(Dated: July 19, 2024)
Quantum state exclusion is an operational task that has significance in studying foundational questions related to interpreting quantum theory. In such a task, one is given a system whose state is randomly selected from a finite set, and the goal is to identify a state from the set that is not the true state of the system. An error, i.e., an unsuccessful exclusion, occurs if and only if the state identified is the true state. In this paper, we study the optimal error probability of quantum state exclusion and its error exponent - the rate at which the error probability decays asymptotically - from an information-theoretic perspective. Our main finding is a single-letter upper bound on the error exponent of state exclusion given by the multivariate log-Euclidean Chernoff divergence, and we prove that this improves upon the best previously known upper bound from [Mishra et al., Letters in Mathematical Physics 114, 76 (2024)]. We also extend our analysis to the more complicated task of quantum channel exclusion, and we establish a single-letter and efficiently computable upper bound on its error exponent, even assuming the use of adaptive strategies. We derive both upper bounds, for state and channel exclusion, based on one-shot analysis and formulate them as a type of multivariate divergence measure called a barycentric Chernoff divergence. Moreover, our result on channel exclusion has implications in two important special cases. First, for the special case of two hypotheses, our upper bound provides the first known efficiently computable upper bound on the error exponent of symmetric binary channel discrimination. Second, for the special case of classical channels, we show that our upper bound is achievable by a nonadaptive strategy, thus solving the exact error exponent of classical channel exclusion and generalising a similar result on symmetric binary classical channel discrimination from [Hayashi, IEEE Transactions on Information Theory 55, 3807 (2009)].

## I. INTRODUCTION

Hypothesis testing has a fundamental and ubiquitous role in quantum information theory [1-4]. In most contexts, it takes the form of a discrimination task, in which an experimenter tries to figure out the true hypothesis among a number of candidates. However, in some other contexts, it may be of interest to consider variations of hypothesis testing in which one is not expected to figure out the true hypothesis completely but is only required to take a significant step towards determining the truth. The most lenient such variation is an exclusion task (which may also be referred to as "hypothesis exclusion"), where the experimenter is merely asked to choose one false hypothesis to rule out. For instance, in quantum state exclusion, the experimenter is given a quantum system and is asked to choose a state from a given tuple $\left(\rho_{1}, \rho_{2}, \ldots, \rho_{r}\right)$ such that the the chosen state is not the true state of the system. The given set of states is said to be "perfectly antidistinguishable" whenever perfect exclusion can be achieved, that is, whenever there exists a measurement such that on observing any of the possible measurement outcomes, the experimenter is able to rule out some state with certainty. Mathematically, this amounts to the existence of a positive operator-valued measure (POVM) $\left(M_{1}, M_{2}, \ldots, M_{r}\right)$ such that $\operatorname{Tr}\left[M_{x} \rho_{x}\right]=0$ for all $x \in\{1,2, \ldots, r\}$.

## A. Literature review

Early treatments of quantum state exclusion (and state antidistinguishability) can be traced back to the study of compatibility of quantum-state assignments [5, 6]. To elaborate, consider a set of quantum states, each representing the belief of a party about a common system. If the set of states is perfectly antidistinguishable, then we know for sure that at least one party's belief is inconsistent with the reality, regardless of the true state of the system. This is because, once the measurement that achieves perfect exclusion is applied to the system, by definition, the measurement outcome would always contradict some party's belief in the sense that this party would not believe such an outcome is possible. This reveals that state antidistinguishability indicates "incompatibility" of beliefs. Understood as a test of belief incompatibility, state exclusion then found applications in ontological interpretations of quantum states [7-9]. Specifically, it serves as a crucial ingredient in the proof of the seminal Pusey-Barrett-Rudolph theorem [7], which, under fairly minimal operational assumptions, disproves $\psi$-epistemic models of quantum theory and essentially concludes that distinct pure quantum states correspond to distinct objective realities rather than different beliefs about a common reality.

A remarkable fact revealed by the aforementioned studies about state exclusion is that, in contrast to perfect distinguishability, perfect antidistinguishability does not require orthogonality in any sense as a precondition, even for pure states [6, 7]. This stimulated a number of works focusing on characterising the conditions for perfect exclusion between pure states [6, 10-14]. It also inspired a spectrum of applications of state exclusion in constructing noncontextuality inequalities [15], proving advantage in communication complexity [16], and devising new cryptographic schemes $[17,18]$. State exclusion between mixed states with finite errors was much less studied in comparison, but in this setting the task is useful in providing operational interpretations for a type of so-called "weight-based" resource measures in quantum resource theories [19, 20].

The information-theoretic treatments of state exclusion, especially the study of its asymptotic features, was initiated recently [21]. The authors of Ref. [21] proved that the asymptotic error exponent of classical state exclusion is exactly characterised by the multivariate classical Chernoff divergence and established various lower and upper bounds on the error exponent of general quantum state exclusion, including a single-letter upper bound that is computable via a semidefinite
program (SDP). This related the task of state exclusion with multivariate divergence measures and, in particular, with a recently proposed methodology for constructing such measures, known as a "barycentric Rényi divergence" [22].

## B. Main results

In this paper, we make a number of contributions to the information-theoretic study of imperfect exclusion between general quantum states, as well as exclusion between quantum channels.

- For quantum state exclusion, our main finding is a single-letter upper bound on the asymptotic error exponent, given by the multivariate log-Euclidean Chernoff divergence (Theorem 2):

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{(n)}\right) \leq C^{b}\left(\rho_{[r]}\right), \tag{1}
\end{equation*}
$$

where $\mathscr{E}^{(n)}$ denotes an $n$-fold ensemble of the tuple of states $\rho_{[r]} \equiv\left(\rho_{1}, \rho_{2}, \ldots, \rho_{r}\right)$. This upper bound is tight for classical states, and we further show that it improves upon the aforementioned SDP upper bound in Ref. [21] for general quantum states.

- For quantum channel exclusion, we establish a single-letter upper bound on the asymptotic error exponent, even assuming that adaptive strategies are allowed (Theorem 3):

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\text {err }}(n ; \mathscr{N}) \leq R^{\widehat{D}}\left(\mathcal{N}_{[r]}\right), \tag{2}
\end{equation*}
$$

where $\mathscr{N}$ denotes an ensemble of the tuple of channels $\mathcal{N}_{[r]} \equiv\left(\mathcal{N}_{1}, \mathcal{N}_{2}, \ldots, \mathcal{N}_{r}\right)$ and $R^{\widehat{D}}$ denotes a barycentric Chernoff channel divergence based on the Belavkin-Staszewski divergence.

- We show that for classical channels, the upper bound in (2) is achievable by a nonadaptive strategy and thus characterises the exact asymptotic error exponent of classical channel exclusion (Theorem 4). Specifically, if all channels in $\mathcal{N}_{[r]}$ are classical, then

$$
\begin{equation*}
\lim _{n \rightarrow \infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N})=\max _{a \in\left[d_{A}\right]} C\left(v_{a,[r]}\right), \tag{3}
\end{equation*}
$$

where $C$ denotes the multivariate classical Chernoff divergence and $v_{a,[r]} \equiv\left(\mathcal{N}_{1}[|a\rangle\langle a|], \ldots\right.$, $\left.\mathcal{N}_{r}[|a\rangle\langle a|]\right)$ denotes the tuple of classical output states of the channels on the input state $|a\rangle\langle a|$.

- As channel exclusion encompasses binary symmetric channel discrimination [23, 24] as a special case, our upper bound in (2) for general quantum channels also provides the first known efficiently computable upper bound for symmetric binary channel discrimination, and our characterisation of the error exponent of classical channel exclusion in (3) generalises Hayashi's result on symmetric binary classical channel discrimination [25].

Our upper bounds in (1) and (2) are both derived based on one-shot analysis, and they both have the desirable features of being universal, single-letter, and efficiently computable.

## C. Outline of the paper

The rest of our paper is outlined as follows. In Section II, we begin by establishing notation (Section II A), followed by a review of the definitions and properties of various divergence measures for states (Section II B) and for channels (Section II C). In Section III, we systematically investigate the mathematical properties of extensions of the sandwiched Rényi divergence and the hypothesis-testing divergence, as a technical preparation for applications in subsequent sections. Our study of quantum state exclusion is presented in Section IV. Section IV A explains the setting of the task in detail and formally defines its error probability and error exponent. Sections IV B and IV C contains the one-shot and asymptotic analyses, respectively, which lead to our log-Euclidean upper bound on the error exponent of state discrimination. In Section V, we extend our study to quantum channel exclusion. The setting of the task is explained in Section V A, and all pertaining results are presented in Section V B. In Section VI, we summarise our findings (Section VI A) and discuss avenues of future research (Section VIB). Appendices A-F complements the main text with proofs of technical lemmas and additional discussions.

## II. PRELIMINARIES

## A. Notation

We provide a summary of notation and corresponding mathematical definitions in Table I.
Let $[r] \equiv\{1,2, \ldots, r\}$ denote the set of the $r$ smallest, distinct positive integers. Throughout the paper, we use $\gamma_{[r]} \equiv\left(\gamma_{1}, \gamma_{2}, \ldots, \gamma_{r}\right)$ to denote a tuple of entities with indices from [r], regardless of the nature of these entities. We also use $\mathrm{S}^{[r]} \equiv\left\{\gamma_{[r]}: \gamma_{x} \in \mathrm{~S} \forall x \in[r]\right\}$ to denote the set of tuples each of whose entities belongs to a set $S$.

Let $\mathbb{H}_{A}$ denote the (finite-dimensional) Hilbert space associated with a quantum system $A$, and let $d_{A} \equiv \operatorname{dim}\left(\mathrm{H}_{A}\right)$ denote the dimensionality of $A$. Let $\mathbb{B}_{A}$ denote the space of bounded operators acting on $\mathrm{H}_{A}$. Let Herm $A$ and $\mathrm{PSD}_{A}$ denote the set of Hermitian operators and the set of positive semidefinite operators in $\mathbb{B}_{A}$, respectively. An operator inequality $\gamma \geq \sigma$ regarding $\gamma, \sigma \in \operatorname{Herm}_{A}$ should be understood as $\gamma-\sigma \in \mathrm{PSD}_{A}$. Let $\operatorname{supp}(\gamma) \equiv\left\{\gamma|\psi\rangle:|\psi\rangle \in \mathbb{H}_{A}\right\}$ denote the support of a Hermitian operator $\gamma \in \operatorname{Herm}_{A}$. For a positive semidefinite operator $\gamma \in \mathrm{PSD}_{A}$, the inverse $\gamma^{-\alpha}$ of order $\alpha \in(0,+\infty)$ and the logarithm $\ln \gamma$ should both be understood as taken on $\operatorname{supp}(\gamma)$.

A quantum state is a unit-trace positive semidefinite operator. Let $D_{A}$ denote the set of quantum states in a system $A$. Let aff $\left(D_{A}\right)$ denote the set of unit-trace Hermitian operators in $\mathbb{B}_{A}$, which is also the affine hull of $D_{A}$.

A quantum channel is a completely positive trace-preserving (CPTP) linear map. Let $\mathrm{CP}_{A \rightarrow B}$ and $\mathrm{C}_{A \rightarrow B}$ denote the set of completely positive linear maps from $\mathrm{B}_{A}$ to $\mathrm{B}_{B}$ and the set of quantum channels from $A$ to $B$, respectively. Every quantum channel realises a transformation between quantum states; that is, for every $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$ and $\rho \in \mathrm{D}_{R A}$, we always have $\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \in \mathrm{D}_{R B}$, where $R A$ is the composite system identified by the Hilbert space $\mathbb{H}_{R A} \equiv H_{R} \otimes H_{A}$ and similarly for $R B$. Let $J_{\mathcal{M}, R B} \equiv \sum_{i, j \in\left[d_{A}\right]}|i\rangle\left\langle\left. j\right|_{R} \otimes \mathcal{M}_{A \rightarrow B}[|i\rangle\langle j|]\right.$ denote the Choi operator of a CP linear map $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$, where $R$ is a system such that $d_{R}=d_{A}$.

A POVM is a tuple of positive semidefinite operators summing to the identity operator. Let $\mathrm{M}_{A, r}$ denote the set of POVMs on a system $A$ with $r$ possible outcomes. According to the Born rule, when applying a POVM $\Lambda_{[r]} \in \mathrm{M}_{A, r}$ to a state $\rho \in \mathrm{D}_{A}$, the probability of obtaining the $x$ th outcome is given by $\operatorname{Tr}\left[\Lambda_{x} \rho\right]$ for each $x \in[r]$. Every POVM $\Lambda_{[r]}$ can be understood as representing a measurement channel:

$$
\begin{equation*}
\mathcal{M} \in \mathrm{C}_{A \rightarrow X}: \rho \mapsto \sum_{x \in[r]} \operatorname{Tr}\left[\Lambda_{x} \rho\right]|x\rangle\langle x|, \tag{4}
\end{equation*}
$$

where $X$ is a classical system. Let $\mathrm{P}_{r}$ denote the set of probability distributions over [ $r$ ]. Let $\operatorname{int}\left(\mathrm{P}_{r}\right)$ denote the set of probability distributions whose support is $[r]$, which is also the interior of $\mathrm{P}_{r}$.

## B. Divergence measures for states

We provide a glossary of divergence measures in Table II.
Divergence measures are functions that quantify the dissimilarity of two or more states. A bivariate real-valued function $\boldsymbol{D}$ is called a generalised divergence whenever it obeys the dataprocessing inequality (DPI), that is, whenever its value does not increase as its arguments are acted upon by the same channel [26-28]:

$$
\begin{equation*}
\boldsymbol{D}(\mathcal{N}[\rho] \| \mathcal{N}[\sigma]) \leq \boldsymbol{D}(\rho \| \sigma) \quad \forall \mathcal{N} \in \mathrm{C}_{A \rightarrow B}, \rho \in \mathrm{D}_{A}, \sigma \in \mathrm{PSD}_{A} \tag{5}
\end{equation*}
$$

In what follows, we review the definitions and properties of several generalised divergences that are relevant to this work. Let $\rho \in \mathrm{D}_{A}$ be a state, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. For $\alpha \in(1,+\infty)$, the sandwiched Rényi divergence is defined as [28, 29]

$$
\widetilde{D}_{\alpha}(\rho \| \sigma):= \begin{cases}\frac{1}{\alpha-1} \ln \left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \rho \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha} & \text { if } \operatorname{supp}(\rho) \subseteq \operatorname{supp}(\sigma)  \tag{6}\\ +\infty & \text { otherwise }\end{cases}
$$

TABLE II. Glossary of divergence measures.

| Symbol | Meaning | Definition |
| :---: | :---: | :---: |
| $\boldsymbol{D}(\rho \\| \sigma)$ | a generalised divergence | Eq. (5) for $\rho \in \mathrm{D}_{A}$ and $\sigma \in \mathrm{PSD}_{A}$ |
| $\widetilde{D}_{\alpha}(\rho \\| \sigma)$ | sandwiched Rényi divergence | Eq. (6) for $\alpha \in(1,+\infty), \rho \in \mathrm{D}_{A}$, and $\sigma \in \mathrm{PSD}_{A}$ |
| $\widetilde{D}_{\alpha}(\gamma \\| \sigma)$ | extended sandwiched Rényi divergence | Eq. (43) for $\alpha \in(1,+\infty), \gamma \in \mathrm{Herm}_{A}$, and $\sigma \in \mathrm{PSD}_{A}$ |
| $D_{\mathrm{H}}^{\varepsilon}(\tau \\| \sigma)$ | extended hypothesis-testing divergence | Eq. (55) for $\varepsilon \in[0,1], \tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$, and $\sigma \in \mathrm{PSD}_{A}$ |
| $D(\rho \\| \sigma)$ | Umegaki divergence | Eq. (8) for $\rho \in \mathrm{D}_{A}$ and $\sigma \in \mathrm{PSD}_{A}$ |
| $\widehat{D}_{\alpha}(\rho \\| \sigma)$ | geometric Rényi divergence | Eq. (10) for $\alpha \in(1,2], \rho \in \mathrm{D}_{A}$, and $\sigma \in \mathrm{PSD}_{A}$ |
| $\widehat{D}(\rho \\| \sigma)$ | Belavkin-Staszewski divergence | Eq. (14) for $\rho \in \mathrm{D}_{A}$ and $\sigma \in \mathrm{PSD}_{A}$ |
| $D_{\alpha}(\rho \\| \sigma)$ | Petz-Rényi divergence | Eq. (E1) for $\alpha \in(1,2], \rho \in \mathrm{D}_{A}$, and $\sigma \in \mathrm{PSD}_{A}$ |
| $R^{\boldsymbol{D}}\left(\rho_{[r]}\right)$ | left $\boldsymbol{D}$-radius | Eq. (16) for $\rho_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ |
| $C^{\text {b }}\left(\rho_{[r]}\right)$ | multivariate log-Euclidean Chernoff divergence | Eq. (22) for $\rho_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ |
| $C\left(\rho_{[r]}\right)$ | multivariate classical Chernoff divergence | Eq. (26) for $\rho_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ with $A$ classical |
| $\boldsymbol{D}(\mathcal{N} \\| \mathcal{M})$ | channel $\boldsymbol{D}$-divergence | Eq. (27) for $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$ and $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$ |
| $\widehat{D}_{\alpha}(\mathcal{N} \\| \mathcal{M})$ | geometric Rényi channel divergence | Eq. (28) for $\alpha \in(1,2], \mathcal{N} \in \mathrm{C}_{A \rightarrow B}$, and $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$ |
| $\widehat{D}(\mathcal{N} \\| \mathcal{M})$ | Belavkin-Staszewski channel divergence | Eq. (38) for $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$ and $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$ |
| $R^{\boldsymbol{D}}\left(\mathcal{N}_{[r]}\right)$ | left channel $\boldsymbol{D}$-radius | Eq. (41) for $\mathcal{N}_{[r]} \in \mathrm{CP}_{A \rightarrow B}^{[r]}$ |

where

$$
\begin{equation*}
\|\gamma\|_{\alpha}:=\left(\operatorname{Tr}\left[\left(\gamma^{\dagger} \gamma\right)^{\frac{\alpha}{2}}\right]\right)^{\frac{1}{\alpha}} \tag{7}
\end{equation*}
$$

denotes the $\alpha$-norm of an operator $\gamma \in \mathbb{B}_{A}$ for $\alpha \in[1,+\infty)$. Apart from obeying the DPI, the sandwiched Rényi divergence has a variety of other properties such as nondecreasing monotonicity in $\alpha$, additivity, and joint quasi-convexity [28-32] (see Refs. [4, 33] for textbooks on the topic). We defer the discussion of these properties to Theorem 1 of Section III, where we introduce an extended definition of the sandwiched Rényi divergence whose first argument can be a general Hermitian operator. The limit of the sandwiched Rényi divergence as $\alpha$ approaches 1 is given by the Umegaki divergence (also known as the quantum relative entropy) [34], which is defined as

$$
\begin{align*}
D(\rho \| \sigma) & := \begin{cases}\operatorname{Tr}[\rho(\ln \rho-\ln \sigma)] & \text { if } \operatorname{supp}(\rho) \subseteq \operatorname{supp}(\sigma), \\
+\infty & \text { otherwise },\end{cases}  \tag{8}\\
& =\lim _{\alpha \searrow 1} \widetilde{D}_{\alpha}(\rho \| \sigma) . \tag{9}
\end{align*}
$$

Another useful generalised divergence is the geometric Rényi divergence [35], which for $\alpha \in(1,2$ ] is defined as

$$
\widehat{D}_{\alpha}(\rho \| \sigma):= \begin{cases}\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\sigma\left(\sigma^{-\frac{1}{2}} \rho \sigma^{-\frac{1}{2}}\right)^{\alpha}\right] & \text { if } \operatorname{supp}(\rho) \subseteq \operatorname{supp}(\sigma)  \tag{10}\\ +\infty & \text { otherwise }\end{cases}
$$

The geometric Rényi divergence obeys the DPI and is additive [35-37]. Moreover, it is monotonically nondecreasing in $\alpha$ [38, Proposition 72.2]: for all $\alpha, \beta \in(1,2]$ such that $\alpha \leq \beta$,

$$
\begin{equation*}
\widehat{D}_{\alpha}(\rho \| \sigma) \leq \widehat{D}_{\beta}(\rho \| \sigma) \quad \forall \rho \in \mathrm{D}_{A}, \sigma \in \mathrm{PSD}_{A}, \tag{11}
\end{equation*}
$$

and it is jointly quasi-convex [4, Eq. (7.6.163)]: for all $\alpha \in(1,2]$,

$$
\begin{equation*}
\widehat{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \rho_{x} \| \sum_{x \in[r]} p_{x} \sigma_{x}\right) \leq \max _{x \in[r]} \widehat{D}_{\alpha}\left(\rho_{x} \| \sigma_{x}\right) \quad \forall \rho_{[r]} \in \mathrm{D}_{A}^{[r]}, \sigma_{[r]} \in \mathrm{PSD}_{A}^{[r]}, p_{[r]} \in \mathrm{P}_{r} . \tag{12}
\end{equation*}
$$

The geometric Rényi divergence provides an upper bound on the sandwiched Rényi divergence [33, 35]: for all $\alpha \in(1,2]$,

$$
\begin{equation*}
\widetilde{D}_{\alpha}(\rho \| \sigma) \leq \widehat{D}_{\alpha}(\rho \| \sigma) \quad \forall \rho \in \mathrm{D}_{A}, \sigma \in \mathrm{PSD}_{A} \tag{13}
\end{equation*}
$$

When defined on a classical system, the above inequality becomes an equality, and both sides reduce to the classical Rényi divergence. The limit of the geometric Rényi divergence as $\alpha$ approaches 1 is given by the Belavkin-Staszewski divergence [39], which is defined as

$$
\begin{align*}
\widehat{D}(\rho \| \sigma) & := \begin{cases}\operatorname{Tr}\left[\rho \ln \left(\rho^{\frac{1}{2}} \sigma^{-1} \rho^{\frac{1}{2}}\right)\right] & \text { if } \operatorname{supp}(\rho) \subseteq \operatorname{supp}(\sigma), \\
+\infty & \text { otherwise, }\end{cases}  \tag{14}\\
& =\lim _{\alpha \searrow 1} \widehat{D}_{\alpha}(\rho \| \sigma) . \tag{15}
\end{align*}
$$

When defined on a classical system, the Belavkin-Staszewski divergence and the Umegaki divergence become equal, and both reduce to the Kullback-Leibler divergence (also known as the classical relative entropy).

Based on bivariate divergence measures, one can devise multivariate divergence measures that quantify the dissimilarity of multiple states. Let $\rho_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ be a tuple of positive semidefinite operators. For a generalised divergence $\boldsymbol{D}$, the left $\boldsymbol{D}$-radius is defined as [40]

$$
\begin{equation*}
R^{\boldsymbol{D}}\left(\rho_{[r]}\right):=\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\tau \| \rho_{x}\right) \tag{16}
\end{equation*}
$$

If $\boldsymbol{D}$ is convex and lower-semicontinuous in its first argument, then the left $\boldsymbol{D}$-radius has an intuitive representation as the radius of the smallest ball (as measured by $\boldsymbol{D}$ ) that contains all the operators in $\rho_{[r]}\left[40\right.$, Proposition A.1] ${ }^{1}$ :

$$
\begin{equation*}
R^{\boldsymbol{D}}\left(\rho_{[r]}\right)=\inf _{\tau \in \mathrm{D}_{A}} \max _{x \in[r]} \boldsymbol{D}\left(\tau \| \rho_{x}\right) \quad \forall \rho_{[r]} \in \mathrm{PSD}_{A}^{[r]} \tag{17}
\end{equation*}
$$

We observe that the left radius obeys the DPI:

$$
\begin{align*}
R^{\boldsymbol{D}}\left(\mathcal{N}\left[\rho_{[r]}\right]\right) & =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{B}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\tau \| \mathcal{N}\left[\rho_{x}\right]\right)  \tag{18}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\mathcal{N}[\tau] \| \mathcal{N}\left[\rho_{x}\right]\right)  \tag{19}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\tau \| \rho_{x}\right) \tag{20}
\end{align*}
$$

[^1]\[

$$
\begin{equation*}
=R^{\boldsymbol{D}}\left(\rho_{[r]}\right) \quad \forall \mathcal{N} \in \mathrm{C}_{A \rightarrow B}, \tag{21}
\end{equation*}
$$

\]

and therefore it provides a legitimate way of quantifying the dissimilarity of multiple states. As a direct corollary of Ref. [22, Proposition 5.29] (also see Ref. [21, Eq. (221)]), the left Umegaki radius is given by the multivariate log-Euclidean Chernoff divergence [21], which is defined as

$$
\begin{align*}
C^{b}\left(\rho_{[r]}\right) & :=\sup _{s_{[r]} \in \mathrm{P}_{r}} \lim _{\varepsilon \searrow 0}-\ln \operatorname{Tr}\left[\exp \left(\sum_{x \in[r]} s_{x} \ln \left(\rho_{x}+\varepsilon I\right)\right)\right]  \tag{22}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}}-\ln \operatorname{Tr}\left[\Pi \exp \left(\sum_{x \in[r]} s_{x} \Pi\left(\ln \rho_{x}\right) \Pi\right)\right]  \tag{23}\\
& =R^{D}\left(\rho_{[r]}\right), \tag{24}
\end{align*}
$$

where (23) provides an alternative representation of the multivariate log-Euclidean Chernoff divergence with $\Pi$ denoting the projector onto $\bigcap_{x \in[r]} \operatorname{supp}\left(\rho_{x}\right)$ [22, Eqs. (3.99) and (3.101)] (also see Ref. [41, Lemma 4.1]). The multivariate log-Euclidean Chernoff divergence is a multivariate generalisation of the bivariate log-Euclidean Chernoff divergence [42, 43]. As a direct corollary of Ref. [44, Proposition 5.49], the multivariate log-Euclidean Chernoff divergence is weakly additive in the sense that

$$
\begin{equation*}
C^{b}\left(\rho_{[r]}^{(n)}\right)=n C^{b}\left(\rho_{[r]}\right) \quad \forall \rho_{[r]} \in \operatorname{PSD}_{A}^{[r]} \tag{25}
\end{equation*}
$$

where $\rho_{[r]}^{(n)} \equiv\left(\rho_{1}^{\otimes n}, \rho_{2}^{\otimes n}, \ldots, \rho_{r}^{\otimes n}\right)$ denotes the $n$-fold tuple resulting from $\rho_{[r]}$. This means that the multivariate log-Euclidean Chernoff divergence is invariant under regularisation. When defined on a classical system, the multivariate log-Euclidean Chernoff divergence reduces to the multivariate classical Chernoff divergence [21], which is defined as

$$
\begin{equation*}
C\left(\rho_{[r]}\right):=\sup _{s_{[r]} \in \mathrm{P}_{r}}-\ln \sum_{a \in\left[d_{A}\right]} \prod_{x \in[r]} p_{a \mid x}^{s_{x}}, \tag{26}
\end{equation*}
$$

where $p_{a \mid x} \equiv\langle a| \rho_{x}|a\rangle$ for all $a \in\left[d_{A}\right]$ and $x \in[r]$ with $\{|a\rangle\}_{a \in\left[d_{A}\right]}$ denoting the computational basis of $\mathbb{H}_{A}$. If a generalised divergence $\boldsymbol{D}$ reduces to the Kullback-Leibler divergence when defined on a classical system, then the left $\boldsymbol{D}$-radius reduces to the multivariate classical Chernoff divergence accordingly, as a consequence of (24). In this case, we say that the left $\boldsymbol{D}$-radius is a barycentric Chernoff divergence. As such, the multivariate log-Euclidean Chernoff divergence is a barycentric Chernoff divergence.

## C. Divergence measures for channels

Divergence measures can also be used to quantify the dissimilarity of channels, based on their definitions for states. Let $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$ be a channel, and let $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$ be a completely positive map. For a generalised divergence $\boldsymbol{D}$, the channel $\boldsymbol{D}$-divergence is defined as [45]

$$
\begin{equation*}
\boldsymbol{D}(\mathcal{N} \| \mathcal{M}):=\sup _{\rho \in \mathrm{D}_{R A}} \boldsymbol{D}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\rho_{R A}\right]\right), \tag{27}
\end{equation*}
$$

where $R$ is a system and $d_{R}$ is allowed to be arbitrarily large. For $\alpha \in(1,2]$, the geometric Rényi channel divergence is defined as [37]

$$
\begin{align*}
\widehat{D}_{\alpha}(\mathcal{N} \| \mathcal{M}) & :=\sup _{\rho \in \mathrm{D} R A} \widehat{D}_{\alpha}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{28}\\
& = \begin{cases}\frac{1}{\alpha-1} \ln \left\|\operatorname{Tr}_{B}\left[J_{\mathcal{M}}^{\frac{1}{2}}\left(J_{\mathcal{M}}^{-\frac{1}{2}} J_{\mathcal{N}} J_{\mathcal{M}}^{-\frac{1}{2}}\right)^{\alpha} J_{\mathcal{M}}^{\frac{1}{2}}\right]\right\|_{\infty} & \text { if } \operatorname{supp}\left(J_{\mathcal{N}}\right) \subseteq \operatorname{supp}\left(J_{\mathcal{M}}\right) \\
+\infty & \text { otherwise }\end{cases} \tag{29}
\end{align*}
$$

where the closed-form expression in terms of the channels' Choi operators in (29) was established in Ref. [37, Theorem 3.2]. The geometric Rényi channel divergence is also known to possess a semidefinite representation for (1,2], and thus it can be evaluated via an SDP [37, Theorem 3.6]. As a direct consequence of (11) and (28), the geometric Rényi channel divergence is monotonically nondecreasing in $\alpha$ : for all $\alpha, \beta \in(1,2]$ such that $\alpha \leq \beta$,

$$
\begin{align*}
\widehat{D}_{\alpha}(\mathcal{N} \| \mathcal{M}) & =\sup _{\rho \in \mathrm{D}_{R A}} \widehat{D}_{\alpha}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{30}\\
& \leq \sup _{\rho \in \mathrm{D}_{R A}} \widehat{D}_{\beta}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{31}\\
& =\widehat{D}_{\beta}(\mathcal{N} \| \mathcal{M}) \quad \forall \mathcal{N} \in \mathrm{C}_{A \rightarrow B}, \mathcal{M} \in \mathrm{CP}_{A \rightarrow B} \tag{32}
\end{align*}
$$

Moreover, as a direct consequence of (12) and (28), the geometric Rényi channel divergence is jointly quasi-convex: for all $\alpha \in(1,2]$,

$$
\begin{align*}
& \widehat{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \mathcal{N}_{x} \| \sum_{x \in[r]} p_{x} \mathcal{M}_{x}\right) \\
& \quad=\sup _{\rho \in \mathrm{D}_{R A}} \widehat{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \mathcal{N}_{x, A \rightarrow B}\left[\rho_{R A}\right] \| \sum_{x \in[r]} p_{x} \mathcal{M}_{x, A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{33}\\
& \quad \leq \sup _{\rho \in \mathrm{D}_{R A}} \max _{x \in[r]} \widehat{D}_{\alpha}\left(\mathcal{N}_{x, A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{x, A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{34}\\
& \quad=\max _{x \in[r]} \sup _{\rho_{[r]} \in \mathrm{D}_{R A}^{[r]}} \widehat{D}_{\alpha}\left(\mathcal{N}_{x, A \rightarrow B}\left[\rho_{x, R A}\right] \| \mathcal{M}_{x, A \rightarrow B}\left[\rho_{x, R A}\right]\right)  \tag{35}\\
& \quad=\max _{x \in[r]} \widehat{D}_{\alpha}\left(\mathcal{N}_{x} \| \mathcal{M}_{x}\right) \quad \forall \mathcal{N}_{[r]} \in \mathrm{C}_{A \rightarrow B}^{[r]}, \mathcal{M}_{[r]} \in \mathrm{CP}_{A \rightarrow B}^{[r]}, p_{[r]} \in \mathrm{P}_{r} . \tag{36}
\end{align*}
$$

We also highlight the following chain rule for our purposes [37, Theorem 3.4]: for all $\alpha \in(1,2$ ],

$$
\begin{align*}
\widehat{D}_{\alpha}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\sigma_{R A}\right]\right) & \leq \widehat{D}_{\alpha}(\mathcal{N} \| \mathcal{M})+\widehat{D}_{\alpha}\left(\rho_{R A} \| \sigma_{R A}\right) \\
& \forall \mathcal{N} \in \mathrm{C}_{A \rightarrow B}, \mathcal{M} \in \mathrm{CP}_{A \rightarrow B}, \rho \in \mathrm{D}_{R A}, \sigma \in \mathrm{PSD}_{R A} \tag{37}
\end{align*}
$$

The limit of the geometric Rényi channel divergence as $\alpha$ approaches 1 is given by the BelavkinStaszewski channel divergence $[37,38]$ :

$$
\begin{align*}
\widehat{D}(\mathcal{N} \| \mathcal{M}) & :=\sup _{\rho \in \mathrm{D}_{R A}} \widehat{D}\left(\mathcal{N}_{A \rightarrow B}\left[\rho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\rho_{R A}\right]\right)  \tag{38}\\
& =\lim _{\alpha \searrow 1} \widehat{D}_{\alpha}(\mathcal{N} \| \mathcal{M}) \tag{39}
\end{align*}
$$

$$
= \begin{cases}\left\|\operatorname{Tr}_{B}\left[J_{\mathcal{N}}^{\frac{1}{2}} \ln \left(J_{\mathcal{N}}^{\frac{1}{2}} J_{\mathcal{M}}^{-1} J_{\mathcal{N}}^{\frac{1}{2}}\right) J_{\mathcal{N}}^{\frac{1}{2}}\right]\right\|_{\infty} & \text { if } \operatorname{supp}\left(J_{\mathcal{N}}\right) \subseteq \operatorname{supp}\left(J_{\mathcal{M}}\right)  \tag{40}\\ +\infty & \text { otherwise }\end{cases}
$$

where the closed-form expression in (40) was established in Ref. [37, Theorem 3.2].
Let $\mathcal{N}_{[r]} \in \mathrm{CP}_{A \rightarrow B}^{[r]}$ be a tuple of completely positive maps. In analogy to (16), for a generalised divergence $\boldsymbol{D}$ that is jointly quasi-convex, we define the left channel $\boldsymbol{D}$-radius as

$$
\begin{equation*}
R^{\boldsymbol{D}}\left(\mathcal{N}_{[r]}\right):=\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\mathcal{T} \| \mathcal{N}_{x}\right) \tag{41}
\end{equation*}
$$

The following lemma states that when defined on a classical input system, the left channel $\boldsymbol{D}$ radius can be expressed in terms of the left $\boldsymbol{D}$-radius maximised over classical input states. This also justifies saying that the left channel $\boldsymbol{D}$-radius is a barycentric Chernoff channel divergence whenever the left $\boldsymbol{D}$-radius is a barycentric Chernoff divergence.

Lemma 1 (Left $\boldsymbol{D}$-radii for classical-to-quantum channels). Let $\mathcal{N}_{[r]} \in \mathrm{CP}_{A \rightarrow B}^{[r]}$ be a tuple of classical-to-quantum completely positive maps, where A is a classical system. Let $\boldsymbol{D}$ be a generalised divergence that is jointly convex and lower-semicontinuous in its first argument. Then

$$
\begin{equation*}
R^{\boldsymbol{D}}\left(\mathcal{N}_{[r]}\right)=\max _{a \in\left[d_{A}\right]} R^{\boldsymbol{D}}\left(v_{a,[r]}\right), \tag{42}
\end{equation*}
$$

where $v_{a, x} \equiv \mathcal{N}_{x}[|a\rangle\langle a|]$ for all $a \in\left[d_{A}\right]$ and $x \in[r]$.
Proof. See Appendix A.

## III. EXTENDED DIVERGENCES AND THEIR PROPERTIES

In this section, we generalise the definitions of the sandwiched Rényi divergence and the hypothesis-testing divergence to an extended domain, with their first argument now allowed to be a Hermitian (and not necessarily positive semidefinite) operator. We also investigate properties of these extended divergence measures.

Let $\gamma \in \operatorname{Herm}_{A}$ be a Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. For $\alpha \in(1,+\infty)$, the extended sandwiched Rényi divergence, first proposed in Ref. [46], is defined as

$$
\widetilde{D}_{\alpha}(\gamma \| \sigma):= \begin{cases}\frac{1}{\alpha-1} \ln \left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha} & \text { if } \operatorname{supp}(\gamma) \subseteq \operatorname{supp}(\sigma)  \tag{43}\\ +\infty & \text { otherwise }\end{cases}
$$

Indeed, the extended definition of the sandwiched Rényi divergence has precisely the same formula as the original definition presented in (6), ${ }^{2}$ except for an enlarged domain of its first argument. This extended definition is justified by multiple desirable properties, as first examined in Ref. [46] and further developed and summarised here.

[^2]Theorem 1 (Properties of the extended $\widetilde{D}_{\alpha}$ ). Let $\gamma \in \operatorname{Herm}_{A}$ be a Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. For all $\alpha \in(1,+\infty)$, the extended sandwiched Rényi divergence has the following properties.

1. Data-processing inequality [46, Lemma 2]. Let $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$ be a channel.

$$
\begin{equation*}
\widetilde{D}_{\alpha}(\mathcal{N}[\gamma] \| \mathcal{N}[\sigma]) \leq \widetilde{D}_{\alpha}(\gamma \| \sigma) \tag{44}
\end{equation*}
$$

2. Nondecreasing monotonicity in $\alpha$ [46, Lemma 5]. For all $\beta \in[\alpha,+\infty)$,

$$
\begin{equation*}
\widetilde{D}_{\alpha}(\gamma \| \sigma)-\frac{\alpha}{\alpha-1} \ln \|\gamma\|_{1} \leq \widetilde{D}_{\beta}(\gamma \| \sigma)-\frac{\beta}{\beta-1} \ln \|\gamma\|_{1} \tag{45}
\end{equation*}
$$

3. Additivity. Let $\gamma^{\prime} \in \operatorname{Herm}_{B}$ be a Hermitian operator, and let $\sigma^{\prime} \in \mathrm{PSD}_{B}$ be a positive semidefinite operator. Then

$$
\begin{equation*}
\widetilde{D}_{\alpha}\left(\gamma \otimes \gamma^{\prime} \| \sigma \otimes \sigma^{\prime}\right)=\widetilde{D}_{\alpha}(\gamma \| \sigma)+\widetilde{D}_{\alpha}\left(\gamma^{\prime} \| \sigma^{\prime}\right) \tag{46}
\end{equation*}
$$

4. Direct-sum property. Let $\gamma_{[r]} \in \operatorname{Herm}_{A}^{[r]}$ be a tuple of Hermitian operators, and let $\sigma_{[r]} \in$ $\mathrm{PSD}_{A}^{[r]}$ be a tuple of positive semidefinite operators. Let $p_{[r]} \in \mathrm{P}_{r}$ be a probability distribution, and let $q_{[r]} \in[0,+\infty)^{[r]}$ be a tuple of nonnegative real numbers. Then

$$
\begin{equation*}
\widetilde{Q}_{\alpha}\left(v_{X A} \| \varsigma_{X A}\right)=\sum_{x \in[r]} p_{x}^{\alpha} q_{x}^{1-\alpha} \widetilde{Q}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right) \tag{47}
\end{equation*}
$$

where $\widetilde{Q}_{\alpha}(\gamma \| \sigma) \equiv \exp \left((\alpha-1) \widetilde{D}_{\alpha}(\gamma \| \sigma)\right)$ denotes the extended sandwiched Rényi quasidivergence and

$$
\begin{align*}
& v_{X A} \equiv \sum_{x \in[r]} p_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \gamma_{x, A},\right.  \tag{48}\\
& \varsigma_{X A} \equiv \sum_{x \in[r]} q_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \sigma_{x, A} .\right. \tag{49}
\end{align*}
$$

5. Joint quasi-convexity. Let $\gamma_{[r]} \in \operatorname{Herm}_{A}^{[r]}$ be a tuple of Hermitian operators, and let $\sigma_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ be a tuple of positive semidefinite operators. Let $p_{[r]} \in \mathrm{P}_{r}$ be a probability distribution. Then

$$
\begin{equation*}
\widetilde{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \gamma_{x} \| \sum_{x \in[r]} p_{x} \sigma_{x}\right) \leq \max _{x \in[r]} \widetilde{D}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right) \tag{50}
\end{equation*}
$$

6. Limit as $\alpha$ approaches 1 .

$$
\begin{equation*}
\lim _{\alpha \searrow 1}\left(\widetilde{D}_{\alpha}(\gamma \| \sigma)-\frac{\alpha}{\alpha-1} \ln \|\gamma\|_{1}\right)=D\left(\frac{|\gamma|}{\|\gamma\|_{1}} \| \sigma\right) \tag{51}
\end{equation*}
$$

where $|\gamma|:=\sqrt{\gamma^{\dagger} \gamma}$. Note that $\frac{|\gamma|}{\|\gamma\|_{1}} \in \mathrm{D}_{A}$.

Proof. See Appendix B.
The limit of the extended sandwiched Rényi divergence as $\alpha$ approaches $+\infty$ is known as the extended max-divergence [46], which is defined as

$$
\begin{align*}
D_{\max }(\gamma \| \sigma) & :=\inf _{\lambda \in[0,+\infty)}\{\ln \lambda:-\lambda \sigma \leq \gamma \leq \lambda \sigma\}  \tag{52}\\
& = \begin{cases}\ln \left\|\sigma^{-\frac{1}{2}} \gamma \sigma^{-\frac{1}{2}}\right\|_{\infty} & \text { if } \operatorname{supp}(\gamma) \subseteq \operatorname{supp}(\sigma), \\
+\infty & \text { otherwise },\end{cases}  \tag{53}\\
& =\lim _{\alpha \rightarrow+\infty} \widetilde{D}_{\alpha}(\gamma \| \sigma) . \tag{54}
\end{align*}
$$

The extended max-divergence reduces to the original max-divergence [47] when its first argument is a state. A systematic study of the properties of the extended max-divergence can be found in Ref. [21, Appendix H].

Let $\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$ be a unit-trace Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. For $\varepsilon \in[0,1]$, we define the extended hypothesis-testing divergence as

$$
\begin{equation*}
D_{\mathrm{H}}^{\varepsilon}(\tau \| \sigma):=\sup _{\Lambda \in \mathrm{PSD}_{A}}\{-\ln \operatorname{Tr}[\Lambda \sigma]: \Lambda \leq I, \operatorname{Tr}[\Lambda \tau] \geq 1-\varepsilon\} \tag{55}
\end{equation*}
$$

The extended hypothesis-testing divergence reduces to the original hypothesis-testing divergence $[48,49]$ when its first argument is a state. The following lemma is a generalisation of a useful bound on the hypothesis-testing divergence in terms of the sandwiched Rényi divergence in Ref. [50, Lemma 5], now applicable to their extended definitions.

Lemma 2 (Extended connection between $D_{\mathrm{H}}^{\varepsilon}$ and $\widetilde{D}_{\alpha}$ ). Let $\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$ be a unit-trace Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. Then for all $\varepsilon \in[0,1)$ and all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
D_{\mathrm{H}}^{\varepsilon}(\tau \| \sigma) \leq \widetilde{D}_{\alpha}(\tau \| \sigma)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{1-\varepsilon}\right) \tag{56}
\end{equation*}
$$

Proof. See Appendix C.

## IV. QUANTUM STATE EXCLUSION

In this section, we define and analyse the task of quantum state exclusion from an informationtheoretic perspective. Our analysis includes an exact characterisation of the one-shot error probability in terms of the extended hypothesis-testing divergence and a converse bound in terms of an extended version of the left sandwiched Rényi radius. The one-shot analysis then leads to an upper bound on the asymptotic error exponent of state exclusion, exactly given by the multivariate log-Euclidean Chernoff divergence.

## A. Setting

In contrast to a discrimination task, which aims at finding out the true hypothesis, an exclusion task is concerned with ruling out a false hypothesis. Despite their equivalence in the binary setting
(i.e., when there are only two hypotheses), the two tasks are significantly different when more hypotheses are involved. In quantum state exclusion, the experimenter receives a state from an uncharacterised source. The source is represented by an ensemble of states, $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ with $r \geq 2$, which indicates that for each $x \in[r]$, there is a prior probability $p_{x}$ with which the state the experimenter received is $\rho_{x} \in \mathrm{D}_{A}$. Without loss of generality (and for technical convenience), we henceforth always assume $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$, i.e., $p_{x} \in(0,1)$ for all $x \in[r]$. The experimenter's goal is to submit an index $x^{\prime} \in[r]$ that differs from the actual label of the state they received. ${ }^{3}$ We can readily see that when $r \geq 3$, state exclusion is in general easier than state discrimination, in the sense that the experimenter has a higher chance of success in the former task than in the latter when faced with the same ensemble.

The most general strategy of the experimenter for state exclusion is to perform a measurement, represented by a general POVM $\Lambda_{[r]} \in \mathrm{M}_{A, r}$, on the state they received and submit the measurement outcome. An error occurs if and only if the outcome coincides with the actual label of the state. Consequently, the (one-shot) error probability of state exclusion for the ensemble $\mathscr{E}$ is given by

$$
\begin{equation*}
P_{\mathrm{err}}(\mathscr{E}):=\inf _{\Lambda_{[r]} \in \mathrm{M}_{A, r}} \sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right] \tag{57}
\end{equation*}
$$

where the infimum over all POVMs is due to the experimenter's motivation to avoid an error. We say that the tuple of states $\rho_{[r]}$ is perfectly antidistinguishable whenever $P_{\mathrm{err}}(\mathscr{E})=0 .{ }^{4}$

When the experimenter has access to $n$ copies of the same state generated by the source, state exclusion is in effect conducted on the $n$-fold ensemble $\mathscr{E}^{(n)} \equiv\left(p_{[r]}, \rho_{[r]}^{(n)}\right)$, where $\rho_{[r]}^{(n)} \equiv$ $\left(\rho_{1}^{\otimes n}, \rho_{2}^{\otimes n}, \ldots, \rho_{r}^{\otimes n}\right)$. As $n$ increases, the error probability decays exponentially fast in general [21], and this motivates us to investigate the (asymptotic) error exponent of state exclusion, which for the ensemble $\mathscr{E}$ is defined as

$$
\begin{equation*}
\liminf _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\operatorname{err}}\left(\mathscr{E}^{(n)}\right)=\liminf _{n \rightarrow+\infty} \sup _{\Lambda_{[r]} \in \mathrm{M}_{A^{n}, r}}-\frac{1}{n} \ln \left(\sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}^{\otimes n}\right]\right) \tag{58}
\end{equation*}
$$

where $A^{n}$ denotes the composite system consisting of $n$ copies of $A$. As shown in Ref. [21, Eq. (30)], the error exponent of state exclusion for the ensemble $\mathscr{E}$ does not depend on the prior probability distribution $p_{[r]}$. Analytical expressions for the error exponent have been derived in several special cases: when $r=2$, it is simply given by the error exponent of binary state discrimination, namely, the quantum Chernoff divergence [51, 52]; when the states in $\rho_{[r]}$ are classical, it is given by the multivariate classical Chernoff divergence [21]. However, a universal formula that applies to general ensembles with $r \geq 3$ has been lacking, although multiple relevant bounds have been established in Ref. [21]. A major contribution of this paper is to derive a universal singleletter upper bound on the error exponent of state exclusion that is tighter than the best efficiently computable upper bound previously known.

## B. Characterisation of the one-shot error probability

Our upper bound on the asymptotic error exponent is derived based on one-shot analysis. The following proposition characterises the error probability of state exclusion in the one-shot regime,

[^3]in terms of the extended hypothesis-testing divergence.
Proposition 1 (Characterisation of the error probability). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. Then
\[

$$
\begin{equation*}
-\ln P_{\mathrm{err}}(\mathscr{E})=\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right) \tag{59}
\end{equation*}
$$

\]

where $\pi_{X} \equiv \frac{1}{r} \sum_{x \in[r]}|x\rangle\left\langle\left. x\right|_{X}\right.$ denotes the uniform state in a system $X$ and

$$
\begin{equation*}
\varrho_{X A} \equiv \sum_{x \in[r]} p_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \rho_{x, A}\right. \tag{60}
\end{equation*}
$$

Proof. For every POVM $\Lambda_{[r]} \in \mathrm{M}_{A, r}$, denote

$$
\begin{equation*}
\Lambda_{X A} \equiv \sum_{x \in[r]}|x\rangle\left\langle\left. x\right|_{X} \otimes \Lambda_{x, A}\right. \tag{61}
\end{equation*}
$$

We observe that $\Lambda \in \mathrm{PSD}_{X A}$ and

$$
\begin{align*}
\Lambda_{X A} & \leq I_{X A},  \tag{62}\\
\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right] & =\sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right],  \tag{63}\\
\operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] & =\frac{1}{r} \sum_{x \in[r]} \operatorname{Tr}\left[\Lambda_{x} \tau\right]=\frac{1}{r} \quad \forall \tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right) . \tag{64}
\end{align*}
$$

Then for all $\tau \in \operatorname{aff}\left(D_{A}\right)$, we have that

$$
\begin{align*}
P_{\mathrm{err}}(\mathscr{E}) & =\inf _{\Lambda_{[r]} \in \mathrm{M}_{A, r}} \sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right]  \tag{65}\\
& \geq \inf _{\Lambda \in \operatorname{PSD}}^{X A}  \tag{66}\\
& \left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \Lambda_{X A} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] \geq \frac{1}{r}\right\}  \tag{67}\\
& =\exp \left(-D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)\right) .
\end{align*}
$$

Here (66) follows from (62)-(64); Eq. (67) follows from the definition of the extended hypothesistesting divergence (see (55)). This shows that

$$
\begin{equation*}
-\ln P_{\mathrm{err}}(\mathscr{E}) \leq \inf _{\tau \in \mathrm{aff}\left(\mathrm{D}_{A}\right)} D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right) \tag{68}
\end{equation*}
$$

To show the opposite inequality, we employ the dual SDP formulation of $P_{\text {err }}(\mathscr{E})$ [53, Eq. (III.15)] (also see Ref. [10, Eq. (4)]), and it follows that

$$
\begin{align*}
P_{\text {err }}(\mathscr{E}) & =\sup _{\sigma \in \operatorname{Herm}_{A}}\left\{\operatorname{Tr}[\sigma]: \sigma \leq p_{x} \rho_{x} \forall x \in[r]\right\}  \tag{69}\\
& =\sup _{\sigma \in \operatorname{Herm}_{A}}\left\{\operatorname{Tr}[\sigma]: I_{X} \otimes \sigma_{A} \leq \varrho_{X A}\right\} \tag{70}
\end{align*}
$$

$$
\begin{align*}
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sup _{\mu \in[0,+\infty)}\left\{\mu: \mu I_{X} \otimes \tau_{A} \leq \varrho_{X A}\right\}  \tag{71}\\
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sup _{\mu \in[0,+\infty)} \inf _{\Lambda \in \operatorname{PSD} \mathrm{D}_{X A}}\left\{\mu+\operatorname{Tr}\left[\Lambda_{X A}\left(\varrho_{X A}-\mu I_{X} \otimes \tau_{A}\right)\right]\right\}  \tag{72}\\
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sup _{\mu \in[0,+\infty)} \inf _{\Lambda \in \mathrm{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]+\mu\left(1-\operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right]\right)\right\}  \tag{73}\\
& \leq \sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \inf _{\Lambda \in \operatorname{PSD}_{A}} \sup _{\mu \in[0,+\infty)}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]+\mu\left(1-\operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right]\right)\right\}  \tag{74}\\
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \inf _{\Lambda \in \operatorname{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right] \geq 1\right\}  \tag{75}\\
& \leq \sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \inf _{\Lambda \in \operatorname{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \Lambda_{X A} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] \geq \frac{1}{r}\right\}  \tag{76}\\
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \exp \left(-D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)\right) . \tag{77}
\end{align*}
$$

Here (69) is the dual SDP formulation of $P_{\text {err }}(\mathscr{E})$; Eq. (71) applies the substitution $\sigma=\mu \tau$ and uses the fact that $\mu=0$ is a feasible solution to the optimisation; Eq. (72) introduces $\Lambda \in \mathrm{PSD}_{X A}$ as a Lagrange multiplier corresponding to the constraint $\mu I_{X} \otimes \tau_{A} \leq \varrho_{X A}$; Eq. (74) follows from an exchange in order between the supremum and infimum; Eq. (75) follows from a reverse Lagrangian reasoning that eliminates the multiplier $\mu$; Eq. (76) follows from the fact that an additional constraint on $\Lambda$ does not decrease the optimal value of the objective function. Combining (68) and (77) leads to the desired statement.

Remark 1 (Necessity of taking the infimum over aff $\left(D_{A}\right)$ in Proposition 1). Note that the infimum on the right-hand side of (59) is taken over unit-trace Hermitian operators instead of over states. This is indeed necessary for the equality in (59) to hold in general, since there are known cases in which taking the infimum on the right-hand side of (59) over states would result in a strictly larger value than $-\ln P_{\text {err }}(\mathscr{E})$. When the states in $\rho_{[r]}$ are classical, it suffices for the infimum on the right-hand side of (59) to be taken over states. As such, the general need for the infimum to be taken over unit-trace Hermitian operators represents a sharp distinction between the classical and quantum theories of information.

Remark 2 (Connection with state discrimination). Proposition 1 can be thought of as a counterpart of Ref. [54, Theorem 1] in state exclusion, while the latter provides an exact characterisation of the one-shot error probability of quantum state discrimination in terms of the hypothesis-testing divergence. We restate Ref. [54, Theorem 1] in Proposition 9 of Appendix D and present an alternative proof thereof, following an approach similar to the proof of Proposition 1.

Recall that Lemma 2 provides an upper bound on the extended hypothesis-testing divergence in terms of the extended sandwiched Rényi divergence. Applying this connection to Proposition 1, we obtain a converse bound on the error probability in terms of an extended version of the left sandwiched Rényi radius.
Proposition 2 (Converse bound on the error probability). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. Then for all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
-\ln P_{\mathrm{err}}(\mathscr{E}) \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right), \tag{78}
\end{equation*}
$$

where $p_{\text {min }} \equiv \min _{x \in[r]} p_{x}$.

Proof. Recall that $\widetilde{Q}_{\alpha}(\rho \| \sigma) \equiv \exp \left((\alpha-1) \widetilde{D}_{\alpha}(\rho \| \sigma)\right)$ denotes the extended sandwiched Rényi quasi-divergence. Following Proposition 1 , for all $\alpha \in(1,+\infty)$, we have that

$$
\begin{align*}
- & \ln P_{\mathrm{err}}\left(\mathscr{E}_{\mathrm{E}}\right) \\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)  \tag{79}\\
& \leq \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \widetilde{D}_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{80}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \frac{1}{\alpha-1} \ln \widetilde{Q}_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{81}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \frac{1}{\alpha-1} \ln \left(\sum_{x \in[r]} \frac{p_{x}^{1-\alpha}}{r^{\alpha}} \widetilde{Q}_{\alpha}\left(\tau \| \rho_{x}\right)\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{82}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \frac{1}{\alpha-1} \ln \left(\sum_{x \in[r]} p_{x}\left(\frac{1}{r p_{x}}\right)^{\alpha} \widetilde{Q}_{\alpha}\left(\tau \| \rho_{x}\right)\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{83}\\
& \leq \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \max _{x \in[r]} \frac{1}{\alpha-1} \ln \left(\left(\frac{1}{r p_{x}}\right)^{\alpha} \widetilde{Q}_{\alpha}\left(\tau \| \rho_{x}\right)\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{84}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \max _{x \in[r]}\left(\widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{r p_{x}}\right)\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{85}\\
& \leq \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \max _{x \in[r]} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{r p_{\min }}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{86}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \max _{x \in[r]} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right)  \tag{87}\\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right)  \tag{88}\\
& =\sup _{s_{r r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right) . \tag{89}
\end{align*}
$$

Here (80) follows from Lemma 2; Eq. (82) uses the direct-sum property of the extended sandwiched Rényi quasi-divergence (see Theorem 1.4); Eq. (89) trivially holds if $\bigcap_{x \in[r]} \operatorname{supp}\left(\rho_{x}\right)=$ $\{0\}$, and it applies the Sion minimax theorem [55] otherwise. The application of the Sion minimax theorem in (89) is justified by the following observations: the feasible regions of $s_{[r]}$ and $\tau$ are both convex with the former being compact; the objective function is linear in $s_{[r]}$, quasi-convex in $\tau$ due to the joint quasi-convexity of the extended sandwiched Rényi divergence (see Theorem 1.5), and lower-semicontinuous in $\tau$ due to the continuity of the $\alpha$-norm (see (43) and (7)).

Remark 3 (Extended version of left $\boldsymbol{D}$-radius). As indicated by the first term on the right-hand side of (78), for a generalised divergence $\boldsymbol{D}$ with a well-defined extension that allows its first argument to be a Hermitian operator, we can accordingly define an extended version of the left $\boldsymbol{D}$-radius by modifying the original infimum in (16) to be over unit-trace Hermitian operators. Following the same reasoning as (18)-(21), the extended left $\boldsymbol{D}$-radius can also be shown to obey the DPI as long as the extension of $\boldsymbol{D}$ does.

Remark 4 (A closed-form converse bound on the error probability). In Proposition 10 of Appendix E, we present a closed-form converse bound on the error probability of state exclusion different from Proposition 2. Specifically, we obtain a relaxation of Proposition 1 by employing the Petz-Rényi divergence $[56,57]$ as an upper bound on the sandwiched Rényi divergence, and we show that the resulting converse bound has a closed-form expression. However, this converse bound is not as useful as the one in Proposition 2 in terms of deriving asymptotic upper bounds on the error exponent due to observed subtleties regarding limit exchange.

## C. Upper bound on the asymptotic error exponent

An upper bound on the asymptotic error exponent arises as a natural consequence of the converse bound on the one-shot error probability provided in Proposition 2. In what follows, we show that this ensuing upper bound can be simplified and is precisely given by the multivariate log-Euclidean Chernoff divergence.

Theorem 2 (Log-Euclidean upper bound on the error exponent). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. Then

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{(n)}\right) \leq \limsup _{n \rightarrow+\infty} \inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{n} \in \mathrm{aff}\left(\mathrm{D}_{A^{n}}\right) \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right) \tag{90}
\end{equation*}
$$

Furthermore, the right-hand side of (90) is bounded from above by the multivariate log-Euclidean Chernoff divergence of the tuple of states $\rho_{[r]}$, as defined in (22). Consequently, we have that

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{(n)}\right) \leq C^{\mathrm{b}}\left(\rho_{[r]}\right) . \tag{91}
\end{equation*}
$$

Proof. Applying Proposition 2 to the $n$-fold ensemble $\mathscr{E}^{(n)}$, for all $\alpha \in(1,+\infty)$, we have that

$$
\begin{equation*}
-\frac{1}{n} \ln P_{\operatorname{err}}\left(\mathscr{E}^{(n)}\right) \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right) \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)+\frac{\alpha}{n(\alpha-1)} \ln \left(\frac{1}{p_{\min }}\right) . \tag{92}
\end{equation*}
$$

Taking the limit superior as $n$ approaches $+\infty$ and then the infimum over $\alpha \in(1,+\infty)$ on both sides, we obtain (90). To show (91), it follows from (90) that

$$
\begin{align*}
& \limsup _{n \rightarrow+\infty} \inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right) \\
& \quad \leq \lim _{n \rightarrow+\infty} \sup _{n \in(1,+\infty)} \inf _{\alpha,} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau^{\otimes n} \| \rho_{x}^{\otimes n}\right)  \tag{93}\\
& \quad=\inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)  \tag{94}\\
& \quad=\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \inf _{\alpha \in(1,+\infty)} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)  \tag{95}\\
& \quad=\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{A}} \sum_{x \in[r]} s_{x} D\left(\tau \| \rho_{x}\right) \tag{96}
\end{align*}
$$

$$
\begin{align*}
& =R^{D}\left(\rho_{[r]}\right)  \tag{97}\\
& =C^{b}\left(\rho_{[r]}\right) . \tag{98}
\end{align*}
$$

Here (93) uses the fact that $\tau^{\otimes n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)$ for all $\tau \in \mathrm{D}_{A}$; Eq. (94) uses the additivity of the sandwiched Rényi divergence (see Theorem 1.3); Eq. (95) trivially holds if $\bigcap_{x \in[r]} \operatorname{supp}\left(\rho_{x}\right)=\{0\}$, and it applies the Mosonyi-Hiai minimax theorem [58, Corollary A.2] otherwise; Eq. (96) uses the nondecreasing monotonicity of the sandwiched Rényi divergence in $\alpha$ (see Theorem 1.2) and its limit as $\alpha$ approaches 1 , which is given by the Umegaki divergence (see (9)); Eq. (97) follows from the definition of the left $D$-radius (see (16)); Eq. (98) follows from the equivalence between the left Umegaki radius and the multivariate log-Euclidean Chernoff divergence (see (24)). The application of the Mosonyi-Hiai minimax theorem in (95) is justified by the following observations: the feasible region of $s_{[r]}$ is convex and compact; the objective function is monotonically nondecreasing in $\alpha$ (see Theorem 1.2), and it is upper-semicontinuous in $s_{[r]}$ as an infimum of a family of linear functions.

Remark 5 (Converse bound on the error exponent in the finite-shot regime). It follows straightforwardly from (92) that, for all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
-\frac{1}{n} \ln P_{\operatorname{err}}\left(\mathscr{E}^{(n)}\right) \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{n} \in \operatorname{aff}\left(\mathrm{D}_{A}\right) \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x}\right)+\frac{\alpha}{n(\alpha-1)} \ln \left(\frac{1}{p_{\min }}\right) . \tag{99}
\end{equation*}
$$

Here (99) uses the fact that $\tau^{\otimes n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)$ for all $\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$ and the additivity of the extended sandwiched Rényi divergence (see Theorem 1.3). This establishes a single-letter converse bound on the error exponent of state exclusion in the $n$-shot regime.

While Theorem 2 already establishes the desired log-Euclidean upper bound on the error exponent of state exclusion, it remains unclear whether the upper bound provided on the right-hand side of (90) is tighter than the log-Euclidean one due to its use of the extended sandwiched Rényi divergence and regularisation. The following proposition addresses this question, showing that the two bounds are in fact equivalent; that is, no improvement can be made from the use of the extended sandwiched Rényi divergence or regularisation. To prove this, we apply the properties established in Theorem 1.

Proposition 3 (Equivalence between the right-hand side of (90) and $C^{b}$ ). Let $\rho_{[r]} \in D_{A}^{[r]}$ be a tuple of states. Then (90) and (91) are equivalent, i.e.,

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty} \inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right) \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)=C^{b}\left(\rho_{[r]}\right) . \tag{100}
\end{equation*}
$$

Proof. Given that the inequality " $\leq$ " has already been established, it remains to prove the inequality " $\geq$." Consider that

$$
\begin{align*}
& \inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right) \\
& \geq \inf _{\alpha \in(1,+\infty)} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x}\left(\widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)-\frac{\alpha}{\alpha-1} \ln \left\|\tau_{n}\right\|_{1}\right)  \tag{101}\\
& \geq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)  \tag{102}\\
& \inf _{\alpha \in(1,+\infty)} \frac{1}{n} \sum_{x \in[r]} s_{x}\left(\widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)-\frac{\alpha}{\alpha-1} \ln \left\|\tau_{n}\right\|_{1}\right)
\end{align*}
$$

$$
\begin{align*}
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x} D\left(\frac{\left|\tau_{n}\right|}{\left\|\tau_{n}\right\|_{1}} \| \rho_{x}^{\otimes n}\right)  \tag{103}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n}^{\prime} \in \mathrm{D}_{A^{n}}} \frac{1}{n} \sum_{x \in[r]} s_{x} D\left(\tau_{n}^{\prime} \| \rho_{x}^{\otimes n}\right)  \tag{104}\\
& =\frac{1}{n} C^{\mathrm{b}}\left(\rho_{[r]}^{(n)}\right)  \tag{105}\\
& =C^{\mathrm{b}}\left(\rho_{[r]}\right) . \tag{106}
\end{align*}
$$

Here (101) follows from observing that $\frac{\alpha}{\alpha-1}>0$ for all $\alpha \in(1,+\infty)$ and that $\left\|\tau_{n}\right\|_{1}=\operatorname{Tr}\left[\left|\tau_{n}\right|\right] \geq$ $\operatorname{Tr}\left[\tau_{n}\right]=1$ for all $\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)$; Eq. (102) follows from an exchange in order between the infimum and supremum; Eq. (103) uses the nondecreasing monotonicity in $\alpha$ of the extended sandwiched Rényi divergence (see Theorem 1.2) and the corresponding limit as $\alpha$ approaches 1 (see Theorem 1.6); Eq. (104) uses the fact that $\frac{\left|\tau_{n}\right|}{\left\|\tau_{n}\right\|_{1}} \in \mathrm{D}_{A^{n}}$ for all $\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)$; Eq. (105) follows from the equivalence between the left Umegaki radius and the multivariate log-Euclidean Chernoff divergence (see (24)); Eq. (106) uses the weak additivity of the multivariate log-Euclidean Chernoff divergence (see (25)).

The establishment of Proposition 3 also enables a transparent comparison between our logEuclidean upper bound and an SDP upper bound previously derived in Ref. [21, Theorem 19], which can be equivalently formulated as the extended left max-radius [21, Theorem 20]. As shown below, the log-Euclidean upper bound is an improvement upon the previous upper bound.

Corollary 1 (Comparison between Theorem 2 and Ref. [21, Theorems 19 and 20]). Let $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$ be a tuple of states. Then

$$
\begin{align*}
C^{b}\left(\rho_{[r]}\right) & \leq-\ln \kappa\left(\rho_{[r]}\right)  \tag{107}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sum_{x \in[r]} s_{x} D_{\max }\left(\tau \| \rho_{x}\right), \tag{108}
\end{align*}
$$

where

$$
\begin{equation*}
\kappa\left(\rho_{[r]}\right):=\sup _{\gamma \in \mathbb{H}_{A}}\left\{\operatorname{Tr}[\gamma]:-\rho_{x} \leq \gamma \leq \rho_{x} \forall x \in[r]\right\}, \tag{109}
\end{equation*}
$$

as defined in Ref. [21, Eq. (189)].
Proof. Although the right-hand side of (108) was only shown to be an upper bound on the righthand side of (107) in Ref. [21, Theorem 20], we observe that they are in fact equal. Specifically, if $\bigcap_{x \in[r]} \operatorname{supp}\left(\rho_{x}\right) \neq\{0\}$, then the inequality in Ref. [21, Eq. (211)] becomes an equality and so does the one in Ref. [21, Eq. (204)]; otherwise, both sides of Ref. [21, Eq. (204)] are equal to 0. This shows that the right-hand sides of (107) and (108) are equal. Therefore, to prove Corollary 1, it remains to compare the multivariate log-Euclidean Chernoff divergence and the extended left max-radius on the right-hand side of (108). It follows from comparing (106) with (102) that

$$
\begin{align*}
C^{b}\left(\rho_{[r]}\right) & \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \inf _{\alpha \in(1,+\infty)} \frac{1}{n} \sum_{x \in[r]} s_{x}\left(\widetilde{D}_{\alpha}\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)-\frac{\alpha}{\alpha-1} \ln \left\|\tau_{n}\right\|_{1}\right)  \tag{110}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x}\left(D_{\max }\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)-\ln \left\|\tau_{n}\right\|_{1}\right) \tag{111}
\end{align*}
$$

$$
\begin{align*}
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x} D_{\max }\left(\tau_{n} \| \rho_{x}^{\otimes n}\right)  \tag{112}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \frac{1}{n} \sum_{x \in[r]} s_{x} D_{\max }\left(\tau^{\otimes n} \| \rho_{x}^{\otimes n}\right)  \tag{113}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sum_{x \in[r]} s_{x} D_{\max }\left(\tau \| \rho_{x}\right) . \tag{114}
\end{align*}
$$

Here (111) uses the nondecreasing monotonicity of the extended sandwiched Rényi divergence in $\alpha$ (see Theorem 1.2) and its limit as $\alpha$ approaches $+\infty$, which is given by the extended maxdivergence (see (54)); Eq. (112) uses the fact that $\left\|\tau_{n}\right\|_{1} \geq 1$ for all $\tau_{n} \in \operatorname{aff}\left(\mathrm{D}_{A^{n}}\right)$; Eq. (114) uses the additivity of the extended max-divergence [21, Proposition 32] (also see Theorem 1.3).

Remark 6 (On the (un)achievability of the log-Euclidean upper bound). For an ensemble of probability distributions (i.e., classical states), it is known that the error exponent of state exclusion is exactly characterised by the multivariate classical Chernoff divergence [21, Theorem 6]. This indicates that the log-Euclidean upper bound in Theorem 2 is achievable when the underlying ensemble of states is classical. Aside from that, the log-Euclidean upper bound is achievable when the ensemble of states contains at least three distinct pure states, as in such a case both the multivariate log-Euclidean Chernoff divergence and the error exponent of state exclusion are infinite, a fact we show in Proposition 11 of Appendix F. However, there are evident (counter)examples in which the log-Euclidean upper bound is not achievable. For instance, in the special case of $r=2$, the bivariate log-Euclidean Chernoff divergence $C^{b}\left(\rho_{1}, \rho_{2}\right)$ deviates from the error exponent, which is characterised by the quantum Chernoff divergence [51,52], which is defined as

$$
\begin{equation*}
C\left(\rho_{1}, \rho_{2}\right):=\sup _{s \in(0,1)}-\ln \operatorname{Tr}\left[\rho_{1}^{s} \rho_{2}^{1-s}\right] . \tag{115}
\end{equation*}
$$

## V. QUANTUM CHANNEL EXCLUSION

In this section, we introduce the task of quantum channel exclusion and analyse its informationtheoretic limit by applying our results from the previous section. We present a single-letter upper bound on the asymptotic error exponent of channel exclusion, given by a barycentric Chernoff channel divergence based on the Belavkin-Staszewski divergence, and it is efficiently computable via an SDP. Our finding also implies, in the special case of $r=2$, an efficiently computable upper bound on the error exponent of symmetric binary channel discrimination. Finally, for classical channels, we show that the upper bound is achievable and thus characterises the exact error exponent of classical channel exclusion, which is given by the multivariate classical Chernoff divergence maximised over classical input states.

## A. Setting

In quantum channel exclusion, as defined in Ref. [59, Appendix E-4], the experimenter is faced with an uncharacterised processing device that implements a fixed channel. The device is represented by an ensemble of channels, $\mathscr{N} \equiv\left(p_{[r]}, \mathcal{N}_{[r]}\right)$ with $r \geq 2$, which indicates that for each $x \in[r]$, there is a prior probability $p_{x}$ with which the device always implements the channel $\mathcal{N}_{x} \in \mathrm{C}_{A \rightarrow B}$. As before, we still assume $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$. The experimenter's goal is to submit an

FIG. 1. A general adaptive strategy for quantum channel exclusion involving $n$ invocations. Each blue box represents an invocation of the processing device being tested. The red boxes and the initial state are components of the strategy that the experimenter is free to choose.
index $x^{\prime} \in[r]$ that differs from the label of the channel that the device actually implements. When $r=2$, the task reduces to symmetric binary channel discrimination (see, e.g., Refs. [23, 24]).

When the experimenter is allowed to invoke the processing device a finite number of times, say, $n$, the most general strategy for channel exclusion is a so-called adaptive strategy, represented by a quantum comb with $n$ empty slots [60-62]. Specifically, such a strategy consists of (i) preparing a bipartite state, (ii) passing one system of the state through the device in each of the $n$ invocations, with ancillary global processing between invocations, and (iii) measuring the state after the final invocation and submitting the outcome (see Figure 1 for an illustration). The strategy is adaptive in the sense that the input of each invocation is allowed to depend on the outputs of all previous invocations. Let $A_{i} \cong A$ and $B_{i} \cong B$ denote the input and output system of the $i$ th invocation of the processing device, respectively, for each $i \in[n]$. Formally, an adaptive strategy with $n$ invocations is represented by a tuple

$$
\begin{equation*}
\mathcal{A}^{(n)} \equiv\left(\rho, \mathcal{A}_{[n-1]}, \Lambda_{[r]}\right), \tag{116}
\end{equation*}
$$

where $\rho \in \mathrm{D}_{R_{1} A_{1}}$ is a state, $\mathcal{A}_{i} \in \mathrm{C}_{R_{i} B_{i} \rightarrow R_{i+1} A_{i+1}}$ is a channel for each $i \in[n-1]$, and $\Lambda_{[r]} \in$ $\mathrm{M}_{R_{n} B_{n}, r}$ is a POVM. We introduce the following shorthand for intermediate states, as also marked in Figure 1:

$$
\begin{align*}
\rho_{x, 1, R_{1} A_{1}} & \equiv \rho_{R_{1} A_{1}},  \tag{117}\\
\rho_{x, i, R_{i} B_{i}}^{\prime} & \equiv \mathcal{N}_{x, A_{i} \rightarrow B_{i}}\left[\rho_{x, i, R_{i} A_{i}}\right] \quad \forall i \in[n],  \tag{118}\\
\rho_{x, i+1, R_{i+1} A_{i+1}} & \equiv \mathcal{A}_{i, R_{i} B_{i} \rightarrow R_{i+1} A_{i+1}}\left[\rho_{x, i, R_{i} B_{i}}^{\prime}\right] \quad \forall i \in[n-1] . \tag{119}
\end{align*}
$$

The error probability of channel exclusion with $n$ invocations for the ensemble $\mathscr{N}$ is thus given by

$$
\begin{equation*}
P_{\operatorname{err}}(n ; \mathscr{N}):=\inf _{\mathcal{A}^{(n)}} \sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x, n}^{\prime}\right] \tag{120}
\end{equation*}
$$

The (asymptotic) error exponent of channel exclusion for the ensemble $\mathscr{N}$ is defined as

$$
\begin{equation*}
\liminf _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N}) \tag{121}
\end{equation*}
$$

Following the same reasoning as in state exclusion [21, Eq. (30)], it can be shown that the error exponent of channel exclusion concerning the ensemble $\mathscr{N}$ does not depend on the prior probability distribution $p_{[r]}$.

## B. Upper bound on the asymptotic error exponent

As suggested by the resemblance between (120) and (57), performing channel exclusion on the ensemble of channels $\mathscr{N}$ with $n$ invocations can in part be translated into performing state exclusion on the induced ensemble of states $\mathscr{E}^{\prime}:=\left(p_{[r]}, \rho_{[r], n}^{\prime}\right)$ in the one-shot regime, where $\rho_{[r], n}^{\prime} \equiv\left(\rho_{1, n}^{\prime}, \rho_{2, n}^{\prime}, \ldots, \rho_{r, n}^{\prime}\right)$. Specifically,

$$
\begin{equation*}
P_{\mathrm{err}}(n ; \mathscr{N})=\inf _{\rho \in \mathrm{D}_{R_{1} A_{1}}, \mathcal{A}_{[n-1]}}\left\{P_{\mathrm{err}}\left(\mathscr{E}^{\prime}\right): \mathcal{A}_{i} \in \mathrm{C}_{R_{i} B_{i} \rightarrow R_{i+1} A_{i+1}} \forall i \in[n-1]\right\} \tag{122}
\end{equation*}
$$

This connection serves as a bridge that enables us to construct a converse bound on the error probability of channel exclusion with $n$ invocations based on the converse bound on the one-shot error probability of state exclusion, which we already established as Proposition 2. In what follows, we construct a converse bound in terms of the left geometric Rényi channel radius, and we further show that it is efficiently computable via an SDP.

Proposition 4 (Converse bound on the error probability for channels). Let $\mathscr{N} \equiv\left(p_{[r]}, \mathcal{N}_{[r]}\right)$ be an ensemble of channels with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\mathcal{N}_{[r]} \in \mathrm{C}_{A \rightarrow B}^{[r]}$. Then for every positive integer $n$ and all $\alpha \in(1,2]$,

$$
\begin{equation*}
-\frac{1}{n} \ln P_{\operatorname{err}}(n ; \mathscr{E}) \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\frac{\alpha}{n(\alpha-1)} \ln \left(\frac{1}{p_{\min }}\right), \tag{123}
\end{equation*}
$$

where $p_{\text {min }} \equiv \min _{x \in[r]} p_{x}$.
Proof. Let $\mathcal{A}^{(n)} \equiv\left(\rho, \mathcal{A}_{[n-1]}, \Lambda_{[r]}\right)$ be an adaptive strategy with $n$ invocations, and let $\mathcal{T} \in \mathrm{C}_{A \rightarrow B}$ be a channel. Define the following states according to (117)-(119) but with $\mathcal{N}_{x}$ substituted with $\mathcal{T}$ :

$$
\begin{align*}
\omega_{1, R_{1} A_{1}} & :=\rho_{R_{1} A_{1}},  \tag{124}\\
\omega_{i, R_{i} B_{i}}^{\prime} & :=\mathcal{T}_{A_{i} \rightarrow B_{i}}\left[\omega_{i, R_{i} A_{i}}\right] \quad \forall i \in[n],  \tag{125}\\
\omega_{i+1, R_{i+1} A_{i+1}} & :=\mathcal{A}_{i, R_{i} B_{i} \rightarrow R_{i+1} A_{i+1}}\left[\omega_{i, R_{i} B_{i}}^{\prime}\right] \quad \forall i \in[n-1] . \tag{126}
\end{align*}
$$

Note that these would be the intermediate states if the adaptive strategy $\mathcal{A}^{(n)}$ were to invoke the channel $\mathcal{T}$ instead of the processing device each time. As such, the intermediate state just before the final measurement $\Lambda_{[r]}$ would be $\omega_{n}^{\prime} \in \mathrm{D}_{R_{n} B_{n}}$. Applying Proposition 2 to the ensemble of states $\mathscr{E}^{\prime} \equiv\left(p_{[r]}, \rho_{[r], n}^{\prime}\right)$, for all $\alpha \in(1,2]$, we have that

$$
\begin{align*}
-\ln P_{\text {err }}\left(\mathscr{E}^{\prime}\right) & \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\tau \| \rho_{x, n}^{\prime}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right)  \tag{127}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widetilde{D}_{\alpha}\left(\omega_{n}^{\prime} \| \rho_{x, n}^{\prime}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right)  \tag{128}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\omega_{n}^{\prime} \| \rho_{x, n}^{\prime}\right)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{p_{\min }}\right) . \tag{129}
\end{align*}
$$

Here (128) follows from observing that $\omega_{n}^{\prime} \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$ for all $\mathcal{T} \in \mathrm{C}_{A \rightarrow B}$; Eq. (129) follows from the order between the sandwiched and geometric Rényi divergences (see (13)). Applying the chain rule for the geometric Rényi channel divergence (see (37)), we have that

$$
\begin{align*}
\widehat{D}_{\alpha}\left(\omega_{i}^{\prime} \| \rho_{x, i}^{\prime}\right) & \leq \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\widehat{D}_{\alpha}\left(\omega_{i} \| \rho_{x, i}\right) \quad \forall i \in[n],  \tag{130}\\
\widehat{D}_{\alpha}\left(\omega_{i+1} \| \rho_{x, i+1}\right) & \leq \widehat{D}_{\alpha}\left(\omega_{i}^{\prime} \| \rho_{x, i}^{\prime}\right) \quad \forall i \in[n-1] \tag{131}
\end{align*}
$$

Here (130) follows from (118) and (125); Eq. (131) follows from (119) and (126) and the fact that $\widehat{D}_{\alpha}(\mathcal{A} \| \mathcal{A})=0$ for every channel $\mathcal{A}$. It follows recursively from (130) and (131) that

$$
\begin{align*}
\widehat{D}_{\alpha}\left(\omega_{n}^{\prime} \| \rho_{x, n}^{\prime}\right) & \leq n \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\widehat{D}_{\alpha}\left(\omega_{1} \| \rho_{x, 1}\right)  \tag{132}\\
& =n \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\widehat{D}_{\alpha}(\rho \| \rho)  \tag{133}\\
& =n \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right) \tag{134}
\end{align*}
$$

Here (133) follows from (117) and (124). Inserting (134) into (129) and dividing both sides of the inequality by $n$, we obtain that

$$
\begin{equation*}
-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{\prime}\right) \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\frac{\alpha}{n(\alpha-1)} \ln \left(\frac{1}{p_{\min }}\right) \tag{135}
\end{equation*}
$$

Finally, since (135) holds for every adaptive strategy $\mathcal{A}^{(n)}$, it follows from (122) that

$$
\begin{align*}
-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N}) & =\sup _{\rho \in \mathrm{D}_{R_{1} A}, \mathcal{A}_{[n-1]}}\left\{-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{\prime}\right): \mathcal{A}_{i} \in \mathrm{C}_{R_{i} A \rightarrow R_{i+1} B} \forall i \in[n-1]\right\}  \tag{136}\\
& \leq \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{C} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)+\frac{\alpha}{n(\alpha-1)} \ln \left(\frac{1}{p_{\min }}\right) \tag{137}
\end{align*}
$$

thus concluding the proof.
Remark 7 (Semidefinite representation of $R^{\widehat{D}_{\alpha}}$ ). We argue that the converse bound in Proposition 4 is efficiently computable via an SDP due to the existence of a semidefinite representation of the left geometric Rényi channel radius. To show this, the left geometric Rényi channel radius can be formulated as

$$
\begin{align*}
R^{\widehat{D}_{\alpha}}\left(\mathcal{N}_{[r]}\right) & =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{138}\\
& =\inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sup _{s_{[r]} \in \mathrm{P}_{r}} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{139}\\
& =\inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \max _{x \in[r]} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{140}\\
& =\inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \inf _{\lambda \in(-\infty,+\infty)}\left\{\lambda: \lambda \geq \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right) \forall x \in[r]\right\} . \tag{141}
\end{align*}
$$

Here (138) follows from the definition of the left $\widehat{D}_{\alpha}$-channel radius (see (41)); Eq. (139) trivially holds if $\bigcap_{x \in[r]} \operatorname{supp}\left(J_{\mathcal{N}_{x}}\right)=\{0\}$, and it applies the Sion minimax theorem [55] otherwise. The application of the Sion minimax theorem in (139) is justified by the following observations: the
feasible regions of $s_{[r]}$ and $\mathcal{T}$ are both convex and compact; the objective function is linear in $s_{[r]}$, and it is quasi-convex in $\mathcal{T}$ due to the joint quasi-convexity of the geometric Rényi channel divergence (see (36)). Combining (141) with Ref. [37, Theorem 3.6], we obtain a semidefinite representation of the left geometric Rényi channel radius: for $\alpha \equiv 1+2^{-\ell} \in(1,2]$ with $\ell$ a nonnegative integer,

For a more general rational number $\alpha \in$ (1,2], we can apply Ref. [63, Theorem 3] to obtain a semidefinite representation of $R^{\widehat{D}_{\alpha}}\left(\mathcal{N}_{[r]}\right)$.

The converse bound on the error probability of channel exclusion in Proposition 4 straightforwardly implies a single-letter upper bound on the asymptotic error exponent, given by the left Belavkin-Staszewski channel radius. Since the Belavkin-Staszewski divergence reduces to the Kullback-Leibler divergence when defined on classical systems, the relevant left channel radius is a barycentric Chernoff channel divergence.

Theorem 3 (Barycentric upper bound on the error exponent for channels). Let $\mathscr{N} \equiv\left(p_{[r]}, \mathcal{N}_{[r]}\right)$ be an ensemble of channels with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\mathcal{N}_{[r]} \in \mathrm{C}_{A \rightarrow B}^{[r]}$. Then

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\text {err }}(n ; \mathscr{N}) \leq R^{\widehat{D}}\left(\mathcal{N}_{[r]}\right) \tag{143}
\end{equation*}
$$

If A is a classical system, then

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N}) \leq \max _{a \in\left[d_{A}\right]} R^{\widehat{D}}\left(v_{a,[r]}\right) \tag{144}
\end{equation*}
$$

where $v_{a, x} \equiv \mathcal{N}_{x}[|a\rangle\langle a|]$ for all $a \in\left[d_{A}\right]$ and $x \in[r]$.
Proof. Taking the limit superior as $n$ approaches $+\infty$ and then the infimum over $\alpha \in(1,2]$ on both sides of (123), we have that

$$
\begin{align*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\text {err }}(n ; \mathscr{N}) & \leq \inf _{\alpha \in(1,2]} \sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{C} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{145}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \inf _{\alpha \in(1,2]} \sum_{x \in[r]} s_{x} \widehat{D}_{\alpha}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{146}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \widehat{D}\left(\mathcal{T} \| \mathcal{N}_{x}\right)  \tag{147}\\
& =R^{\widehat{D}}\left(\mathcal{N}_{[r]}\right) . \tag{148}
\end{align*}
$$

Here (146) applies the Mosonyi-Hiai minimax theorem [58, Corollary A.2]; Eq. (147) uses the nondecreasing monotonicity of the geometric Rényi channel divergence in $\alpha$ (see (32)) and its
limit as $\alpha$ approaches 1 , which is given by the Belavkin-Staszewski channel divergence (see (39)); Eq. (148) follows from the definition of the left $\widehat{D}$-channel radius (see (41)). The application of the Mosonyi-Hiai minimax theorem in (146) is justified by the following observations: the feasible region $s_{[r]}$ is convex and compact; the objective function is monotonically nondecreasing in $\alpha$ (see (32)), and it is upper-semicontinuous in $s_{[r]}$ as an infimum of a family of linear functions. This proves (143). Since the Belavkin-Staszewski divergence is jointly convex [38, Proposition 83.4] and lower-semicontinuous in its first argument, applying Lemma 1 to (143) leads to (144).

Remark 8 (Efficient computability of the barycentric upper bound). Since the Belavkin-Staszewski channel divergence is the limit of the geometric Rényi channel divergence as $\alpha$ approaches 1 (see (39)), as $\ell$ is increased, the right-hand side of (142) quickly converges to the left BelavkinStaszewski channel radius. This shows that the barycentric upper bound on the error exponent of channel exclusion in Theorem 3 can be efficiently evaluated via an SDP.

Remark 9 (Binary channel discrimination as a special case). In the special case of $r=2$, Theorem 3 provides an upper bound on the error exponent of symmetric binary channel discrimination. Specifically, the error exponent of symmetric channel discrimination between a pair of channels $\mathcal{N}_{1}, \mathcal{N}_{2} \in \mathrm{C}_{A \rightarrow B}$ is bounded from above by

$$
\begin{equation*}
\sup _{s \in[0,1]} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}}\left(s \widehat{D}\left(\mathcal{T} \| \mathcal{N}_{1}\right)+(1-s) \widehat{D}\left(\mathcal{T} \| \mathcal{N}_{2}\right)\right) . \tag{149}
\end{equation*}
$$

This is the first known such upper bound that is universal and efficiently computable.
Furthermore, we show that the barycentric upper bound in Theorem 3 is achievable when the channels in $\mathcal{N}_{[r]}$ are classical, thus solving the exact error exponent of classical channel exclusion. In this case, the error exponent has a simple expression and is given by the multivariate classical Chernoff divergence maximised over classical input states. The proof of achievability is based on a nonadaptive strategy and employs the error exponent of classical state exclusion in Ref. [21, Theorem 6]. This means that adaptive strategies provide no advantage for classical channel exclusion in the asymptotic regime, generalising a similar result on symmetric binary classical channel discrimination [25].

Theorem 4 (Exact error exponent for classical channels). Let $\mathscr{N} \equiv\left(p_{[r]}, \mathcal{N}_{[r]}\right)$ be an ensemble of classical channels with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\mathcal{N}_{[r]} \in \mathrm{C}_{A \rightarrow B}^{[r]}$, where $A$ and $B$ are classical systems. Then

$$
\begin{equation*}
\lim _{n \rightarrow \infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N})=\max _{a \in\left[d_{A}\right]} C\left(v_{a,[r]}\right) \tag{150}
\end{equation*}
$$

where $v_{a, x} \equiv \mathcal{N}_{x}[|a\rangle\langle a|]$ for all $x \in[r]$. Furthermore, the error exponent of classical channel exclusion can be achieved using a nonadaptive protocol.

Proof. It follows from Theorem 3 that

$$
\begin{align*}
\limsup _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N}) & \leq \max _{a \in\left[d_{A}\right]} R^{\widehat{D}}\left(v_{a,[r]}\right)  \tag{151}\\
& =\max _{a \in\left[d_{A}\right]} R^{D}\left(v_{a,[r]}\right)  \tag{152}\\
& =\max _{a \in\left[d_{A}\right]} C^{b}\left(v_{a,[r]}\right) \tag{153}
\end{align*}
$$

$$
\begin{equation*}
=\max _{a \in\left[d_{A}\right]} C\left(v_{a,[r]}\right) . \tag{154}
\end{equation*}
$$

Here (152) uses the fact that the Belavkin-Staszewski and Umegaki divergences are equal when defined on a classical system; Eq. (153) follows from the equivalence between the left Umegaki radius and the multivariate log-Euclidean Chernoff divergence (see (24)); Eq. (154) uses the fact that the multivariate log-Euclidean Chernoff divergence reduces to the multivariate classical Chernoff divergence when defined on a classical system (see (26)). To show the achievability, consider the following nonadaptive strategy with $n$ invocations: (i) for each invocation, pass the state $\left|a_{\star}\right\rangle\left\langle a_{\star}\right|$ through the device, where $a_{\star}:=\arg \max _{a \in\left[d_{A}\right]} C\left(v_{a,[r]}\right)$, and collect the output state; (ii) perform state exclusion on the joint system containing all the $n$ output states. This strategy reduces channel exclusion to state exclusion for the ensemble of states $\mathscr{V} \equiv\left(p_{[r]}, v_{a_{\star},[r]}\right)$, and we thus have that

$$
\begin{align*}
\liminf _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}(n ; \mathscr{N}) & \geq \liminf _{n \rightarrow+\infty}-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{V}^{(n)}\right)  \tag{155}\\
& =C\left(v_{a_{\star},[r]}\right)  \tag{156}\\
& =\max _{a \in\left[d_{A}\right]} C\left(v_{a,[r]}\right) \tag{157}
\end{align*}
$$

Here (156) uses the fact that the error exponent of classical state exclusion is given by the multivariate classical Chernoff divergence [21, Theorem 6]. Combining (154) and (157) leads to the desired statement.

## VI. CONCLUSION

## A. Summary of results

In this paper, we investigated the fundamental limit of quantum state exclusion and quantum channel exclusion from an information-theoretic perspective, in both the nonasymptotic and asymptotic regimes. We particularly focused on developing converse bounds on the error probabilities and upper bounds on the error exponents of these tasks. The upper bounds on the error exponents take the form of a barycentric Chernoff divergence.

In the study of quantum state exclusion, we first provided an exact characterisation of the oneshot error probability in terms of the extended hypothesis-testing divergence (Proposition 1), and this serves as the very basis of our entire converse bound approach. Leveraging a quantitative relation between the extended hypothesis-testing divergence and the extended sandwiched Rényi divergence (Lemma 2), this characterisation then leads to a converse bound on the error probability in terms of an extended version of the left sandwiched Rényi radius (Proposition 2). Taking this converse bound to the asymptotic regime, we end up with a single-letter upper bound on the error exponent of state exclusion, given by the multivariate log-Euclidean Chernoff divergence (Theorem 2). In fact, the log-Euclidean upper bound can be shown to be the tightest possible asymptotic upper bound one can construct based on the aforementioned one-shot converse bound (Proposition 3). In addition, it is an improvement upon the upper bound presented in Ref. [21, Theorem 20] (Corollary 1), making it the best efficiently computable upper bound on the error exponent of state exclusion discovered so far. As a separate remark, the various properties of the extended sandwiched Rényi divergence that we established (Theorem 1) played an instrumental role in the derivation and analysis of the log-Euclidean upper bound. These properties may be of independent interest, and we expect them to find further applications apart from their immediate use in state exclusion.

We also studied the task of quantum channel exclusion, which was originally introduced in Ref. [59, Appendix E-4]. We reviewed the error probability of channel exclusion and the ensuing error exponent in the asymptotic regime, when the most general adaptive strategy is allowed. Observing that every channel exclusion strategy involves state exclusion as a subprocedure, we derived a converse bound on the nonasymptotic error probability of channel exclusion based on the just-established converse bound for state exclusion, in terms of the left geometric Rényi channel radius (Proposition 4). This further leads to a single-letter upper bound on the asymptotic error exponent of channel exclusion, given by a barycentric Chernoff divergence based on the Belavkin-Staszewski divergence (Theorem 3). Both the nonasymptotic and asymptotic bounds can be efficiently evaluated via an SDP, and in the special case of $r=2$, they provide the first known universal and efficiently computable converse bounds for symmetric binary channel discrimination. Finally, we showed that when the channels are classical, our upper bound on the error exponent of channel exclusion is achievable by a nonadaptive strategy. This solves the exact error exponent of classical channel exclusion, thus generalising previous results on classical state exclusion and symmetric binary classical channel discrimination.

## B. Future directions

There are still many important and unanswered questions in the study of quantum state and channel exclusion. The foremost open problem is to solve the exact expression for the error exponent of state exclusion. While this paper establishes a simple upper bound in terms of the multivariate log-Euclidean Chernoff divergence, our understanding of the achievability (i.e., lower bound) part of the problem is relatively limited. What we do know is that the log-Euclidean upper bound is not achievable in general, as it fails to reduce to the quantum Chernoff divergence in the special case of $r=2$. This further implies that the exact expression for the error exponent must fall beyond the family of barycentric Chernoff divergences, due to the minimality of the multivariate $\log$-Euclidean Chernoff divergence within the family. Another anomalous aspect of state exclusion is exclusion between pure states. The error exponent of state exclusion becomes infinite as long as the underlying ensemble contains at least three distinct pure states, but the same cannot be said if only two distinct pure states are found. This sharp contrast poses a significant challenge to conjecturing an potential formula for the error exponent, since few recipes are known to generate functions consistent with these special cases. All this evidence suggests that constructing multivariate divergence measures of a novel nature is much needed for the exact expression for the error exponent of state exclusion to be completely solved.

On the other hand, the tasks of quantum state and channel exclusion provide an operational context and motivation for studying multivariate divergence measures. Remarkably, while previous studies of discrimination between multiple states in both symmetric [64] and asymmetric [6568] settings drew considerable attention to divergence measures with multiple arguments, none of these entailed measures are "inherently multivariate," as they all take the form of an optimisation of pairwise divergences. In contrast, state exclusion leads us to divergence measures that are multivariate in a "truer" sense, such as the barycentric Chernoff divergences, or more generally, the left $\boldsymbol{D}$-radii, involved in this paper. We expect exclusion tasks to be the arena where such inherently multivariate divergence measures find their operational interpretations and applications.

## ACKNOWLEDGEMENTS

MM and MMW are grateful to Johannes Jakob Meyer for inviting them to the "Friends of Hypothesis Testing" email exchange, which reminded them of Ref. [54, Theorem 1]. HKM and MMW are also grateful to Prof. Michael Nussbaum for many discussions during the development of Ref. [21], which helped to shape their thinking about the quantum hypothesis exclusion problem.

KJ acknowledges support from the NSF under grant no. 2329662. HKM and MMW acknowledge support from the NSF under grant no. 2304816 and grant no. 2329662 and AFRL under agreement no. FA8750-23-2-0031.

## Appendix A: Proof of Lemma 1

Lemma 1 (Left $\boldsymbol{D}$-radii for classical-to-quantum channels, restatement). Let $\mathcal{N}_{[r]} \in \mathrm{CP}_{A \rightarrow B}^{[r]}$ be a tuple of classical-to-quantum completely positive maps, where $A$ is a classical system. Let $\boldsymbol{D}$ be a generalised divergence that is jointly convex and lower semi-continuous in its first argument. Then

$$
\begin{equation*}
R^{\boldsymbol{D}}\left(\mathcal{N}_{[r]}\right)=\max _{a \in\left[d_{A}\right]} R^{\boldsymbol{D}}\left(v_{a,[r]}\right), \tag{A1}
\end{equation*}
$$

where $v_{a, x} \equiv \mathcal{N}_{x}[|a\rangle\langle a|]$ for all $a \in\left[d_{A}\right]$ and $x \in[r]$.
Proof. For a classical channel $\mathcal{N} \in \mathrm{C}_{A \rightarrow B}$, a classical positive map $\mathcal{M} \in \mathrm{CP}_{A \rightarrow B}$, and a quantumclassical state

$$
\begin{equation*}
\varrho_{R A} \equiv \sum_{a \in\left[d_{A}\right]} p_{a} \rho_{a, R} \otimes|a\rangle\left\langle\left. a\right|_{A}\right. \tag{A2}
\end{equation*}
$$

with $p_{\left[d_{A}\right]} \in \mathrm{P}_{r}$ and $\rho_{\left[d_{A}\right]} \in \mathrm{D}_{R}^{\left[d_{A}\right]}$, we always have that

$$
\begin{align*}
\boldsymbol{D} & \left(\mathcal{N}_{A \rightarrow B}\left[\varrho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\varrho_{R A}\right]\right) \\
& =\boldsymbol{D}\left(\sum_{a \in\left[d_{A}\right]} p_{a} \rho_{a} \otimes \mathcal{N}[|a\rangle\langle a|] \| \sum_{a \in\left[d_{A}\right]} p_{a} \rho_{a} \otimes \mathcal{M}[|a\rangle\langle a|]\right)  \tag{A3}\\
& \leq \sum_{a \in\left[d_{A}\right]} p_{a} \boldsymbol{D}\left(\rho_{a} \otimes \mathcal{N}[|a\rangle\langle a|] \| \rho_{a} \otimes \mathcal{M}[|a\rangle\langle a|]\right)  \tag{A4}\\
& \leq \max _{a \in\left[d_{A}\right]} \boldsymbol{D}\left(\rho_{a} \otimes \mathcal{N}[|a\rangle\langle a|] \| \rho_{a} \otimes \mathcal{M}[|a\rangle\langle a|]\right)  \tag{A5}\\
& =\max _{a \in\left[d_{A}\right]} \boldsymbol{D}(\mathcal{N}[|a\rangle\langle a|] \| \mathcal{M}[|a\rangle\langle a|]) . \tag{A6}
\end{align*}
$$

Here (A4) uses the joint convexity of $\boldsymbol{D}$; Eq. (A6) follows from the DPI under the preparation channel $\mathcal{P} \in \mathrm{C}_{S \rightarrow R}: 1 \mapsto \rho_{a}$, where $S$ is a system such that $d_{S}=1$. This implies that

$$
\begin{align*}
\boldsymbol{D}(\mathcal{N} \| \mathcal{M}) & =\sup _{\varrho \in \mathrm{D}_{R A}} \boldsymbol{D}\left(\mathcal{N}_{A \rightarrow B}\left[\varrho_{R A}\right] \| \mathcal{M}_{A \rightarrow B}\left[\varrho_{R A}\right]\right)  \tag{A7}\\
& =\max _{a \in\left[d_{A}\right]} \boldsymbol{D}(\mathcal{N}[|a\rangle\langle a|] \| \mathcal{M}[|a\rangle\langle a|]) \tag{A8}
\end{align*}
$$

Then it follows from (41) that

$$
\begin{align*}
& R^{\boldsymbol{D}}\left(\mathcal{N}_{[r]}\right)=\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \boldsymbol{D}\left(\mathcal{T} \| \boldsymbol{N}_{x}\right)  \tag{A9}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\mathcal{T} \in \mathrm{C}_{A \rightarrow B}} \sum_{x \in[r]} s_{x} \max _{a \in\left[d_{A}\right]} D\left(\mathcal{T}[|a\rangle\langle a|] \| \mathcal{N}_{x}[|a\rangle\langle a|]\right)  \tag{A10}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{\left[d_{A}\right]} \in \mathrm{D}_{B}^{\left[d_{A}\right]}} \sum_{x \in[r]} s_{x} \max _{a \in\left[d_{A}\right]} \boldsymbol{D}\left(\tau_{a} \| v_{a, x}\right)  \tag{A11}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\tau_{\left[d_{A}\right]} \in \mathrm{D}_{B}^{\left[d_{A}\right]}} \sum_{x \in[r]} s_{x} \sup _{p_{\left[d_{A}\right]} \in \mathrm{P}_{d_{A}}} \sum_{a \in\left[d_{A}\right]} p_{a} \boldsymbol{D}\left(\tau_{a} \| v_{a, x}\right)  \tag{A12}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \inf _{\left.\tau_{\left[d_{A}\right]}\right]} \mathrm{D}_{B}^{\left[d_{A}\right]} \sup _{p_{\left[d_{A}\right] \mid[r]} \in \mathrm{P}_{d_{A}}^{[r]}} \sum_{x \in[r]} \sum_{a \in\left[d_{A}\right]} s_{x} p_{a \mid x} \boldsymbol{D}\left(\tau_{a} \| v_{a, x}\right)  \tag{A13}\\
& =\sup _{s_{[r]} \in \mathrm{P}_{r}} \sup _{p_{\left[d_{A}\right] \mid[r]} \in \mathrm{P}_{d_{A}}^{[r]}} \inf _{\tau_{\left[d_{A}\right]} \in \mathrm{D}_{B}^{\left[d_{A}\right]}} \sum_{x \in[r]} \sum_{a \in\left[d_{A}\right]} s_{x} p_{a \mid x} \boldsymbol{D}\left(\tau_{a} \| v_{a, x}\right)  \tag{A14}\\
& =\sup _{t_{\left[d_{A}\right]} \in \mathrm{P}_{d_{A}}} \sup _{q_{[r] \mid\left[d_{A}\right]} \in \mathrm{P}_{r}^{\left[d_{A}\right]} \tau_{\left[d_{A}\right]} \inf _{B}^{\left[d_{A}\right]}} \sum_{x \in[r]} \sum_{a \in\left[d_{A}\right]} t_{a} q_{x \mid a} \boldsymbol{D}\left(\tau_{a} \| v_{a, x}\right)  \tag{A15}\\
& =\sup _{t_{\left[d_{A}\right]} \in \mathrm{P}_{d_{A}}} \sum_{a \in\left[d_{A}\right]} t_{a} \sup _{\left.q_{[r}\right] \in \mathrm{P}_{r}} \inf _{\tau \in \mathrm{D}_{B}} \sum_{x \in[r]} q_{x} \boldsymbol{D}\left(\tau \| v_{a, x}\right) \tag{A16}
\end{align*}
$$

$$
\begin{align*}
& =\sup _{\left.t_{\left[d_{A}\right]}\right] \mathrm{P}_{d_{A}}} \sum_{a \in\left[d_{A}\right]} t_{a} R^{\boldsymbol{D}}\left(v_{a,[r]}\right)  \tag{A17}\\
& =\max _{a \in\left[d_{A}\right]} R^{\boldsymbol{D}}\left(v_{a,[r]}\right) \tag{A18}
\end{align*}
$$

Here (A10) follows from (A8); Eq. (A11) applies the substitution $\mathcal{T}:|a\rangle\langle a| \mapsto \tau_{a}$ and $\mathcal{N}_{x}:|a\rangle\langle a| \mapsto$ $v_{a, x}$ for all $x \in[r]$; Eq. (A13) applies an exchange in order between the summation over $x$ and the supremum over $p_{\left[d_{A}\right]}$; Eq. (A14) applies he Farkas-Révész minimax theorem [69, Theorem 5.2]; Eq. (A15) applies the substitution $s_{x} p_{a \mid x}=t_{a} q_{x \mid a}$ for all $a \in\left[d_{A}\right]$ and $x \in[r]$ according to the Bayes rule; Eq. (A16) applies an exchange in order between the infimum over $\tau_{\left[d_{A}\right]}$ and the summation over $a$ followed by another exchange between the supremum over $q_{[r] \mid\left[d_{A}\right]}$ and the summation over $a$; Eq. (A17) follows from the definition of the left $\boldsymbol{D}$-radius (see (16)). The application of the Farkas-Révész minimax theorem in (A14) is justified by the following observations: the feasible regions of $\tau_{\left[d_{A}\right]}$ and $p_{\left[d_{A}\right] \mid[r]}$ are both convex and compact; the objective function is linear in $p_{\left[d_{A}\right][r]}$, convex in $\tau_{\left[d_{A}\right]}$ due to the joint convexity of $\boldsymbol{D}$, and lower-semicontinuous in $\tau_{\left[d_{A}\right]}$ due to the lower semicontinuity of $\boldsymbol{D}$ in its first argument.

## Appendix B: Proof of Theorem 1

## 1. Proof of Theorem $\mathbf{1 . 3}$

Proposition 5 (Additivity of the extended $\widetilde{D}_{\alpha}$, Theorem 1.3). Let $\gamma \in \operatorname{Herm}_{A}$ and $\gamma^{\prime} \in \operatorname{Herm}_{B}$ be two Hermitian operators, and let $\sigma \in \mathrm{PSD}_{A}$ and $\sigma^{\prime} \in \mathrm{PSD}_{B}$ be two positive semidefinite operators. Then for all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
\widetilde{D}_{\alpha}\left(\gamma \otimes \gamma^{\prime} \| \sigma \otimes \sigma^{\prime}\right)=\widetilde{D}_{\alpha}(\gamma \| \sigma)+\widetilde{D}_{\alpha}\left(\gamma^{\prime} \| \sigma^{\prime}\right) \tag{B1}
\end{equation*}
$$

Proof. The proof is a straightforward generalisation of that for the original sandwiched Rényi divergence whose first argument is a state. Note that $\operatorname{supp}\left(\gamma \otimes \gamma^{\prime}\right) \subseteq \operatorname{supp}\left(\sigma \otimes \sigma^{\prime}\right)$ if and only if $\operatorname{supp}(\gamma) \subseteq \operatorname{supp}(\sigma)$ and $\operatorname{supp}\left(\gamma^{\prime}\right) \subseteq \operatorname{supp}\left(\sigma^{\prime}\right)$. If $\operatorname{supp}\left(\gamma \otimes \gamma^{\prime}\right) \nsubseteq \operatorname{supp}\left(\sigma \otimes \sigma^{\prime}\right)$, then both sides of (B1) are equal to $+\infty$. Otherwise, it follows from (43) that

$$
\begin{align*}
\widetilde{D}_{\alpha}\left(\gamma \otimes \gamma^{\prime} \| \sigma \otimes \sigma^{\prime}\right) & =\frac{1}{\alpha-1} \ln \left\|\left(\sigma \otimes \sigma^{\prime}\right)^{\frac{1-\alpha}{2 \alpha}}\left(\gamma \otimes \gamma^{\prime}\right)\left(\sigma \otimes \sigma^{\prime}\right)^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{B2}\\
& =\frac{1}{\alpha-1} \ln \left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}} \otimes \sigma^{\frac{1-\alpha}{2 \alpha}} \gamma^{\prime} \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{B3}\\
& =\frac{1}{\alpha-1} \ln \left(\left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}\left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma^{\prime} \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}\right)  \tag{B4}\\
& =\frac{1}{\alpha-1}\left(\ln \left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}+\ln \left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma^{\prime} \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}\right)  \tag{B5}\\
& =\widetilde{D}_{\alpha}(\gamma \| \sigma)+\widetilde{D}_{\alpha}\left(\gamma^{\prime} \| \sigma^{\prime}\right) . \tag{B6}
\end{align*}
$$

Here (B4) uses the multiplicativity of the $\alpha$-norm under tensor products (see, e.g., Ref. [4, Eq. (2.2.96)]): for all $\alpha \in[1,+\infty)$, we have $\left\|\xi \otimes \xi^{\prime}\right\|_{\alpha}=\|\xi\|_{\alpha}\left\|\xi^{\prime}\right\|_{\alpha}$ for all $\xi \in \mathbb{B}_{A}$ and $\xi^{\prime} \in \mathbb{B}_{B}$.

## 2. Proof of Theorem 1.4

Proposition 6 (Direct-sum property of the extended $\widetilde{D}_{\alpha}$, Theorem 1.4). Let $\gamma_{[r]} \in \operatorname{Herm}_{A}^{[r]}$ be a tuple of Hermitian operators, and let $\sigma_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ be a tuple of positive semidefinite operators.

Let $p_{[r]} \in \mathrm{P}_{r}$ be a probability distribution, and let $q_{[r]} \in[0,+\infty)^{[r]}$ be a tuple of nonnegative real numbers. Then for all $\alpha \in[1,+\infty)$,

$$
\begin{equation*}
\widetilde{Q}_{\alpha}\left(v_{X A} \| \varsigma_{X A}\right)=\sum_{x \in[r]} p_{x}^{\alpha} q_{x}^{1-\alpha} \widetilde{Q}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right), \tag{B7}
\end{equation*}
$$

where $\widetilde{Q}_{\alpha}(\gamma \| \sigma) \equiv \exp \left((\alpha-1) \widetilde{D}_{\alpha}(\gamma \| \sigma)\right)$ denotes the extended sandwiched Rényi quasi-divergence and

$$
\begin{align*}
& v_{X A} \equiv \sum_{x \in[r]} p_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \gamma_{x, A},\right.  \tag{B8}\\
& \varsigma_{X A} \equiv \sum_{x \in[r]} q_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \sigma_{x, A} .\right. \tag{B9}
\end{align*}
$$

Proof. The proof is a straightforward generalisation of that for the original sandwiched Rényi divergence whose first argument is a state. Note that $\operatorname{supp}\left(v_{X A}\right) \subseteq \operatorname{supp}\left(\varsigma_{X A}\right)$ if and only if $\operatorname{supp}\left(\gamma_{x}\right) \subseteq \operatorname{supp}\left(\sigma_{x}\right)$ for all $x \in[r]$. If $\operatorname{supp}\left(v_{X A}\right) \nsubseteq \operatorname{supp}\left(\varsigma_{X A}\right)$, then both sides of (B7) are equal to $+\infty$. Otherwise, it follows from (43) and the definition of the extended sandwiched Rényi quasi-divergence that

$$
\begin{align*}
\widetilde{Q}_{\alpha} & \left(v_{X A} \| S_{X A}\right) \\
& =\left\|\varsigma_{X A}^{\frac{1-\alpha}{2 \alpha}} v_{X A} \varsigma_{X A}^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{B10}\\
& =\left\|\left(\sum_{x \in[r]} q_{x}^{\frac{1-\alpha}{2 \alpha}}|x\rangle\langle x| \otimes \sigma_{x}^{\frac{1-\alpha}{2 \alpha}}\right)\left(\sum_{x \in[r]} p_{x}|x\rangle\langle x| \otimes \gamma_{x}\right)\left(\sum_{x \in[r]} q_{x}^{\frac{1-\alpha}{2 \alpha}}|x\rangle\langle x| \otimes \sigma_{x}^{\frac{1-\alpha}{2 \alpha}}\right)\right\|_{\alpha}^{\alpha}  \tag{B11}\\
& =\| \sum_{x \in[r]} p_{x} q_{x}^{\frac{1-\alpha}{\alpha}}|x\rangle\langle x| \otimes \sigma_{x}^{\frac{1-\alpha}{2 \alpha}} \gamma_{x} \sigma_{x}^{\frac{1-\alpha}{2 \alpha}} \|_{\alpha}^{\alpha}  \tag{B12}\\
& =\sum_{x \in[r]}\left\|p_{x} q_{x}^{\frac{1-\alpha}{\alpha}} \sigma_{x}^{\frac{1-\alpha}{2 \alpha}} \gamma_{x} \sigma_{x}^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{B13}\\
& =\sum_{x \in[r]} p_{x}^{\alpha} q_{x}^{1-\alpha} \widetilde{Q}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right) \tag{B14}
\end{align*}
$$

Here (B13) uses the direct-sum property of the $\alpha$-norm (see, e.g., Ref. [4, Eq. (2.2.97)]): for all $\alpha \in[1,+\infty)$,

$$
\begin{equation*}
\| \sum_{x \in[r]}|x\rangle\langle x| \otimes \xi_{x}\left\|_{\alpha}^{\alpha}=\sum_{x \in[r]}\right\| \xi_{x} \|_{\alpha}^{\alpha} \quad \forall \xi_{[r]} \in \mathbb{B}_{A}^{[r]}, \tag{B15}
\end{equation*}
$$

thus concluding the proof.

## 3. Proof of Theorem 1.5

Proposition 7 (Quasi-convexity of the extended $\widetilde{D}_{\alpha}$, Theorem 1.5). Let $\gamma_{[r]} \in \operatorname{Herm}_{A}^{[r]}$ be a tuple of Hermitian operators, and let $\sigma_{[r]} \in \mathrm{PSD}_{A}^{[r]}$ be a tuple of positive semidefinite operators. Let
$p_{[r]} \in \mathrm{P}_{r}$ be a probability distribution. Then for all $\alpha \in[1,+\infty)$,

$$
\begin{equation*}
\widetilde{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \gamma_{x} \| \sum_{x \in[r]} p_{x} \sigma_{x}\right) \leq \max _{x \in[r]} \widetilde{D}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right) \tag{B16}
\end{equation*}
$$

Proof. The proof is a straightforward generalisation of that for the original sandwiched Rényi divergence whose first argument is a state. Consider that

$$
\begin{align*}
\widetilde{D}_{\alpha}\left(\sum_{x \in[r]} p_{x} \gamma_{x} \| \sum_{x \in[r]} p_{x} \sigma_{x}\right) & \leq \widetilde{D}_{\alpha}\left(\sum_{x \in[r]} p_{x}|x\rangle\langle x| \otimes \gamma_{x} \| \sum_{x \in[r]} p_{x}|x\rangle\langle x| \otimes \sigma_{x}\right)  \tag{B17}\\
& =\frac{1}{\alpha-1} \ln \widetilde{Q}_{\alpha}\left(\sum_{x \in[r]} p_{x}|x\rangle\langle x| \otimes \gamma_{x} \| \sum_{x \in[r]} p_{x}|x\rangle\langle x| \otimes \sigma_{x}\right)  \tag{B18}\\
& =\frac{1}{\alpha-1} \ln \left(\sum_{x \in[r]} p_{x} \widetilde{Q}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right)\right)  \tag{B19}\\
& \leq \max _{x \in[r]} \frac{1}{\alpha-1} \ln \widetilde{Q}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right)  \tag{B20}\\
& =\max _{x \in[r]} \widetilde{D}_{\alpha}\left(\gamma_{x} \| \sigma_{x}\right) . \tag{B21}
\end{align*}
$$

Here (B17) follows from the DPI under the partial-trace channel $\operatorname{Tr}_{X}$ (see Theorem 1.1); Eq. (B19) uses the direct-sum property of the extended sandwiched Rényi quasi-divergence (see Theorem 1.4).

## 4. Proof of Theorem 1.6

Proposition 8 (Limit of the extended $\widetilde{D}_{\alpha}$ as $\alpha$ approaches 1, Theorem 1.6). Let $\gamma \in \operatorname{Herm}_{A}$ be a Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. Then for all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
\lim _{\alpha \searrow 1}\left(\widetilde{D}_{\alpha}(\gamma \| \sigma)-\frac{\alpha}{\alpha-1} \ln \|\gamma\|_{1}\right)=D\left(\frac{|\gamma|}{\|\gamma\|_{1}} \| \sigma\right) . \tag{B22}
\end{equation*}
$$

Proof. The proof generalises that for the original sandwiched Rényi divergence, whose first argument is a state. If $\operatorname{supp}(\gamma) \nsubseteq \operatorname{supp}(\sigma)$, then both sides of (B22) are equal to $+\infty$. Otherwise, we have $\operatorname{supp}(\gamma) \subseteq \operatorname{supp}(\sigma)$ and thus $\sigma^{0} \gamma \sigma^{0}=\gamma$, where $\sigma^{0} \in \mathrm{PSD}_{A}$ denotes the projector onto $\operatorname{supp}(\sigma)$. Recall that

$$
\begin{align*}
\widetilde{Q}_{\alpha}(\gamma \| \sigma) & =\exp \left((\alpha-1) \widetilde{D}_{\alpha}(\gamma \| \sigma)\right)  \tag{B23}\\
& =\left\|\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{B24}\\
& =\operatorname{Tr}\left[\left(\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right)^{\frac{\alpha}{2}}\right] . \tag{B25}
\end{align*}
$$

Here (B25) follows from the definition of the $\alpha$-norm (see (7)). Note that

$$
\begin{align*}
\widetilde{Q}_{1}(\gamma \| \sigma) & =\operatorname{Tr}\left[\left(\sigma^{0} \gamma \sigma^{0} \gamma \sigma^{0}\right)^{\frac{1}{2}}\right]  \tag{B26}\\
& =\operatorname{Tr}\left[\left(\gamma^{2}\right)^{\frac{1}{2}}\right]  \tag{B27}\\
& =\|\gamma\|_{1} . \tag{B28}
\end{align*}
$$

Here (B27) uses the facts $\sigma^{0}=\sigma^{0} \sigma^{0}$ and $\sigma^{0} \gamma \sigma^{0}=\gamma$. It follows that

$$
\begin{align*}
\lim _{\alpha \searrow 1}\left(\widetilde{D}_{\alpha}(\gamma \| \sigma)-\frac{\alpha}{\alpha-1} \ln \|\gamma\|_{1}\right) & =\lim _{\alpha \searrow 1} \frac{1}{\alpha-1}\left(\ln \widetilde{Q}_{\alpha}(\gamma \| \sigma)-\ln \|\gamma\|_{1}\right)-\ln \|\gamma\|_{1}  \tag{B29}\\
& =\lim _{\alpha \searrow 1} \frac{1}{\alpha-1}\left(\ln \widetilde{Q}_{\alpha}(\gamma \| \sigma)-\ln \widetilde{Q}_{1}(\gamma \| \sigma)\right)-\ln \|\gamma\|_{1}  \tag{B30}\\
& =\left.\frac{\mathrm{d}}{\mathrm{~d} \alpha} \ln \widetilde{Q}_{\alpha}(\gamma \| \sigma)\right|_{\alpha=1}-\ln \|\gamma\|_{1}  \tag{B31}\\
& =\left.\frac{1}{\widetilde{Q}_{1}(\gamma \| \sigma)} \frac{\mathrm{d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha}(\gamma \| \sigma)\right|_{\alpha=1}-\ln \|\gamma\|_{1}  \tag{B32}\\
& =\left.\frac{1}{\|\gamma\|_{1}} \frac{\mathrm{~d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha}(\gamma \| \sigma)\right|_{\alpha=1}-\ln \|\gamma\|_{1} \tag{B33}
\end{align*}
$$

For $\alpha, \beta \in[1,+\infty)$, define the following function:

$$
\begin{equation*}
\widetilde{Q}_{\alpha, \beta}(\gamma \| \sigma):=\operatorname{Tr}\left[\left(\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right)^{\frac{\beta}{2}}\right] . \tag{B34}
\end{equation*}
$$

Note from (B25) that $\widetilde{Q}_{\alpha, \alpha}(\gamma \| \sigma)=\widetilde{Q}_{\alpha}(\gamma \| \sigma)$. As

$$
\begin{equation*}
\left.\frac{\mathrm{d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha}(\gamma \| \sigma)\right|_{\alpha=1}=\left.\frac{\mathrm{d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha, 1}(\gamma \| \sigma)\right|_{\alpha=1}+\left.\frac{\mathrm{d}}{\mathrm{~d} \beta} \widetilde{Q}_{1, \beta}(\gamma \| \sigma)\right|_{\beta=1}, \tag{B35}
\end{equation*}
$$

we need to calculate both derivatives on the right-hand side of (B35) to find the desired limit. For the first derivative, consider that

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha, 1}(\gamma \| \sigma)= & \frac{\mathrm{d}}{\mathrm{~d} \alpha} \operatorname{Tr}\left[\left(\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right)^{\frac{1}{2}}\right]  \tag{B36}\\
= & \frac{1}{2} \operatorname{Tr}\left[\left(\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right)^{-\frac{1}{2}} \frac{\mathrm{~d}}{\mathrm{~d} \alpha}\left(\sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right)\right]  \tag{B37}\\
= & \frac{1}{2} \operatorname{Tr}\left[( \sigma ^ { \frac { 1 - \alpha } { 2 \alpha } } \gamma \sigma ^ { \frac { 1 - \alpha } { \alpha } } \gamma \sigma ^ { \frac { 1 - \alpha } { 2 \alpha } } ) ^ { - \frac { 1 } { 2 } } \left(-\frac{1}{2 \alpha^{2}} \sigma^{\frac{1-\alpha}{2 \alpha}}(\ln \sigma) \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}\right.\right. \\
& \left.\left.-\frac{1}{\alpha^{2}} \sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}}(\ln \sigma) \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}-\frac{1}{2 \alpha^{2}} \sigma^{\frac{1-\alpha}{2 \alpha}} \gamma \sigma^{\frac{1-\alpha}{\alpha}} \gamma \sigma^{\frac{1-\alpha}{2 \alpha}}(\ln \sigma)\right)\right] . \tag{B38}
\end{align*}
$$

Then

$$
\left.\frac{\mathrm{d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha, 1}(\gamma \| \sigma)\right|_{\alpha=1}
$$

$$
\begin{align*}
& =-\frac{1}{4} \operatorname{Tr}\left[\left(\sigma^{0} \gamma \sigma^{0} \gamma \sigma^{0}\right)^{-\frac{1}{2}}\left(\sigma^{0}(\ln \sigma) \gamma \sigma^{0} \gamma \sigma^{0}+2 \sigma^{0} \gamma \sigma^{0}(\ln \sigma) \gamma \sigma^{0}+\sigma^{0} \gamma \sigma^{0} \gamma \sigma^{0}(\ln \sigma)\right)\right]  \tag{B39}\\
& =-\frac{1}{4}\left(\operatorname{Tr}\left[\left(\gamma^{2}\right)^{-\frac{1}{2}}(\ln \sigma) \gamma^{2}\right]+2 \operatorname{Tr}\left[\left(\gamma^{2}\right)^{-\frac{1}{2}} \gamma(\ln \sigma) \gamma\right]+\operatorname{Tr}\left[\left(\gamma^{2}\right)^{-\frac{1}{2}} \gamma^{2} \ln \sigma\right]\right)  \tag{B40}\\
& =-\operatorname{Tr}[|\gamma| \ln \sigma] . \tag{B41}
\end{align*}
$$

For the second derivative, consider that

$$
\begin{align*}
\left.\frac{\mathrm{d}}{\mathrm{~d} \beta} \widetilde{Q}_{1, \beta}(\gamma \| \sigma)\right|_{\beta=1} & =\left.\frac{\mathrm{d}}{\mathrm{~d} \beta} \operatorname{Tr}\left[\left(\sigma^{0} \gamma \sigma^{0} \gamma \sigma^{0}\right)^{\frac{\beta}{2}}\right]\right|_{\beta=1}  \tag{B42}\\
& =\left.\frac{\mathrm{d}}{\mathrm{~d} \beta} \operatorname{Tr}\left[|\gamma|^{\beta}\right]\right|_{\beta=1}  \tag{B43}\\
& =\left.\operatorname{Tr}\left[|\gamma|^{\beta} \ln |\gamma|\right]\right|_{\beta=1}  \tag{B44}\\
& =\operatorname{Tr}[|\gamma| \ln |\gamma|] \tag{B45}
\end{align*}
$$

Inserting (B41) and (B45) into (B35), and then to (B33), we obtain that

$$
\begin{align*}
& \lim _{\alpha \searrow 1}\left(\widetilde{D}_{\alpha}(\gamma \| \sigma)-\frac{\alpha}{\alpha-1} \ln \|\gamma\|_{1}\right) \\
& \quad=\frac{1}{\|\gamma\|_{1}}\left(\left.\frac{\mathrm{~d}}{\mathrm{~d} \alpha} \widetilde{Q}_{\alpha, 1}(\gamma \| \sigma)\right|_{\alpha=1}+\left.\frac{\mathrm{d}}{\mathrm{~d} \beta} \widetilde{Q}_{1, \beta}(\gamma \| \sigma)\right|_{\beta=1}\right)-\ln \|\gamma\|_{1}  \tag{B46}\\
& \quad=\frac{1}{\|\gamma\|_{1}} \operatorname{Tr}[|\gamma|(\ln |\gamma|-\ln \sigma)]-\ln \|\gamma\|_{1}  \tag{B47}\\
& \quad=\operatorname{Tr}\left[\frac{|\gamma|}{\|\gamma\|_{1}}\left(\ln \left(\frac{|\gamma|}{\|\gamma\|_{1}}\right)-\ln \sigma\right)\right]  \tag{B48}\\
& \quad=D\left(\frac{|\gamma|}{\|\gamma\|_{1}} \| \sigma\right) \tag{B49}
\end{align*}
$$

Here (B49) follows from the fact that $\frac{|\gamma|}{\|\gamma\|_{1}} \in D_{A}$ for all $\gamma \in \operatorname{Herm}_{A}$ and the definition of the Umegaki divergence (see (8)).

## Appendix C: Proof of Lemma 2

Lemma 2 (Connection between the extended $D_{\mathrm{H}}^{\varepsilon}$ and $\widetilde{D}_{\alpha}$, restatement). Let $\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)$ be a unit-trace Hermitian operator, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. Then for all $\varepsilon \in[0,1)$ and all $\alpha \in(1,+\infty)$,

$$
\begin{equation*}
D_{\mathrm{H}}^{\varepsilon}(\tau \| \sigma) \leq \widetilde{D}_{\alpha}(\tau \| \sigma)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{1-\varepsilon}\right) \tag{C1}
\end{equation*}
$$

Proof. The proof is a straightforward generalisation of that regarding the original hypothesis testing and sandwiched Rényi divergences whose first argument is a state. If $\operatorname{supp}(\tau) \nsubseteq \operatorname{supp}(\sigma)$,
then the right-hand side of (C1) is equal to $+\infty$ and (C1) holds trivially. Henceforth we assume $\operatorname{supp}(\tau) \subseteq \operatorname{supp}(\sigma)$. Let $\Lambda \in \mathrm{PSD}_{A}$ be a positive semidefinite operator satisfying $\Lambda \leq I$ and $\operatorname{Tr}[\Lambda \tau] \geq 1-\varepsilon$. Let

$$
\begin{equation*}
\left.\mathcal{M} \in \mathrm{C}_{A \rightarrow X}: \rho \mapsto \operatorname{Tr}[\Lambda \tau]|1\rangle<1|+\operatorname{Tr}[(I-\Lambda) \rho]| 2\right\rangle\langle 2| \tag{C2}
\end{equation*}
$$

denote the measurement channel represented by the $\operatorname{POVM}(\Lambda, I-\Lambda) \in \mathrm{M}_{A, 2}$. It follows from the DPI under the measurement channel $\mathcal{M}$ (see Theorem 1.1) that

$$
\begin{align*}
\widetilde{D}_{\alpha}(\tau \| \sigma) & \geq \widetilde{D}_{\alpha}(\mathcal{M}[\tau] \| \mathcal{M}[\sigma])  \tag{C3}\\
& =\frac{1}{\alpha-1} \ln \left\|(\mathcal{M}[\sigma])^{\frac{1-\alpha}{2 \alpha}} \mathcal{M}[\tau](\mathcal{M}[\sigma])^{\frac{1-\alpha}{2 \alpha}}\right\|_{\alpha}^{\alpha}  \tag{C4}\\
& =\frac{1}{\alpha-1} \ln \left(\left|\operatorname{Tr}[\Lambda \tau] \operatorname{Tr}[\Lambda \sigma]^{\frac{1-\alpha}{\alpha}}\right|^{\alpha}+\left|\operatorname{Tr}[(I-\Lambda) \tau] \operatorname{Tr}[(I-\Lambda) \sigma]^{\frac{1-\alpha}{\alpha}}\right|^{\alpha}\right)  \tag{C5}\\
& \geq \frac{1}{\alpha-1} \ln \left(\left|\operatorname{Tr}[\Lambda \tau] \operatorname{Tr}[\Lambda \sigma]^{\frac{1-\alpha}{\alpha}}\right|^{\alpha}\right)  \tag{C6}\\
& =\frac{1}{\alpha-1} \ln \left(\operatorname{Tr}[\Lambda \tau]^{\alpha} \operatorname{Tr}[\Lambda \sigma]^{1-\alpha}\right)  \tag{C7}\\
& =\frac{\alpha}{\alpha-1} \ln \operatorname{Tr}[\Lambda \tau]-\ln \operatorname{Tr}[\Lambda \sigma]  \tag{C8}\\
& \geq \frac{\alpha}{\alpha-1} \ln (1-\varepsilon)-\ln \operatorname{Tr}[\Lambda \sigma] \tag{C9}
\end{align*}
$$

Here (C5) uses the direct-sum property of the $\alpha$-norm (see (B15)); Eqs. (C7) and (C9) use the fact $\operatorname{Tr}[\Lambda \tau] \geq 1-\varepsilon>0$. Since (C9) holds for every $\Lambda \in \operatorname{PSD}_{A}$ satisfying $\Lambda \leq I$ and $\operatorname{Tr}[\Lambda \tau] \geq 1-\varepsilon$, it follows that

$$
\begin{align*}
D_{\mathrm{H}}^{\varepsilon}(\tau \| \sigma) & =\sup _{\Lambda \in \mathrm{PSD}_{A}}\{-\ln \operatorname{Tr}[\Lambda \sigma]: \Lambda \leq I, \operatorname{Tr}[\Lambda \tau] \geq 1-\varepsilon\}  \tag{C10}\\
& \leq \widetilde{D}_{\alpha}(\tau \| \sigma)+\frac{\alpha}{\alpha-1} \ln \left(\frac{1}{1-\varepsilon}\right) \tag{C11}
\end{align*}
$$

thus concluding the proof.

## Appendix D: Characterisation of the one-shot error probability of state discrimination

Proposition 9 (Characterisation of error probability of state discrimination, [54, Theorem 1]). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. Then

$$
\begin{equation*}
-\ln P_{\mathrm{err}}^{\mathrm{SD}}(\mathscr{E})=\inf _{\tau \in \mathrm{D}_{A}} D_{\mathrm{H}}^{\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right) \tag{D1}
\end{equation*}
$$

where

$$
\begin{equation*}
P_{\mathrm{err}}^{\mathrm{SD}}(\mathscr{E}):=1-\sup _{\Lambda_{[r]} \in \mathrm{M}_{A, r}} \sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right] \tag{D2}
\end{equation*}
$$

denotes the (one-shot) error probability of state discrimination for the ensemble $\mathscr{E}$ and

$$
\begin{equation*}
\varrho_{X A} \equiv \sum_{x \in[r]} p_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \rho_{x, A} .\right. \tag{D3}
\end{equation*}
$$

Proof. For every POVM $\Lambda_{[r]} \in \mathrm{M}_{A, r}$, denote

$$
\begin{equation*}
\Lambda_{X A} \equiv \sum_{x \in[r]}|x\rangle\left\langle\left. x\right|_{X} \otimes \Lambda_{x, A}\right. \tag{D4}
\end{equation*}
$$

We observe that $\Lambda \in \mathrm{PSD}_{X A}$ and

$$
\begin{align*}
\Lambda_{X A} & \leq I_{X A},  \tag{D5}\\
\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right] & =\sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right],  \tag{D6}\\
\operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] & =\frac{1}{r} \sum_{x \in[r]} \operatorname{Tr}\left[\Lambda_{x} \tau\right]=\frac{1}{r} \quad \forall \tau \in \mathrm{D}_{A} . \tag{D7}
\end{align*}
$$

Then for all $\tau \in \mathrm{D}_{A}$, we have that

$$
\begin{align*}
P_{\mathrm{err}}^{\mathrm{SD}}(\mathscr{E}) & =1-\sup _{\Lambda_{[r]} \in \mathrm{M}_{A, r}} \sum_{x \in[r]} p_{x} \operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right]  \tag{D8}\\
& \geq 1-\sup _{\Lambda \in \mathrm{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \Lambda_{X A} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] \leq \frac{1}{r}\right\}  \tag{D9}\\
& =\inf _{\Lambda^{\prime} \in \mathrm{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A}^{\prime} \varrho_{X A}\right]: \Lambda_{X A}^{\prime} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}^{\prime}\left(\pi_{X} \otimes \tau_{A}\right)\right] \geq 1-\frac{1}{r}\right\}  \tag{D10}\\
& =\exp \left(-D_{\mathrm{H}}^{\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)\right) . \tag{D11}
\end{align*}
$$

Here (D9) follows from (D5)-(D7); Eq. (D10) applies the substitution $\Lambda=I-\Lambda^{\prime}$; Eq. (D11) follows from the definition of the hypothesis-testing divergence (see (55)). This shows that

$$
\begin{equation*}
-\ln P_{\mathrm{err}}^{\mathrm{SD}}(\mathscr{E}) \leq \inf _{\tau \in \mathrm{D}_{A}} D_{\mathrm{H}}^{\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right) \tag{D12}
\end{equation*}
$$

To show the opposite inequality, we employ the dual SDP formulation of $P_{\text {err }}^{\mathrm{SD}}(\mathscr{E})$ [53] (also see Refs. [70, Eq. (19)] and [71, Theorem 1]), and it follows that

$$
\begin{align*}
P_{\mathrm{err}}^{\mathrm{SD}}(\mathscr{E}) & =1-\inf _{\sigma \in \operatorname{Herm}}\left\{\operatorname{Tr}[\sigma]: \sigma \geq p_{x} \rho_{x} \forall x \in[r]\right\}  \tag{D13}\\
& =1-\inf _{\sigma \in \mathrm{PSD}_{A}}\left\{\operatorname{Tr}[\sigma]: I_{X} \otimes \sigma_{A} \geq \varrho_{X A}\right\}  \tag{D14}\\
& =1-\inf _{\tau \in \mathrm{D}_{A}} \inf _{\mu \in[0,+\infty)}\left\{\mu: \mu I_{X} \otimes \tau_{A} \geq \varrho_{X A}\right\}  \tag{D15}\\
& =1-\inf _{\tau \in \mathrm{D}_{A}} \inf _{\mu \in[0,+\infty)} \sup _{\Lambda \in \mathrm{PSD}_{X A}}\left\{\mu+\operatorname{Tr}\left[\Lambda_{X A}\left(\varrho_{X A}-\mu I_{X} \otimes \tau_{A}\right)\right]\right\}  \tag{D16}\\
& =1-\inf _{\tau \in \mathrm{D}_{A}} \inf _{\mu \in[0,+\infty)} \sup _{\Lambda \in \operatorname{PSD_{XA}}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]+\mu\left(1-\operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right]\right)\right\}  \tag{D17}\\
& \leq 1-\inf _{\tau \in \mathrm{D}_{A}} \sup _{\Lambda \in \mathrm{PSD}_{A}} \inf _{\mu \in[0,+\infty)}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]+\mu\left(1-\operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right]\right)\right\}  \tag{D18}\\
& =1-\inf _{\tau \in \mathrm{D}_{A}} \sup _{\Lambda \in \mathrm{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \operatorname{Tr}\left[\Lambda_{X A}\left(I_{X} \otimes \tau_{A}\right)\right] \leq 1\right\}  \tag{D19}\\
& \leq 1-\inf _{\tau \in \mathrm{D}_{A}} \sup _{\Lambda \in \mathrm{PSD}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A} \varrho_{X A}\right]: \Lambda_{X A} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}\left(\pi_{X} \otimes \tau_{A}\right)\right] \leq \frac{1}{r}\right\} \tag{D20}
\end{align*}
$$

$$
\begin{align*}
& =\sup _{\tau \in \mathrm{D}_{A}} \inf _{\Lambda^{\prime} \in \mathrm{PSD} \mathrm{D}_{X A}}\left\{\operatorname{Tr}\left[\Lambda_{X A}^{\prime} \varrho_{X A}\right]: \Lambda_{X A}^{\prime} \leq I_{X A}, \operatorname{Tr}\left[\Lambda_{X A}^{\prime}\left(\pi_{X} \otimes \tau_{A}\right)\right] \geq 1-\frac{1}{r}\right\}  \tag{D21}\\
& =\sup _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} \exp \left(-D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)\right) \tag{D22}
\end{align*}
$$

Here (D13) is the dual SDP formulation of $P_{\text {err }}^{\mathrm{SD}}(\mathscr{E})$; Eq. (D15) applies the substitution $\sigma=\mu \tau$ and uses the fact that $\mu=0$ is a feasible solution to the optimisation; Eq. (D16) introduces $\Lambda \in \mathrm{PSD}_{X A}$ as the Lagrange multiplier corresponding to the constraint $\mu I_{X} \otimes \tau_{A} \geq \varrho_{X A}$; Eq. (D18) follows from an exchange in order between the infimum and supremum; Eq. (D19) follows from a reverse Lagrangian reasoning that eliminates the multiplier $\mu$; Eq. (D20) uses the fact that an additional constraint on $\Lambda$ does not increase the optimal value of the objective function; Eq. (D21) applies the substitution $\Lambda=I-\Lambda^{\prime}$. Combining (D12) and (D22) leads to the desired statement.

## Appendix E: A closed-form converse bound on the error probability of state exclusion

Let $\rho \in \mathrm{D}_{A}$ be a state, and let $\sigma \in \mathrm{PSD}_{A}$ be a positive semidefinite operator. For $\alpha \in(1,2]$, the Petz-Rényi divergence is defined as $[56,57]$

$$
D_{\alpha}(\rho \| \sigma):= \begin{cases}\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\rho^{\alpha} \sigma^{1-\alpha}\right] & \text { if } \operatorname{supp}(\rho) \subseteq \operatorname{supp}(\sigma)  \tag{E1}\\ +\infty & \text { otherwise }\end{cases}
$$

The Petz-Rényi divergence obeys the DPI, and it is additive, monotonically nondecreasing in $\alpha$, and jointly quasi-convex [72]. Moreover, it is monotonically nonincreasing in its second argument [4, Proposition 7.26.4]: for all $\alpha \in(1,2]$,

$$
\begin{equation*}
D_{\alpha}\left(\rho \| \sigma+\sigma^{\prime}\right) \leq D_{\alpha}(\rho \| \sigma) \quad \forall \rho \in \mathrm{D}_{A}, \sigma, \sigma^{\prime} \in \mathrm{PSD}_{A} \tag{E2}
\end{equation*}
$$

This implies a supremum representation of the Petz-Rényi divergence [4, Propositions 7.21]: for all $\alpha \in(1,2]$,

$$
\begin{equation*}
D_{\alpha}(\rho \| \sigma)=\sup _{\varepsilon \in(0,+\infty)} \frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\rho^{\alpha}(\sigma+\varepsilon I)^{1-\alpha}\right] \tag{E3}
\end{equation*}
$$

The Petz-Rényi divergence provides an upper bound on the sandwiched Rényi divergence [28] and a lower bound on the geometric Rényi divergence [33, 35]: for all $\alpha \in(1,2]$,

$$
\begin{equation*}
\widetilde{D}_{\alpha}(\rho \| \sigma) \leq D_{\alpha}(\rho \| \sigma) \leq \widehat{D}(\rho \| \sigma) \quad \forall \rho \in \mathrm{D}_{A}, \sigma \in \mathrm{PSD}_{A} \tag{E4}
\end{equation*}
$$

For a bipartite state $\rho \in \mathrm{D}_{A B}$ and a state $\sigma \in \mathrm{D}_{A}$, the Petz-Rényi lautum information ${ }^{5}$ is defined as

$$
\begin{equation*}
L_{\alpha}(A ; B)_{\rho \mid \sigma}:=\inf _{\tau \in \mathrm{D}_{B}} D_{\alpha}\left(\sigma_{A} \otimes \tau_{B} \| \rho_{A B}\right) \tag{E5}
\end{equation*}
$$

If $A$ is a classical system, then the Petz-Rényi lautum information is also called the Petz-Rényi oveloH information. ${ }^{6}$

[^4]Lemma 3 (Closed-form expression for the Petz-Rényi lautum information). Let $\rho \in \mathrm{PSD}_{A B}$ be a positive semidefinite operator, and let $\sigma \in \mathrm{D}_{A}$ be a state. Define the following state:

$$
\begin{equation*}
\tau_{\star}:=\frac{\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}}{\operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]} \tag{E6}
\end{equation*}
$$

If $\operatorname{supp}\left(\sigma_{A} \otimes \tau_{\star, B}\right) \subseteq \operatorname{supp}\left(\rho_{A B}\right)$, then for all $\alpha \in(1,2]$,

$$
\begin{align*}
L_{\alpha}(A ; B)_{\rho \mid \sigma} & =D_{\alpha}\left(\sigma_{A} \otimes \tau_{\star, B} \| \rho_{A B}\right)  \tag{E7}\\
& =-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right] . \tag{E8}
\end{align*}
$$

Proof. For all $\tau \in \mathrm{D}_{B}$ such that $\operatorname{supp}\left(\sigma_{A} \otimes \tau_{B}\right) \subseteq \operatorname{supp}\left(\rho_{A B}\right)$, it follows from (E1) that

$$
\begin{align*}
D_{\alpha}\left(\sigma_{A} \otimes \tau_{B} \| \rho_{A B}\right) & =\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\left(\sigma_{A}^{\alpha} \otimes \tau_{B}^{\alpha}\right) \rho_{A B}^{1-\alpha}\right]  \tag{E9}\\
& =\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\tau_{B}^{\alpha} \operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right]  \tag{E10}\\
& =\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\tau_{B}^{\alpha}\left(\tau_{\star, B} \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]\right)^{1-\alpha}\right]  \tag{E11}\\
& =\frac{1}{\alpha-1} \ln \operatorname{Tr}\left[\tau^{\alpha} \tau_{\star}^{1-\alpha}\right]-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]  \tag{E12}\\
& =D_{\alpha}\left(\tau \| \tau_{\star}\right)-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right] . \tag{E13}
\end{align*}
$$

Here (E11) follows from (E6); Eq. (E13) follows from (E1). Since $\operatorname{supp}\left(\sigma_{A} \otimes \tau_{\star, B}\right) \subseteq \operatorname{supp}\left(\rho_{A B}\right)$, it follows from (E5) and (E13) that

$$
\begin{align*}
L_{\alpha} & (A ; B)_{\rho \mid \sigma} \\
& =\inf _{\tau \in \mathrm{D}_{B}} D_{\alpha}\left(\sigma_{A} \otimes \tau_{B} \| \rho_{A B}\right)  \tag{E14}\\
& =\inf _{\tau \in \mathrm{D}_{B}}\left\{D_{\alpha}\left(\tau \| \tau_{\star}\right)-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]: \operatorname{supp}\left(\sigma_{A} \otimes \tau_{B}\right) \subseteq \operatorname{supp}\left(\rho_{A B}\right)\right\}  \tag{E15}\\
& =-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{A}\left[\sigma_{A}^{\alpha} \rho_{A B}^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right] . \tag{E16}
\end{align*}
$$

Here the infimum on $\tau \in \mathrm{D}_{B}$ in (E15) is achieved by $\tau_{\star}$, using the fact that $D_{\alpha}\left(\tau \| \tau_{\star}\right) \geq$ $D_{\alpha}\left(\tau_{\star} \| \tau_{\star}\right)=0$ for all $\tau \in \mathrm{D}_{B}$.

Proposition 10 (Closed-form converse bound on the error probability). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. Then for all $\alpha \in(1,2]$,

$$
\begin{equation*}
-\ln P_{\mathrm{err}}(\mathscr{E}) \leq \lim _{\varepsilon \searrow 0}-\ln \operatorname{Tr}\left[\left(\sum_{x \in[r]}\left(p_{x} \rho_{x}+\varepsilon I\right)^{1-\alpha}\right)^{\frac{1}{1-\alpha}}\right] \tag{E17}
\end{equation*}
$$

$$
\begin{equation*}
=-\ln \operatorname{Tr}\left[\left(\sum_{x \in[r]}\left(p_{x} \Pi \rho_{x} \Pi\right)^{1-\alpha}\right)^{\frac{1}{1-\alpha}}\right] \tag{E18}
\end{equation*}
$$

where $\Pi$ denotes the projector onto $\bigcap_{x \in[r]} \operatorname{supp}\left(\rho_{x}\right)$.
Proof. Denote

$$
\begin{equation*}
\varrho_{X A} \equiv \sum_{x \in[r]} p_{x}|x\rangle\left\langle\left. x\right|_{X} \otimes \rho_{x, A} .\right. \tag{E19}
\end{equation*}
$$

It follows from Proposition 1 that

$$
\begin{align*}
- & \ln P_{\operatorname{err}}(\mathscr{E}) \\
& =\inf _{\tau \in \operatorname{aff}\left(\mathrm{D}_{A}\right)} D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)  \tag{E20}\\
& \leq \inf _{\tau \in \mathrm{D}_{A}} D_{\mathrm{H}}^{1-\frac{1}{r}}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)  \tag{E21}\\
& =\inf _{\tau \in \mathrm{D}_{A}} \widetilde{D}_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{E22}\\
& \leq \inf _{\tau \in \mathrm{D}_{A}} D_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{E23}\\
& =\inf _{\tau \in \mathrm{D}_{A}} \sup _{\varepsilon \in(0,+\infty)} D_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}+\varepsilon I_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{E24}\\
& =\sup _{\varepsilon \in(0,+\infty)} \inf _{\tau \in \mathrm{D}_{A}} D_{\alpha}\left(\pi_{X} \otimes \tau_{A} \| \varrho_{X A}+\varepsilon I_{X A}\right)+\frac{\alpha}{\alpha-1} \ln r  \tag{E25}\\
& =\sup _{\varepsilon \in(0,+\infty)} L_{\alpha}(X ; A)_{\varrho+\varepsilon I \mid \pi}+\frac{\alpha}{\alpha-1} \ln r  \tag{E26}\\
& =\sup _{\varepsilon \in(0,+\infty)}-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{X}\left[\pi_{X}^{\alpha}\left(\varrho_{X A}+\varepsilon I_{X A}\right)^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]+\frac{\alpha}{\alpha-1} \ln r  \tag{E27}\\
& =\sup _{\varepsilon \in(0,+\infty)}-\ln \operatorname{Tr}\left[\left(\operatorname{Tr}_{X}\left[\sum_{x \in[r]} \frac{p_{x}^{1-\alpha}}{r^{\alpha}}|x\rangle\left\langle\left. x\right|_{X} \otimes\left(\rho_{x, A}+\varepsilon I_{A}\right)^{1-\alpha}\right]\right)^{\frac{1}{1-\alpha}}\right]+\frac{\alpha}{\alpha-1} \ln r\right.  \tag{E28}\\
& =\sup _{\varepsilon \in(0,+\infty)}-\ln \operatorname{Tr}\left[\left(\sum_{x \in[r]}\left(p_{x} \rho_{x}+\varepsilon I\right)^{1-\alpha}\right)^{\frac{1}{1-\alpha}}\right]  \tag{E29}\\
= & \lim _{\varepsilon \searrow 0}-\ln \operatorname{Tr}\left[\left(\sum_{x \in[r]}\left(p_{x} \rho_{x}+\varepsilon I\right)^{1-\alpha}\right)^{\frac{1}{1-\alpha}}\right] . \tag{E30}
\end{align*}
$$

Here (E22) follows from Lemma 2; Eq. (E23) follows from the order between the sandwiched Rényi and Petz-Rényi divergences (see (E4)); Eq. (E24) uses the supremum representation of the Petz-Rényi divergence (see (E3)); Eq. (E25) applies the Mosonyi-Hiai minimax theorem [58, Corollary A.2]; Eq. (E26) follows from the definition of the Petz-Rényi lautum information (see
(E5)); Eq. (E27) follows from Lemma 3; Eq. (E30) uses the nonincreasing monotonicity of the Petz-Rényi divergence in its second argument (see (E2)). The application of the Mosonyi-Hiai minimax theorem in (E25) is justified by the following observations: the feasible region of $\tau$ is convex and compact; the objective function is monotonically nonincreasing in $\varepsilon$ (see (E2)), and it is lower-semicontinuous in $\tau$ due to the continuity of the Petz-Rényi divergence (see (E1)) when the support of its first argument is contained in that of its second argument. Equation (E18) follows straightforwardly from (E30).

## Appendix F: Exact error exponent of state exclusion between multiple pure states

Proposition 11 (Exact error exponent for pure states). Let $\mathscr{E} \equiv\left(p_{[r]}, \rho_{[r]}\right)$ be an ensemble of states with $p_{[r]} \in \operatorname{int}\left(\mathrm{P}_{r}\right)$ and $\rho_{[r]} \in \mathrm{D}_{A}^{[r]}$. If there exists $\left\{x_{1}, x_{2}, x_{3}\right\} \subseteq[r]$ such that $\rho_{x_{1}}, \rho_{x_{2}}$, and $\rho_{x_{3}}$ are three distinct pure states, then

$$
\begin{equation*}
\lim _{n \rightarrow \infty}-\frac{1}{n} \ln P_{\mathrm{err}}\left(\mathscr{E}^{(n)}\right)=+\infty . \tag{F1}
\end{equation*}
$$

Proof. Let $\rho_{x_{1}} \equiv\left|\psi_{x_{1}}\right\rangle\left\langle\psi_{x_{1}}\right|, \rho_{x_{2}} \equiv\left|\psi_{x_{2}}\right\rangle\left\langle\psi_{x_{2}}\right|$, and $\rho_{x_{3}} \equiv\left|\psi_{x_{3}}\right\rangle\left\langle\psi_{x_{3}}\right|$ be three distinct pure states such that $\left\{x_{1}, x_{2}, x_{3}\right\} \subseteq[r]$. Denote $a \equiv\left|\left\langle\psi_{x_{1}} \mid \psi_{x_{2}}\right\rangle\right|^{2}, b \equiv\left|\left\langle\psi_{x_{2}} \mid \psi_{x_{3}}\right\rangle\right|^{2}$, and $c \equiv\left|\left\langle\psi_{x_{3}} \mid \psi_{x_{1}}\right\rangle\right|^{2}$. According to Ref. [6, Section V.B] (also see Ref. [9, Eq. (9)]), the tuple of three pure states ( $\rho_{x_{1}}, \rho_{x_{2}}, \rho_{x_{3}}$ ) is perfectly antidistinguishable by an orthogonal rank-1 projective measurement if and only if

$$
\left\{\begin{array}{l}
a+b+c<1  \tag{F2}\\
(a+b+c-1)^{2} \geq 4 a b c
\end{array}\right.
$$

Define $m:=\max \{a, b, c\}<1$. Let $n^{\prime}$ be a finite positive integer such that $m^{n^{\prime}} \leq \frac{1}{4}$. It follows that

$$
\begin{align*}
a^{n^{\prime}}+b^{n^{\prime}}+c^{n^{\prime}} \leq 3 m^{n^{\prime}} \leq \frac{3}{4}<1,  \tag{F3}\\
\left(a^{n^{\prime}}+b^{n^{\prime}}+c^{n^{\prime}}-1\right)^{2} \geq\left(1-3 m^{n^{\prime}}\right)^{2} \geq \frac{1}{16} \geq 4\left(m^{n^{\prime}}\right)^{3} \geq 4 a^{n^{\prime}} b^{n^{\prime}} c^{n^{\prime}} . \tag{F4}
\end{align*}
$$

This implies, according to the criterion in (F2), that the $n^{\prime}$-fold tuple of pure states ( $\rho_{x_{1}}^{\otimes n^{\prime}}, \rho_{x_{2}}^{\otimes n^{\prime}}, \rho_{x_{3}}^{\otimes n^{\prime}}$ ) is perfectly antidistinguishable. In addition, the $n^{\prime}$-fold tuple of the original $r$ states $\rho_{[r r]}^{\left(n^{\prime}\right)}$ is also perfectly antidistinguishable, since any exclusion strategy that incurs no error on ( $\rho_{x_{1}}^{\otimes n^{\prime}}, \rho_{x_{2}}^{\otimes n^{\prime}}, \rho_{x_{3}}^{\otimes n^{\prime}}$ ) also incurs no error on $\rho_{[r]}^{\left(n^{\prime}\right)}$. Consequently, there exists a finite $n^{\prime}$ such that $P_{\text {err }}\left(\mathscr{E}^{(n)}\right)=0$ for all $n \geq n^{\prime}$, which leads to (F1).

Remark 10 (On the infinite error exponent for pure states). While the error exponent of state exclusion between two distinct pure states is finite unless the states are orthogonal [51, 52], the error exponent for three or more distinct pure states is always infinite, regardless of their orthogonality. In addition, the error exponent being infinite does not mean that the states are perfectly antidistinguishable. As implied by the proof of Proposition 11, it is possible that the error probability reaches strictly zero within a finite number of shots but has a nonzero value in the one-shot regime.

    ${ }^{\dagger}$ milan.mosonyi@gmail.com
    § wilde@cornell.edu

[^1]:    ${ }^{1}$ In Ref. [40, Eq. (IV.15)], the term " $\boldsymbol{D}$-radius" originally refers to the intuitive representation in (17) with $\tau$ and $\rho_{x}$ in reverse order. For our purposes, we adopt the other representation in (16) as a definition and use the term "left $\boldsymbol{D}$-radius" (first used in Ref. [22]) to signify the reverse order of $\tau$ and $\rho_{x}$ here compared to the convention in Ref. [40].

[^2]:    ${ }^{2}$ However, there are alternative expressions (see, e.g., Refs. [29, Definition 2] and [28, Eq. (4)]) for the original sandwiched Rényi divergence that are equivalent to (6) on states but not well defined (let alone being equivalent to (43)) when the first argument is a Hermitian operator.

[^3]:    ${ }^{3}$ In comparison, in quantum state discrimination, the experimenter's goal is to submit an index equal to the actual label of the state.
    ${ }^{4}$ Note that $P_{\text {err }}(\mathscr{E})=0$ if and only if there exists a POVM $\Lambda_{[r]} \in \mathrm{M}_{A, r}$ such that $\operatorname{Tr}\left[\Lambda_{x} \rho_{x}\right]=0$ for all $x \in[r]$. This implies that perfect antidistinguishability is a property of the tuple of states $\rho_{[r]}$ and is independent of the prior probability distribution $p_{[r]}$.

[^4]:    ${ }^{5}$ The word "lautum" is "mutual" spelled in reverse order; also see Ref. [73].
    ${ }^{6}$ The word "oveloH" is "Holevo" spelled in reverse order; also see Ref. [44, Eq. (5.133)].
