## Signalling and Control in Nonlinear Stochastic Systems: An Information State Approach with Applications

Charalambos D. Charalambous<sup>1</sup> and Stelios Louka<sup>2</sup>

Abstract-We consider optimal signalling and control of discrete-time nonlinear partially observable stochastic systems in state space form. In the first part of the paper, we characterize the operational control-coding capacity,  $C_{FB}$  in bits/second, by an information theoretic optimization problem of encoding signals or messages into randomized controllerencoder strategies, and reproducing the messages at the output of the system using a decoder or estimator with arbitrary small asymptotic error probability. Our analysis of  $C_{FB}$  is based on realizations of randomized strategies (controllerencoders), in terms of information states of nonlinear filtering theory, and either uniform or arbitrary distributed random variables (RVs). In the second part of the paper, we analyze the linear-quadratic Gaussian partially observable stochastic system (LQG-POSS). We show that simultaneous signalling and control leads to randomized strategies described by finitedimensional sufficient statistics, that involve two Kalman-filters, and consist of control, estimation and signalling strategies. We apply decentralized optimization techniques to prove a separation principle, and to derive the optimal control part of randomized strategies explicitly in terms of a control matrix difference Riccati equation (DRE).

#### I. INTRODUCTION, MAIN RESULTS, LITERATURE

In this paper we analyze the problem of simultaneous signalling and control for partially observable discrete-time nonlinear stochastic control systems, with respect to an average pay-off. Our protocol for simultaneous signalling and control is a slight generalization of Shannon's [1] operation definition for reliable communication of signals or messages over noisy channels, subject to a total transmitter power constraint of  $\kappa \in [0,\infty)$  units of power, called *coding rate and coding* capacity, in the theory of information transmission [2]-[4]. By analogy to Shannon [1], we quantify an achievable control-coding (CC) rate R in bits/second, by the number of messages that can be encoded into randomized control strategies (consisting of controller, encoder and estimation strategies) subject to the average pay-off constraint, and reproduced by the decoder or estimator at the output of the stochastic control system, with arbitrary small asymptotic error probability. We call the maximum achievable CC rate the *control-coding capacity*,  $C_{FB}(\kappa)$  bits/second, of the stochastic control system. Embedded in the operational definition of an achievable CC rate is the dual role of randomized control strategies,

(1) to control the state of the stochastic control system while meeting the average pay-off constraint at each time instant and asymptotically, and

(2) to signal the messages encoded into the randomized control strategies using the stochastic control system as a communication channel, and to reproduce the messages at the output of the decoder, with arbitrary small asymptotic error probability.

Our first goal is to characterize  $C_{FB}(\kappa)$  as function of  $\kappa \in [0, \infty)$ , by an information theoretic optimization problem over randomized strategies subject to the average pay-off constraint, using nonlinear filtering theory and sufficient statistics. The analysis of  $C_{FB}(\kappa)$  includes as degenerate cases, many problems of classical stochastic optimal control theory. In particular, for signalling to occur it is necessary that  $C_{FB}(\kappa) \in (0,\infty)$  for  $\kappa \in (\kappa_{min},\infty)$ , where  $\kappa_{min}$  is precisely the minimum asymptotic average pay-off over deterministic control strategies (i.e., nonrandomized) of the partially observable nonlinear stochastic system [5] [6]–[8].

Our second goal is to characterize  $C_{FB}(\kappa)$  for partially observable stochastic Linear-Quadratic-Gaussian (LQG) control systems. The analysis of of  $C_{FB}(\kappa)$  includes as degenerate cases, many noisy communication channels with memory, often used in communication applications, such as, channels with Gaussian noise represented by state space models [9]–[15], molecular communication channels [16], [17], communication channels with finite states known to the encoder and/or the decoder [2], [18], [18]–[22], etc.

In the rest of this section, we present the problem formulation, a brief summary of our main results, followed by their relations to past literature.

### A. Problem Formulations and Main Results

1) Nonlinear Partially Observable Stochastic System (N-POSS): We consider a N-POSS with inputs  $A^n \stackrel{\triangle}{=} \{A_1, \ldots, A_n\}, A_t : \Omega \to \mathbb{A}$ , outputs  $Y^n \stackrel{\triangle}{=} \{Y_1, \ldots, Y_n\}, Y_t : \Omega \to \mathbb{Y}$ , and states  $X^n \stackrel{\triangle}{=} \{X_1, \ldots, X_n\}, X_t : \Omega \to \mathbb{X}$ , with conditional distributions,  $\forall t \in \mathbb{Z}_+^n \stackrel{\triangle}{=} \{1, 2, \ldots, n\}$ :

$$\mathbb{P}\left\{X_{t+1} \in dx_{t+1} | Y_t, X_t, A_t\right\} = \mathbf{P}_{X_{t+1}|Y_t, X_t, A_t}$$
  
=  $S_{t+1}(dx_{t+1}|Y_t, X_t, A_t),$  (I.1)

$$\mathbb{P}\{Y_t \in dy_t | X_t, A_t\} = \mathbf{P}_{Y_t | X_t, A_t} = Q_t(dy_t | X_t, A_t).$$
(1.2)

These distributions are induced by the nonlinear recursive equations subject to an average cost constraint:

$$X_{t+1} = f_t(X_t, A_t, W_t), \quad X_1 = x_1, \quad \forall t \in \mathbb{Z}_+^{n-1},$$
 (I.3)

$$Y_t = h_t(X_t, A_t, W_t), \quad \forall t \in \mathbb{Z}_+^n, \tag{I.4}$$

$$\frac{1}{n}\mathbf{E}\left\{c_{n}(A^{n},X^{n})\right\} \leq \kappa \in [0,\infty),\tag{I.5}$$

<sup>&</sup>lt;sup>1</sup>C. D. Charalambous (Bambos) is with the Faculty of Department of Electrical and Computer Engineering, University of Cyprus, Nicosia, Cyprus chadcha@ucy.ac.cy

 $<sup>^{2}</sup>$ S. Louka is a Ph.D. student with the Department of Electrical and Computer Engineering, University of Cyprus, Nicosia, Cyprus slouka01@ucy.ac.cy

$$\mathbf{P}_{X_1,W^n} = P_{X_1} \times \prod_{t=1}^n \mathbf{P}_{W_t} \quad (W^n \text{ indep. and inde. of } X_1).$$
(I.6)

Here,  $W^n \stackrel{\triangle}{=} \{W_1, \ldots, W_n\}, W_t : \Omega \to \mathbb{W}$  is the noise process, and  $f_t(\cdot), h_t(\cdot), c_n(\cdot), \forall t$  are measurable functions. The cost function  $c_n(\cdot)$  depends on  $(A^n, X^n)$  to reflect the cost of controlling  $(X^n, Y^n)$  via  $A^n$ . Throughout the paper, unless otherwise stated,  $(\mathbb{A}, \mathbb{Y}, \mathbb{X}, \mathbb{W})$ , are abstract Borel spaces, which include finite-alphabet spaces, finite-dimensional Euclidean spaces, etc. The N-POSS may correspond to stable/unstable control or communication channels with state  $X^n$  [6].

Operational Signalling and Control Protocol. Given the N-POSS, we consider a code denoted by  $\{(n, \mathcal{M}^{(n)}, \varepsilon_n, \kappa) | n = 1, ... \}$ , as follows.

(a) Uniformly distr. messages  $M : \Omega \to \mathcal{M}^{(n)} \stackrel{\triangle}{=}$  $\{1, 2, \ldots, M^{(n)}\}.$ 

(b) Controller-Encoder strategies  $g^n(\cdot) \stackrel{\triangle}{=} (g_1(\cdot), \dots, g_n(\cdot))$ mapping messages M, and feedback information into inputs<sup>1</sup>,  $A_1 = g_1(M), A_2 = g_2(M, g_1(M), Y_1), A_3 =$  $g_3(M, g_1(M), g_2(M, g_1(M), Y_1), Y^2), \dots, \text{ of block length}$ *n*, defined by<sup>2</sup>

$$\mathscr{E}_n(\kappa) \triangleq \left\{ g_t : \mathscr{M}^{(n)} \times \mathbb{A}^{t-1} \times \mathbb{Y}^{t-1} \to \mathbb{A}_t, A_1 = g_1(M), \right.$$

$$A_{2} = g_{2}(M, g_{1}(M), Y_{1}), \dots, A_{n} = g_{n}(M, g^{n-1}(M, Y^{n-2}), Y^{n-1}) |$$

condition (C1)) holds, 
$$\frac{1}{n} \mathbf{E}^g \{ c_n(A^n, X^n) \} \le \kappa \},$$
 (I.7)

(C1) 
$$\mathbf{P}_{A_t|A^{t-1},Y^{t-1},W^t,X^t} = \mathbf{P}_{A_t|A^{t-1},Y^{t-1}}, \forall t \in \mathbb{Z}_+^n.$$
 (I.8)

Conditional independence (C1) is equivalent to the Markov chain (MC),  $(W^t, X^t) \leftrightarrow (A^{t-1}, Y^{t-1}) \leftrightarrow A_t, \forall t \in \mathbb{Z}_+^n$ . We assume  $(X_1, W^n)$  is independent of the messages *M*. The information to the controller-encoder strategies is  $\mathscr{I}_{t}^{g} \stackrel{\triangle}{=} \{M, A^{t-1}, Y^{t-1}\}, A_{t} = g_{t}(\mathscr{I}_{t}^{g}), \forall t \in \mathbb{Z}_{+}^{n}.$ (c) Decoder function,  $y^{n} \mapsto d_{n}(y^{n}) \in \mathscr{M}^{(n)}$ , with average error probability  $\mathbf{P}_{e}^{(n)} = \frac{1}{M^{(n)}} \sum_{i=1}^{M^{(n)}} \mathbb{P}\{d_{n}(Y^{n}) \neq i | M = i\} = 0$ 

 $\varepsilon_n \in [0,1].$ 

A rate R is called an *achievable CC rate*, if there exists a controller-encoder and a decoder sequence satisfying  $\lim_{n\to\infty} \varepsilon_n = 0$  and  $\liminf_{n\to\infty} \frac{1}{n} \log M^{(n)} \ge R$ . The operational definition of the CC capacity is  $C_{FB}(\kappa) \triangleq$  $\sup\{R | R \text{ is achievable}\}.$ 

Main Results of N-POSS. Our main results include the following.

1.1) Analysis of the sequential information theoretic characterization of CFB under Dobrushin's information stability [23] defined by (see [15])

$$C_{FB}(\kappa) \stackrel{\triangle}{=} \lim_{n \to \infty} \frac{1}{n} C_{n,FB}(\kappa), \tag{I.9}$$

$$C_{FB,n}(\kappa) = \sup_{\mathcal{P}_n \stackrel{\triangle}{=} \{P_t(da_t | a^{t-1}, y^{t-1})\}_{t=1}^n, \frac{1}{n} \mathbf{E}^P\{c_n(A^n, X^n)\} \le \kappa}$$
(I 10)

 $^{1}(A_{t} = A_{t}^{g}, Y_{t} = Y^{g}, X_{t} = X_{t}^{g})$  since these are generated from  $g(\cdot)$ .

<sup>2</sup>The superscript on expectation operator  $\mathbf{E}^{g}$  indicates that the corresponding distribution  $\mathbf{P} = \mathbf{P}^{\hat{g}}$  depends the encoding strategy g.

$$I^{P}(A^{n} \to Y^{n}) \stackrel{\triangle}{=} \sum_{t=1}^{n} I^{P}(A^{t}; Y_{t} | Y^{t-1}), \qquad (I.11)$$

$$I^{P}(A^{t};Y_{t}|Y^{t-1}) = H^{P}(Y_{t}|Y^{t-1}) - H^{P}(Y_{t}|Y^{t-1},A^{t})$$
 (I.12)

where  $H^{P}(\cdot|\cdot)$  denotes conditional (differential) entropy [3].

Cost-Rate Optimization Problem. A dual optimization problem to  $C_{FB,n}(\kappa)$  is the cost-rate optimization problem defined by

$$\kappa_n(C) \triangleq \inf_{\mathscr{P}_n, \text{ such that } \frac{1}{n}I(A^n \to Y^n) \ge C} \mathbf{E}^P \{ c_n(A^n, X^n) \} \quad (I.13)$$

where  $C \in [0,\infty]$ . By [15],  $\kappa_n(C)$  is a convex non-decreasing function in  $C \in (0,\infty)$ . Next, we relate  $\kappa_n(C)$  to classical stochastic optimal control.

Relation to Classical Stochastic Optimal Control Problems. Let  $\mathscr{E}_n^D$  denote the restriction of randomized strategies  $\mathscr{P}_n$  to the set of deterministic strategies  $\mathscr{E}_n^D \triangleq \{a_j =$  $e_i(a^{j-1}, y^{j-1})|j = 1, \dots, n$ . Define the two stochastic optimal control problems with randomized and deterministic strategies, respectively, by

$$J_n^{SC}(P^*) \stackrel{\triangle}{=} \inf_{\mathscr{P}_n} \mathbf{E}^P \big\{ c_n(A^n, X^n) \big\}, \ J_n^{SC}(e^*) \stackrel{\triangle}{=} \inf_{\mathscr{E}_n^D} \mathbf{E}^e \big\{ c_n(A^n, X^n) \big\}$$

Using the fact that deterministic strategies in  $J_n^{SC}(e^*)$  (when they exists) achieve the performance of randomized strategies in  $J_n^{SC}(P^*)$  (see [24]), we also have (by  $I(A^n \to Y^n) \ge 0$ ),

$$\frac{1}{n}\kappa_n(C) \geq \frac{1}{n}\kappa_n(C)\big|_{C=0} = \frac{1}{n}J_n^{SC}(P^*) = \frac{1}{n}J_n^{SC}(e^*) = \kappa_{n,min}.$$

Consequently,  $\kappa_{n,min} \in [0,\infty)$  is the minimum cost required to control the N-POSS with zero signalling rate. The cost of information signalling at a rate  $C \in (0,\infty)$  is  $\kappa(C) - \kappa(0) \stackrel{\scriptscriptstyle \bigtriangleup}{=}$  $\lim_{n \to \infty} \frac{1}{n} \kappa_n(C) - \lim_{n \to \infty} \frac{1}{n} \kappa_n(0)$  provided the supremums and limits exist and they are finite. For a non-zero CC rate,  $C_{FB}(\kappa) \stackrel{\triangle}{=} \lim_{n \to \infty} \frac{1}{n} C_{FB,n}(\kappa) \in (0,\infty)$ , it is necessary that  $\kappa$  exceeds the critical value  $\kappa_{min} \stackrel{\triangle}{=} \kappa(0)$ . Hence,  $\kappa_{min} = \lim_{n \longrightarrow \infty} \frac{1}{n} J_n^{SC}(e^*)$  is precisely the asymptotic minimum cost of the classical stochastic optimal control with partial observations (i.e., corresponding to zero information signalling).

Our analysis is based on generalizations of the concepts of the "information state" and "sufficient statistic" often used in stochastic optimal control theory with deterministic or nonrandomized strategies [5], [25]-[27]. In particular, for the analysis of  $C_{FB,n}(\kappa)$  (and hence  $C_{FB}(\kappa)$ ) we show the following main results.

1.2) Theorem II.2. A sufficient statistic for the input distribution is (i) the information state defined by the a posteriori conditional distribution  $\xi_t(A^{t-1}, Y^{t-1}) \stackrel{\triangle}{=} \mathbf{P}_{\mathbf{X}, |A^{t-1}, Y^{t-1}, \forall t \in \mathbf{Y}$  $Y^n$ ),  $\mathbb{Z}^n_+$ , and (ii) independent uniformly distributed RVs  $U^n \stackrel{ riangle}{=}$  $\{U_1,\ldots,U_n\}, U_t: \Omega \to \mathbb{U} \stackrel{\triangle}{=} [0,1],$  with distribution  $\mathbf{P}_{U_i}$ , in the sense that, there exists functions  $\mu_t^u(\cdot)$  such that

$$A_{t} = \mu_{t}^{u}(\xi_{t}(A^{t-1}, Y^{t-1}), U_{t}), \quad \forall t \in \mathbb{Z}_{+}^{n},$$
(I.14)  
$$P_{t}(da_{t}|a^{t-1}, y^{t-1}) = \mathbf{P}_{U_{t}}(u_{t} \in \mathbb{U} | \mu_{t}^{u}(\xi_{t}(a^{t-1}, y^{t-1}), u_{t}) \in da_{t}).$$

We also show that strategies (I.14) can be replaced by another function  $\mu^{z}(\cdot, Z_{t})$ , with  $U^{n}$  replaced by arbitrary independent RVs  $Z^{n}, Z_{t} : \Omega \to \mathbb{Z}$  with distribution  $\mathbf{P}_{Z_{t}}$ .

1.3) Theorem II.3. Equivalent expressions of  $C_{FB,n}(\kappa)$  using  $\mu^{\mu}(\cdot)$  and  $\mu^{z}(\cdot)$ , with  $I^{P}(A^{n} \to y^{n}) = I^{\mu^{\mu}}(U^{n} \to Y^{n}) = I^{\mu^{z}}(Z^{n} \to Y^{n})$ .

2) Linear-Quadratic-Gaussian Decision Model (LQG-POSS): We analyze (the multiple-input multiple output (MIMO)) LQG-POSS with  $A_t : \Omega \to \mathbb{R}^{n_a}$ ,  $X_t : \Omega \to \mathbb{R}^{n_x}$ ,  $Y_t : \Omega \to \mathbb{R}^{n_y}$ , correlated noise  $V_t : \Omega \to \mathbb{R}^{n_y}$ ,  $(n_a, n_y, n_v, n_x)$ positive integers, defined by

$$Y_t = D_t A_t + V_t, \quad V_t = C_t X_t + N_t W_t, \quad \forall t \in \mathbb{Z}^n_+, \tag{I.15}$$

$$X_{t+1} = F_t X_t + B_t A_t + G_t W_t, \quad \forall t \in \mathbb{Z}^{n-1}_+, \tag{I.16}$$

$$X_1 \in G(\mu_{X_1}, K_{X_1}), \quad K_{X_1} \succeq 0$$
 (pos. semi-definite), (I.17)

$$W_t \in G(0, K_{W_t}), \quad K_{W_t} \succeq 0, \quad N_t K_{W_t} N_t^T \succ 0, \quad \forall t \in \mathbb{Z}_+^n \quad (I.18)$$

$$\frac{1}{n} \mathbf{E} \{ c_n(A^n, X^n) \} \le \kappa, \quad c_n(a^n, x^n) \stackrel{\triangle}{=} \sum_{t=1}^n \gamma_i(a_t, x_t), \qquad (I.19)$$

$$\gamma_t(a_t, x_t) \stackrel{\triangle}{=} \langle a_t, R_t a_t \rangle + \langle x_t, Q_t x_t \rangle, \ Q_t \succeq 0, \ R_t \succ 0, \ \forall t \quad (I.20)$$

where  $X \in G(\mu_X, K_X)$  means the RV X is Gaussian with distribution  $\mathbf{P}_X$ , having mean  $\mu_X$  and covariance  $K_X$ , and  $\langle \cdot, \cdot \rangle$  denotes inner product. We show the following main results.

2.1) Lemma III.1, Lemma III.2.  $C_{FB,n}(\kappa)$  is a maximum entropy problem, because  $\mathbf{P}_{X_t|A^{t-1},Y^{t-1}}$  has conditional covariance  $\Sigma_t$ , independent of  $(A^{t-1},Y^{t-1})$ , satisfying a filtering matrix DRE (see (III.41)) and implies,

$$H(Y_t|Y^{t-1},A^t) = H(I_t), \quad I_t \stackrel{\triangle}{=} Y_t - \mathbf{E}\left\{Y_t|Y^{t-1},A^t\right\}, \quad \forall t \in \mathbb{Z}_+^n,$$

$$H(I_t) = \frac{1}{2} \log \left( (2\pi e)^{n_y} \det \left( C_t \Sigma_t C_t^I + N_t K_{W_t} N_t^I \right) \right).$$
(I.21)

2.2) Theorem III.1. An equivalent characterization of  $C_{FB,n}(\kappa)$  corresponding to the optimal strategy of  $A^n$  is realized by

$$A_{t} = \Gamma_{t}^{1} \hat{X}_{t} + U(Y^{t-1}) + Z_{t}, \ U(Y^{t-1}) = \Gamma_{t}^{2} \hat{X}_{t}, \ \forall t \in \mathbb{Z}_{+}^{n},$$
(I.22)
$$\hat{X}_{t} \stackrel{\triangle}{=} \mathbf{E} \{ X_{t} | Y^{t-1}, A^{t-1} \}, \ \hat{X}_{t} \stackrel{\triangle}{=} \mathbf{E} \{ \hat{X}_{t} | Y^{t-1} \}, \ Z_{t} \in G(0, K_{Z_{t}})$$

where  $Z^n$  is an independent Gaussian process, independent of  $(\hat{X}^n, \hat{\hat{X}}^n)$ . The above means, for each t,  $\mu_t^z(\cdot)$  depends on the *finite-dimensional sufficient statistic*  $(\hat{X}_t, \hat{X}_t, Z_t)$ . Moreover,  $C_{FB,n}(\kappa)$  is expressed, as a functional of two matrix DREs of filtering theory of Gaussian systems,  $\Sigma_t$ and  $K_t \stackrel{\triangle}{=} \mathbf{E}\{(\hat{X}_t - \hat{X}_t)(\hat{X}_t - \hat{X}_t)^T | Y^{t-1}\}$ , which is also independent of  $Y^{t-1}$ .

2.3) *Theorem III.1.* A decentralized separation principle holds as follows:

(i) The optimal strategy  $U(\cdot)$  is explicitly determined from the solution of a stochastic LQG optimal control problem of minimizing the average cost [6], and involves the solution of a control matrix DRE  $P_t \succeq 0$ , evolving backward in time. (ii) The optimal strategy ( $\Gamma^1, K_Z$ ) is determined by maximizing the differential entropy of  $H(Y^n)$  subject to the average constraint with optimal  $U(\cdot)$  obtained in (i).

Finally, we discuss the limit convergence,  $C_{FB} \stackrel{\triangle}{=} \lim_{n \longrightarrow \infty} \frac{1}{n} C_{FB,n}$ , using the convergence properties of matrix DRE to analogous matrix algebraic Riccati equations (AREs), as in [28, Section III].

#### B. Relations to Past Literature

 $C_{FB}(\kappa)$  of channels with memory is often characterized by directed information from the input of the channel  $A^n$  to the output of the channel  $Y^n$ , i.e.,  $I(A^n \to Y^n)$  optimized over channel inputs with feedback,  $P_t(da_t|a^{t-1}, y^{t-1}), \forall t \in \mathbb{Z}^n_+$ subject to cost constraints [29], [30]. Cover and Pombra [4, Theorem 1] characterized  $C_{FB}(\kappa)$  of additive Gaussian noise (AGN) channels,  $Y_t = X_t + V_t, \forall t \in \mathbb{Z}^n_+, \frac{1}{n} \mathbb{E}\{\sum_{t=1}^n (A_t)^2\} \le \kappa$ , with nonstationary and nonergodic jointly Gaussian noise  $V^n$ .  $C_{FB}(\kappa)$  of Cover and Pombra AGN channel is characterized in [12], [14], [31], [31] for the degenerate case when the noise is asymptotically stationary, with state space realization of  $V^n$ .  $V_t = C_t X_t + W_t$ ,  $X_{t+1} = F_t X_t + W_t$ ,  $\forall t$ , such that  $P_t(da_t|a^{t-1}, y^{t-1}) = P_t(da_t|x^t, y^{t-1})$ , i.e., the encoder distribution at each time t, knows the state of the channel  $X^{t}$  (see the hidden assumptions in [13, Theorem 6.1, Lemma 6.1] and [14]). These assumptions are explicit in the analysis in [12]. When the state  $X^n$  is not known to the encoder, a sequential version of the Cover and Pombra  $C_{FB}(\kappa)$  is first derived in [28, Theorem II.3] and is different from [13, Theorem 6.1, Lemma 6.1] and [12], [14]. The method of [28] is used in [32] to derive  $C_{FB}(\kappa)$  for MIMO channels. For finite-state channels with memory [20], [22], treated  $C_{FB}(\kappa)$ , when the state of the channel is known to the encoder.

The N-POSS (I.3)-(I.6) includes the models of the above references. More importantly, the code does not assume knowledge of the state  $X^n$  at the encoder, and  $X^n$  is affected by  $A^{n-1}$ . This generality requires additional concepts to characterize  $C_{FB}(\kappa)$ . However, in Remark III.1, we show that from  $C_{FB,n}(\kappa)$  of the LQG-POSS, we recover  $C_{FB,n}(\kappa)$  of [28], [32] and [12], [14], [31], [31] as special cases.

# II. CHARACTERIZATION OF $C_{FB,n}$ via Information State

First, we introduce the characterization of  $C_{FB,n}(\kappa)$  of the N-POSS.

## **Theorem II.1.** ( $C_{FB,n}$ with randomized strategies)

Consider the N-POSS, the code  $\{(n, \mathcal{M}^{(n)}, \varepsilon_n, \kappa)|n = 1, 2, ...\}$ , and assume the conditions of the converse/direct coding theorems in [15] hold. Define the randomized strategies  $\mathcal{P}_n(\kappa)$  by

$$\mathscr{P}_{n}(\kappa) \stackrel{\triangle}{=} \left\{ \mathbf{P}_{A_{t}|A^{t-1},Y^{t-1}} = P_{t}(da_{t}|a^{t-1},y^{t-1}), \forall t \in \mathbb{Z}_{+}^{n} \right\}$$
(C1) holds and  $\frac{1}{n} \mathbf{E}^{P}(c_{n}(X^{n},A^{n})) \leq \kappa \right\} \subseteq \mathscr{E}_{n}(\kappa)$ 

where (C1) follows from the definition of the feedback code. The directed information from  $A^n$  to  $Y^n$  is defined by

$$I^{P}(A^{n} \to Y^{n}) \stackrel{\triangle}{=} \mathbf{E}^{P} \left\{ \sum_{t=1}^{n} \log \left( \frac{\mathbf{P}^{P}_{Y_{t}|Y^{t-1},A^{t}}}{\mathbf{P}^{P}_{Y_{t}|Y^{t-1}}} \right) \right\}$$
(II.23)

where  $\mathbf{P}^{P}_{Y_{t}|Y^{t-1},A^{t}}$  and  $\mathbf{P}^{P}_{Y_{t}|Y^{t-1}}$ , for  $\forall t \in \mathbb{Z}^{n}_{+}$  are given by

$$\mathbf{P}_{Y_{t}|Y^{t-1},A^{t}}^{P} = \int_{\mathbb{X}} \mathcal{Q}_{t}(dy_{t}|x_{t},a_{t}) \mathbf{P}_{t}^{P}(dx_{t}|y^{t-1},a^{t-1}), \quad (\text{II.24})$$
$$\mathbf{P}_{Y_{t}|Y^{t-1}}^{P} = \int_{\mathbb{A}^{t} \times \mathbb{X}^{t}} \mathcal{Q}_{t}(dy_{t}|x_{t},a_{t}) P_{t}(da_{t}|y^{t-1},a^{t-1})$$

$$\mathbf{P}_{t}^{P}(dx_{t}|a^{t-1},y^{t-1})\mathbf{P}_{t}^{P}(da^{t-1}|y^{t-1}). \quad (\text{II}.25)$$

The CC capacity is given by  $C_{FB}(\kappa) \stackrel{\triangle}{=} \lim_{n \to \infty} \frac{1}{n} C_{FB,n}(\kappa)$ , where  $C_{FB,n}(\kappa) \stackrel{\triangle}{=} \sup_{\mathscr{P}_n(\kappa)} I^P(A^n \to Y^n)$ .

*Proof.* The derivation is based on of the proof of the converse/direct coding theorems in [15], hence we omit it.  $\Box$ 

In  $C_{FB,n}(\kappa)$ , the fundamental element that determines the properties of the maximizing elements  $\{P_t(da_t|a^{t-1}, y^{t-1})|t \in \mathbb{Z}_+^n\}$  is the a posteriori distribution  $\{\mathbf{P}_t^P(dx_t|a^{t-1}, y^{t-1})|t \in \mathbb{Z}_+^n\}$ , and its relation to an informations state, as defined in Appendix VI-A.

#### A. Information States and Sufficient Statistics

Now we prepare to show the statements of Section I-A.

**Lemma II.1.** (*Consistent family of randomized strategies*) (a) For any element of  $\mathscr{P}_n(\kappa)$  there exist independent uniformly distributed RVs  $U^n$ ,  $U_t : \Omega \to \mathbb{U}_t = [0,1], \forall t \in \mathbb{Z}_+^n$ , and measurable functions  $\mu_t^u(\cdot)$  of  $\{a^{t-1}, y^{t-1}, u_t\}$ , such that

 $a_{t} = \mu_{t}^{u}(a^{t-1}, y^{t-1}, u_{t}), \quad \forall t \in \mathbb{Z}_{+}^{n},$ (II.26)  $P_{t}(da_{t}|a^{t-1}, y^{t-1}) = \mathbf{P}_{U_{t}}(u_{t} \in [0,1] | \mu_{t}^{u}(a^{t-1}, y^{t-1}, u_{t}) \in da_{t}),$ (C2).  $U^{n}$  independent RVs,  $U_{t}$  independent of  $(W^{t}, X_{1}),$ 

$$\mathbf{P}_{A_t|A^{t-1},Y^{t-1},W^t,X^t} = P_t(da_t|a^{t-1},y^{t-1}), \forall t \in \mathbb{Z}_+^n.$$

Moreover,  $\delta_t^u \stackrel{\triangle}{=} (a^{t-1}, y^{t-1}, u_t)$  is a sufficient statistic for  $P_t(da_t|a^{t-1}, y^{t-1})$ .

(b) Similarly to (a) there exist arbitrary independent RVs  $Z^n$ ,  $Z_t : \Omega \to \mathbb{Z}_t, \forall t \in \mathbb{Z}_+^n$ , and meas. functions  $\mu_i^z(\cdot)$  such that

$$a_{t} = \mu_{t}^{z}(a^{t-1}, y^{t-1}, z_{t}), \quad \forall t \in \mathbb{Z}_{+}^{n},$$
(II.27)  

$$P_{t}(da_{t}|a^{t-1}, y^{t-1}) = \mathbf{P}_{Z_{t}}(z_{t} \in \mathbb{Z}_{t} | \mu_{t}^{z}(a^{t-1}, y^{t-1}, z_{t}) \in da_{t})$$
(C3).  $Z^{n}$  independent RVs,  $Z_{t}$  independent of  $(W^{t}, X_{1}),$   

$$\mathbf{P}_{A_{t}|A^{t-1}, Y^{t-1}, W^{t}, X^{t}} = P_{t}(da_{t}|a^{t-1}, y^{t-1}), \forall t \in \mathbb{Z}_{+}^{n}.$$

Moreover,  $\delta_t^z \stackrel{\triangle}{=} (a^{t-1}, y^{t-1}, z_t)$  is a sufficient statistic for  $P_t(da_t|a^{t-1}, y^{t-1})$ .

*Proof.* (a) The existence of  $\mu_t^u$  with the stated properties is an application of [24, Lemma 1.2], as described in [33, Section III]; (C2) is inherited from condition (C1), and  $\delta_t^u$ is due to the definition of Definition VI.1.(b). (b) Follows from properties of quantile representation of distributions [33, Section III].

Next, we verify  $\mathbf{P}_t^P(dx_t|a^{t-1}, y^{t-1})$  is an information state using strategies  $\mu_t^{u}(\cdot), \mu_t^{z}(\cdot), \forall t \in \mathbb{Z}_+^n$  of Lemma II.1.

**Theorem II.2.** (Information state and separated strategies) Consider the N-POSS and  $C_{n,FB}(\kappa)$  of Theorem II.1. (a) The a posteriori distribution  $\mathbf{P}_{t+1}^{P}(dx_{t+1}|a^{t},y^{t})$  satisfies

(a) The a posteriori distribution  $\mathbf{P}_{t+1}^{*}(ax_{t+1}|a^{*},y^{*})$  satisfies the recursion<sup>3</sup>,  $\forall t \in \mathbb{Z}_{+}^{n}$ :

$$\mathbf{P}_{t+1}^{P}(dx_{t+1}|a^{t},y^{t}) \quad (\text{II.28}) \\
= \frac{\mathbf{T}_{t+1}(y_{i},a_{t},\mathbf{P}_{t}^{P}(\cdot|a^{t-1},y^{t-1}))(dx_{t+1})}{\int_{\mathbb{X}}\mathbf{T}_{t+1}(y_{t},a_{t},\mathbf{P}_{t}^{P}(\cdot|a^{t-1},y^{t-1}))(dx_{t+1})}, \mathbf{P}_{1}^{P}(dx_{1}|y^{0}) = \mathbf{P}_{X_{1}} \\
\mathbf{T}_{t+1}(y_{t},a_{t},\mathbf{P}_{t}^{P}(\cdot|a^{t-1},y^{t-1}))(dx_{t+1}) \stackrel{\triangle}{=} \int_{\mathbb{X}} S_{t+1}(dx_{t+1}|y_{t},x_{t},a_{t}) \\
\otimes Q_{t}(dy_{t}|x_{t},a_{t}) \otimes \mathbf{P}_{t}^{P}(dx_{t}|a^{t-1},y^{t-1}). \quad (\text{II.29})$$

and  $\{\mathbf{P}_{t+1}^{P}(dx_{t+1}|a^{t},y^{t})|t \in \mathbb{Z}_{+}^{n}\}$  is an information state. (b)  $\forall t \in \mathbb{Z}_{+}^{n}$ , distr.  $P_{t}(da_{t}|a^{t-1},y^{t-1})$  in the definition of distr.  $\mathbf{P}_{Y_{t}|Y^{t-1}}^{P}$ , i.e., (II.25), are induced by  $\mu^{u}(\cdot)$  or  $\mu^{z}(\cdot)$  of Lemma II.1.(a), (b).

(c)  $C_{FB,n}(\kappa)$  is re-formulated using separated strategies,  $a_t = \mu_t^u(\xi_t(a^{t-1}, y^{t-1}), u_t)$  or  $a_t = \mu_t^z(\xi_t(a^{t-1}, y^{t-1}), z_t),$  $\xi_t(a^{t-1}, y^{t-1}) \stackrel{\triangle}{=} \mathbf{P}_t^P(dx_t | a^{t-1}, y^{t-1})$  as follows.

$$C_{FB,n}(\kappa)$$
 (II.30)

$$= \sup_{\{\mu_t^u(\xi_t(a^{t-1},y^{t-1}),u_t)\}_{t=1}^n, \frac{1}{n} \mathbf{E}^{\mu^u}(c_n(A^n,X^n)) \le \kappa^{t-1}} \sum_{k=1}^n I^{\mu^u}(A^t;Y_t|Y^{t-1})$$
  
= 
$$\sup_{\{\mu_t^z(\xi_t(a^{t-1},y^{t-1}),z_t)\}_{t=1}^n, \frac{1}{n} \mathbf{E}^{\mu^z}(c_n(A^n,X^n)) \le \kappa^{t-1}} \sum_{k=1}^n I^{\mu^z}(A^t;Y_t|Y^{t-1}).$$

*Proof.* (a) By the existence of probability densities,  $\mathbf{P}_{t+1}^{P}(dx_{t+1}|a^{t},y^{t}) = \mathbf{p}_{t+1}^{P}(x_{t+1}|a^{t},y^{t})dx_{t+1},$  $\mathbf{p}_{t+1}^{P}(x_{t+1}|a^{t},y^{t}) = \frac{\mathbf{p}_{t+1}^{P}(x_{t+1},a^{t},y^{t})}{\mathbf{p}_{t}^{P}(a^{t},y^{t})}$ . Then  $\mathbf{p}_{t+1}^{P}(x_{t+1},a^{t},y^{t}) = \int_{\mathbb{X}_{t}} \mathbf{p}_{t+1}^{P}(x_{t+1},x_{t},a^{t},y^{t})$ . Using the N-POSS distributions and condition (C1) we obtain the recursion. By Definition VI.1 the a posteriori distribution is an information state. (b) Follows from Lemma II.1. (c) Follows from (a), (b).  $\Box$ Next, we restrict  $\mu^{u}(\cdot), \mu^{z}(\cdot)$  to be information lossless to show  $I^{P}(A^{n} \to Y^{n}) = \sum_{t=1}^{n} I^{\mu^{u}}(U^{t}; Y_{t}|Y^{t-1}) = \sum_{t=1}^{n} I^{\mu^{z}}(Z^{t}; Y_{t}|Y^{t-1}).$ 

**Theorem II.3.** (Equivalent characterizations of  $C_{FB,n}(\kappa)$ ) Consider the N-POSS and  $C_{FB,n}(\kappa)$  of Theorem II.1. Define the set of information lossless strategies,

$$\mathcal{P}_{n}^{IL,\mu^{u}}(\kappa) \stackrel{\triangle}{=} \left\{ a_{t} = \mu_{t}^{u}(a^{t-1}, y^{t-1}, u_{t}), \forall t \in \mathbb{Z}_{+}^{n} \middle| the maps \\ \mu_{t}^{u}(a^{t-1}, y^{t-1}, \cdot) : \mathbb{U}_{t} \to a_{t}, \forall \mathbb{Z}_{+}^{n} are bijections, with meas. \\ inverses, (C2) holds, \mathbf{E}^{\mu^{u}} \{c_{n}(A^{n}, X^{n})\} \leq \kappa n \right\}.$$
(II.31)

Similarly, define  $\mathscr{P}_n^{IL,\mu^z}(\kappa)$  with  $(u_t, \mathbb{U}_t)$  replaced by  $(z_t, \mathbb{Z}_t)$ . Then

$$C_{FB,n}(\kappa) = \sup_{\mathscr{P}_n^{IL,\mu^u}(\kappa)} \sum_{t=1}^n I(U^t; Y_t | Y^{t-1})$$
(II.32)

$$= \sup_{\{\mathbf{P}_{Z_{t}}\}_{t=1}^{n}, \mathcal{P}_{n}^{IL,\mu^{z}}(\kappa)^{t=1}} \sum_{t=1}^{n} I(Z^{t}; Y_{t}|Y^{t-1}).$$
(II.33)

<sup>3</sup>All distributions are assumed to have probability densities i.e.,  $\mathbf{P}_{t+1}^{P}(dx_{t+1}|a^{t},y^{t}) = \mathbf{p}_{t+1}^{P}(x_{t+1}|a^{t},y^{t})dx_{t+1}$ .

Moreover, in (II.32) and (II.33)  $\mathcal{P}_n^{IL,\mu^u}(\kappa)$  and  $\mathcal{P}_n^{IL,\mu^z}(\kappa)$  can be replaced by separated strategies (see Definition VI.1).

*Proof.* (II.32), (II.33) follow from the bijection property of the information lossless strategies and Theorem II.2.  $\Box$ 

In Section III we use information states, sufficient statistics, and separated strategies to characterize  $C_{FB,n}(\kappa)$  of the LQG-POSS.

## III. CHARACTERIZATION OF FEEDBACK CAPACITY OF LQG-POSS VIA INFORMATION STATE

We characterize  $C_{FB,n}(\kappa)$  of the LQG-POSS (I.15)-(I.20) in several steps, using Section II, and a generalization of the sufficient statistic approach in [28], [32].

Step #1. Gaussian  $(A^n, X^n, Y^n)$  are optimal. We show the statement of Section I-A.2, under 2.1).

**Lemma III.1.** (*Calculation of*  $H^P(Y_t|Y^{t-1}, A^t)$ ) Consider the LQG-DM (I.15)-(I.20). Define  $\forall t \in \mathbb{Z}_+^n$ ,

$$\hat{I}_{t} \stackrel{\triangle}{=} Y_{t} - \mathbf{E} \{ Y_{t} | Y^{t-1}, A^{t} \}, \text{ innovations wrt } Y^{t-1}, A^{t} \quad (\text{III.34})$$

$$\mu_{Y_{t} | Y^{t-1}, A^{t}} \stackrel{\triangle}{=} \mathbf{E} \{ Y_{t} | Y^{t-1}, A^{t} \}, K_{Y_{t} | Y^{t-1}, A^{t}} \stackrel{\triangle}{=} cov(Y_{t}, Y_{t} | Y^{t-1}, A^{t})$$

$$\hat{X}_{t} \stackrel{\triangle}{=} \mathbf{E} \{ X_{t} | A^{t-1}, Y^{t-1} \}, \Sigma_{t} \stackrel{\triangle}{=} cov(X_{t}, X_{t} | A^{t-1}, Y^{t-1}).$$

(a) The solution of the recursion of Theorem II.2.(a) is conditionally Gaussian given by

$$\mathbf{P}_{t}^{P}(dx_{t}|A^{t-1},Y^{t-1}) \in G(\hat{X}_{t};\Sigma_{t}), \quad \forall t \in \mathbb{Z}_{+}^{n}$$
(III.35)

where  $\hat{X}_t$  is linear in  $(A^{n-1}, Y^{t-1})$ ,  $\Sigma_t = \mathbf{E}\{(X_t - \hat{X}_t)(X_t - \hat{X}_t)^T\}$  is independent of  $(A^{t-1}, Y^{t-1})$ , and satisfy recursions: (i)  $\hat{X}_t$  satisfies the generalized Kalman-filter recursion,

$$\hat{X}_{t+1} = F_t \hat{X}_t + B_t A_t + M_t (\Sigma_t) \hat{I}_t, \ \hat{X}_1 = \mu_{X_1}, \ \forall t \in \mathbb{Z}_+^{n-1},$$
(III.36)

$$M_t(\Sigma_t) \stackrel{\simeq}{=} \left( F_t \Sigma_t C_t^T + G_t K_{W_t} N_t^T \right) \left( N_t K_{W_t} N_t^T + C_t \Sigma_t C_t^T \right)^{-1},$$
  

$$\hat{I}_t = Y_t - C_t \hat{X}_t - D_t A_t = C_t \left( X_t - \hat{X}_t \right) + N_t W_t, \quad (\text{III.37})$$

$$\hat{I}_t \in G(0, K_{\hat{I}_t})$$
 orth. process indep. of  $Y^{t-1}, A^t$ , (III.38)

$$K_{\hat{f}_{t}} \stackrel{\triangle}{=} cov(\hat{I}_{t}, \hat{I}_{t}) = C_{t} \Sigma_{t} C_{t}^{T} + N_{t} K_{W_{t}} N_{t}^{T} = K_{Y_{t}|Y^{t-1}, A^{t}}, \quad (\text{III.39})$$
$$\mu_{Y_{t}|Y^{t-1}, A^{t}} = C_{t} \hat{X}_{t} + D_{t} A_{t}. \quad (\text{III.40})$$

(*ii*)  $\Sigma_t$  satisfies the matrix DRE,

$$\begin{split} \Sigma_{t+1} &= F_t \Sigma_t F_t^T + G_t K_{W_t} G_t^T - \left( F_t \Sigma_t C_t^T + G_t K_{W_t} N_t^T \right) \\ &\cdot \left( N_t K_{W_t} N_t^T + C_t \Sigma_t C_t^T \right)^{-1} \left( F_t \Sigma_t C_t^T + G_t K_{W_t} N_t^T \right)^T, \\ &\Sigma_t \succeq 0, \quad \forall t \in \mathbb{Z}_+^n, \quad \Sigma_1 = K_{X_1} \succeq 0. \end{split}$$
(III.41)

(b) The conditional entropy  $H^{P}(Y_{t}|Y^{t-1},A^{t})$  is given by

$$H^{P}(Y_{t}|Y^{t-1},A^{t}) = H(\hat{I}_{t}), \quad \forall t \in \mathbb{Z}_{+}^{n}$$
(III.42)

$$= \frac{1}{2} \log \left( (2\pi e)^{n_y} \det \left( C_t \Sigma_t C_t^T + N_t K_{W_t} N_t^T \right) \right). \quad \text{(III.43)}$$

*Proof.* All statements follow by verifying that  $\mathbf{P}_{t}^{P}(dx_{t}|A^{t-1},Y^{t-1}) = \frac{1}{(2\pi)^{n_{x}/2}(\det(\Sigma_{t}))^{1/2}} \exp\left(-\frac{1}{2}(x_{t} - \hat{X}_{t})\Sigma_{t}^{-1}(x_{t} - \hat{X}_{t})^{T}\right), \forall t \in \mathbb{Z}_{+}^{n}$  satisfies recursion (II.28).

## Lemma III.2. (Optimality of Gaussian inputs)

Consider the LQG-POSS (1.15)-(1.20). The optimal  $P(\cdot|\cdot) \in \mathscr{P}_n(\kappa)$  which maximizes  $I(A^n \to Y^n)$  is induced by the realization of jointly Gaussian  $A^n$ , given by

$$A_{t} = \mu_{t}^{z}(Y^{t-1}, A^{t-1}, Z_{t}) = \mu_{t}^{0}(A^{t-1}, Y^{t-1}) + Z_{t},$$
(III.44)

$$\mu_t^0(A^{t-1}, Y^{t-1})$$
 is linear in the RVs  $(A^{t-1}, Y^{t-1})$ , (III.45)

$$Z_t \in G(0, K_{Z_t}), K_{Z_t} \succeq 0, \forall t \in \mathbb{Z}_+^n \text{ indep. proc.}$$
 (III.46)

$$Z_i$$
 indep. of  $(X^t, W^t, A^{t-1}, Y^{t-1}), \forall t \in \mathbb{Z}_+^n$ . (III.47)

*Proof.* Follows from Lemma III.1.(b), by the maximum entropy principle, because  $I(A^n \to Y^n) = H(Y^n) - \sum_{t=1}^n H(\hat{I}_t)$ , and the average cost constraint is quadratic. By Lemma II.1.(b), one realization of  $A^n$  is (III.44)-(III.47).

Step #2. Equivalent Characterization of  $C_{FB,n}(\kappa)$  via Information State and Sufficient Statistics. First, we invoke Lemma III.1, to identify a sufficient statistic for  $\mathscr{P}_n(\kappa)$ .

**Lemma III.3.** Preliminary char. of  $C_{FB,n}(\kappa)$  for LQG-POSSs Consider the LQG-POSS (1.15)-(1.20). Then

$$Y_t = C_t \hat{X}_t + D_t A_t + \hat{I}_t, \quad t = 1, \dots, n,$$
 (III.48)

$$\mathbf{P}_t(dy_t|y^{t-1}, a^t) = \mathbf{P}_t(dy_t|a_t, \hat{x}_t), \qquad \text{(III.49)}$$

$$\mathbf{P}_{t}(dy_{t}|y^{t-1}) = \int \mathbf{P}_{t}(dy|a_{t},\hat{x}_{t})\mathbf{P}_{t}(da_{t}|\hat{x}_{t},y^{t-1})$$

$$\mathbf{P}_{t}(d\hat{x}_{t}|y^{t-1}), \qquad (\text{III.50})$$

$$\mathbf{P}(da_{t}|a^{t-1},y^{t-1}) = \mathbf{P}(da_{t}|\hat{x}_{t},y^{t-1}) \qquad (\text{III.51})$$

$$P_t(da_t|a^{t-1}, y^{t-1}) = \mathbf{P}_t(da_t|\hat{x}_t, y^{t-1})$$
(III.51)

$$A_{t} = \Gamma_{t}^{t} X_{t} + U_{t}(Y^{t-1}) + Z_{t}, \quad U_{t}(Y^{t-1}) \equiv \Gamma_{t}^{2} Y^{t-1}, \quad (\text{III.52})$$
  
$$Z_{t} \in G(0, K_{Z_{t}}) \quad indep. \ of \quad (X^{t}, \hat{X}^{t}, \hat{I}^{t}, A^{t-1}, Y^{t-1}). \quad (\text{III.53})$$

where  $(\Gamma_t^1, \Gamma_t^2)$  are nonrandom. An equivalent  $C_{FB,n}(\kappa)$  is

$$C_{FB,n}(\boldsymbol{\kappa}) = \sup_{\mathscr{P}_{n}^{\hat{X}}(\boldsymbol{\kappa}) t=1} \sum_{t=1}^{n} I(A_{t}, \hat{X}_{t}; Y_{t}|Y^{t-1}), \quad (\text{III.54})$$
$$\mathscr{P}_{n}^{\hat{X}}(\boldsymbol{\kappa}) \stackrel{\triangle}{=} \left\{ \{ \mathbf{P}_{t}(da_{t}|\hat{x}_{t}, y^{t-1}) \}_{t=1}^{n} \left| \frac{1}{n} \mathbf{E} \left( \sum_{t=1}^{n} \hat{\gamma}_{t}(A_{t}, \hat{X}_{t}) \right) \leq \boldsymbol{\kappa} \right\}$$
$$\hat{\gamma}_{t}(A_{t}, \hat{X}_{t}) \stackrel{\triangle}{=} \langle A_{t}, R_{t}A_{t} \rangle + \langle \hat{X}_{t}, Q_{t}\hat{X}_{t} \rangle + trace(Q_{t}\Sigma_{t}). \quad (\text{III.55})$$

Proof. See Section VI-B.

Step #3. Complete Characterization of  $C_{FB,n}(\kappa)$ . Now, we show the statements of Section I-A.2, under 2.2). We use Lemma III.3 to find another equivalent  $Y^n$  to compute  $\mathbf{P}_{Y_t|Y^{t-1}}$ , which is required in the optimization of  $H(Y^n)$ .

**Theorem III.1.** Complete char. of  $C_{FB,n}(\kappa)$  for LQG-POSSs Consider the LQG-POSS (1.15)-(1.20). Define

$$I_{t} \stackrel{\triangle}{=} Y_{t} - \mathbf{E} \{Y_{t} | Y^{t-1}\}, Y^{t} \text{ generated by (III.48), (III.56)}$$
$$\hat{\hat{X}}_{t} \stackrel{\triangle}{=} \mathbf{E} \{\hat{X}_{t} | Y^{t-1}\}, \forall t \in \mathbb{Z}_{+}^{n}, \hat{\hat{X}}_{1} \stackrel{\triangle}{=} \mu_{X_{1}}, K_{1} \stackrel{\triangle}{=} 0,$$
$$K_{t} \stackrel{\triangle}{=} cov(\hat{X}_{t}, \hat{X}_{t} | Y^{t-1}) = \mathbf{E} \{(\hat{X}_{t} - \hat{X}_{t})(\hat{X}_{t} - \hat{X}_{t})^{T} | Y^{t-1}\}.$$

(a) An equivalent representation of  $(A^n, Y^n)$  is

$$Y_t = \left(C_t + D_t \Gamma_t^1\right) \hat{X}_t + D_t U_t(Y^{t-1}) + I_t, \quad \forall t \in \mathbb{Z}_+^n, \quad \text{(III.57)}$$

$$A_{t} = \Gamma_{t}^{1} \hat{X}_{t} + U_{t}(Y^{t-1}) + Z_{t}, \quad U_{t}(Y^{t-1}) \stackrel{\bigtriangleup}{=} \Gamma_{t}^{2} Y^{t-1}, \quad (\text{III.58})$$

$$Z_t \in G(0, K_{Z_t})$$
 ind. of  $(X^t, \hat{X}^t, \hat{X}_t, \hat{I}^t, A^{t-1}, Y^{t-1})$  (III.59)

where  $\hat{X}_t$  and  $K_t$  are given under (i) and (ii) below. (i)  $\hat{X}_t$  satisfies the Kalman-filter recursion,

$$\widehat{X}_{t+1} = F_t(\Gamma_t^1)\widehat{X}_t + B_t U_t 
+ F_t^{CL}(\Sigma_t, K_t, \Gamma_t^1)I_t, \ \widehat{X}_1 = \mu_{X_1}, \quad \forall t \in \mathbb{Z}_+^{n-1},$$
(III.60)

$$F_t(\Gamma_t^1) \stackrel{\simeq}{=} F_t + B_t \Gamma_t^1, \ C_t(\Gamma_t^1) \stackrel{\simeq}{=} C_t + D_t \Gamma_t^1,$$
(III.61)

$$\begin{aligned} F_{t}^{CD}(\Sigma_{t},K_{t},\Gamma_{t}^{T}) &= \left(F_{t}(\Gamma_{t}^{T})K_{t}\left(C_{t}(\Gamma_{t}^{T})\right)^{T} + B_{t}K_{Z_{t}}D^{T} \quad (III.62) \right. \\ &+ M_{t}(\Sigma_{t})K_{\hat{f}_{t}}\right) \left\{K_{\hat{f}_{t}} + D_{t}K_{Z_{t}}D_{t}^{T} + \left(C_{t}(\Gamma_{t}^{1})\right)K_{t}\left(C_{t}(\Gamma_{t}^{1})\right)^{T}\right\}^{-1}, \\ I_{t} &= Y_{t} - C_{t}\widehat{X}_{t} - D_{t}\Gamma_{t}^{1}\widehat{X}_{t} - D_{t}U(Y^{t-1}) \\ &= C_{t}(\Gamma_{t}^{1})\left(\widehat{X}_{t} - \widehat{X}_{t}\right) + \widehat{f}_{t} + D_{t}Z_{t}, \quad \forall t \in \mathbb{Z}_{+}^{n}, \qquad (III.63) \\ I_{t} &\in G(0; K_{I_{t}}), \; \forall t \in \mathbb{Z}_{+}^{n} \; orthogonal \; innovations \; proc. \\ K_{I_{t}} &= K_{Y_{t}|Y^{t-1}} \stackrel{\triangle}{=} cov(I_{t}, I_{t}) = \left(C_{t}(\Gamma_{t}^{1})\right)K_{t}\left(C_{t}(\Gamma_{t}^{1})\right)^{T} \\ &+ K_{\hat{f}_{t}} + D_{t}K_{Z_{t}}D_{t}^{T}, \quad K_{\hat{f}_{t}} \; given \; by \; (III.39). \qquad (III.64) \end{aligned}$$

(ii) 
$$K_t = \mathbf{E}\left\{\widehat{E}_t\widehat{E}_t^T\right\}, \ \widehat{E}_t = \widehat{X}_t - \widehat{X}_t \ \text{satisfies the matrix DRE}$$
  
 $K_{t+1} = F_t(\Gamma_t^1)K_t\left(F_t(\Gamma_t^1)^T + M_t(\Sigma_t)K_{\hat{f}_t}\left(M_t(\Sigma_t)\right)^T + B_tK_{Z_t}B_t^T - \left(F_t(\Gamma_t^1)K_t\left(C_t(\Gamma_t^1)\right)^T + B_tK_{Z_t}D_t^T + M_t(\Sigma_t)K_{\hat{f}_t}\right)$   
 $\cdot \left(K_{\hat{f}_t} + D_tK_{Z_t}D_t^T + \left(C_t(\Gamma_t^1)K_t\left(C_t(\Gamma_t^1)\right)^T\right)^{-1}\left(F_t(\Gamma_t^1)K_t\left(C_t(\Gamma_t^1)\right)^T + B_tK_{Z_t}B_t^T + M_t(\Sigma_t)K_{\hat{f}_t}\right)^T, \ K_t \succeq 0, \forall t \in \mathbb{Z}_+^n, \ K_1 = 0.$ 
(III.65)

(b) An equivalent characterization of  $C_{FB,n}(\kappa)$  is

$$C_{FB,n}(\kappa) = \sup_{\mathscr{P}_n^{\widehat{X}}(\kappa)} \sum_{t=1}^n I(A_t, \hat{X}_t; Y_t | Y^{t-1}), \qquad (\text{III.66})$$

$$I(A_t, \hat{X}_t; Y_t | Y^{t-1}) = \frac{1}{2} \log \frac{\det(K_{I_t})}{\det(K_{\hat{I}_t})} =$$
(III.67)

$$\frac{1}{2}\log\Big\{\frac{\det\left(C_t(\Gamma_t^1)K_t(C_t(\Gamma_t^1)^T + K_{\hat{f}_t} + D_tK_{Z_t}D_t^T)\right)}{\det\left(K_{\hat{f}_t}\right)}\Big\},\tag{III.68}$$

$$\mathcal{P}_{n}^{\widehat{X}}(\kappa) \stackrel{\triangle}{=} \left\{ \{U_{t}, \Gamma_{t}^{1}, K_{Z_{t}}\}_{t=1}^{n} \middle| \frac{1}{n} \mathbf{E} \left( \sum_{t=1}^{n} \widehat{\gamma}_{t}(U_{t}, \widehat{X}_{t}, \Gamma_{t}^{1}, K_{Z_{t}}) \right) \leq \kappa \right\} \quad \begin{pmatrix} Q_{t} \\ Q_{t} \\ \widehat{\gamma}_{t}(U_{t}, \widehat{X}_{t}, \Gamma_{t}^{1}K_{Z_{t}}) \stackrel{\triangle}{=} \langle U_{t}, R_{t}U_{t} \rangle + \langle \widehat{X}_{t}, Q_{t}(\Gamma_{t}^{1})\widehat{X}_{t} \rangle + \langle \widehat{X}_{t}, L_{t}(\Gamma_{t}^{1})U_{t} \rangle \\ + \langle L_{t}(\Gamma_{t}^{1})U_{t}, \widehat{X}_{t} \rangle + trace \left( Q_{t}\Sigma_{t} + Q_{t}(\Gamma_{t}^{1})K_{t} + R_{t}K_{Z_{t}} \right), \tag{III.69}$$

$$Q_t(\Gamma_t^1) \stackrel{\triangle}{=} Q_t + (\Gamma_t^1)^T R_t \Gamma_t^1, \quad L_t(\Gamma_t^1) \stackrel{\triangle}{=} (\Gamma_t^1)^T R_t.$$
(III.70)

*Proof.* (a) By definition of  $I_t$  with  $Y^t$  generated by (III.48), we obtain (III.57). The rest of equations under (i) and (ii) follow by repeating the derivation of Kalman-filter equations. (b) (III.68) follows from  $I(A_t, \hat{X}_t; Y_t | Y^{t-1}) = H(Y_t | Y^{t-1}) - H(\hat{I}_t)$  from (III.43), and  $H(Y_t | Y^{t-1})$  is computed from (III.64).  $\mathscr{P}_n^{\hat{X}}(\kappa)$  follows from Lemma III.3, (III.55) by  $\mathbf{E}\{\hat{\gamma}_t(A_t, \hat{X}_t)\} = \mathbf{E}\{\mathbf{E}\{\hat{\gamma}_t(A_t, \hat{X}_t) | Y^{t-1}\}\}.$ 

#4. Separation Principle. Now, we show the statement of Section I-A.2, under 2.3): the strategy  $U_t(Y^{t-1}) = \Gamma_t^2 Y^{t-1}$ , is determined independently of  $(\Gamma_t^1 \hat{X}_t, K_{Z_t}), \forall t \in \mathbb{Z}_+^n$ .

## **Theorem III.2.** (Decentralized separation principle) Consider $C_{FB,n}(\kappa)$ of Theorem III.1.(b). Define the Cost-Rate, i.e., dual of $C_{FB,n}(\kappa)$ , by

$$\kappa_n(C) \stackrel{\triangle}{=} \inf_{\{\left(\Gamma_t^1, U_t, K_{Z_t} \succeq 0\right)\}_{t=1}^n} \mathbf{E} \left\{ \sum_{t=1}^n \widehat{\gamma}_t(U_t, \widehat{X}_t, \Gamma_t^1, K_{Z_t}) \right\}$$
  
such that (III.60) holds,  $\frac{1}{2} \sum_{t=1}^n \log \frac{\det(K_{I_t})}{\det(K_{I_t})} \ge nC.$  (III.71)

(a) Decentralized Separation Principle.

(i) The optimal strategy  $\{U_t^*(\cdot, \Gamma^1, K_Z) | t \in \mathbb{Z}_+^n\}$  is a solution of the stochastic optimal control problem

$$J_n^{SC}(U^*,\Gamma^1,K_Z) \stackrel{\triangle}{=} \inf_{U(\cdot)} \mathbf{E} \Big\{ \sum_{t=1}^n \widehat{\gamma}_t(U_t,\widehat{X}_t,\Gamma_t^1,K_{Z_t}) \Big\} \quad (\text{III.72})$$

and it is given by the following equations.

$$U_{t}^{*}(Y^{t-1},\Gamma^{1},K_{Z}) = \Gamma_{t}^{2,*}\hat{X}_{t}, \quad \forall t \in \mathbb{Z}_{+}^{n-1},$$
(III.73)  
$$\Gamma_{t}^{2,*} = -\left(R_{t} + B_{t}^{T}P_{t+1}B_{t}\right)^{-1}\left(\left(L_{t}(\Gamma_{t}^{1})\right)^{T} + B_{t}^{T}P_{t+1}F_{t}(\Gamma_{t}^{1})\right), \quad \Gamma_{n}^{2,*} = -R_{n}^{-1}\left(L_{n}(\Gamma_{n}^{1})\right)^{T}$$
(III.74)

where  $P_t \succeq 0$  satisfies the backward matrix DRE,

$$P_{t} = \left(F_{t}(\Gamma_{t}^{1})\right)^{T} P_{t+1} F_{t}(\Gamma_{t}^{1}) - \left(\left(F_{t}(\Gamma_{t}^{1})\right)^{T} P_{t+1} B_{t} + L_{t}(\Gamma_{t}^{1})\right)$$
$$\cdot \left(R_{t} + B_{t}^{T} P_{t+1} B_{t}\right)^{-1} \left(\left(F_{t}(\Gamma_{t}^{1})\right)^{T} P_{t+1} B_{t} + L_{t}(\Gamma_{t}^{1})\right)^{T} + Q_{t}(\Gamma_{t}^{1}), \forall t \in \mathbb{Z}_{+}^{n-1}, \quad P_{n} = Q_{n}(\Gamma_{n}^{1}). \quad (\text{III.75})$$

The optimal cost-rate is given by

Т

$$J_n^{SC}(U^*, \Gamma^1, K_Z) = \langle \mu_{X_1}, P_1 \mu_{X_1} \rangle + \sum_{t=1}^n \left\{ trace \left( F_t^{CL} K_{I_t} (F_t^{CL})^T P_t \right) + trace \left( Q_t \Sigma_t + Q_t (\Gamma_t^1) K_t + R_t K_{Z_t} \right) \right\}.$$
 (III.76)

(ii) The optimal  $\{(\Gamma_t^{1,*}, K_{Z_t}^*)|t \in \mathbb{Z}_+^n\}$  is determined from (III.66), with  $\mathscr{P}_n^{\hat{X}}(\kappa)$  replaced by  $\frac{1}{n}J_n^{SC}(U^*, \Gamma^1, K_Z) \leq \kappa$ , i.e.,  $U(\cdot) = U^*(\cdot)$ .

**Remark III.1.** The characterizations of  $C_{FB,n}(\kappa)$  in [28], [32] correspond to  $B_t = 0, Q_t = 0, R_t = I, \forall t$ . Using these values in  $U^*(\cdot)$  of (III.73), (III.74), and  $C_{FB,n}(\kappa)$  of Theorem III.1, the optimal input reduces to  $A_t = \Gamma_t^1(\hat{X}_t - \hat{X}_t) + Z_t, \forall t \in \mathbb{Z}_+^n$ , with corresponding  $C_{FB,n}(\kappa)$ , which coincides with the expression in [28], [32]. Reference [28] discusses relations to the expressions of  $C_{FB,n}(\kappa)$  derived in [12]–[14], [34].

#### IV. ASYMPTOTIC LIMIT

In this section we consider the limit  $C_{FB}(\kappa) = \lim_{n \leftrightarrow \infty} \frac{1}{n} C_{FB,n}(\kappa)$ , based on Assumptions IV.1.

## Assumptions IV.1. Asymptotically time-invariant

(1) The LQG-POSS (1.15)-(1.20) is asymptotically timeinvariant (ATI),  $\lim_{n\to\infty} (F_n, B_n, C_n, D_n, N_n, K_{W_n}, R_n, Q_n) = (F, B, C, D, N, K_W, R, Q).$ 

(2) The controller-encoder strategies are ATI,  $\lim_{n \to \infty} (\Gamma_n^1, K_{Z_n}) = (\Gamma^1, K_Z), K_Z \succeq 0.$ 

(3) The solutions to the matrix DREs  $(\Sigma_n, K_n, P_n)$ are such that  $\lim_{n\to\infty} (\Sigma_n, K_n, P_n) = (\Sigma, K, P)$ , where  $\Sigma \succeq 0, K \succeq 0, P \succeq 0$  are unique stabilizing solutions of corresponding matrix algebraic Riccati equations (AREs),

$$\Sigma = F\Sigma F^{T} - \left(F\Sigma C^{T} + GK_{W}N^{T}\right) \left(NK_{W}N^{T} + C\Sigma C^{T}\right)^{-1}$$
$$\left(F\Sigma C^{T} + GK_{W}N^{T}\right)^{T} + GK_{W}G^{T}, \quad \Sigma \succeq 0, \qquad (IV.77)$$

similarly for 
$$(K, P)$$
. (IV.78)

**Theorem IV.1.** Asymptotic char. of  $C_{FB}(\kappa)$  for LQG-POSSs Consider the LQG-POSS (1.15)-(1.20), and suppose Assumptions IV.1 hold. The CC capacity  $C_{FB}(\kappa)$  is given by

$$C_{FB}(\kappa) = \lim_{n \leftrightarrow \infty} \frac{1}{n} C_{FB,n}(\kappa) = \sup_{\mathscr{P}_{\infty}^{\hat{X}}(\kappa)} \frac{1}{2} \log \frac{\det(K_I)}{\det(K_{\hat{I}})} \quad (IV.79)$$

$$= \sup_{\mathscr{P}_{\infty}^{\hat{X}}(\kappa)} \frac{1}{2} \log \left\{ \frac{\det\left(C(\Gamma^1)K(C(\Gamma^1)^T + K_{\hat{I}} + DK_Z D^T\right)}{\det(K_{\hat{I}})} \right\},$$

$$\mathscr{P}_{\infty}^{\hat{X}} \stackrel{\triangle}{=} \left\{ (\Gamma^1, K_Z) \middle| K_Z \succeq 0, \quad trace\left(F^{CL}K_I(F^{CL})^T P\right) + trace\left(Q\Sigma + Q(\Gamma^1)K + RK_Z\right) \le \kappa \right\},$$
s.t.  $\Sigma \succeq 0, K \succeq 0, P \succeq 0$  satisfy the matrix AREs

where the limit is the uniform limit over all initial conditions, *i.e.*, is independent of  $\Sigma_1$ ,  $P_1$ ,  $K_1$ .

Moreover, sufficient conditions for Assumptions IV.1.(3) to hold, are (i) detectability and (ii) stabilizability of the AREs.

*Proof.* Using Theorem III.2 and Theorem III.1.(b) and Assumptions IV.1, we repeat the proof given in [35] to show the limit over  $n \longrightarrow \infty$  and supremum over the strategies can be interchanged, the asymptotic limit is a uniform limit over all initial conditions. The fact that (i) detectability and (ii) stabilizability of the matrix AREs are sufficient for Assumptions IV.1.(3) to hold follows from the continuous dependence of solutions of matrix DREs on the parameters.

#### V. CONCLUSION

In this paper we applied the concepts of information state and sufficient statistic to characterize feedback capacity  $C_{FB}$  of nonlinear partially observable stochastic systems, with input dependent states, which are not available to the encoder and

the decoder. In addition, we applied these concepts to linearquadratic-Gaussian partially observable stochastic systems (LQG-POSS). For LQG-POSS,  $C_{FB}$  is expressed in terms of 2 filtering Riccati equations and 1 control Riccati equation. For certain special cases we recover recent expressions of  $C_{FB}$  that appeared in [28], [32], for Gaussian channels with memory, without state dependent inputs.

### VI. APPENDIX

## A. Definition of Information State and Sufficient Statistic

**Definition VI.1.** (Information state and sufficient statistic) (a) The a posteriori distribution  $\{\mathbf{P}_t^P(dx_t|a^{t-1}, y^{t-1})|t \in \mathbb{Z}_+^n\}$  is called an information state if the next state  $\mathbf{P}_{t+1}^P(dx_{t+1}|a^t, y^t)$  is determined from  $(y_t, a_t)$ , the current state  $\mathbf{P}_t^P(dx_t|a^{t-1}, y^{t-1})$ , and possibly  $P_t(da_t|a^{t-1}, y^{t-1})$ ,  $\forall t \in \mathbb{Z}_+^n$ .

(b) A statistic  $\{\delta_t | t \in \mathbb{Z}_+^n\}, \delta_t : \Omega \to \mathbb{D}$  is called a sufficient statistic for the strategies  $P(\cdot|\cdot) \in \mathscr{P}_n(\kappa)$  if  $P_i(da_t|a^{t-1}, y^{t-1})$  is induced by  $A_t = \mu_i(\delta_t)$  for some measurable function  $\mu_t(\cdot)$ ,  $\forall t \in \mathbb{Z}_+^n$ .

(c) The strategies  $P(\cdot|\cdot) \in \mathscr{P}_n(\kappa)$  are called separated strategies if they are generated by  $A_t = \mu_t^z(\xi_t(A^{t-1}, Y^{t-1}), Z_t))$ , where  $\xi_t(a^{t-1}, y^{t-1}) \stackrel{\triangle}{=} \mathbf{P}_t^P(dx_t|a^{t-1}, y^{t-1}), \mu_t^z(\cdot)$  is a measurable function, and  $Z_t : \Omega \to \mathbb{Z}$  is a RV (responsible for the randomization),  $\forall t \in \mathbb{Z}_+^n$  (i.e.,  $\delta_t = (\xi_t(A^{t-1}, Y^{t-1}), Z_t)$  is a sufficient statistic). The set of separated strategies is denoted by  $\mathscr{P}_n^{sep}(\kappa)$ .

## B. LQG-POSS

**Proof of Lemma III.3** We show (III.47), (III.48) last. First, (III.44) is a re-statement of the first equality in (III.33) in Lemma III.1.(a).(i). The conditional distributions (III.45), (III.46) follow directly from (III.44), and the orthogonality of  $\hat{I}_t$  and  $(A^t, Y^{t-1})$ , as follows.

$$\mathbb{P}\left\{Y_{t} \in dy \middle| Y^{t-1}, X^{t}\right\} = \mathbf{P}_{t}(dy | Y^{t-1}, A^{t}),$$
  
= $\mathbf{P}_{t}(dy | A^{t}, Y^{t-1}, \hat{X}^{t}), \text{ by } \hat{X}_{t} = \mathbf{E}\left\{X_{t} \middle| Y^{t-1}, A^{t-1}\right\}$   
= $\mathbf{P}_{t}(dy | A_{t}, \hat{X}_{t}), \text{ by (III.44).}$ 

The equivalent representation of  $\hat{\gamma}_t(A_t, \hat{X}_t)$  in the average cost (III.51) is obtain by reconditioning,  $\mathbf{E}\left\{\sum_{t=1}^n \gamma_t(A_t, X_t)\right\} = \sum_{t=1}^n \mathbf{E}\left\{\mathbf{E}\left\{\gamma_t(A_t, X_t) \middle| A^t, Y^{t-1}\right\}\right\}$ , using the quadratic definition of  $\gamma_i(\cdot)$  of (I.16), Lemma III.1, and the Markov chain  $X_t \leftrightarrow (A^{t-1}, Y^{t-1}) \leftrightarrow A_t$ . This shows the new channel (III.44) is linear in  $(\hat{X}_t, A_t)$  and cost is quadratic in  $(\hat{X}_t, A_t)$ . Since  $\mathbf{P}_{\hat{X}_t}|_{\hat{X}^{t-1}, A^{t-1}} = \mathbf{P}_{\hat{X}_t}|_{\hat{X}_{t-1}, A_{t-1}}$ , and  $I^P(A^n \to Y^n) = \mathbf{E}^P\left\{\log\left(\frac{\mathbf{P}_t(dY_t|Y^{t-1}, A^t)}{\mathbf{P}_t(dY_t|Y^{t-1})}\right)\right\} = \mathbf{E}\left\{\log\left(\frac{\mathbf{P}_t(dY_t|X_t, \hat{X}_t)}{\mathbf{P}_t(dY_t|Y^{t-1})}\right)\right\}$ , by Markov decision theory the optimization over  $\mathscr{P}_n(\kappa)$  of  $I(A^n \to Y^n)$  occurs in the set  $\mathscr{P}_n^{\hat{X}}(\kappa)$ , i.e., (III.47). holds. By (III.47),  $\mathbf{P}_t(da_t|\hat{X}_t, y^{t-1})$  is induced by the realization (III.48). Hence, we obtain (III.50) we use the distributions (III.45)-(III.47).

**Proof of Theorem III.2.** (a) In  $C_{FB,n}(\kappa)$  defined by (III.62), the terms  $I(A_t, \hat{X}_t; Y_t | Y^{t-1})$  given by (III.63) do not depend on the strategy  $U_t(\cdot), \forall t \in \mathbb{Z}_+^n$ , hence we can apply the person-by-person optimality concepts stated under (i) and (ii). (b)

We express  $\hat{\gamma}_t(U_t, \hat{X}_t, \Gamma_t^1, K_{Z_t})$  defined by (III.65) as follows.

$$\widehat{\hat{\gamma}}_{t}(U_{t},\widehat{\hat{X}}_{t},\Gamma_{t}^{1},K_{Z_{t}}) = \begin{bmatrix} \widehat{\hat{X}}_{t} \\ U_{t} \end{bmatrix}^{T} \begin{bmatrix} Q_{t}(\Gamma_{t}^{1}) & L_{t}(\Gamma_{t}^{1}) \\ (L_{t}(\Gamma_{t}^{1}))^{T} & R_{t} \end{bmatrix} \begin{bmatrix} \widehat{\hat{X}}_{t} \\ U_{t} \end{bmatrix} + \text{additional terms.} \qquad (\text{VI.80})$$

Then we have a linear-quadratic Gaussian stochastic optimal control problem, and its solution is the one stated under (i) [6]. Since we determined  $U^*(\cdot)$  it remains to solve  $C_{FB,n}(\kappa)$  as stated under (ii).
