{n}=\arg \max _{f \in \mathcal{F}} \sigma_{n}(f)\).
        \(V_{n+1}:=\operatorname{span}\left(V_{n} \oplus\left\{f_{n}\right\}\right)\).
    end for
```

Obviously, line 2 means that $f_{n}$ minimizes the distance to $V_{n}$, which explains the name strong greedy.
2.2. The Kolmogorov $n$-width. We are interested in the decay of $\sigma_{n}$ as $n \rightarrow \infty$, i.e., the question how well $\mathcal{F}$ is approximated by $V_{n}$ in an $L_{\infty}(\mathcal{F})$-sense. Since $V_{n}$ is a linear space, the best we can achieve is expressed by the Kolmogorov n-width $d_{n}(\mathcal{F})$ of $\mathcal{F}$
defined for $n \in \mathbb{N}$ by

$$
d_{n} \equiv d_{n}(\mathcal{F}):=\inf _{\substack{X_{n} \subset X \\ \operatorname{dim}\left(X_{n}\right)=n}} \sup _{f \in \mathcal{F}} \operatorname{dist}\left(f, X_{n}\right),
$$

and we set $d_{0} \equiv d_{0}(\mathcal{F}):=\max _{f \in \mathcal{F}}\|f\|=: \sigma_{0}(\mathcal{F}) \leq 1$. If the infimum in the definition of $d_{n}$ is attained, the corresponding argument $X_{n}$ is called optimal in the sense of Kolmogorov. We aim that the spaces $V_{n}$ generated by the greedy method are possibly close to such optimal space $X_{n}$. Hence, we would hope that $\sigma_{n}=\mathcal{O}\left(d_{n}\right)$, see [1, 5] and references therein for corresponding results.
2.3. The classical weak greedy algorithm. Realizing line 2 in algorithm 1 , namely determining the distance w.r.t. $\mathcal{F}$ is either impossible or at least computationally too costly. In fact, in a reduced basis framework, the greedy method selects sample parameters $\mu^{(n)}$ and the elements are then the numerical detailed solution $f_{n}=u\left(\mu^{(n)}\right)$ (also called snapshots) for the chosen parameter. In the strong variant of the greedy algorithm we would need to compute the snapshot of every parameter $\mu$ in a training set. This is not feasible in practice and therefore the strong greedy method is mainly of theoretical interest and not appropriate for numerical computations. To circumvent this problem, we introduce a weak variant of the greedy algorithm, described in Algorithm 2.

```
Algorithm 2 Weak Greedy Algorithm
Require: Fix a constant \(0<\gamma \leq 1, V_{0}:=\emptyset\).
    for \(n=0,1,2,3, \ldots\) do
        Choose \(f_{n} \in \mathcal{F}\) such that \(\sigma_{n}\left(f_{n}\right) \geq \gamma \sigma_{n}(\mathcal{F})\)
        \(V_{n+1}:=\operatorname{span}\left(V_{n} \oplus\left\{f_{n}\right\}\right)\).
    end for
```

In the weak form, one is able to make the choice of $f_{n}$ without computing it beforehand. This is usually realized by an error surrogate $r_{n}(f)$ for which holds $c_{r} r_{n}(f) \leq$ $\sigma_{n}(f) \leq C_{r} r_{n}(f)$ for all $f \in \mathcal{F}$ with some fixed constants $c_{r}, C_{r}$. Line 2 of Algorithm 2 is then realized by setting $\gamma=\frac{c_{r}}{C_{r}}$ and choosing $f_{n}$ such that $f_{n}=\arg \max _{f \in \mathcal{F}} r_{n}(f)$, [1]. Only the chosen snapshot $f_{n}=u\left(\mu^{(n)}\right)$ is then computed. Note that for $\gamma=1$, the weak greedy algorithm coincides with the strong greedy algorithm. Moreover, neither the greedy algorithm nor the weak greedy algorithm gives a unique sequence $\left(f_{n}\right)_{n \geq 0}$; also the sequence $\left(\sigma_{n}\right)_{n \geq 0}$ is not unique. In all that follows, the notation reflects any sequence which can arise in the implementation of the weak greedy selection for the fixed value of $\gamma$.
2.4. A weak batch greedy algorithm. Our aim is to incorporate (more) parallel processing into the (weak) greedy algorithm. Of course, parallel computing can be used for each single snapshot computation, but the outer greedy algorithm will always remain serial. To overcome this, if in one iteration $\ell=0,1,2, \ldots$ of a greedy algorithm $b \geq 2$ sample parameters $\mu^{(\ell, k)}, k=0, \ldots, b-1$, are chosen, the corresponding snapshots can be computed in parallel, which potentially significantly improves the computational efficiency. This already describes the idea of a batch greedy method with batch size $b$, which is described in detail in Algorithm 3. For $b=1$, the batch greedy reduces to the standard one. The following analysis is for the weak version of the batch greedy, but by choosing $\gamma=1$ we also get results for the strong variant.

```
Algorithm 3 Weak Batch Greedy Algorithm
Require: Batch size \(b\), fix a constant \(0<\gamma \leq 1, V_{0}:=\emptyset\).
    for \(\ell=0,1,2,3, \ldots\) do
        Set \(\underset{\sim}{n}:=b \ell\) and \(\widetilde{n}:=b(\ell+1)-1\).
        Choose \(f_{\underset{n}{n}}\) such that \(\sigma_{\underset{n}{n}}\left(f_{\sim}^{n}\right) \geq \gamma \max _{f \in \mathcal{F}} \sigma_{\sim}^{n}(f)\).
        for \(n=\tilde{n}+1, \ldots, \widetilde{n}\) do
                        \(f_{n}:=\underset{f \in \mathcal{F} \backslash\left\{f_{\underline{n}}, \ldots, f_{n-1}\right\}}{\arg \max } r_{n}(f)\)
        end for
        Compute \(f_{\underset{\sim}{n}}, \ldots, f_{\widetilde{n}}\) in parallel.
```

```
        (Orthogonalize \(V_{\widetilde{n}}\).)
    end for
```

Remark 2.1. (a) With the introduction of the batch, the iteration number of the greedy algorithm and the dimension of the reduced space do no longer coincide. In Algorithm 3, we denote by $\ell$ the greedy iteration while $n$ (as well as $\underset{\sim}{n}$ and $\widetilde{n}$ ) refer to the dimension of the reduced space. The connection of $\ell$ and $n$ is given by $n:=(\ell, k):=b \ell+k$ for $\ell=0,1, \ldots$ and $k=0,1, \ldots, b-1$. The numbers $\underline{n}=(\ell, 0)=b \ell$ and $\tilde{n}=(\ell, b-1)=b(\ell+1)-1$ refer to the first and last index in a batch.
(b) In line 3 of Algorithm 3, the first function of every batch $f_{n}$ is chosen by the same criterium as in the classical weak greedy algorithm.
(c) Line 5 means that the remaining $b-1$ elements of the batch are chosen as the next largest values of $\sigma_{n}\left(f_{n}\right)$. For our analysis in Section 3 below, we actually do not need to fix how the remaining $b-1$ elements are chosen as long as the first one is chosen according to line 3. Our numerical experiments in Section 4 are based upon the choice in Algorithm 3.

## 3. Error analysis

We are now going to present the error analysis of Algorithm 3. This reduces mainly to modifications of the proofs already published in $[1,5]$. Hence, we will particularly concentrate on those issues which turn out be relevant when introducing a batch size $b \geq 2$. If there are only minor modifications, we indicate them in blue. This refers in particular to the dependency on the batch size, also in order to show that the case $b=1$ reduces to the known results for the weak greedy method.

As before we will assume that $X$ is a Hilbert space; the generalization to Banach spaces can be found in Appendix A. Since in general the greedy algorithm does not terminate, we set $f_{m}:=0$ for $m>N$, if the algorithm terminates at $N$, i.e., if $\sigma_{N}(\mathcal{F})=$ 0 . $\operatorname{By}\left(f_{n}^{*}\right)_{n \geq 0}$, we denote the orthogonal system obtained from $\left(f_{n}\right)_{n \in \mathbb{N}_{0}}$ e.g. by GramSchmidt. The orthogonal projector $P_{n}: X \rightarrow V_{n}$ is given by $P_{n} f=\sum_{i=0}^{n-1}\left\langle f, f_{i}^{*}\right\rangle f_{i}^{*}$, and, in particular,

$$
f_{n}=P_{n+1} f_{n}=\sum_{j=0}^{n} a_{n, j} f_{j}^{*}, \quad \text { where } a_{n, j}=\left\langle f_{n}, f_{j}^{*}\right\rangle, j \leq n
$$

Without loss of generality, we may assume that $X$ is the sequence space $\ell_{2}\left(\mathbb{N}_{0}\right)$ and $f_{j}^{*}=e_{j}$, where $e_{j}$ is the unit sequence, i.e., $\left(e_{j}\right)_{i}=\delta_{j, i}$. Next, consider the (infinitedimensional) lower triangular matrix (setting $a_{i, j}:=0$ for $j>i$ )

$$
\begin{equation*}
A:=\left(a_{i, j}\right)_{i, j \in \mathbb{N}_{0}} \tag{3.1}
\end{equation*}
$$

which incorporates all the information about the greedy algorithm. This matrix representation is going to be critical in the error analysis.

Now, we are in position to present the error analysis adjusted to the batch case. We start by modifying [1, p. 1462], [5, p. 459]. For $b=1$, the subsequent statement coincides with the original result.

Lemma 3.1. For Algorithm 3 and $A$ in (3.1), we have for all $n \in \mathbb{N}_{0}$ that
(P1) the diagonal elements satisfy $\gamma \sigma_{n+b-1} \leq\left|a_{n, n}\right| \leq \sigma_{n}$;
(P2) for every $m \geq n$ one has $\sum_{j=n}^{m} a_{m, j}^{2} \leq \sigma_{n}$.
Proof. As in [1,5] we have $a_{n, n}^{2}=\left\|f_{n}\right\|^{2}-\left\|P_{n} f_{n}\right\|^{2}=\left\|f_{n}-P_{n} f_{n}\right\|^{2}$ due to orthogonality. In particular, $a_{n, n}=\left\langle f_{n}, f_{n}^{*}\right\rangle=\left(f_{n}\right)_{n}$ since $X=\ell_{2}$. Therefore we have

$$
\begin{equation*}
\left|a_{n, n}\right|=\left\|f_{n}-P_{n} f_{n}\right\|=\sigma_{n}\left(f_{n}\right) \leq \max _{f \in \mathcal{F}}\left\|f-P_{n} f\right\|=\sigma_{n}(\mathcal{F})=\sigma_{n} \tag{3.2}
\end{equation*}
$$

which proves the upper inequality in (P1). Now let $n \in \mathbb{N}$ be arbitrary. Then, there are unique $\ell \in \mathbb{N}$ and $k \in\{0, \ldots, b-1\}$ such that $n=(\ell, k)$. Set $\underset{\sim}{n}:=n(\ell, 0)$ and $\widetilde{n}:=n(\ell, b-1)$, then $n \in\left[\frac{n}{n}, \widetilde{n}\right]$. Since $f_{\underline{n}}$ and $f_{\tilde{n}+1}$ are chosen as in the standard greedy, we have by line 3 in Algorithm 3 that $\sigma_{\underset{n}{n}}\left(f_{\sim}^{n}\right) \geq \gamma \sigma_{\widetilde{n}}$ and $\sigma_{\widetilde{n}+1}\left(f_{\widetilde{n}+1}\right) \geq \gamma \sigma_{\widetilde{n}+1}$. If $n=\underset{\sim}{n}$, then we have, by our selection

$$
\left|a_{n, n}\right|=\sigma_{n}\left(f_{n}\right)=\sigma_{\underline{n}}\left(f_{\underset{\sim}{n}}\right) \geq \gamma \sigma_{\underline{n}} \geq \gamma \sigma_{n+b-1} .
$$

Otherwise we have for $n \in(\underset{\sim}{n}, \tilde{n}]$

$$
\left|a_{n, n}\right|=\sigma_{n}\left(f_{n}\right) \geq \sigma_{\widetilde{n}}\left(f_{n}\right) \geq \sigma_{\widetilde{n}+1}\left(f_{\widetilde{n}+1}\right)=\left|a_{\widetilde{n}+1, \widetilde{n}+1}\right| \geq \gamma \sigma_{\widetilde{n}+1} \geq \gamma \sigma_{n+b-1}
$$

since $\widetilde{n} \leq n+b-1$, which proves the lower estimate in (P1). The proof of (P2) follows by the same arguments as in [1,5]: We have for $m \geq n$

$$
\sum_{j=n}^{m} a_{m, j}^{2}=\left\|f_{m}-P_{n} f_{m}\right\|^{2} \leq \max _{f \in \mathcal{F}}\left\|f-P_{n} f\right\|^{2} \leq \sigma_{n}^{2}
$$

which concludes the proof.
The following result from [5] is a key to continue with the analysis.
Lemma 3.2 ([5, Lemma 2.1]). Let $G=\left(g_{i, j}\right) \in \mathbb{R}^{K \times K}, K \in \mathbb{N}$, be a lower triangular matrix with rows $\mathbf{g}_{1}, \ldots, \mathbf{g}_{K}$. If $W_{m} \subset \mathbb{R}^{K}, m<K$, is an m-dimensional subspace of with the associated orthogonal projection $P_{m}$, then

$$
\prod_{i=1}^{K} g_{i, i}^{2} \leq\left[\frac{1}{m} \sum_{i=1}^{K}\left\|P_{m} \mathbf{g}_{i}\right\|_{\ell_{2}}^{2}\right]^{m}\left[\frac{1}{K-m} \sum_{i=1}^{K}\left\|\mathbf{g}_{i}-P_{m} \mathbf{g}_{i}\right\|_{\ell_{2}}^{2}\right]^{K-m}
$$

where $\|\cdot\|_{e_{2}}$ denotes the Euclidean norm of a vector in $\mathbb{R}^{K}$.
Next, we generalize [5, Thm. 3.2] to the case of a batch. Again, for $b=1$, we recover the original result.

Theorem 3.3. Let $X$ be a Hilbert space, then we have for $N \in \mathbb{N}_{0}, K \in \mathbb{N}$ and $1 \leq m<K$

$$
\begin{equation*}
\prod_{i=1}^{K} \sigma_{N+b-1+i}^{2} \leq \gamma^{-2 K}\left[\frac{K}{m}\right]^{m}\left[\frac{K}{K-m}\right]^{K-m} \sigma_{N+1}^{2 m} d_{m}^{2(K-m)} \tag{3.3}
\end{equation*}
$$

Proof. The proof essentially coincides with the proof of [5, Thm. 3.2]. We only need the adapted property ( $\mathbf{P 1}$ ) in Lemma 3.1 that changes the statement. We consider the $K \times K$ matrix $G=\left(g_{i, j}\right)_{i, j=1, \ldots, K}$ which is formed by the rows and columns of $A$ with indices from $\{n+1, \ldots, n+K\}$. Each row $\mathbf{g}_{i}$ is the restriction of $f_{n+i}$ to the coordinates $n+1, \ldots, n+K$.

Let $X_{m}$ be an $m$-dimensional optimal subspace of $X$ in the sense of Kolmogorov, i.e., $\operatorname{dist}\left(\mathcal{F}, X_{m}\right)=d_{m}, m=1, \ldots, K$. Let $\widetilde{W}$ be the linear space airing from the restriction of $X_{m}$ to the coordinates $n+1, \ldots, n+K$. Hence, $\operatorname{dim}(\widetilde{W}) \leq m$. Let $W$ be an $m$-dimensional space, $W \subset \operatorname{span}\left\{e_{n+1}, \ldots, e_{n+K}\right\}$, such that $\widetilde{W} \subset W$ and $P$ and $\widetilde{P}$ are the projections in $\mathbb{R}^{K}$ onto $W$ and $\widetilde{W}$, respectively. As in [5, Thm. 3.2] for the classical weak greedy we have

$$
\begin{equation*}
\left\|P \mathbf{g}_{i}\right\|_{e_{2}} \leq\left\|\mathbf{g}_{i}\right\|_{\ell_{2}} \leq \sigma_{n+1}, \quad i=1, \ldots, K \tag{3.4}
\end{equation*}
$$

by using property ( $\mathbf{P} 2$ ), as well as for $i=1, \ldots, K$

$$
\begin{equation*}
\left\|\mathbf{g}_{i}-P \mathbf{g}_{i}\right\|_{e_{2}} \leq\left\|\mathbf{g}_{i}-\widetilde{P} \mathbf{g}_{i}\right\|_{e_{2}}=\operatorname{dist}\left(\mathbf{g}_{i}, \widetilde{W}\right) \leq \operatorname{dist}\left(f_{n+i}, X_{m}\right) \leq d_{m} \tag{3.5}
\end{equation*}
$$

From the (adapted) property (P1) it follows that

$$
\begin{equation*}
\prod_{i=1}^{K}\left|a_{n+i, n+i}\right|=\prod_{i=1}^{K} \sigma_{n+i}\left(f_{n+i}\right) \geq \gamma^{K} \prod_{i=1}^{K} \sigma_{N+b-1+i} \tag{3.6}
\end{equation*}
$$

Using (3.6) together with Lemma 3.2, (3.4) and (3.5) we get

$$
\begin{aligned}
\prod_{i=1}^{K} \sigma_{n+b-1+i}^{2} & \leq \gamma^{-2 K} \prod_{i=1}^{K}\left|a_{n+i, n+i}\right|^{2} \leq \gamma^{-2 K} \prod_{i=1}^{K}\left|g_{i, i}\right|^{2} \\
& \leq \gamma^{-2 K}\left[\frac{1}{m} \sum_{i=1}^{K}\left\|P \mathbf{g}_{i}\right\|_{\ell_{2}}^{2}\right]^{m}\left[\frac{1}{K-m} \sum_{i=1}^{K}\left\|\mathbf{g}_{i}-P \mathbf{g}_{i}\right\|_{\ell_{2}}^{2}\right]^{K-m} \\
& \leq \gamma^{-2 K}\left[\frac{1}{m} \sum_{i=1}^{K} \sigma_{n+1}^{2}\right]^{m}\left[\frac{1}{K-m} \sum_{i=1}^{K} d_{m}^{2}\right]^{K-m} \\
& =\gamma^{-2 K}\left[\frac{K}{m}\right]^{m}\left[\frac{K}{K-m}\right]^{K-m} \sigma_{n+1}^{2 m} d_{m}^{2 K-2 m}
\end{aligned}
$$

which completes the proof.
We note some special cases as a generalization of [5, Cor. 3.3], which generalize [1, Thm. 3.1] and [1, Thm. 3.2].

Theorem 3.4. For Algorithm 3 with constant $\gamma$ and batch size $b$ we have:
(i) For any compact set $\mathcal{F}$ and $n \geq 1$, we have

$$
\begin{equation*}
\sigma_{n+b-1}(\mathcal{F}) \leq \sqrt{2} \gamma^{-1} \min _{1 \leq m<n} d_{m}(\mathcal{F})^{\frac{n-m}{m}} \tag{3.7}
\end{equation*}
$$

In particular, $\sigma_{2 n+b-1}(\mathcal{F}) \leq \sqrt{2} \gamma^{-1} \sqrt{d_{n}(\mathcal{F})}$ for $n \in \mathbb{N}$.
(ii) If $d_{n}(\mathcal{F}) \leq C_{0} n^{-\alpha}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1}(n, b) n^{-\alpha}$ with

$$
C_{1}(n, b):=\max \left\{C_{0} 2^{\alpha+1} \gamma^{-2}\left\lceil 4+\frac{b-1}{n}\right\rceil^{2 \alpha},(b+2)^{\alpha}\right\}
$$

(iii) If $d_{n}(\mathcal{F}) \leq C_{0} e^{-c_{0} n^{\alpha}}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1} e^{-c_{1}(n, b) n^{\alpha}}$ with $C_{1}:=\sqrt{2 C_{0}} \gamma^{-1}$ and

$$
c_{1}(n, b):=\min \left\{c_{0} 2^{-(\alpha+1)}\left\lceil 2+\frac{b-1}{n}\right\rceil^{-\alpha}, \ln \left(C_{1}\right) b^{-\alpha}\right\} .
$$

Proof. (i) We take, as in [5], $N=0, K=n$, and any $1 \leq m<n$ in Theorem 3.3, and use the monotonicity of $\left(\sigma_{n}\right)_{n \geq 0}$ and the fact that $\sigma_{0} \leq 1$ to obtain

$$
\sigma_{n+b-1}^{2 n} \leq \prod_{i=1}^{n} \sigma_{b-1+i}^{2} \leq \gamma^{-2 n}\left[\frac{n}{m}\right]^{m}\left[\frac{n}{n-m}\right]^{n-m} \sigma_{1}^{2 m} d_{m}^{2 n-2 m}
$$

which is equivalent to

$$
\begin{aligned}
\sigma_{n+b-1} & \leq \gamma^{-1}\left(\left[\frac{n}{m}\right]^{\frac{m}{n}}\left[\frac{n}{n-m}\right]^{\frac{n-m}{n}}\right)^{1 / 2} \sigma_{1}^{\frac{m}{n}} d_{m}^{\frac{n-m}{n}} \leq \gamma^{-1} \sqrt{2} \sigma_{0}^{\frac{m}{n}} d_{m}^{\frac{n-m}{n}} \\
& \leq \sqrt{2} \gamma^{-1} \min _{1 \leq m<n} d_{m}^{\frac{n-m}{n}}
\end{aligned}
$$

Here we also used that $x^{-x}(1-x)^{x-1} \leq 2$ for $0<x=\frac{m}{n}<1$.
(ii) Now, we use Theorem 3.3 with $N=K=n$, and any $1 \leq m<n$ to obtain

$$
\sigma_{2 n+b-1}^{2 n} \leq \prod_{j=n+1}^{2 n} \sigma_{b-1+j}^{2} \leq \gamma^{-2 n}\left[\frac{n}{m}\right]^{m}\left[\frac{n}{n-m}\right]^{n-m} \sigma_{n+1}^{2 m} d_{m}^{2 n-2 m}
$$

which is equivalent to

$$
\sigma_{2 n+b-1} \leq \gamma^{-1}\left(\left[\frac{n}{m}\right]^{\frac{m}{n}}\left[\frac{n}{n-m}\right]^{\frac{n-m}{n}}\right)^{\frac{1}{2}} \sigma_{n}^{\frac{m}{n}} d_{m}^{\frac{n-m}{n}} \leq \gamma^{-1} \sqrt{2} \sigma_{n}^{\frac{m}{n}} d_{m}^{\frac{n-m}{n}}
$$

In the case $n=2 s$ and $m=s$, we have $\sigma_{4 s+b-1} \leq \sqrt{2} \gamma^{-1} \sqrt{\sigma_{2 s} d_{s}}$. We now prove the claim by contradiction. Suppose that the statement in (ii) does not hold and let $M$ be the first value where $\sigma_{M}(\mathcal{F})>C_{1} M^{-\alpha}$.
Case 1: $M=\left\lceil 4+\frac{b-1}{s}\right\rceil s$ with $s \geq 1$ : Since $\left\lceil 4+\frac{b-1}{s}\right\rceil s \geq 4 s+b-1$, we have

$$
C_{1}\left(\left[4+\frac{b-1}{s}\right\rceil s\right)^{-\alpha}<\sigma_{\left[4+\frac{b-1}{s}\right]_{s} \leq \sigma_{4 s+b-1} \leq \sqrt{2} \gamma^{-1} \sqrt{\sigma_{2 s} d_{s}} . . . . . .}
$$

By using $\sigma_{2 s} \leq C_{1}(2 s)^{-\alpha}$ and $d_{s} \leq C_{0} s^{-\alpha}$ we get

$$
\begin{equation*}
C_{1}\left(\left\lceil 4+\frac{b-1}{s}\right\rceil s\right)^{-\alpha}<\sigma_{\left\lceil 4+\frac{b-1}{s}\right\rceil_{s}} \leq \sqrt{2^{1-\alpha} C_{0} C_{1}} \gamma^{-1} S^{-\alpha} \tag{3.8}
\end{equation*}
$$

which yields the desired contradiction

$$
C_{1}<2^{1-\alpha} \gamma^{-2}\left\lceil 4+\frac{b-1}{s}\right\rceil^{2 \alpha} C_{0}<2^{\alpha+1} \gamma^{-2}\left\lceil 4+\frac{b-1}{s}\right\rceil^{2 \alpha} C_{0} .
$$

Case 2: $M=\left\lceil 4+\frac{b-1}{s}\right\rceil s+q$ with $q \in\left\{1, \ldots,\left\lceil 4+\frac{b-1}{s}\right\rceil-1\right\}$ for $s \geq 1$ :
Note that $\left\lceil 4+\frac{b-1}{s}\right\rceil s+q<2\left\lceil 4+\frac{b-1}{s}\right\rceil s$. It then follows from (3.8) that

$$
\begin{aligned}
& C_{1} 2^{-\alpha}\left(\left[4+\frac{b-1}{s}\right\rceil s\right)^{-\alpha}=C_{1}\left(2\left\lceil 4+\frac{b-1}{s}\right\rceil s\right)^{-\alpha} \\
& \quad<C_{1}\left(\left[4+\frac{b-1}{s}\right\rceil s+q\right)^{-\alpha}<\sigma_{\left[4+\frac{b-1}{s}\right]_{s+q} \leq \sigma_{\left[4+\frac{b-1}{s}\right]} \leq \sigma_{4 s+b-1}} \\
& \quad \leq \sqrt{2^{1-\alpha} C_{0} C_{1}} \gamma^{-1} s^{-\alpha} .
\end{aligned}
$$

This yields the desired contradiction $C_{1}<2^{\alpha+1} \gamma^{-2}\left\lceil 4+\frac{b-1}{s}\right\rceil^{2 \alpha} C_{0}$.
Case 3: $1 \leq M<3+b$ : From the assumption $\|f\|_{X} \leq 1$, the definition of $C_{1}$ and the monotonicity of $\left(\sigma_{n}\right)_{n \geq 0}$ we obtain the contradiction as $1 \geq \sigma_{0} \geq \sigma_{M}>C_{1} M^{-\alpha} \geq$ $C_{1}(2+b)^{-\alpha} \geq 1$, which concludes the proof.
(iii) From (i) we have

$$
\begin{equation*}
\sigma_{2 s+b-1} \leq \sqrt{2} \gamma^{-1} \sqrt{d_{s}} \leq \sqrt{2} \gamma^{-1} \sqrt{C_{0} e^{-c_{0} s^{\alpha}}}=C_{1} e^{-\frac{1}{2} c_{0} s^{\alpha}} \tag{3.9}
\end{equation*}
$$

We prove the claim again by contradiction. Suppose that the statement (iii) does not hold and let $M$ be the first value where $\sigma_{M}(\mathcal{F})>C_{1} e^{-c_{1} M^{\alpha}}$.
Case 1: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s$ with $s \geq 1$ : Note, that $\left\lceil 2+\frac{b-1}{s}\right\rceil s \geq 2 s+b-1$. Therefore we have with (3.9)

$$
C_{1} e^{-c_{1}\left(\left[2+\frac{b-1}{s}\right] s\right)^{\alpha}}<\sigma_{\left[2+\frac{b-1}{s}\right] s} \leq \sigma_{2 s+b-1} \leq C_{1} e^{-\frac{1}{2} c_{0} s^{\alpha}}
$$

This yields the desired contradiction by comparison of the exponents, i.e.

$$
c_{1}>\frac{1}{2}\left\lceil 2+\frac{b-1}{s}\right\rceil^{-\alpha} c_{0}>2^{-1-\alpha}\left\lceil 2+\frac{b-1}{s}\right\rceil^{-\alpha} c_{0}
$$

Case 2: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s+q$ with $q \in\left\{1,2, \ldots,\left\lceil 2+\frac{b-1}{s}\right\rceil-1\right\}$ for $s \geq 1$ : It then follows from (3.9) that

$$
C_{1} e^{-c_{1}\left(\left[2+\frac{b-1}{s}\right]_{s+q}\right)^{\alpha}}<\sigma_{\left[2+\frac{b-1}{s}\right]_{s+q}} \leq \sigma_{\left[2+\frac{b-1}{s}\right]_{s}} \leq \sigma_{2 s+b-1} \leq C_{1} e^{-\frac{1}{2} c_{0} s^{\alpha}}
$$

Comparing the exponents yields

$$
c_{1}>\frac{1}{2}\left(\left\lceil 2+\frac{b-1}{s}\right\rceil s+q\right)^{-\alpha} s^{\alpha} c_{0}
$$

Note that $\left\lceil 2+\frac{b-1}{s}\right\rceil s+q<2\left\lceil 2+\frac{b-1}{s}\right\rceil s$ and therefore

$$
\begin{aligned}
c_{1} & >\frac{1}{2}\left(\left\lceil 2+\frac{b-1}{s}\right\rceil s+q\right)^{-\alpha} s^{\alpha} c_{0}>\frac{1}{2}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil s\right)^{-\alpha} s^{\alpha} c_{0} \\
& =2^{-1-\alpha}\left\lceil 2+\frac{b-1}{s}\right\rceil^{-\alpha} c_{0}
\end{aligned}
$$

which is the desired contradiction.
Case 3: $1 \leq M<b+1$ : From the assumption that $\|f\|_{X} \leq 1$ and the definition of $c_{1}$ we see the desired contradiction as $1 \geq \sigma_{0} \geq \sigma_{M}>C_{1} e^{-c_{1} M^{\alpha}} \geq C_{1} e^{-c_{1} b^{\alpha}} \geq 1$, which concludes the proof.

Remark 3.5. (a) The constants $C_{1}(n, b)$ of (ii) and $c_{1}(n, b)$ of (iii) depend on $n$ but their values improve ( $C_{1}(n, b)$ decreases and $c_{1}(n, b)$ increases) for increasing $n$, so that the estimates get even sharper.
(b) If the maximum in the definition of $C_{1}(n, b)$ in (ii) is attained by the first term, i.e., $C_{0} 2^{\alpha+1} \gamma^{-2}\lceil 4+(b-1) / n\rceil^{2 \alpha}$, the dependency w.r.t. $n$ is given by the factor $\rho(n, b):=\lceil 4+(b-1) / n\rceil^{2 \alpha}$ (the second term in the maximum is independent of $n$ ). Note, that $(3+b)^{2 \alpha} \geq \rho(n, b) \geq 4^{2 \alpha}$. For $n \geq b-1$ and $b \geq 2$, we have that $\rho(n, b) \equiv 5^{2 \alpha}$. For $b=1$, i.e. the classical weak greedy, we have $\rho(n, 1) \equiv 4^{2 \alpha}$ independent of $n$, which corresponds to the results of [5].
(c) Similar observations hold for $c_{1}(n, b)$ in (iii) with the $n$-dependent quantity $\rho(n, b)$ replaced by $\rho(n, b):=\lceil 2+(b-1) / n\rceil^{-\alpha}$. For $b \geq 2$, we have $(1+b)^{-\alpha} \leq \rho(n, b) \leq$ $3^{-\alpha}$. Moreover, $\rho(n, b)$ increases for increasing $n$ and $\rho(n, 1) \equiv 2^{-\alpha}$ for $b=1$, which corresponds to the results of [5].

Remark 3.6. Taking a closer look at the proof of Theorem 3.4 and the above remark, we can slightly reformulate the results for $b \geq 2$ as follows.
(a) If $d_{n}(\mathcal{F}) \leq C_{0} n^{-\alpha}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1}(n, b) n^{-\alpha}$ with

$$
C_{1}(n, b):= \begin{cases}(b+2)^{\alpha}, & 1 \leq n \leq b+2 \\ 2 \cdot 50^{\alpha} \gamma^{-2} C_{0}, & n \geq b+3\end{cases}
$$

(b) If $d_{n}(\mathcal{F}) \leq C_{0} e^{-c_{0} n^{\alpha}}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1} e^{-c_{1}(n, b) n^{\alpha}}$ with

$$
c_{1}(n, b):= \begin{cases}\ln \left(C_{1}\right) b^{-\alpha}, & 1 \leq n \leq b \\ \frac{1}{2} 6^{-\alpha} c_{0}, & n \geq b+1\end{cases}
$$

and $C_{1}:=\sqrt{2 C_{0}} \gamma^{-1}$.
From a practical point of view, the case (iii) in Theorem 3.4 is the most relevant one as one would use (linear) model order reduction techniques only in those cases where the the Kolmogorov $n$-width and the greedy decay rate are exponential. In this case, we can quantify the asymptotic loss due to the batch.
Corollary 3.7. If $n \geq b \geq 2$ and $d_{n}(\mathcal{F}) \leq C_{0} e^{-c_{0} n^{\alpha}}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1} e^{-c_{1}(n, b) n^{\alpha}}$ with

$$
\begin{equation*}
c_{1}(n, b)=\left[\frac{2}{3}\right]^{\alpha} c_{1}(n, 1) \tag{3.10}
\end{equation*}
$$

Proof. We have $c_{1}(n, 1)=\frac{c_{0}}{2} 4^{-\alpha}$ and for $c_{1}(n, b)=\frac{c_{0}}{2} 6^{-\alpha}$.
The above statement means that the asymptotic rate might decay from $e^{-c_{1} n^{\alpha}}$ to $e^{-c_{1}\left[\frac{2}{3} n\right]^{\alpha}}$ by using a batch. We will investigate this in our numerical experiments in Section 4 below.

## 4. NUMERICAL EXPERIMENTS

Finally, we present results from some of our numerical experiments concerning the (parallel) weak batch greedy algorithm.
4.1. Implementation and hardware. Our implementation is based upon the wellknown Python-based model order reduction library named pyMOR, [6, 13]. The weak batch greedy algorithm, the error estimator and the parallel computation of the snapshots use an MPI-based worker pool enabled by $\operatorname{pyMOR}$, [3, 12]. Moreover, pyMOR uses NumPy and SciPy with backends from OpenBLAS and UMFPACK, [4, 8, 19, 20]. All computations have been performed on a Linux server with two AMD EPYC 7302 CPUs with 16 cores each and 256GB RAM. If not specified otherwise, the MPI-based worker pool was used with 30 workers, i.e., we use up to 30 CPU cores in parallel.

The snapshot computation boils down to a sparse LU factorization using SciPys routine splu, which is based upon SuperLU, [11, 17]. In turn, SuperLU is a parallelized implementation that uses $B L A S$ and $L A P A C K$ backends. Unfortunately, we observed that splu was fastest on a single core and got slightly slower the more cores it was allowed to use. This was the case on multiple $B L A S$ and $L A P C K$ backends. The fastest computation times were achieved by using splu from $U M F P A C K$, which replaces $\operatorname{SuperLU}$, [4, 16]. However, the $U M F P A C K$ implementation of splu does not run in parallel.
4.2. Model problem. We choose the thermal block problem, which is a well-known and widely studied model problem for model reduction, see for example [15, Rem. 3.6], [9, Sec. 6.1.4]. This choice allows us to investigate the effect of taking a batch in the offline phase in comparison to the standard greed scheme. Of course, the batch greedy algorithm is applicable (and most likely more meaningful) for more demanding problems. However, then one often needs additional components like the (discrete) interpolation method, whose consideration would pollute the differences between the batch greedy and the classical greedy algorithm. Therefore, we stick to this rather simple "fruit fly" problem.

Let $\Omega:=(0,1)^{2}=\cup_{p=1}^{P} \Omega_{p}$ be subdivided in $P=p_{x} \times p_{y}$ sub-blocks. We report results for $p_{x}=p_{y}=2, P=4$ and $p_{x}=p_{y}=3, P=9$, but remark that we obtained similar results also for other choices of $p_{x}$ and $p_{y}$. The bilinear form of the corresponding Dirichlet problem reads $a_{\mu}(u, v):=\sum_{p=1}^{P} \mu_{p}(\nabla u, \nabla v)_{L_{2}\left(\Omega_{p}\right)}$ and choose $\mu \in \mathcal{P}:=[0.1,1]^{P} \subset \mathbb{R}^{P}$. With respect to Section 3, we have $X=H_{0}^{1}(\Omega)$ and $\mathcal{F}=\{u(\mu): \mu \in \mathcal{P}\}$.

We use the pyMOR demo thermalblock as a basis implementation and discretize $\Omega$ by $\operatorname{pyMOR}$ using triangular elements with a maximal diameter of $10^{-3}$. This results in 2.002.001 degrees of freedom. This fine grid is chosen in order to ensure that the snapshot computation is significant for parallel computing. The parameter space $\mathcal{P}:=[0.1,1]^{P}$ is discretized for $P=4$ by 25 and for $P=9$ by 5 equidistant points per dimension, resulting in a training set of size $25^{4}$ and $5^{9}$, respectively.
4.3. Batch greedy error decay. We start by investigating the error of the reduced problem as the number $n$ of basis functions (i.e., the dimension of the reduced problem) increases. It is known from [2,14] that the greedy algorithm for the thermal block converges exponentially fast w.r.t. $n$, i.e., $\sigma_{n}(\mathcal{F}) \leq C e^{-c n^{\alpha}}$ for (unknown) constants $0<\alpha, c, C$. Hence, this sets the benchmark for the batch greedy method (see also the blue line indicating $b=1$ in Figure 1). However, we aim at investigating the asymptotic error decay of the batch greedy error, which requires to estimate the unknown constants $\alpha, c, C$. This has been done here by fitting these constants to obtain a lower bound $\underset{\sim}{\sigma}(n)$ for the classical greedy and a manually fittet upper bound
$\widetilde{\sigma}(n)=C e^{-c(2 / 3)^{\alpha} n^{\alpha}}$ for the batch greedy with $b=16$; for the factor $2 / 3$ see Corollary 3.7. Those functions are shifted vertically to get lower and upper bounds in Figure 1.

Figure 1. Error decay in $\|\cdot\|_{1 ; \Omega}$ for different batch sizes. The markers indicate the batches.

We have depicted the relative error $\epsilon_{\text {max, rel },|\cdot|_{1 ; \Omega}}(n)$ maximized over a test set $\mathcal{P}_{\text {test }} \subset$ $\mathcal{P}$ in the seminorm $|v|_{1 ; \Omega}:=\|\nabla v\|_{0 ; \Omega}$ for the batch greedy with $b \in\{1,2,4,8,16\}$. Each batch greedy was stopped when reaching a relative tolerance of $\epsilon_{\text {tol }}=10^{-5}$ (indicated by the dashed line). There are a number of observations in Figure 1:

- For most cases, the error decay of the batch greedy is very similar to the one of the classical week greedy (blue lines, $b=1$ ). Only the cases $(2 \times 2, b=8)$ and $(2 \times 2, b=16)$ in Figure 1a are closer to the upper bound $\widetilde{\sigma}(n)$ corresponding to the slower rate in Corollary 3.7. For the $3 \times 3$ case, all curves show the same asymptotical behavior as the standard greedy method.
- For increasing values $b$ of the batch size the error is not strictly increasing. There are even some (few) cases, where the error for fixed $n$ is smaller for a larger value of $b$. This might be due to the fact that the weak greedy is based upon the error estimate, whereas the true error is shown in Figure 1.
- The error decay is not strictly monotone w.r.t. increasing $n$. To explain this, we have shown the batches by markers. Consider the case $(2 \times 2, b=16)$ in Figure 1a, where the first diamond is at $n=16$; but we also show the error $\epsilon_{\text {max, rel },|\cdot|_{1 ; \Omega}}(n)$ for $n=1, \ldots, 15$, which explains the constant slope (or the nonmonotonic slope in other cases). Again for $(2 \times 2, b=16)$, we see that we cannot reach the target accuracy with two batches, so that we need to add another 16 functions, even though a posteriori we would have reached the tolerance already with 33 basis functions.
This first experiment confirms our theoretical findings, namely that the asymptotic rate of the greedy algorithm is preserved for "moderate" values $b$ of the batch size. However, as we see e.g. for $(2 \times 2, b=16)$, the rate may deteriorate if $b$ is too large for a given problem, or the problem is too simple to benefit from a larger batch size. This can be seen from Figure 1b, where the slope of all curves are similar to the standard greedy case. Hence, more challenging problems (here, larger values of $p_{x}$ and $p_{y}$ ) allow for larger values of the batch size, which means that more complicated problems can benefit from larger batch sizes and parallel computing in the offline phase.
4.4. Offline \& online computing times. Our next aim is the investigation of the computational times since the ultimate aim of the introduction of a batch is to reduce computing times in particular in the offline stage.

Dimensions. As a first step, we fix the target relative training tolerance again as $10^{-5}$ and compare the dimension of the reduced system determined by the batch greedy method as well as the number of greedy iterations. The latter one is related to the overall offline computing time as we determine all $b$ selected snapshots in parallel. The results are depicted in Figure 2. As we see, the dimension of the reduced system increases as $b$ increases (which means that online computing times and storage demands will grow), but the growth is moderate, in particular for $3 \times 3$. On the other hand, for larger values of $b$ we only need very few greedy iterations resulting in a significant reduction of the offline computing time as we will see next.

Computing times. In Figure 3, we show computing times (CPU) for the offline and the online phase. We normalize the CPU times w.r.t. the classical greedy, namely, we indicate the ratio of the CPU time for a given $b$ and the time for the standard greedy (which is the reason, why we start by 1 for $b=1$ ). For determining the online time, we calculated the average computing time of a reduced solution for 500 randomly chosen parameters. Again, we normalized w.r.t. the classical greedy.

First of all, we observe that the slopes in Figure 3 are quite similar to those in Figure 2 , which means in fact that batch greedy iterations and reduced dimensions relate to CPU times. For $b \geq 2$, we observe reduction in the offline phase by a third and up to $80 \%$ as compared to the classical greedy algorithm. The reduction is more pronounced for the more complicated $3 \times 3$ case as compared to the $2 \times 2$ one. On the other hand, online CPU times grows, but this is very moderate, in particular for the $3 \times 3$ case.

Next, we consider the influence of the batch size to the "break-even point", which determines the number of parameter-queries from which a reduced simulation (including offline and online computing times) pays off as compared to a repeated call of the full order model. To be precise, $k^{*}=\left\lceil t_{\text {offline }} /\left(t_{\text {full }}-t_{\text {online }}\right)\right]$ is the break-even point, where $t_{\text {offline }}$ denotes the offline time, $t_{\text {full }}$ the time to calculate a full order solution (also for the snapshots), and $t_{\text {online }}$ is the time it takes to compute a reduced

Figure 2. Final basis size and the number of greedy iterations for different batch sizes.
solution. In Table 1, we see that for the parallel batch greedy algorithm the break-even points are substantially lower than for the classical variant.

|  | $2 \times 2$ |  | $3 \times 3$ |  |
| :---: | :---: | :---: | :---: | :---: |
| (in sec) | classical | batch $(b=10)$ | classical | batch $(b=16)$ |
| $t_{\text {full }}$ | 52.87 | 52.87 | 52.87 | 52.87 |
| $t_{\text {offline }}$ | 1656 | 489 | 124351 | 19790 |
| $t_{\text {online }}$ | 0.0177 | 0.0212 | 0.1363 | 0.1738 |
| $k^{*}$ | 32 | 10 | 2359 | 376 |

TABLE 1. Break-even points $k^{*}$ for the reduced models of the classical greedy compared to the parallel batch greedy algorithm.
4.5. CPU times in detail. Finally, we investigate the offline CPU times a bit more in detail and show a split-up of the offline phase into the parts, namely

- Solve: solution of the full order model for the snapshot computation;
- Evaluate: evaluation of the error estimator on the training set:

Figure 3. Normalized offline and online computation times for different batch sizes.

- Extend: extension of the reduced basis including the orthogonalization;
- Reduce: Update of the reduced model, error estimator and projectors.

The results are shown in Figure 4.
We start commenting the case $(2 \times 2)$, where we may have detected from the previous results $b=10$ as a possible good choice for the batch size. In that case, the offline computing time is minimal with a reduction of more than $70 \%$ compared to the classical greedy. Also the increase of $22 \%$ in the online time is relatively low for this choice of $b$. A more detailed split-up shows a drastic reduction of the snapshot computing time, as we compute 10 snapshots in parallel thrice instead of 23 snapshots in series, which also reduces the evaluation time of the error estimate.

As before, we see from the comparison of the $2 \times 2$ with the $3 \times 3$ case, that the benefit of the batch greedy and parallel computing is much more pronounced for the more complicated $3 \times 3$ case, see Figure 4 b.

Remark 4.1. Our above results indicate that it might be interesting to a priori determine an optimal batch size in order to balance offline and online times for a given problem. However, we believe that the choice of batch size should be motivated more by the hardware to be used in order to maximize the usage of all available CPU cores. In most

FIGURE 4. Split-up of the offline computing time for different batch sizes.
cases it seems meaningful to choose the batch size equal to the number of parallel processes via MPI (with the assumption that the number of available CPU cores is low double digits).

## Appendix A. Error analysis in Banach spaces

We briefly report on the generalization to the batch greedy algorithm of the result in Section 3 to Banach spaces analogous to [5, Sec. 4]. As in the Hilbert space case this mainly amounts minor adaptions, which are highlighted in blue.

Again, we will view the results of the weak batch greedy method as a lower triangular matrix $A:=\left(a_{i, j}\right)_{i, j \in \mathbb{N}_{0}}$ (see (3.1)) to make use of Lemma 3.2. Therefore, we will use the abbreviations $\sigma_{n}:=\sigma_{n}(\mathcal{F})_{X}$ and $d_{n}:=d_{n}(\mathcal{F})_{X}$ as before, where $X$ is now a Banach space with norm $\|\cdot\| \equiv\|\cdot\|_{X}$. For each $j=0,1, \ldots$ we denote by $\lambda_{j} \in X^{*}$ the
linear functional of norm one that satisfies

$$
\text { (i) } \lambda_{j}\left(V_{j}\right)=0, \quad \text { (ii) } \lambda_{j}\left(f_{j}\right)=\operatorname{dist}\left(f_{j}, V_{j}\right)_{X}
$$

where the existence of such $\lambda_{j}$ is a consequence of the Hahn-Banach theorem (see [10, Cor. IV.14.13]). The entries of $A$ are then given by

$$
\begin{equation*}
a_{i, j}:=\lambda_{j}\left(f_{i}\right) \tag{A.1}
\end{equation*}
$$

We have similar properties of $A$ as before.
Lemma A.1. For Algorithm 3 and $A$ in (A.1), we have for all $n, m \in \mathbb{N}_{0}$ with $m>n$
(P1) the diagonal elements satisfy $\gamma \sigma_{n+b-1} \leq\left|a_{n, n}\right| \leq \sigma_{n}$;
(P2) the entries in the lower triangular half satisfy $\left|a_{m, n}\right| \leq \sigma_{n}$.
Proof. The upper inequality of ( $\mathbf{P 1}$ ) is easy to see since

$$
a_{n, n}=\operatorname{dist}\left(f_{n}, v_{n}\right)_{X}=\sigma_{n}\left(f_{n}\right) \leq \max _{f \in \mathcal{F}} \operatorname{dist}\left(f, V_{n}\right)=\sigma_{j}(\mathcal{F})=\sigma_{n} .
$$

For the lower inequality we will employ the same idea as for ( $\mathbf{P 1}$ ) in Lemma 3.1. Let $n \in \mathbb{N}$ be arbitrary. Then, there are unique $\ell \in \mathbb{N}$ and $k \in\{0, \ldots, b-1\}$ such that $n=(\ell, k)$. Set $\underset{\sim}{n}:=(\ell, 0)$ and $\widetilde{n}:=(\ell, b-1)$, then $n \in[\underset{\sim}{n}, \tilde{n}]$. Since $f_{\sim}^{n}$ and $f_{\tilde{n}+1}$ are chosen as in the standard greedy, we have by line 3 in Algorithm 3 that $\sigma_{\underline{n}}\left(f_{\underline{n}}\right) \geq \gamma \sigma_{\underline{n}}$ and $\sigma_{\widetilde{n}+1}\left(f_{\widetilde{n}+1}\right) \geq \gamma \sigma_{\widetilde{n}+1}$. If $n=\underset{\sim}{n}$, we have by our selection

$$
\left|a_{n, n}\right|=\operatorname{dist}\left(f_{n}, V_{n}\right)_{X}=\sigma_{n}\left(f_{n}\right)=\sigma_{\underline{n}}\left(f_{\underline{n}}\right) \geq \gamma \sigma_{\underline{n}} \geq \gamma \sigma_{n+b-1} .
$$

Otherwise we have for $n \in(\underset{\sim}{n}, \tilde{n}]$

$$
\left|a_{n, n}\right|=\operatorname{dist}\left(f_{n}, V_{n}\right)_{X}=\sigma_{n}\left(f_{n}\right) \geq \sigma_{\widetilde{n}+1}\left(f_{\widetilde{n}+1}\right)=\left|a_{\widetilde{n}+1, \widetilde{n}+1}\right| \geq \gamma \sigma_{\widetilde{n}+1} \geq \gamma \sigma_{n+b-1}
$$

since $\tilde{n} \leq n+b-1$. For (P2) we have with $n<m$

$$
\left|a_{m, n}\right|=\lambda_{n}\left(f_{m}\right)=\lambda_{n}\left(f_{m}-g\right) \leq\left\|\lambda_{n}\right\|_{X^{*}}\left\|f_{m}-g\right\|=\left\|f_{m}-g\right\|
$$

for every $g$ in $V_{n}$ since $\lambda_{n}\left(V_{n}\right)=0$. Therefore, $\left|a_{m, n}\right| \leq \operatorname{dist}\left(f_{m}, V_{n}\right)=\sigma_{n}\left(f_{m}\right) \leq \sigma_{n}$, which concludes the proof.

This allows us to generalize [5, Thm. 4.1] to the case of a batch. Again, for $b=1$, we recover the original result.
Theorem A.2. Let $X$ be a Banach space, then for $N \in N_{0}, K \in \mathbb{N}$ and $1 \leq m<K$

$$
\begin{equation*}
\prod_{i=1}^{K} \sigma_{N+b-1+i}^{2} \leq 2^{K} K^{K-m} \gamma^{-2 K}\left[\sum_{i=1}^{K} \sigma_{N+i}^{2}\right]^{m} d_{m}^{2(K-m)} \tag{A.2}
\end{equation*}
$$

Proof. The proof essentially coincides with the proof of [5, Thm. 4.1]. We only need to employ the adapted property ( $\mathbf{P 1}$ ) from Lemma A.1. To this end, we consider the $K \times K$ matrix $G=\left(g_{i, j}\right)$ which is formed by the rows and columns of $A$ with indices from $\{n+1, \ldots, n+K\}$. Each row $\mathbf{g}_{i}$ is the restriction of $f_{n+i}$ to the coordinates $n+1, \ldots, n+K$.

Let $X_{m}$ be an $m$-dimensional optimal subspace of $X$ in the sense of Kolmogorov, i.e., $\operatorname{dist}\left(\mathcal{F}, X_{m}\right)=d_{m}, m=1, \ldots, K$. For each $i$, there is an element $h_{i} \in X_{m}$ such that

$$
\left\|f_{i}-h_{i}\right\|=\operatorname{dist}\left(f_{i}, X_{m}\right)_{X} \leq d_{m}
$$

and therefore

$$
\begin{equation*}
\left|\lambda_{j}\left(f_{i}\right)-\lambda_{j}\left(h_{i}\right)\right|=\left|\lambda_{j}\left(f_{i}-h_{i}\right)\right| \leq\left\|\lambda_{j}\right\|_{X^{*}}\left\|f_{i}-h_{i}\right\| \leq d_{m} \tag{A.3}
\end{equation*}
$$

The vectors $\left(\lambda_{n+1}(h), \ldots, \lambda_{n+K}(h)\right)$ for $h \in X_{m}$ then span a space $W \subset \mathbb{R}^{K}$ with $\operatorname{dim} W \leq$ $m$. As in [5, Thm. 4.1], we assume without loss of generality that $\operatorname{dim} W=m$. It follows from (A.3) that each row $\mathbf{g}_{i}$ in $G$ can be approximated by a vector from $W$ in the $\ell_{\infty}$ norm to the accuracy $d_{m}$ and therefore to accuracy $\sqrt{K} d_{m}$ in the $\ell_{2}$ norm. With $P$ as the orthogonal projection of $\mathbb{R}^{K}$ onto $W$ we have

$$
\begin{equation*}
\left\|\mathbf{g}_{i}-P \mathbf{g}_{i}\right\|_{\ell_{2}} \leq \sqrt{K} d_{m}, \quad i=1, \ldots, K \tag{A.4}
\end{equation*}
$$

From (P2) it follows

$$
\begin{equation*}
\sum_{i=1}^{K}\left\|P \mathbf{g}_{i}\right\|_{\ell_{2}}^{2} \leq \sum_{i=1}^{K} \sum_{j=1}^{i} \sigma_{n+j}^{2} \leq K \sum_{i=1}^{K} \sigma_{n+i}^{2} \tag{A.5}
\end{equation*}
$$

Now we can apply Lemma 3.2 for this $G$ and $W$ together with (P1), (A.4) and (A.5)

$$
\begin{aligned}
\gamma^{2 K} \prod_{i=1}^{K} \sigma_{n+b-1+i} & \leq\left[\frac{K}{m} \sum_{i=1}^{K} \sigma_{n+i}^{2}\right]^{m}\left[\frac{K}{K-m}\left(\sqrt{K} d_{m}\right)^{2}\right]^{K-m} \\
& \leq K^{K-m} 2^{K}\left[\sum_{i=1}^{K} \sigma_{n+i}^{2}\right]^{m} d_{m}^{2(K-m)}
\end{aligned}
$$

This concludes the proof.
We note some special cases of Theorem A. 2 as a generalization of [5, Cor. 4.2].
Theorem A.3. For Algorithm 3 with constant $\gamma$ and batch size $b$ we have:
(i) For any compact set $\mathcal{F}$ and $n \geq 1$, we have

$$
\begin{equation*}
\sigma_{n+b-1} \leq \sqrt{2} \gamma^{-1} \min _{1 \leq m<n} n^{\frac{n-m}{2 n}}\left[\sum_{i=1}^{n} \sigma_{i}^{2}\right]^{\frac{m}{2 n}} d_{m}^{\frac{n-m}{n}} \tag{A.6}
\end{equation*}
$$

In particular, $\sigma_{2 n+b-1} \leq 2 \gamma^{-1} \sqrt{n d_{n}}$.
(ii) If for $\alpha>\frac{1}{2}$, we have $d_{n} \leq C_{0} n^{-\alpha}, n \in \mathbb{N}$, then for any $0<\beta<\min \left\{\alpha-\frac{1}{2}, \frac{1}{2}\right\}$ we have $\sigma_{n}(\mathcal{F}) \leq C_{1}(n, b) n^{-\alpha+1 / 2+\beta}$ with

$$
\begin{gathered}
C_{1}(n, b):=\max \left\{64 C_{0} \gamma^{-4}\left(\frac{2 \beta+1}{2 \beta}\right)^{\alpha}\left(2\left\lceil 2+\frac{b-1}{n}\right\rceil\right)^{4(\alpha-\beta-1 / 2)}\right. \\
\left.4\left(\left[2+\frac{b-1}{4}\right\rceil-1\right)^{\alpha-\beta-1 / 2}\right\}
\end{gathered}
$$

(iii) If for any $\alpha>0$, we have $d_{n}(\mathcal{F}) \leq C_{0} e^{-c_{0} n^{\alpha}}, n \in \mathbb{N}$, then $\sigma_{n}(\mathcal{F}) \leq C_{1} \sqrt{n} e^{-c_{1}(n, b) n^{\alpha}}$ with $C_{1}:=\sqrt{2 C_{0}} \gamma^{-1}$ and

$$
c_{1}(n, b):=\min \left\{\frac{c_{0}}{2}\left(2\left\lceil 2+\frac{b-1}{n}\right\rceil\right)^{-\alpha}, \ln \left(c_{1} \sqrt{b}\right) b^{-\alpha}\right\}
$$

Remark A.4. For $0<\alpha \leq 1 / 2$ in Theorem A. 3 (ii) the exponent of $n$ in $\sigma_{n}$ would be non-negative for all $0<\beta<\min \{\alpha, 1 / 2\}$ which means there is no real convergence. We choose to only look at the meaningful case where the exponent of $n$ in $\sigma_{n}$ can be negative, compared to [5, Cor. 4.2 (ii)] where the result is formulated for $\alpha>0$.

Proof of Theorem A.3. The proofs are similar to those of Theorem 3.4 and, of course, [5, Cor. 4.2].
(i) We take Theorem A. 2 with $N=0, K=n$ and any $1 \leq m<n$ and use the monotonicity of $\left(\sigma_{n}\right)_{n \geq 0}$ to obtain

$$
\sigma_{n+b-1}^{2 n} \leq \prod_{i=1}^{n} \sigma_{b-1+i}^{2} \leq 2^{n} n^{n-m} \gamma^{-2 n}\left[\sum_{i=1}^{n} \sigma_{i}^{2}\right]^{m} d_{m}^{2 n-2 m}
$$

Taking the $2 n$-th root yields the desired result. In particular for $n=2 s, m=s$ and with $\sigma_{0} \leq 1$ we get

$$
\begin{equation*}
\sigma_{2 s+b-1} \leq \sqrt{2} \gamma^{-1}(2 s)^{\frac{1}{4}}\left[\sum_{i=1}^{2 s} \sigma_{i}^{2}\right]^{\frac{1}{4}} \sqrt{d_{s}} \leq \sqrt{2} \gamma^{-1}(2 s)^{\frac{1}{4}}(2 s)^{\frac{1}{4}} \sqrt{d_{s}}=2 \gamma^{-1} \sqrt{s d_{s}} \tag{A.7}
\end{equation*}
$$

(ii) We now take $N=K=n$ and any $1 \leq m<n$ to obtain from Theorem A. 2

$$
\begin{equation*}
\sigma_{2 n+b-1} \leq \sqrt{2} \gamma^{-1} n^{\frac{n-m}{2 n}}\left[n \sigma_{n}^{2}\right]^{\frac{m}{2 n}} d_{m}^{\frac{n-m}{n}} \leq \sqrt{2 n} \gamma^{-1} \sigma_{n}^{\delta} d_{m}^{1-\delta} \tag{A.8}
\end{equation*}
$$

by taking the $2 n$-th root and setting $\delta:=\frac{m}{n}$. With an arbitrary but fixed $0<\beta<$ $\min \left\{\alpha-\frac{1}{2}, \frac{1}{2}\right\}$ we set $m:=\left\lfloor\frac{2 \beta}{2 \beta+1} n\right\rfloor+1$ and therefore $\delta:=\frac{m}{n} \in\left(\frac{2 \beta}{2 \beta+1}, \frac{2 \beta}{2 \beta+1}+\frac{1}{n}\right)$.

We now prove the claim by contradiction. Suppose that the statement in (ii) does not hold and let $M$ be the first value where $\sigma_{M}(\mathcal{F})>C_{1} M^{-\alpha}$.

Case 1: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s$ with $s \geq 4$ : Since $\left\lceil 2+\frac{b-1}{s}\right\rceil s \geq 2 s+b-1$, (A.8) with $\delta:=\frac{m}{s}$ yields

$$
\begin{aligned}
C_{1}\left(\left[2+\frac{b-1}{s}\right\rceil s\right)^{-\alpha+\beta+\frac{1}{2}} & <\sigma_{\left[2+\frac{b-1}{s}\right]_{s} \leq \sigma_{2 s+b-1} \leq \sqrt{2 s} \gamma^{-1} \sigma_{s}^{\delta} d_{m}^{1-\delta}} \\
& \leq \sqrt{2 s} \gamma^{-1}\left\{C_{1} s^{-\alpha+\beta+\frac{1}{2}}\right\}^{\delta}\left\{C_{0}(\delta s)^{-\alpha}\right\}^{1-\delta}
\end{aligned}
$$

where we used $\sigma_{s} \leq C_{1} s^{-\alpha+\beta+1 / 2}$ and $d_{m} \leq C_{0} m^{-\alpha}=C_{0}(\delta s)^{-\alpha}$. Simplifying this yields

$$
C_{1}<C_{0} \sqrt{2}^{\frac{1}{1-\delta}} \gamma^{-\frac{1}{1-\delta}} \delta^{-\alpha} S^{\frac{2 \beta+1}{2(1-\delta)}\left(\delta-\frac{2 \beta}{2 \beta+1}\right)}\left\lceil 2+\frac{b-1}{S}\right\rceil^{\frac{\alpha-\beta-1 / 2}{1-\delta}}
$$

For $s \geq 4>2(2 \beta+1)$ we know from [5, Cor. 4.2] that

$$
\frac{1}{1-\delta}<2(2 \beta+1) \text { and } \frac{2 \beta+1}{2(1-\delta)}\left(\delta-\frac{2 \beta}{2 \beta+1}\right)<\frac{(2 \beta+1)^{2}}{s}
$$

Thus $s^{\frac{2 \beta+1}{2(1-\delta)}\left(\delta-\frac{2 \beta}{2 \beta+1}\right)}<s^{\frac{(2 \beta+1)^{2}}{s}}<2^{(2 \beta+1)^{2}}$. Hence with $\delta>\frac{2 \beta}{2 \beta+1}$ and $2 \beta+1<2$,

$$
\begin{aligned}
C_{1} & <C_{0} 2^{(2 \beta+1)+(2 \beta+1)^{2}} \gamma^{-2(2 \beta+1)}\left(\frac{2 \beta+1}{2 \beta}\right)^{\alpha}\left[2+\frac{b-1}{s}\right]^{(\alpha-\beta-1 / 2) 2(2 \beta+1)} \\
& <C_{0} 2^{6} \gamma^{-4}\left(\frac{2 \beta+1}{2 \beta}\right)^{\alpha}\left[2+\frac{b-1}{s}\right\rceil^{4(\alpha-\beta-1 / 2)} \\
& <C_{0} 2^{6} \gamma^{-4}\left(\frac{2 \beta+1}{2 \beta}\right)^{\alpha}\left(2\left[2+\frac{b-1}{s}\right\rceil\right)^{4(\alpha-\beta-1 / 2)}
\end{aligned}
$$

which is the desired contradiction.
Case 2: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s+q$ with $q \in\left\{1, \ldots,\left\lceil 2+\frac{b-1}{s}\right\rceil-1\right\}$ for $s \geq 4$ : Note that $\left\lceil 2+\frac{b-1}{s}\right\rceil s+q<2\left\lceil 2+\frac{b-1}{s}\right\rceil s$. It then follows from (A.8) that

$$
\begin{aligned}
C_{1}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil s\right)^{-\alpha+\beta+1 / 2} & <C_{1}\left(\left[2+\frac{b-1}{s}\right] s+q\right)^{-\alpha+\beta+1 / 2} \\
& <\sigma_{\left[2+\frac{b-1}{s}\right] s+q} \leq \sigma_{\left[2+\frac{b-1}{s}\right] s} \leq \sigma_{2 s+b-1} \\
& \leq \sqrt{2 s} \gamma^{-1}\left[C_{1} s^{-\alpha+\beta+\frac{1}{2}}\right]^{\delta}\left[C_{0}(\delta s)^{-\alpha}\right]^{1-\delta}
\end{aligned}
$$

Simplifying this yields

$$
C_{1}<C_{0} \sqrt{2}^{\frac{1}{1-\delta}} \gamma^{-\frac{1}{1-\delta}} \delta^{-\alpha} S^{\frac{2 \beta+1}{2(1-\delta)}\left(\delta-\frac{2 \beta}{2 \beta+1}\right)}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil\right)^{\frac{\alpha-\beta-1 / 2}{1-\delta}} .
$$

With the same arguments as in case 1 we have

$$
C_{1}<C_{0} 2^{6} \gamma^{-4}\left(\frac{2 \beta+1}{2 \beta}\right)^{\alpha}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil\right)^{4(\alpha-\beta-1 / 2)}
$$

which is the desired contradiction.
Case 3: $1 \leq M<\left\lceil 2+\frac{b-1}{4}\right\rceil$ 4: From the assumption $\|f\| \leq 1$, the definition of $C_{1}$ and the monotonicity of $\left(\sigma_{n}\right)_{n \geq 0}$ we obtain the contradiction as

$$
1 \geq \sigma_{0} \geq \sigma_{M}>C_{1} M^{-\alpha+\beta+1 / 2} \geq C_{1}\left(\left\lceil 2+\frac{b-1}{4}\right\rceil 4-1\right)^{-\alpha+\beta+1 / 2} \geq 1
$$

which concludes the proof.
(iii) From (A.7) we have with $d_{s} \leq C_{0} e^{-c_{0} s^{\alpha}}$

$$
\begin{equation*}
\sigma_{2 s+b-1} \leq 2 \gamma^{-1} \sqrt{s d_{s}} \leq 2 \gamma^{-1} \sqrt{s C_{0} e^{-c_{0} s^{\alpha}}}=C_{1} \sqrt{s} e^{-\frac{1}{2} c_{0} s^{\alpha}} \tag{A.9}
\end{equation*}
$$

We prove the claim again by contradiction. Suppose that the statement (iii) does not hold and let $M$ be the first value where $\sigma_{M}(\mathcal{F})>C_{1} \sqrt{M} e^{-c_{1} M^{\alpha}}$.
Case 1: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s$ with $s \geq 1$ : Note, that $\left\lceil 2+\frac{b-1}{s}\right\rceil s \geq 2 s+b-1$ and by (A.9)

$$
\begin{aligned}
C_{1} \sqrt{\left\lceil 2+\frac{b-1}{s}\right\rceil} s e^{-c_{1}\left(\left[2+\frac{b-1}{s}\right] s\right)^{\alpha}} & <\sigma_{\left\lceil 2+\frac{b-1}{s}\right] s} \leq \sigma_{2 s+b-1} \leq C_{1} \sqrt{s} e^{-\frac{1}{2} c_{0} s^{\alpha}} \\
& <C_{1} \sqrt{\left\lceil 2+\frac{b-1}{s}\right\rceil} s e^{-\frac{1}{2} c_{0} s^{\alpha}}
\end{aligned}
$$

This yields the desired contradiction by comparison of the exponents, i.e.

$$
c_{1}>\frac{1}{2}\left\lceil 2+\frac{b-1}{s}\right\rceil^{-\alpha} c_{0}>\frac{1}{2}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil\right)^{-\alpha} c_{0} .
$$

Case 2: $M=\left\lceil 2+\frac{b-1}{s}\right\rceil s+q$ with $q \in\left\{1,2, \ldots,\left\lceil 2+\frac{b-1}{s}\right\rceil-1\right\}$ for $s \geq 1$ : Note, that $\left\lceil 2+\frac{b-1}{s}\right\rceil s+q \geq 2\left\lceil 2+\frac{b-1}{s}\right\rceil s$. Therefore, with (A.9) and the arguments from Case 1

$$
\begin{aligned}
&\left.C_{1} \sqrt{2\lceil 2}+\frac{b-1}{s}\right\rceil s e^{-c_{1}\left(2\left\lceil 2+\frac{b-1}{s}\right] s\right)^{\alpha}} \leq C_{1} \sqrt{\left\lceil 2+\frac{b-1}{s}\right\rceil} s+q e^{-c_{1}\left(\left\lceil 2+\frac{b-1}{s}\right] s+q\right)^{\alpha}} \\
& \quad<\sigma_{\left\lceil 2+\frac{b-1}{s}\right] s+q} \leq \sigma_{\left\lceil 2+\frac{b-1}{s}\right]_{s}}<C_{1} \sqrt{\left\lceil 2+\frac{b-1}{s}\right\rceil} s e^{-\frac{1}{2} c_{0} s^{\alpha}} \\
& \quad<C_{1} \sqrt{2\left\lceil 2+\frac{b-1}{s}\right\rceil} s e^{-\frac{1}{2} c_{0} s^{\alpha}}
\end{aligned}
$$

Comparing the exponents yields

$$
c_{1}>\frac{1}{2}\left(2\left\lceil 2+\frac{b-1}{s}\right\rceil\right)^{-\alpha} c_{0}
$$

which is the desired contradiction.
Case 3: $1 \leq M<b+1$ : From the assumption that $\|f\| \leq 1$, the definition of $c_{1}$ and the monotonicity of $\left(\sigma_{n}\right)_{n \geq 0}$ we see the desired contradiction directly as

$$
1 \geq \sigma_{0} \geq \sigma_{M}>C_{1} \sqrt{M} e^{-c_{1} M^{\alpha}} \geq C_{1} \sqrt{b} e^{-c_{1} b^{\alpha}} \geq 1
$$

which concludes the proof.
