

FOUR-MANIFOLDS DEFINED BY VECTOR-COLORINGS OF SIMPLE POLYTOPES

NIKOLAI EROKHOVETS

ABSTRACT. We consider (non-necessarily free) actions of subgroups $H \subset \mathbb{Z}_2^m$ on the real moment-angle manifold $\mathbb{R}\mathcal{Z}_P$ over a simple n -polytope P . The orbit space $N(P, H) = \mathbb{R}\mathcal{Z}_P/H$ has an action of \mathbb{Z}_2^m/H . For general n we introduce the notion of a Hamiltonian $\mathcal{C}(n, k)$ -subcomplex generalizing the three-dimensional notions of a Hamiltonian cycle, theta- and K_4 -subgraphs. Each $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$ corresponds to a subgroup H_C such that $N(P, H_C) \simeq S^n$. We prove that in dimensions $n \leq 4$ this correspondence is a bijection. Any subgroup $H \subset \mathbb{Z}_2^m$ defines a complex $\mathcal{C}(P, H) \subset \partial P$. We prove that each Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \mathcal{C}(P, H)$ inducing H corresponds to a hyperelliptic involution $\tau_C \in \mathbb{Z}_2^m/H$ on the manifold $N(P, H)$ (that is, an involution with the orbit space homeomorphic to S^n) and in dimensions $n \leq 4$ this correspondence is a bijection. We prove that for the geometries $\mathbb{X} = \mathbb{S}^4$, $\mathbb{S}^3 \times \mathbb{R}$, $\mathbb{S}^2 \times \mathbb{S}^2$, $\mathbb{S}^2 \times \mathbb{R}^2$, $\mathbb{S}^2 \times \mathbb{L}^2$, and $\mathbb{L}^2 \times \mathbb{L}^2$ there exists a compact right-angled 4-polytope P with a free action of H such that the geometric manifold $N(P, H)$ has a hyperelliptic involution in \mathbb{Z}_2^m/H , and for $\mathbb{X} = \mathbb{R}^4$, \mathbb{L}^4 , $\mathbb{L}^3 \times \mathbb{R}$ and $\mathbb{L}^2 \times \mathbb{R}^2$ there are no such polytopes.

1. INTRODUCTION

The paper is motivated by questions arisen during discussions of results of [E24] with A.D. Mednykh.

For an introduction to the polytope theory we refer to [Gb03, Z95]. We will use definitions and notations from [E24], but for convenience try to write them explicitly. In this paper for topological spaces the notation $X \simeq Y$ means that X and Y are homeomorphic, and for complexes $C_1 \simeq C_2$ means that C_1 and C_2 are equivalent.

Toric topology (see [BP15, DJ91]) assigns to each simple n -polytope with m facets F_1, \dots, F_m the *real moment-angle manifold*

$$\mathbb{R}\mathcal{Z}_P = P \times \mathbb{Z}_2^m / \sim, \text{ where } (p, a) \sim (q, b) \text{ if and only if } p = q \text{ and } a - b \in \langle \mathbf{e}_i : p \in F_i \rangle,$$

and $\mathbf{e}_1, \dots, \mathbf{e}_m$ is the standard basis in \mathbb{Z}_2^m . $\mathbb{R}\mathcal{Z}_P$ is a smooth manifold with a smooth action of \mathbb{Z}_2^m such that $\mathbb{R}\mathcal{Z}_P / \mathbb{Z}_2^m = P$.

We consider (non-necessarily free) actions of subgroups $H \subset \mathbb{Z}_2^m$ on $\mathbb{R}\mathcal{Z}_P$. Each subgroup H of rank $m - r$ can be described as a kernel of an epimorphism $\mathbb{Z}_2^m \rightarrow \mathbb{Z}_2^r$ mapping the basis vector \mathbf{e}_i to $\Lambda_i \in \mathbb{Z}_2^r$.

Definition 1.1. We call a mapping $\Lambda: \{F_1, \dots, F_m\} \rightarrow \mathbb{Z}_2^r, F_i \rightarrow \Lambda_i$, such that $\langle \Lambda_1, \dots, \Lambda_m \rangle = \mathbb{Z}_2^r$ a *vector-coloring of P of rank r* . The subgroup H is uniquely defined by Λ , while Λ is defined up to a linear automorphism of \mathbb{Z}_2^r . A vector-coloring is *linearly independent* if for each face $F_{i_1} \cap \dots \cap F_{i_k} \neq \emptyset$ the vectors $\Lambda_{i_1}, \dots, \Lambda_{i_k}$ are linearly independent. Each vector-coloring Λ of rank r defines the orbit space $N(P, \Lambda) = \mathbb{R}\mathcal{Z}_P / H$ with an action of $\mathbb{Z}_2^r \simeq \mathbb{Z}_2^m / H$.

It can be shown that the action of H is free if and only if Λ is linearly independent. In this case $N(P, \Lambda)$ is a smooth manifold. In particular, linearly independent vector-colorings of rank n correspond to *small covers* $N(P, \Lambda)$ introduced in [DJ91].

Linearly independent-vector colorings also arise in the following construction of geometric manifolds developed in the papers by A.Yu. Vesnin and A.D. Mednykh in [MV86, V87, M90, VM99M, V17].

Construction 1.2. Let P be a compact right-angled polytope in some geometry \mathbb{X} (in this paper we will use geometries of the form $\mathbb{X} = \mathbb{X}_1 \times \dots \times \mathbb{X}_k$, where $\mathbb{X}_i \in \{\mathbb{S}^{n_i}, \mathbb{R}^{n_i}, \mathbb{L}^{n_i}\}$ and by a right-angled polytope we mean the product of the corresponding right-angled polytopes).

The polytope P corresponds to a right-angled coxeter group

$$\langle \rho_1, \dots, \rho_m \rangle / (\rho_1^2, \dots, \rho_m^2, \rho_i \rho_j = \rho_j \rho_i, \text{ if } F_i \cap F_j \neq \emptyset).$$

This group is isomorphic to a subgroup $G(P)$ of isometries of \mathbb{X} generated by reflections in facets of P , where ρ_i corresponds to the reflection in F_i . The group $G(P)$ acts on \mathbb{X} discretely, P is a fundamental domain and the orbit space, and for any point of P its stabilizer is generated by reflections in facets containing this point (see [VS88, Theorem 1.2 in Chapter 5]).

A linearly independent vector coloring Λ of rank r defines the epimorphism $\varphi_\Lambda: G(P) \rightarrow \mathbb{Z}_2^r$ by the rule $\varphi_\Lambda(\rho_i) = \Lambda(F_i)$. The subgroup $\text{Ker } \varphi_\Lambda$ acts freely on \mathbb{X} , and the quotient space $\mathbb{X} / \text{Ker } \varphi_\Lambda$ is a closed manifold with the geometric structure modelled on \mathbb{X} . It is easy to see that $N(P, \Lambda) \simeq \mathbb{X} / \text{Ker } \varphi_\Lambda$ (see more details in [E22M, Construction 4.11]).

For a general (not necessarily linearly independent) vector-coloring Λ it was proved in [E24, Theorem 5.1] (jointly with D.V. Gugin) that $N(P, \Lambda)$ is a closed topological manifold if and only if for each face $F_{i_1} \cap \cdots \cap F_{i_k} \neq \emptyset$ **different** vectors among $\{\Lambda_{i_1}, \dots, \Lambda_{i_k}\}$ are linearly independent. (This result also can be extracted from the general results by M.A. Mikhailova and C. Lange [M85, LM16, L19].) This gives rise to the following definition.

Definition 1.3. [E24, Definition 2.1] A coloring c of a simple polytope P in l colors is a surjective mapping from $\{F_1, \dots, F_m\}$ to a finite set of l elements. For convenience we identify the set with $[l] = \{1, \dots, l\}$, but in this paper often this is a subset in \mathbb{Z}_2^r . For any coloring c define a complex $\mathcal{C}(P, c) \subset \partial P$ as follows. Its “facets” are connected components of unions of all the facets of P of the same color, “ k -faces” are connected components of intersections of $(n-k)$ different facets. By definition each k -face is a union of k -faces of P . We choose a linear order of all the facets G_1, \dots, G_M . Two complexes $\mathcal{C}(P, c)$ and $\mathcal{C}(Q, c')$ are *equivalent* (we write $\mathcal{C}(P, c) \simeq \mathcal{C}(Q, c')$) if there is a homeomorphism $P \rightarrow Q$ sending facets of $\mathcal{C}(P, c)$ to facets of $\mathcal{C}(Q, c')$.

Each k -face of $\mathcal{C}(P, c)$ is a connected orientable k -manifold, perhaps with a boundary (see Lemma 2.9). The closed manifold $N(P, \Lambda)$ is orientable if and only if for some change of coordinates in \mathbb{Z}_2^r we have $\Lambda_i = (1, \lambda_i)$ (see [E24, Corollary 1.15]). We call the mapping $\lambda: F_i \rightarrow \lambda_i$ an *affine coloring* of P of rank $(r-1)$.

It can be shown (see [E24, Proposition 2.6]) that for any coloring c of the simplex Δ^n in k colors the complex $\mathcal{C}(\Delta^n, c)$ is equivalent to the complex given on

$$S_{k, \geq 0}^n = \{x_1^2 + \cdots + x_{n+1}^2 = 1, x_1 \geq 0, \dots, x_k \geq 0\}$$

by the facets $S_{k, \geq 0}^n \cap \{x_i = 0\}$, $i = 1, \dots, k$, and ([E24, Corollary]) to the complex given on

$$B_{k-1, \geq}^n = \{(x_1, \dots, x_n) \in \mathbb{R}^n: x_1 \geq 0, \dots, x_{k-1} \geq 0, x_1^2 + \cdots + x_n^2 \leq 1\}$$

by the facets $B_{k-1, \geq}^n \cap \{x_s = 0\}$, $s = 1, \dots, k-1$, and $B_{k-1, \geq}^n \cap \{x_1^2 + \cdots + x_n^2 = 1\}$. We denote the equivalence class of these complexes $\mathcal{C}(n, k)$. For $n = 3$ the complex $\mathcal{C}(3, 1)$ has a single facet ∂P , the complex $\mathcal{C}(3, 1)$ corresponds a simple edge-cycle in ∂P , $\mathcal{C}(3, 2)$ – to a theta-subgraph in ∂P consisting of two disjoint vertices of P and three disjoint (outside these vertices) simple edge-paths connecting them, and $\mathcal{C}(3, 4)$ corresponds to a K_4 -subgraph in ∂P consisting of 4 disjoint vertices of P pairwise connected by a set of disjoint simple edge-paths.

It is easy to see that if for a vector coloring of rank r the complex $\mathcal{C}(P, \Lambda)$ is equivalent to $\mathcal{C}(n, r)$, then $N(P, \Lambda) \simeq S^n$ (see [E24, Construction 5.8]). The converse trivially holds for $n = 2$. It was proved in [E24, Theorem 10.1] that the converse also holds for $n = 3$. **The first main result** (Theorem 3.14) of this paper states that this holds for $n = 4$. Namely, *for a vector-coloring Λ of rank r of a simple polytope of dimension $n \leq 4$ we have $N(P, \Lambda) \simeq S^n$ if and only if $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, r)$.* For general n we prove (Lemma 3.10 and Corollary 3.11) that *if $N(P, \Lambda) \simeq S^n$, then for each $\omega = \omega_1 \sqcup \cdots \sqcup \omega_k \subset [M]$ the set $\left(\bigcup_{i_1 \in \omega_1} G_{i_1}\right) \cap \cdots \cap \left(\bigcup_{i_k \in \omega_k} G_{i_k}\right)$ is a rational homology $(n-k)$ -disk if $\omega \neq [M]$, and a rational homology $(n-k)$ -sphere if $\omega = [M]$.*

In particular, $M \leq n+1$ and each k -face of the complex $\mathcal{C}(P, \Lambda)$ is either a k -RHD or a k -RHS (by definition we assume that for $k < 0$ a k -RHD is a point, and a k -RHS is empty).

On the base of these results we study hyperelliptic involutions in the group \mathbb{Z}_2^r acting on the manifold $N(P, \Lambda)$.

Definition 1.4. Following [VM99S1] we call a closed n -manifold M *hyperelliptic* if it has an involution τ such that $M/\langle \tau \rangle \simeq S^n$. The corresponding involution τ is called a *hyperelliptic involution*.

In dimension $n = 3$ in the papers [M90, VM99M, VM99S2] A.D. Mednykh and A.Yu. Vesnin constructed examples of hyperelliptic 3-manifolds in five of eight Thurston's geometries: \mathbb{S}^3 , \mathbb{R}^3 , \mathbb{L}^3 , $\mathbb{S}^2 \times \mathbb{R}$, and $\mathbb{L}^2 \times \mathbb{R}$. Each manifold was constructed using a Hamiltonian cycle, a Hamiltonian theta-subgraph or a Hamiltonian K_4 -subgraph in a compact right-angled 3-polytope, where a subgraph is *Hamiltonian*, if it contains all the vertices of P . In [E24, Theorem 11.5] it was proved that for a 3-manifold $N(P, \Lambda)$ over a 3-polytope hyperelliptic involutions in \mathbb{Z}_2^r are in bijection with a Hamiltonian empty set, cycles, theta-subgraphs and K_4 -subgraphs in $\mathcal{C}(P, \Lambda)$ inducing Λ , where for a Hamiltonian subgraph Γ of the above types in the 1-skeleton of $\mathcal{C}(P, c)$ there is a canonical way to construct a vector-coloring $\tilde{\Lambda}_\Gamma$ of P induced by Γ such that $\mathcal{C}(P, c) = \mathcal{C}(P, \tilde{\Lambda}_\Gamma)$. Also in [E24, Theorem 11.7] the classification of vector-colorings with more than one hyperelliptic involutions was presented.

In this paper we generalize [E24, Theorem 11.5] to dimension $n = 4$. For this purpose we introduce the notion of a *Hamiltonian $\mathcal{C}(n, k)$ -subcomplex* $C \subset \mathcal{C}(P, c)$ (Definition 4.32) and explain (Construction 4.38) how to build a canonical induced vector-coloring $\tilde{\Lambda}_C$ of rank $k+1$ such that $\mathcal{C}(P, c) = \mathcal{C}(P, \tilde{\Lambda}_C)$ and $N(P, \tilde{\Lambda}_C)$ has a canonical hyperelliptic involution in \mathbb{Z}_2^{k+1} . Then for a vector-coloring Λ of rank r any Hamiltonian $\mathcal{C}(n, r-1)$ -subcomplex $C \subset \mathcal{C}(P, \Lambda)$ inducing Λ corresponds to a hyperelliptic involution $\tau_C \in \mathbb{Z}_2^r$. Our **second main result** (Theorem 4.39) is that *in dimensions $n \leq 4$ this correspondence is a bijection*.

The third main result (Theorem 4.76 and Remark 4.47) of this paper is the answer to the following question in dimension $n = 4$.

Question 1. *For which geometries of the form $\mathbb{X} = \mathbb{X}_1 \times \cdots \times \mathbb{X}_k$, where $\mathbb{X}_i \in \{\mathbb{S}^{n_i}, \mathbb{R}^{n_i}, \mathbb{L}^{n_i}\}$ there exists a right-angled polytope P and a linearly independent vector-coloring Λ of rank r such that the geometric manifold $N(P, \Lambda)$ has a hyperelliptic involution in the group \mathbb{Z}_2^r canonically acting on it.*

In dimension $n = 4$ there are 10 geometries of this form. We prove that *for the geometries \mathbb{S}^4 , $\mathbb{S}^3 \times \mathbb{R}$, $\mathbb{S}^2 \times \mathbb{S}^2$, $\mathbb{S}^2 \times \mathbb{R}^2$, $\mathbb{S}^2 \times \mathbb{L}^2$, and $\mathbb{L}^2 \times \mathbb{L}^2$ there is such a pair (P, Λ) , and for the geometries \mathbb{R}^4 , \mathbb{L}^4 , $\mathbb{L}^3 \times \mathbb{R}$, $\mathbb{L}^2 \times \mathbb{R}^2$ there are no such pairs.*

The paper is organized as follows.

In Section 2 on the base of results from [CP17, CP20] we give a criterion (Lemma 2.4) when $N(P, \Lambda)$ is a rational homology n -sphere and specify it (Theorem 2.7) for dimensions $n \leq 4$.

In Section 3 we prove our **first main result** (Theorem 3.14) – a criterion when $N(P, \Lambda) \simeq S^n$ for $n \leq 4$. For the proof we use the Armstrong theorem and results from Section 2. For general n we give a necessary condition (Lemma 3.10 and Corollary 3.11).

In Section 4 we study hyperelliptic involutions in \mathbb{Z}_2^r acting on manifolds $N(P, \Lambda)$.

In Subsection 4.1 we introduce the notions of a *subcomplex* $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ (Construction 4.2) and a *Hamiltonian subcomplex* (Definition 4.3). We give a criterion (Lemma 4.4) when the subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is Hamiltonian. We introduce (Definition 4.5) the notion of *defining* $(n-2)$ -*faces* of a subcomplex and reformulate (Proposition 4.6) the criterion in terms of the defining faces. In Proposition 4.7 we give a criterion when a set of disjoint $(n-2)$ -faces is a set of defining faces of a Hamiltonian subcomplex.

In Subsection 4.2 we introduce (Definition 4.8) the notion of the *adjacency graph* of a Hamiltonian subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$. If this graph is bipartite we call the Hamiltonian subcomplex *bipartite* (Definition 4.9).

- In Construction 4.11 we show how to induce the vector-coloring from a bipartite Hamiltonian subcomplex and in Example 4.13 we explain how a bipartite Hamiltonian subcomplex C defines a canonical vector-coloring *induced by* C .
- In Proposition 4.14 we show that for a closed manifold $N(P, \Lambda)$ there is a bijection between the involutions in $\mathbb{Z}_2^r \setminus \{0\}$ and proper bipartite Hamiltonian subcomplexes $C \subset \mathcal{C}(P, \Lambda)$ such that Λ is induced from some vector-coloring of C .
- In Proposition 4.15 we give a criterion when for a closed manifold $N(P, \Lambda)$ and an involution $\tau \in \mathbb{Z}_2^r$ the orbit space $N(P, \Lambda)/\langle \tau \rangle$ is also a closed manifold.
- In Proposition 4.16 we prove that if the vector-coloring of a bipartite Hamiltonian subcomplex defines a closed manifold, then so does the induced vector-coloring.

In Subsection 4.3 using the notion of a bipartite Hamiltonian subcomplex we reformulate (Corollary 4.20) the four color theorem for a simple 3-polytope P in terms of a disjoint union of circles containing all the vertices of P .

In Subsection 4.4 we study the structure of faces of the complex $\mathcal{C}(P, c)$ (Lemmas 4.22 and 4.23, Corollary 4.25).

- In Proposition 4.27 for a closed manifold $N(P, \Lambda)$ and a face G of $\mathcal{C}(P, \Lambda)$ we describe the submanifold in $N(P, \Lambda)$ arising as a preimage of G under the projection $N(P, \Lambda) \rightarrow P$.
- In Proposition 4.28 we describe the face structure of defining faces M_q of a Hamiltonian subcomplex $C \subset \mathcal{C}(P, c)$ in terms of the intersections of M_q with faces of C .
- In Proposition 4.29 and Corollary 4.30 we describe k -faces of a Hamiltonian subcomplex $C \subset \mathcal{C}(P, c)$ as unions of k -faces of $\mathcal{C}(P, c)$ separated by $(k-1)$ -faces of defining faces.

In Subsection 4.5 for a closed manifold $N(P, \Lambda)$ and an involution $\tau \in \mathbb{Z}_2^r$ such that $N(P, \Lambda)/\langle \tau \rangle$ is also a closed manifold we describe the mapping $N(P, \Lambda) \rightarrow N(P, \Lambda)/\langle \tau \rangle$ as a two-sheeted branched covering.

In Subsection 4.6 we introduce (Definition 4.32) the notions of a $\mathcal{C}(n, k)$ -*subcomplex* and a *Hamiltonian* $\mathcal{C}(n, k)$ -*subcomplex*.

- In Corollary 4.33 we describe explicitly the subgroup $H(C) \subset \mathbb{Z}_2^m$ corresponding to a $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$.
- In Corollary 4.34 we reformulate our **first main result** in terms of $\mathcal{C}(n, k)$ -subcomplexes $C \subset \partial P$ of a polytope P of dimension $n \leq 4$.

- In Proposition 4.35 we prove that for any facet \tilde{G} of a proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \mathcal{C}(P, c)$ the adjacency graph of facets of $\mathcal{C}(P, c)$ lying in \tilde{G} is a tree. In particular, any proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex is bipartite.
- In Construction 4.38 we show that any proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \mathcal{C}(P, c)$ induces a canonical vector-coloring $\tilde{\Lambda}_C$ of rank $(k + 1)$ such that $\mathcal{C}(P, c) = \mathcal{C}(P, \tilde{\Lambda}_C)$ and $N(P, \tilde{\Lambda}_C)$ is a hyperelliptic manifold with a canonical hyperelliptic involution in \mathbb{Z}_2^{k+1} corresponding to C .
- In Theorem 4.39 we formulate our **second main result**, namely that for $n \leq 4$ and a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed manifold hyperelliptic involutions are in bijection with proper Hamiltonian $\mathcal{C}(n, r - 1)$ -subcomplexes $C \subset \mathcal{C}(P, \Lambda)$ inducing Λ .
- In Proposition 4.41 we prove that for a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex $C \subset \mathcal{C}(P, c)$ if a k -face \tilde{G} of C is not a circle, then the adjacency graph $\Gamma(\tilde{G})$ of k -faces G of $\mathcal{C}(P, c)$ lying in \tilde{G} is a tree.
- Using this fact in Proposition 4.43 we obtain the formula expressing the number of k -faces of a complex $\mathcal{C}(P, c)$ in terms of the numbers of k -faces and $(k - 1)$ -faces of defining faces of a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex.
- In Proposition 4.44 we prove that for any defining $(n - 2)$ -face M_q of a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex $C \subset \mathcal{C}(P, c)$ its facets can be colored in $(r - 1)$ colors in such a way that adjacent facets have different colors.

In Subsection 4.7 we study geometric structures on hyperelliptic manifolds $N(P, \Lambda)$. Our main tool is Construction 4.45 of a geometric hyperelliptic manifold using a proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex C in the boundary of a compact right-angled polytope P in some geometry \mathbb{X} . This construction is a direct generalization of the construction from [M90, VM99M, VM99S2] based on a Hamiltonian cycle, theta- or K_4 -subgraph in the boundary of a right-angled 3-polytope.

- In Corollary 4.49 we show that \mathbb{I}^n does not admit Hamiltonian $\mathcal{C}(n, k)$ -subcomplexes for $n \leq 4$. In particular, the geometry \mathbb{R}^n does not admit Construction 4.45 for $n \geq 4$.
- In Corollaries 4.51 and 4.53 and Remark 4.52 we show that if P admits a Hamiltonian $\mathcal{C}(n, n - 1)$ -subcomplex, then each defining face is a polytope with only even-gonal 2-faces.
- In Proposition 4.56 we show that if a 4-polytope P admits a proper Hamiltonian $\mathcal{C}(4, r)$ -subcomplex, then P has at least one 2-face with three or four edges. In particular, the geometry \mathbb{L}^4 does not admit Construction 4.45, as well as \mathbb{L}^n for $n \geq 5$ since in the latter geometries there are no compact right-angled polytopes due to results by V.V. Nikulin [N82] (see [V17]).
- In Proposition 4.57 we show that if a 4-polytope $P = Q \times I$ admits a proper Hamiltonian $\mathcal{C}(4, r)$ -subcomplex, then one of the defining faces is a triangle. In particular, the geometries $\mathbb{L}^3 \times \mathbb{R}$ and $\mathbb{L}^2 \times \mathbb{R}^2$ do not admit Construction 4.45.

- In Proposition 4.58 we show that Δ^n admits a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex. In particular, the geometry \mathbb{S}^n admits Construction 4.45 for $n \geq 2$.
- In Proposition 4.61 we show that the prism $\Delta^{n-1} \times I$ admits Hamiltonian $\mathcal{C}(n, n)$ and $\mathcal{C}(n, n+1)$ -subcomplexes for $n \geq 4$. In particular, the geometry $\mathbb{S}^{n-1} \times \mathbb{R}$ admits Construction 4.45 for $n \geq 3$.
- In Construction 4.62 we describe the operation of cutting off a face and show that the initial polytope defines a proper Hamiltonian subcomplex in the resulting polytope. As a result in Corollary 4.68 we show that the polytope $P^n = \Delta^p \times \Delta^q$ has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex for $p, q \geq 1$. In particular, the geometry $\mathbb{S}^p \times \mathbb{S}^q$, $p, q \geq 2$, admits Construction 4.45.
- In Proposition 4.70 we show that if P^n has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex such that its defining faces $\{M_1, \dots, M_s\}$ do not intersect a facet $F_i \simeq \Delta^{n-1}$, then for any $k \geq 1$ the polytope $\Delta^k \times P$ has a Hamiltonian $\mathcal{C}(n+k, n+k+1)$ -subcomplex, and in Corollary 4.71 we show that for any $p, q \geq 1$ the polytope $P^n = \Delta^p \times \Delta^q \times I$ has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex. In particular, the geometries $\mathbb{S}^p \times \mathbb{S}^q \times \mathbb{R}$, $p, q \geq 2$, and $\mathbb{S}^p \times \mathbb{R}^2$, $p \geq 2$, admit Construction 4.45.
- In Proposition 4.72 we show that if an n -polytope P has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex C such that its defining faces $\{M_1, \dots, M_s\}$ do not intersect an $(n-2)$ -face $G \subset P$, then $G \simeq \Delta^{n-2}$, and P has a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex. Using this fact in Corollary 4.73 we show that $\Delta^2 \times \Delta^{n-2}$ has a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex for $n \geq 3$, and in Corollary 4.74 we show that for $p \geq 1$ the polytope $P^n = \Delta^p \times P_k$, where P_k is a k -gon, $k \geq 3$, admits Hamiltonian $\mathcal{C}(n, n)$ - and $\mathcal{C}(n, n+1)$ -subcomplexes. In particular, the geometries $\mathbb{S}^p \times \mathbb{S}^2$, $\mathbb{S}^p \times \mathbb{R}^2$ and $\mathbb{S}^p \times \mathbb{L}^2$, $p \geq 2$, admit Construction 4.45.
- In Example 4.75 we show that the polytope $P_5 \times P_5$ admits a Hamiltonian $\mathcal{C}(4, 5)$ -subcomplex. In particular, the geometry $\mathbb{L}^2 \times \mathbb{L}^2$ admits Construction 4.45.
- In Lemma 4.60 we show that if for a defining $(n-2)$ -face F of a Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$ different facets of F correspond to different facets of C , then in the branch set of the covering $N(P, \tilde{\Lambda}_C) \rightarrow S^n$ the preimage of F is a disjoint union of 2^{k-1-m_F} copies of $\mathbb{R}\mathcal{Z}_F$, where m_F is the number of facets of F .
- Using Lemma 4.60 and Proposition 4.31 for each Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$ arising in this subsection we describe the branch set of the corresponding 2-sheeted branched covering of S^n .

We conclude Subsection 4.7 with our **third main result** – Theorem 4.76.

2. RATIONAL HOMOLOGY 4-SPHERES AMONG $N(P, \Lambda)$

Definition 2.1. We call a topological space X a *rational homology n -sphere* (n -RHS), if X is a compact closed topological n -manifold and $H_k(X, \mathbb{Q}) = H_k(S^n, \mathbb{Q})$ for all k . By definition X is an n -RHS for $n < 0$, if $X = \emptyset$.

We call X a *rational homology n -disk* (n -RHD), if X is a compact orientable topological n -manifold with a boundary such that $H_k(X, \mathbb{Q}) = H_k(D^n, \mathbb{Q})$ for all k , where $D^n =$

$\{(x_1, \dots, x_n) \in \mathbb{R}^n : x_1^2 + \dots + x_n^2 \leq 1\}$ is an n -disk. By definition X is an n -RHD for $n < 0$, if $X = \text{pt}$.

Lemma 2.2. *If X is an n -RHD, then ∂X is an $(n - 1)$ -RHS for $n \geq 1$.*

Proof. This follows from the long exact sequence in homology

$$\dots \rightarrow \tilde{H}_k(\partial X) \rightarrow \tilde{H}_k(X) \rightarrow H_k(X, \partial X) \rightarrow \tilde{H}_{k-1}(\partial X) \rightarrow \dots$$

the Poincare-Lefschets duality $H_k(X, \partial X) \simeq H^{n-k}(X)$ and the universal coefficients formula. \square

We will use the following result, which was first proved for small covers and \mathbb{Q} coefficients in [ST12, T12]. Let us identify the subsets $\omega \subset [m] = \{1, \dots, m\}$ with vectors $\mathbf{x} \in \mathbb{Z}_2^m$ by the rule $\omega = \{i : x_i = 1\}$. For a vector-coloring Λ of rank $(r + 1)$ denote by $\text{row } \Lambda$ the subspace in \mathbb{Z}_2^m generated by the row vectors of the matrix Λ . Equivalently,

$$\text{row } \Lambda = \{(x_1, \dots, x_m) \in \mathbb{Z}_2^m : \exists \mathbf{c} \in (\mathbb{Z}_2^{r+1})^* : x_i = \mathbf{c}\Lambda_i, i = 1, \dots, m\}.$$

Remind that $P_\omega = \bigcup_{i \in \omega} F_i$.

Theorem 2.3. [CP17, Theorem 4.5](see also [CP20, Theorem 1.1]) *Let Λ be a vector-coloring of rank $(r + 1)$ of a simple n -polytope P and R be a commutative ring in which 2 is a unit. Then there is an R -linear isomorphism*

$$H^k(N(P, \Lambda), R) \simeq \bigoplus_{\omega \in \text{row } \Lambda} \tilde{H}^{k-1}(P_\omega, R)$$

Let is remind that a closed orientable manifold $N(P, \Lambda)$ is defined by a an affine coloring λ of rank r , where for some change of coordinates in \mathbb{Z}_2^{r+1} we have $\Lambda_i = (1, \lambda_i)$. Theorem 2.3 and the universal coefficients formula imply

Proposition 2.4. *Let λ be an affine coloring of rank r of a simple n -polytope P . The space $N(P, \lambda)$ is a rational homology n -sphere if and only if one of the following equivalent conditions holds:*

- (1) $\bigcup_{i: \lambda_i \in \pi} F_i$ is an $(n - 1)$ -RHD for any affine hyperplane $\pi \subset \mathbb{Z}_2^r$;
- (2) $\bigcup_{i: \lambda_i \in \pi} F_i$ is an $(n - 1)$ -RHD for any affine hyperplane $\pi \subset \mathbb{Z}_2^r$ passing through some pint $\mathbf{p} \in \mathbb{Z}_2^r$.

We will use the following *Generalized Shoenflies theorem*.

Theorem 2.5. [B60, Theorem 5] *Let h be a homeomorphic embedding of $S^{n-1} \times I$ into S^n . Then the closure of either complementary domain of $h(S^{n-1} \times \frac{1}{2})$ is homeomorphic to D^n .*

Lemma 2.6. *Let $n \leq 4$. If P_ω is an $(n - 1)$ -RHD, then it is homeomorphic to an $(n - 1)$ -disk D^{n-1} .*

Proof. For $n \leq 2$ this is trivial. Let $n \in \{3, 4\}$. If P_ω is an $(n-1)$ -RHD, then by Lemma 2.2 ∂P_ω is an $(n-2)$ -RHS. For $n \in \{3, 4\}$ this means that ∂P_ω is homeomorphic to S^{n-2} . Since P_ω and $P_{[m]\setminus\omega}$ are compact piecewise linear manifolds (see Lemma 2.10), their common boundary ∂P_ω has a collar neighbourhood in both spaces and the embedding $S^{n-2} \simeq \partial P_\omega$ to $\partial P \simeq S^{n-1}$ can be extended to an embedding of $S^{n-2} \times I$. Then by Theorem 2.5 P_ω and $P_{[m]\setminus\omega}$ are topological $(n-1)$ -disks. \square

This leads to the following result.

Theorem 2.7. *Let λ be an affine coloring of rank r of a simple n -polytope P , where $2 \leq n \leq 4$. The space $N(P, \lambda)$ is a rational homology n -sphere if and only if one of the following equivalent conditions holds:*

- (1) $\bigcup_{i: \lambda_i \in \pi} F_i$ is an $(n-1)$ -disk for any affine hyperplane $\pi \subset \mathbb{Z}_2^r$;
- (2) $\bigcup_{i: \lambda_i \in \pi} F_i$ is an $(n-1)$ -disk for any affine hyperplane $\pi \subset \mathbb{Z}_2^r$ passing through some pint $\mathbf{p} \in \mathbb{Z}_2^r$.

Definition 2.8. We call a subset $A \subset B$ *proper*, if $\emptyset \neq A \neq B$. For a collection of pairwise disjoint subsets $\omega_1, \dots, \omega_k \subset [m]$ define $P_{\omega_1, \dots, \omega_k} = P_{\omega_1} \cap P_{\omega_2} \cap \dots \cap P_{\omega_k}$.

Lemma 2.9. *For any simple n -polytope P and any collection of pairwise disjoint proper subsets $\omega_1, \dots, \omega_k \subset [m]$, if $P_{\omega_1, \dots, \omega_k} \neq \emptyset$, then it is an orientable $(n-k)$ -manifold, perhaps with a boundary.*

Proof. As it is mentioned in [E24, Corollary 2.4], $P_{\omega_1, \dots, \omega_k}$ is an $(n-k)$ -manifold, perhaps with a boundary. This is based on the following fact which we will use later.

Lemma 2.10. [E24, Lemma 2.2] *Let a point $p \in \partial P$ belong to exactly $l \geq 0$ facets G_{i_1}, \dots, G_{i_l} of $\mathcal{C}(P, c)$. Then there is a piecewise linear homeomorphism φ of a neighbourhood $U \subset P$ of p such that $U \cap G_j = \emptyset$ for $j \notin \{i_1, \dots, i_l\}$ to a neighbourhood $V \subset \mathbb{R}_{\geq}^l \times \mathbb{R}^{n-l}$ such that $\varphi(G_{j_s} \cap U) = V \cap \{y_s = 0\}$, $s = 1, \dots, l$.*

Remark 2.11. It is not stated explicitly in [E24, Lemma 2.2] that $U \cap G_j = \emptyset$ for $j \notin \{i_1, \dots, i_l\}$ but this condition can be achieved using a smaller neighbourhood.

Let us proof that the manifold $P_{\omega_1, \dots, \omega_k}$ is orientable. Indeed for $k = 1$ the set P_ω is a manifold with a boundary, and $P_\omega \setminus \partial P_\omega$ is in open subset in $\partial P \simeq S^{n-1}$. Hence, P_ω is orientable. Assume that our claim is valid for $1, \dots, k-1$. Then $P_{\omega_1, \dots, \omega_k} = P_{\omega_1, \dots, \omega_{k-1}} \cap P_{\omega_k}$ and $P_{\omega_1, \dots, \omega_k} \setminus \partial P_{\omega_1, \dots, \omega_k}$ is an open subset in $\partial P_{\omega_1, \dots, \omega_{k-1}}$, which is an orientable manifold, since it is a boundary of an orientable manifold. Thus, $P_{\omega_1, \dots, \omega_k}$ is orientable. \square

Lemma 2.12. *Let P be an n -polytope, and let $\omega_1, \omega_2 \subset [m]$ be subsets such that $\omega_1 \cap \omega_2 = \emptyset$, and $P_{\omega_1}, P_{\omega_2}$ are $(n-1)$ -RHD.*

- If $P_{\omega_1 \sqcup \omega_2}$ is an $(n-1)$ -RHD, then $P_{\omega_1} \cap P_{\omega_2}$ is an $(n-2)$ -RHD.
- If $P_{\omega_1 \sqcup \omega_2}$ is an $(n-1)$ -RHS, then $\omega_1 \sqcup \omega_2 = [m]$ and $P_{\omega_1} \cap P_{\omega_2}$ is an $(n-2)$ -RHS.

Proof. The first item follows from Lemma 2.9 and the Mayer-Vietoris sequence in reduced homology

$$\cdots \rightarrow \tilde{H}_k(P_{\omega_1} \cap P_{\omega_2}) \rightarrow \tilde{H}_k(P_{\omega_1}) \oplus \tilde{H}_k(P_{\omega_2}) \rightarrow \tilde{H}_k(P_{\omega_1 \sqcup \omega_2}) \rightarrow \tilde{H}_{k-1}(P_{\omega_1} \cap P_{\omega_2}) \rightarrow \cdots$$

The second item follows from these facts and the Alexander duality $\tilde{H}^k(P_\omega) = \tilde{H}_{n-2-k}(P_{[m] \setminus \omega})$ in the sphere $\partial P \simeq S^{n-1}$, since $P_{[m] \setminus \omega}$ is homotopy equivalent to $\partial P \setminus P_\omega$. \square

Corollary 2.13. *Let P be an n -polytope, $n \leq 4$, and let $\omega_1, \omega_2 \subset [m]$ be subsets such that $\omega_1 \cap \omega_2 = \emptyset$, and $P_{\omega_1}, P_{\omega_2}$ are $(n-1)$ -disks.*

- *If $P_{\omega_1 \sqcup \omega_2}$ is an $(n-1)$ -disk, then $P_{\omega_1} \cap P_{\omega_2}$ is an $(n-2)$ -disk.*
- *If $P_{\omega_1 \sqcup \omega_2}$ is an $(n-1)$ -sphere, then $\omega_1 \sqcup \omega_2 = [m]$, and $P_{\omega_1} \cap P_{\omega_2}$ is an $(n-2)$ -sphere.*

3. A CRITERION WHEN $N(P, \Lambda) \simeq S^4$

We will use the following result.

Theorem 3.1. (*Armstrong, [A65, Theorem 3]*). *Let X be a connected simply connected simplicial complex and let a finite group G acts on X by simplicial homeomorphisms. Let H be a subgroup in G generated by all the elements $h \in G$ such that the set of fixed points X^h is nonempty. Then $\pi_1(X/G)$ is isomorphic to G/H .*

For any, not necessarily right-angled, simple polytope P define the right-angled Coxeter group

$$\mathcal{G}(P) = \langle \rho_1, \dots, \rho_m \rangle / (\rho_1^2 = \cdots = \rho_m^2 = e, \rho_i \rho_j = \rho_j \rho_i, \text{ if } F_i \cap F_j \neq \emptyset).$$

Definition 3.2 (see [V71, D83, D08]). Define a space

$$W(P) = P \times \mathcal{G}(P) / \sim,$$

$$\text{where } (p, g_1) \sim (q, g_2) \text{ if and only if } p = q \text{ and } g_1^{-1} g_2 \in \langle \rho_i : p \in F_i \rangle$$

Proposition 3.3. [D83, Theorems 10.1 and 13.5] *We have $\pi_1(W(P)) = 0$.*

The proof of the following fact is straightforward.

Proposition 3.4. *The space $W(P)$ is a connected topological n -manifold. Moreover, it has a structure of a simplicial complex such that $\mathcal{G}(P)$ acts on it simplicially (the action comes from the action of $\mathcal{G}(P)$ on itself $g(x) = gx$). Moreover, $W(P)/\mathcal{G}(P) \simeq P$.*

Any vector-coloring Λ defines an epimorphism $\varphi_\Lambda: \mathcal{G}(P) \rightarrow \mathbb{Z}_2^r$.

Proposition 3.5. *We have $N(P, \Lambda) = W(P)/\text{Ker } \varphi$.*

Corollary 3.6. *We have $\pi_1(N(P, \Lambda)) \simeq \text{Ker } \varphi / K$, where the subgroup K is generated by kernels of the mappings $\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle \simeq \mathbb{Z}_2^n \rightarrow \mathbb{Z}_2^r$, $g\rho_{i_s}g^{-1} \rightarrow \Lambda_{i_s}$, for all elements $g \in G$ and all vertices $F_{i_1} \cap \cdots \cap F_{i_n}$ of P .*

Proof. We have $St_{\mathcal{G}(P)}[p, g] = \langle g\rho_i g^{-1} : p \in F_i \rangle$. Therefore, $St_{\text{Ker } \varphi}[p, g] = \text{Ker } \varphi \cap \langle g\rho_i g^{-1} : p \in F_i \rangle$. Any such a subgroup lies in a subgroup corresponding to some vertex of P . \square

Lemma 3.7. *Let $\pi_1(N(P, \Lambda)) = 0$. Then different vectors among $\Lambda_1, \dots, \Lambda_m$ are linearly independent and form a basis in \mathbb{Z}_2^r .*

Proof. If $\pi_1(N(P, \Lambda)) = 0$, then $\text{Ker } \varphi$ is generated by kernels of the mappings $\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle \simeq \mathbb{Z}_2^n \rightarrow \mathbb{Z}_2^r$, $g\rho_{i_s}g^{-1} \rightarrow \Lambda_{i_s}$, for all elements $g \in \mathcal{G}(P)$ and all vertices $F_{i_1} \cap \dots \cap F_{i_n}$ of P .

Consider the composition $\mathcal{G}(P) \rightarrow \mathbb{Z}_2^m \rightarrow \mathbb{Z}_2^r$, where the first mapping $\pi: \rho_i \rightarrow \mathbf{e}_i$ is the abelianization homomorphism, and the second mapping Λ is a linear mapping defined by the condition $\mathbf{e}_i \rightarrow \Lambda_i$. We have $\pi^{-1}(\text{Ker } \Lambda) = \text{Ker } \varphi$ and

$$\pi \langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle = \pi \langle \rho_{i_1}, \dots, \rho_{i_n} \rangle = \langle \mathbf{e}_{i_1} \dots \mathbf{e}_{i_n} \rangle.$$

In particular, the restrictions of π to $\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle$ is injective for any vertex v and any $g \in \mathcal{G}(P)$. Also

$$\pi^{-1}(\text{Ker } \Lambda |_{\langle \mathbf{e}_{i_1} \dots \mathbf{e}_{i_n} \rangle}) = \text{Ker } \varphi |_{\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle}.$$

Since $\text{Ker } \varphi$ is generated by kernels $\text{Ker } \varphi |_{\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle}$, the group $\pi(\text{Ker } \varphi) = \text{Ker } \Lambda$ is generated by the subgroups $\pi(\text{Ker } \varphi |_{\langle g\rho_{i_1}g^{-1}, \dots, g\rho_{i_n}g^{-1} \rangle}) = \text{Ker } \Lambda |_{\langle \mathbf{e}_{i_1} \dots \mathbf{e}_{i_n} \rangle}$ for all vertices $F_{i_1} \cap \dots \cap F_{i_n}$ of P , that is

$$(1) \quad \text{Ker } \Lambda = \sum_{v \in P} \text{Ker } \Lambda |_{\langle \mathbf{e}_{i_1} \dots \mathbf{e}_{i_n} \rangle}$$

If $N(P, \Lambda)$ is a closed topological manifold, then by [E24, Theorem 5.1] at each vertex $F_{i_1} \cap \dots \cap F_{i_n}$ different vectors among $\{\Lambda_{i_1}, \dots, \Lambda_{i_n}\}$ are linearly independent. In particular, $\text{Ker } \Lambda |_{\langle \mathbf{e}_{i_1} \dots \mathbf{e}_{i_n} \rangle}$ is generated by the vectors $\mathbf{e}_{i_a} + \mathbf{e}_{i_b}$ with $\Lambda_{i_a} = \Lambda_{i_b}$. We have $[m] = \{1, \dots, m\} = S_1 \sqcup \dots \sqcup S_t$, where $\Lambda_i = \Lambda_j$ (equivalently, $\mathbf{e}_i + \mathbf{e}_j \in \text{Ker } \Lambda$) if and only if i and j lie in the same set S_k . Assume that there is a linear dependence $\Lambda_{j_1} + \dots + \Lambda_{j_l} = 0$, where all the vectors $\{\Lambda_{j_1}, \dots, \Lambda_{j_l}\}$ are pairwise different, that is $e_{j_p} \in S_{i_p}$, where $i_p \neq i_q$ if $j_p \neq j_q$. Then $\mathbf{e}_{j_1} + \dots + \mathbf{e}_{j_l} \in \text{Ker } \Lambda$, and by (1)

$$\mathbf{e}_{j_1} + \dots + \mathbf{e}_{j_l} = \sum_{i=1}^t \sum_{a,b \in S_i, a < b} \lambda_{a,b} (\mathbf{e}_a + \mathbf{e}_b).$$

Since there is a direct sum $\mathbb{Z}_2^m = \bigoplus_{i=1}^t \langle \mathbf{e}_j : j \in S_i \rangle$, we have $\mathbf{e}_{j_p} = \sum_{a,b \in S_{i_p}, a < b} \lambda_{a,b} (\mathbf{e}_a + \mathbf{e}_b)$. But on the left side the sum $x_1 + \dots + x_m$ of all the coordinates of the vector is 1, and on the right side it is 0. A contradiction. Thus, all different vectors among $\{\Lambda_1, \dots, \Lambda_m\}$ are linearly independent. In particular, they form a basis in \mathbb{Z}_2^r . \square

Definition 3.8. For a subset $\omega \subset [M] = \{1, \dots, M\}$ define $G_\omega = \bigcup_{i \in \omega} G_i$. For a collection of pairwise disjoint subsets $\omega_1, \dots, \omega_k \subset [M]$ define $G_{\omega_1, \dots, \omega_k} = G_{\omega_1} \cap \dots \cap G_{\omega_k}$.

Corollary 3.9. *Let $N(P, \Lambda) \simeq S^n$. Then for each proper subset $\omega \subset [M]$ the set G_ω is an $(n-1)$ -RHD. For $\omega = [M]$ we have $G_\omega = \partial P \simeq S^{n-1}$.*

Proof. This follows directly from Theorem 2.3 and Proposition 2.4. \square

Lemma 3.10. *Let $N(P, \Lambda) \simeq S^n$. Then for each collection of pairwise disjoint proper subsets $\omega_1, \dots, \omega_k \subset [M]$ the set $G_{\omega_1, \dots, \omega_k}$ is*

- an $(n - k)$ -RHD, if $\omega_1 \sqcup \dots \sqcup \omega_k \neq [M]$;
- an $(n - k)$ -RHS, if $\omega_1 \sqcup \dots \sqcup \omega_k = [M]$;

Proof. We will prove this by induction on k . For $k \leq 2$ this follows from Lemma 2.12 and Corollary 3.9. Let the lemma hold for $1, \dots, k - 1$. We have $G_{\omega_1, \dots, \omega_k} = G_{\omega_1, \dots, \omega_{k-2}, \omega_{k-1}} \cap G_{\omega_1, \dots, \omega_{k-2}, \omega_k}$, where $G_{\omega_1, \dots, \omega_{k-2}, \omega_{k-1}} \cup G_{\omega_1, \dots, \omega_{k-2}, \omega_k} = G_{\omega_1, \dots, \omega_{k-2}, \omega_{k-1} \sqcup \omega_k}$. Now the proof follows from the Mayer-Vietoris sequence and Lemma 2.9. \square

Corollary 3.11. *Let $N(P, \Lambda) \simeq S^n$. Then $M \leq n + 1$ and each k -face of the complex $C(P, \Lambda)$ is either a k -RHD or a k -RHS.*

Proof. Indeed, $G_1 \cap \dots \cap G_{M-1}$ is an $(n - M + 1)$ -RHD. In particular, it is nonempty. But the intersection of any $n + 1$ facets of P is empty, hence $M - 1 \leq n$. Each k -face of $C(P, \Lambda)$ is a connected component of $G_{i_1} \cap \dots \cap G_{i_{n-k}}$, hence by Lemma 3.10 it is a k -RHD if $n - k < M$, and a k -RHD if $n - k = M$. \square

Corollary 3.12. *Let $n \leq 4$. If $N(P, \Lambda) \simeq S^n$, then $M \leq n + 1$ and for each collection of pairwise disjoint proper subsets $\omega_1, \dots, \omega_k \subset [M]$ the set $G_{\omega_1, \dots, \omega_k}$ is*

- an $(n - k)$ -disk, if $\omega_1 \sqcup \dots \sqcup \omega_k \neq [M]$;
- an $(n - k)$ -sphere, if $\omega_1 \sqcup \dots \sqcup \omega_k = [M]$.

Proof. This follows from Lemmas 3.10 and 2.6 and the fact that an n -RHS is a topological n -sphere for $n \leq 2$ and an n -RHD is a topological 2-disk for $n \leq 2$. \square

Lemma 3.13. *Let $n \leq 4$. If for a complex $\mathcal{C}(P, \Lambda)$ we have $M \leq n + 1$ and for each collection of pairwise disjoint proper subsets $\omega_1, \dots, \omega_k \subset [M]$ the set $G_{\omega_1, \dots, \omega_k}$ is*

- an $(n - k)$ -disk, if $\omega_1 \sqcup \dots \sqcup \omega_k \neq [M]$;
- an $(n - k)$ -sphere, if $\omega_1 \sqcup \dots \sqcup \omega_k = [M]$,

then $\mathcal{C}(P, \Lambda)$ is equivalent to $\mathcal{C}(n, M)$.

Proof. For $n = 2$ the statement is trivial.

Let $n = 3$. If $M = 1$, then $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 1)$. If $M = 2$, then G_1 and G_2 are 2-disks such that $\partial G_1 = \partial G_2 = G_1 \cap G_2$ is a circle. Hence, $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 2)$. If $M = 3$, then G_1, G_2 and G_3 are 2-disks such that $G_i \cap G_j$ is a simple path for any $i \neq j$, and all these three paths have common ends, which form the 0-sphere $G_1 \cap G_2 \cap G_3$. Thus, the 1-skeleton of $\mathcal{C}(P, \Lambda)$ is a theta-graph, and $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 3)$. If $M = 4$, then each G_i is a disk, the intersection $G_i \cap G_j$ of each two such disks is a simple path, the intersection of any three such disks is a point, and the intersection of all the 4-disks is empty. Then the 1-skeleton of $\mathcal{C}(P, \Lambda)$ is a K_4 -graph, and $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 3)$.

Let $n = 4$. If $M = 1$, then $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 1)$. If $M = 2$, then G_1 and G_2 are 3-disks such that $\partial G_1 = \partial G_2 = G_1 \cap G_2$ is a 2-sphere. Hence, $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 2)$. If $M = 3$, then G_1, G_2 and G_3 are 3-disks, such that $G_i \cap G_j$ is a 2-disk for $i < j$, and $G_1 \cap G_2 \cap G_3$ is a circle. We have $G_1 \cup G_2$ is a 3-disk with a circle $G_1 \cap G_2 \cap G_3 = \partial(G_1 \cap G_2)$ on its boundary, and the complement to this disk is the interior of G_3 . Hence, $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 3)$. If $M = 4$, then G_1, G_2, G_3, G_4 are 4-disks,

$G_i \cap G_j$ is a 2-disk for any $i < j$, $G_i \cap G_j \cap G_k$ is a simple path for any $i < j < k$, and all these four paths have the common ends, which form the 0-sphere $G_1 \cap G_2 \cap G_3 \cap G_4$. Then $G_1 \cup G_2 \cup G_3$ is a 3-disk with the theta-graph on the boundary formed by paths $G_i \cap G_j \cap G_4$, $i < j < 4$. There is the path $G_1 \cap G_2 \cap G_3$ inside this disk connecting the vertices of the theta-graph and each $G_i \cap G_j$ is a 2-disk bounded by the paths $G_1 \cap G_2 \cap G_3$ and $G_i \cap G_j \cap G_4$. The complement to $G_1 \cup G_2 \cup G_3$ in ∂P is the interior of G_4 . Thus, $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 4)$. If $M = 5$, then each G_i is a 3-disk, each intersection $G_i \cap G_j$, $i < j$, is a 2-disk, each intersection $G_i \cap G_j \cap G_k$, $i < j < k$, is a simple path, each intersection $G_i \cap G_j \cap G_k \cap G_l$, $i < j < k < l$, is a point, and $G_1 \cap G_2 \cap G_3 \cap G_4 \cap G_5 = \emptyset$. Then $G_1 \cup G_2 \cup G_3 \cup G_4$ is a 3-disk with a K_4 -graph on its boundary formed by vertices $G_i \cap G_j \cap G_k \cap G_5$ and edges $G_i \cap G_j \cap G_5$. There is a point $G_1 \cap G_2 \cap G_3 \cap G_4$ inside this disk such that the face structure in the disk $G_1 \cup G_2 \cup G_3 \cup G_4$ is a cone over the face structure on its boundary with this apex. Also the complement to this disk is the interior of G_5 . Thus, $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, 5) \simeq \partial \Delta^4$. □

As a corollary we obtain the following theorem.

Theorem 3.14. *Let Λ be a vector-coloring of rank r of a simple polytope of dimension $n \leq 4$. Then $N(P, \Lambda) \simeq S^n$ if and only if $\mathcal{C}(P, \Lambda) \simeq \mathcal{C}(n, r)$.*

Proof. The if part follows from [E24, Construction 5.8]. The only if part follows from Corollary 3.12 and Lemma 3.13. □

4. HYPERELLIPTIC MANIFOLDS $N(P, \Lambda)$

Theorem 3.14 implies the following result (see [E24, Construction 8.6] and [E24, Corollary 10.8]).

Corollary 4.1. *Let Λ be a vector-coloring of rank r of a simple n -polytope P , $n \leq 4$. Then an involution $\tau \in \mathbb{Z}_2^r$ is hyperelliptic (that is $N(P, \lambda) \simeq S^n$) if and only if τ is special (that is $\mathcal{C}(P, \Lambda_\tau) \simeq \mathcal{C}(n, r - 1)$).*

4.1. Hamiltonian subcomplexes.

Construction 4.2. For two colorings $c_1: \{F_1, \dots, F_m\} \rightarrow [l_1]$ and $c_2: \{F_1, \dots, F_m\} \rightarrow [l_2]$ we call $\mathcal{C}(P, c_2)$ a *subcomplex* in $\mathcal{C}(P, c_1)$ (and write $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$), if there is a mapping $\pi: [l_1] \rightarrow [l_2]$ such that $c_2 = \pi \circ c_1$. Each facet of $\mathcal{C}(P, c_2)$ is a union of facets of $\mathcal{C}(P, c_1)$. More generally, for any $q \geq 0$ each q -face of $\mathcal{C}(P, c_2)$ is a union of q -faces of $\mathcal{C}(P, c_1)$.

Definition 4.3. We call a subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ *Hamiltonian*, if each q -skeleton of $\mathcal{C}(P, c_1)$ belongs to the $(q + 1)$ -skeleton of $\mathcal{C}(P, c_2)$.

Lemma 4.4. *A subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is Hamiltonian if and only if one of the following equivalent conditions holds:*

- (1) *For each nonempty intersection $G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset$ of different facets of $\mathcal{C}(P, c_1)$ at least $(k - 1)$ of these facets lie in different facets of $\mathcal{C}(P, c_2)$.*

- (2) For each nonempty intersection $G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset$ of $k = 3$ or $k = 4$ different facets of $\mathcal{C}(P, c_1)$ at least $(k - 1)$ of these facets lie in different facets of $\mathcal{C}(P, c_2)$.
- (3) The following two conditions hold:
- $G_{i_1} \cap G_{i_2} \cap G_{i_3} = \emptyset$, if $c_2(G_{i_1}) = c_2(G_{i_2}) = c_2(G_{i_3})$ and $i_1 < i_2 < i_3$,
 - $G_{i_1} \cap G_{i_2} \cap G_{i_3} \cap G_{i_4} = \emptyset$, if $c_2(G_{i_1}) = c_2(G_{i_2}) \neq c_2(G_{i_3}) = c_2(G_{i_4})$ and $i_1 \neq i_2$, $i_3 \neq i_4$;
- (4) Any $(n - 4)$ -face of $\mathcal{C}(P, c_1)$ lies in an $(n - 3)$ -face of $\mathcal{C}(P, c_2)$, and any closed manifold among $(n - 3)$ -faces of $\mathcal{C}(P, c_1)$ lies in an $(n - 2)$ -face of $\mathcal{C}(P, c_2)$.

Proof. By Lemma 2.10 the facets of $\mathcal{C}(P, c)$ intersect locally as coordinate hyperplanes in \mathbb{R}^n (moreover, other facets do not intersect this local neighbourhood). By definition if $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is Hamiltonian, then the set $G_{i_1} \cap \dots \cap G_{i_k}$ lies in the $(n - k - 1)$ -skeleton of $\mathcal{C}(P, c_2)$. Take any point $p \in G_{i_1} \cap \dots \cap G_{i_k}$ such that $p \notin G_{j_l}$ for each facet G_{j_l} of $\mathcal{C}(P, c_1)$ different from G_{i_1}, \dots, G_{i_k} (such a point exists by the above argument). Then $p \in \tilde{G}_{j_1} \cap \dots \cap \tilde{G}_{j_{k-1}}$, where $\tilde{G}_{j_1}, \dots, \tilde{G}_{j_{k-1}}$ are different facets of $\mathcal{C}(P, c_2)$. We have $\tilde{G}_{j_p} = \bigcup_{G_q \subset \tilde{G}_{j_p}} G_q$ and

$$\tilde{G}_{j_1} \cap \dots \cap \tilde{G}_{j_{k-1}} = \left(\bigcup_{G_{q_1} \subset \tilde{G}_{j_1}} G_{q_1} \right) \cap \dots \cap \left(\bigcup_{G_{q_{k-1}} \subset \tilde{G}_{j_{k-1}}} G_{q_{k-1}} \right) = \bigcup_{q_1, \dots, q_{k-1}} G_{q_1} \cap \dots \cap G_{q_{k-1}}$$

Then $p \in G_{q_1} \cap \dots \cap G_{q_{k-1}}$ for some q_1, \dots, q_{k-1} . Therefore, by the choice of p we have $\{q_1, \dots, q_{k-1}\} \subset \{i_1, \dots, i_k\}$, where $G_{q_p} \subset \tilde{G}_{j_p}$. This implies item (1). On the other hand, if item (1) holds, then by definition the subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is Hamiltonian.

Item (1) implies item (2). Item (3) is a reformulation of item (2), so these items are equivalent.

Let item (2) hold. Consider a nonempty intersection $G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset$ of different facets of $\mathcal{C}(P, c_1)$. For $k \leq 4$ item (1) holds. Assume that $k \geq 5$ and item (1) does not hold. Then $|\{c_2(G_{i_1}), \dots, c_2(G_{i_k})\}| \leq k - 2$ and either $c_2(G_{i_{p_1}}) = c_2(G_{i_{p_2}}) = c_2(G_{i_{p_3}})$ for $p_1 < p_2 < p_3$, or $c_2(G_{i_{p_1}}) = c_2(G_{i_{p_2}}) \neq c_2(G_{i_{p_3}}) = c_2(G_{i_{p_4}})$ for $p_1 \neq p_2$ and $p_3 \neq p_4$. This contradicts item (3).

Item (2) implies item (4). If item (4) holds, then the argument in the beginning of the proof implies that item (3) hold for $k = 4$ and closed manifolds for $k = 3$. If $G_{i_1} \cap G_{i_2} \cap G_{i_3}$ is not a closed manifold, then there is a facet G_{i_4} of $\mathcal{C}(P, c_1)$ such that $G_{i_1} \cap G_{i_2} \cap G_{i_3} \cap G_{i_4} \neq \emptyset$. Then by the above argument it is impossible that G_{i_1}, G_{i_2} and G_{i_3} lie in the same facet of $\mathcal{C}(P, c_2)$. Hence, item (3) holds. \square

Lemma 4.4 leads to the following definition.

Definition 4.5. For a subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ let us call each connected component of a nonempty intersection $G_{i_1} \cap G_{i_2}$, where G_{i_1}, G_{i_2} are facets of $\mathcal{C}(P, c_1)$ and $c_2(G_{i_1}) = c_2(G_{i_2})$, a *defining* $(n - 2)$ -face.

Proposition 4.6. A subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is Hamiltonian if and only if any two defining $(n - 2)$ -facets are disjoint.

Proof. Let any two defining $(n-2)$ -facets be disjoint. If $c_2(G_{i_1}) = c_2(G_{i_2}) = c_2(G_{i_3})$ and $i_1 < i_2 < i_3$, then either one of the intersections $G_{i_1} \cap G_{i_2}$ and $G_{i_1} \cap G_{i_3}$ is empty, or each intersection is a disjoint union of defining faces and any two faces from different unions are also disjoint. Then

$$G_{i_1} \cap G_{i_2} \cap G_{i_3} = (G_{i_1} \cap G_{i_2}) \cap (G_{i_1} \cap G_{i_3}) = \emptyset.$$

If $c_2(G_{i_1}) = c_2(G_{i_2}) \neq c_2(G_{i_3}) = c_2(G_{i_4})$ and $i_1 \neq i_2, i_3 \neq i_4$, then either one of the intersection $G_{i_1} \cap G_{i_2}$ and $G_{i_3} \cap G_{i_4}$ is empty, or each intersection is a disjoint union of defining faces and any two faces from different unions are also disjoint. Then

$$G_{i_1} \cap G_{i_2} \cap G_{i_3} \cap G_{i_4} = (G_{i_1} \cap G_{i_2}) \cap (G_{i_3} \cap G_{i_4}) = \emptyset$$

Then the subcomplex is Hamiltonian by Lemma 4.4(3).

Now let the subcomplex be Hamiltonian. Consider two defining faces. If they are connected components of the same intersection $G_{i_1} \cap G_{i_2}$, then they are disjoint by definition. If they belong to different intersections $G_{i_1} \cap G_{i_2}$ and $G_{i_3} \cap G_{i_4}$, then there are two possibilities. First possibility is $c(G_{i_1}) = c(G_{i_2}) = c(G_{i_3}) = c(G_{i_4})$. Then without loss of generality we can assume that $i_3 \notin \{i_1, i_2\}$. Hence, $G_{i_1} \cap G_{i_2} \cap G_{i_3} = \emptyset$ by Lemma 4.4(3) and $(G_{i_1} \cap G_{i_2}) \cap (G_{i_3} \cap G_{i_4}) = \emptyset$. The second possibility is $c(G_{i_1}) = c(G_{i_2}) \neq c(G_{i_3}) = c(G_{i_4})$. Then $(G_{i_1} \cap G_{i_2}) \cap (G_{i_3} \cap G_{i_4}) = \emptyset$ by Lemma 4.4(3). This finishes the proof. \square

Proposition 4.7. *A set $\mathcal{S} = \{M_1^{n-2}, \dots, M_q^{n-2}\}$ of pairwise disjoint $(n-2)$ -faces of a complex $\mathcal{C}(P, c_1)$ is a set of defining faces of a Hamiltonian subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ if and only if for each two facets $G_i \neq G_j$ of $\mathcal{C}(P, c_1)$ admitting a sequence of facets $G_i = G_{i_1}, G_{i_2}, \dots, G_{i_p} = G_j$ such that for all s the intersection $G_{i_s} \cap G_{i_{s+1}}$ contains a face from \mathcal{S} either $G_i \cap G_j = \emptyset$ or each connected component of $G_i \cap G_j$ belongs to \mathcal{S} .*

Proof. If \mathcal{S} satisfies the above conditions then one can define a coloring c_2 by the rule $c_2(G_i) = c_2(G_j)$ if and only if G_i and G_j admit a sequence of the above type. Then each connected component of the intersection of two facets of the same color belongs to \mathcal{S} and this is indeed the set of defining facets. Since any two of them are disjoint, the subcomplex is Hamiltonian.

On the other hand, if \mathcal{S} is the set of defining faces of a Hamiltonian subcomplex, then the facets G_i and G_j admitting the above sequence necessarily have the same color. Hence, if $G_i \cap G_j \neq \emptyset$, then each connected component of $G_i \cap G_j$ belongs to \mathcal{S} . \square

4.2. Bipartite Hamiltonian subcomplexes and orbit spaces of involutions.

Definition 4.8. For a Hamiltonian subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ and a facet $\tilde{G} \in \mathcal{C}(P, c_2)$ define an *adjacency graph* $\Gamma(\tilde{G})$. Its vertices are facets G_i of $\mathcal{C}(P, c_1)$ lying in \tilde{G} . Its edges bijectively correspond to connected components of nonempty intersections $G_i \cap G_j \neq \emptyset$ of such facets, that is to defining $(n-2)$ -faces lying in \tilde{G} . This graph is connected and may have multiple edges corresponding to different connected components of $G_i \cap G_j \neq \emptyset$. Define an *adjacency graph*

$$\Gamma(P, c_1, c_2) = \bigsqcup_{\tilde{G} - \text{a facet of } \mathcal{C}(P, c_2)} \Gamma(\tilde{G}).$$

Definition 4.9. We call a Hamiltonian subcomplex $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ *bipartite*, if the adjacency graph $\Gamma(P, c_1, c_2)$ is bipartite, that is there is a coloring $\chi: \{G_1, \dots, G_{M_1}\} \rightarrow \{0, 1\}$ of facets of $\mathcal{C}(P, c_1)$ in two colors 0 and 1 such that if G_i and G_j lie in the same facet of $\mathcal{C}(P, c_2)$ and $G_i \cap G_j \neq \emptyset$, then $\chi(G_i) \neq \chi(G_j)$. We will call such colorings *nice*.

Remark 4.10. If $\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is a proper subcomplex and $\mathcal{C}(P, c_2)$ has M_2 facets, then there are 2^{M_2} nice colorings χ .

Construction 4.11 (The vector-coloring induced **from** a bipartite Hamiltonian subcomplex). Let $\Lambda: \{F_1, \dots, F_m\} \rightarrow \mathbb{Z}_2^r$ be a vector-coloring of rank r of a simple n -polytope P . Let $\mathcal{C}(P, \Lambda) \subset \mathcal{C}(P, c)$ be a proper bipartite Hamiltonian subcomplex and $\chi: \{G_1, \dots, G_{M_1}\} \rightarrow \{0, 1\}$ be one of its nice colorings. Define the vector-coloring $\Lambda_\chi: \{F_1, \dots, F_m\} \rightarrow \mathbb{Z}_2^r \times \mathbb{Z}_2 \simeq \mathbb{Z}_2^{r+1}$ of rank $r+1$ as $\Lambda_\chi(F_i) = (\Lambda(F_i), \chi(F_i))$. We call Λ_χ , as well as any vector-coloring obtained from it by a linear change of coordinates in \mathbb{Z}_2^{r+1} , a vector-coloring *induced from a bipartite Hamiltonian subcomplex*. By definition $\mathcal{C}(P, c) = \mathcal{C}(P, \Lambda_\chi)$.

Remark 4.12. It can be shown that in general different nice colorings χ_1 and χ_2 may produce vector colorings Λ_{χ_1} and Λ_{χ_2} that can not be connected by a linear change of coordinates in \mathbb{Z}_2^{r+1} .

Example 4.13 (A vector-coloring induced **by** a bipartite Hamiltonian subcomplex). For any complex $C = \mathcal{C}(P, c)$ with M facets G_1, \dots, G_M there is a canonical vector-coloring Λ_C of rank M of the polytope P defined as $\Lambda_C(F_i) = \mathbf{e}_j$, where $F_i \subset G_j$ and $\mathbf{e}_1, \dots, \mathbf{e}_M$ is the standard basis in \mathbb{Z}_2^M . (Note that different colorings c may produce the same complex $C = \mathcal{C}(P, c)$. Therefore, Λ_C is defined by the coloring c only if for each color the union of facets of the same color is connected.) Then if $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ is a proper bipartite Hamiltonian subcomplex, there is a canonical vector-coloring Λ_{c_2, c_1} *induced by* C . It is induced from the canonical vector-coloring Λ_C described above. Moreover, in this case for each $i = 1, \dots, M$ there is a linear isomorphism defined on basis as

$$(\mathbf{e}_1, \dots, \mathbf{e}_i, \dots, \mathbf{e}_M, \mathbf{e}_{M+1}) \rightarrow (\mathbf{e}_1, \dots, \mathbf{e}_i + \mathbf{e}_{M+1}, \dots, \mathbf{e}_M, \mathbf{e}_{M+1})$$

exchanging \mathbf{e}_i and $\mathbf{e}_i + \mathbf{e}_{M+1}$ and fixing \mathbf{e}_i and $\mathbf{e}_j + \mathbf{e}_{M+1}$ for all $j \neq i$. Therefore, Λ_{c_2, c_1} does not depend on χ up to a change of coordinates in \mathbb{Z}_2^{M+1} (see also [E24, Construction 8.6]).

For any vector-coloring Λ of rank r each nonzero involution $\tau \in \mathbb{Z}_2^r \simeq \mathbb{Z}_2^m / H(\Lambda)$ corresponds to a projection $\Pi_\tau: \mathbb{Z}_2^r \rightarrow \mathbb{Z}_2^r / \langle \tau \rangle \simeq \mathbb{Z}_2^{r-1}$ and a vector-coloring $\Lambda_\tau = \Lambda \circ \Pi_\tau$ such that $N(P, \Lambda) / \langle \tau \rangle \simeq N(P, \Lambda_\tau)$.

Proposition 4.14. *Let Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold. Then nonzero involutions $\tau \in \mathbb{Z}_2^r \setminus \{0\}$ are in bijection with proper bipartite Hamiltonian subcomplexes $\mathcal{C}(P, c) \subset \mathcal{C}(P, \Lambda)$ such that one of the following equivalent conditions holds:*

- (1) Λ is induced from some vector-coloring of $\mathcal{C}(P, c)$;
- (2) there is $\tau \in \mathbb{Z}_2^r \setminus \{0\}$ such that for any nonempty intersection of two different facets G_i and G_j of $\mathcal{C}(P, \Lambda)$ we have $\Lambda_i + \Lambda_j = \tau$ if and only if $c(G_i) = c(G_j)$.

Proof. First let us prove that for a proper bipartite Hamiltonian subcomplex $\mathcal{C}(P, c) \subset \mathcal{C}(P, \Lambda)$ conditions (1) and (2) are equivalent. Indeed, by Construction 4.11 (1) implies (2). On the other hand, if (2) holds, then the vector-coloring Λ_τ is constant on facets of $\mathcal{C}(P, c)$ and differs for its adjacent facets. Thus, $\mathcal{C}(P, c) = \mathcal{C}(P, \Lambda_\tau)$. Using the change of coordinates corresponding to an isomorphism $\mathbb{Z}_2^r / \langle \tau \rangle \oplus \langle \tau \rangle \simeq \mathbb{Z}_2^r$ we see that Λ is induced from Λ_τ . Thus, (1) holds.

Now consider a nonzero involution $\tau \in \mathbb{Z}_2^r$. The subcomplex $\mathcal{C}(P, \Lambda_\tau) \subset \mathcal{C}(P, \Lambda)$ is Hamiltonian by [E24, Proposition 5.12]. Moreover, it is bipartite. Indeed, for any two facets G_i, G_j of $\mathcal{C}(P, \Lambda)$ lying in the same facet of $\mathcal{C}(P, \Lambda_\tau)$ we have $\Pi_\tau(\Lambda_i) = \Pi_\tau(\Lambda_j)$. Then either $\Lambda_i = \Lambda_j$, or $\Lambda_i = \Lambda_j + \tau$. Moreover, if $G_i \cap G_j \neq \emptyset$, then $\Lambda_i = \Lambda_j + \tau$, since these vectors are different. Also condition (2) holds by definition of Λ_τ .

On the other hand, for a proper bipartite Hamiltonian subcomplex $\mathcal{C}(P, c)$ the condition (2) uniquely defines the involution τ such that $\mathcal{C}(P, c) = \mathcal{C}(P, \Lambda_\tau)$. \square

Proposition 4.15. *Let Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold. For an involution $\tau \in \mathbb{Z}_2^r \setminus \{0\}$ the space $N(P, \Lambda) / \langle \tau \rangle$ is a closed topological manifold if and only if*

$$\begin{aligned} & \tau \notin \{ \Lambda_{i_1} + \dots + \Lambda_{i_k} : k \neq 2, i_1 < \dots < i_k, G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset \} = \\ & \{ \Lambda_{j_1} + \dots + \Lambda_{j_k} : k \neq 2, j_1 < \dots < j_k, F_{j_1} \cap \dots \cap F_{j_k} \neq \emptyset, \Lambda_{j_a} \neq \Lambda_{j_b} \text{ for } a \neq b \}. \end{aligned}$$

Proof. By [E24, Theorem 5.1] $N(P, \Lambda)$ is a closed topological manifold if and only if for any vertex $F_{j_1} \cap \dots \cap F_{j_n}$ of P different vectors among $\{ \Lambda_{j_1}, \dots, \Lambda_{j_n} \}$ are linearly independent. This is equivalent to the fact that for any collection of indices $i_1 < \dots < i_k, k \geq 1$, such that $G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset$ the vectors $\{ \Lambda_{i_1}, \dots, \Lambda_{i_k} \}$ are linearly independent and to the fact that for any collection of indices $j_1 < \dots < j_k, k \geq 1$, such that $F_{j_1} \cap \dots \cap F_{j_k} \neq \emptyset$ and $\Lambda_{j_a} \neq \Lambda_{j_b}$ for $a \neq b$ the vectors $\{ \Lambda_{j_1}, \dots, \Lambda_{j_k} \}$ are linearly independent.

Let us denote by $[\Lambda_j]$ the image of Λ_j under the projection $\mathbb{Z}_2^r \rightarrow \mathbb{Z}_2^r / \langle \tau \rangle$. Assume that for a collection of indices $j_1 < \dots < j_k, k \geq 1$, such that $F_{j_1} \cap \dots \cap F_{j_k} \neq \emptyset$ we have $[\Lambda_{j_a}] \neq [\Lambda_{j_b}]$ for $a \neq b$. Then $\Lambda_{j_a} + \Lambda_{j_b} \notin \{0, \tau\}$. For $\{ [\Lambda_{j_1}], \dots, [\Lambda_{j_k}] \}$ to be linearly independent it is necessary and sufficient that $\Lambda_{j_{q_1}} + \dots + \Lambda_{j_{q_s}} \notin \{0, \tau\}$ for any nonempty subset $\{q_1, \dots, q_s\} \subset \{j_1, \dots, j_k\}$. Since $N(P, \Lambda)$ is a closed manifold, $\Lambda_{j_{q_1}} + \dots + \Lambda_{j_{q_s}} \neq 0$. This finishes the proof. \square

Proposition 4.16. *Let Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold. Let $\mathcal{C}(P, \Lambda) \subset \mathcal{C}(P, c)$ be a proper bipartite Hamiltonian subcomplex. Then for any nice coloring χ the space $N(P, \Lambda_\chi)$ is a closed topological manifold.*

Proof. Indeed, by Lemma 4.4(1) if $G_{i_1} \cap \dots \cap G_{i_k} \neq \emptyset$, then at least $k - 1$ of these facets lie in different facets of $\mathcal{C}(P, \Lambda)$. Then either all of them lie in different facets, or $k - 1$ lie in different facets and two of them lie in the same facet. By definition of Λ_χ the vectors $\Lambda_\chi(G_{i_1}), \dots, \Lambda_\chi(G_{i_k})$ are linearly independent. \square

4.3. Bipartite Hamiltonian subcomplexes and the four color theorem. Orientable small covers $N(P, \Lambda)$ over 3-polytopes correspond to colorings of P in four colors. In this case the image of Λ consists either of three linearly independent vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$, or four vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \mathbf{v}_4$ such that each three of them are linearly independent and $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 + \mathbf{v}_4 = 0$.

Lemma 4.17. *For $\tau \in \mathbb{Z}_2^3 \setminus \{0\}$ the space $N(P, \Lambda)/\langle \tau \rangle = N(P, \Lambda_\tau)$ is a closed 3-manifold if and only if $\tau \in \{\mathbf{v}_1 + \mathbf{v}_2, \mathbf{v}_1 + \mathbf{v}_3, \mathbf{v}_2 + \mathbf{v}_3\}$. Moreover, each manifold $N(P, \Lambda_\tau)$ is hyperelliptic with the hyperelliptic involution $\mu = [\mathbf{v}_1 + \mathbf{v}_3], [\mathbf{v}_2 + \mathbf{v}_3], [\mathbf{v}_1 + \mathbf{v}_2]$ respectively.*

Proof. The first statement is a corollary of Proposition 4.15. For the manifold $N(P, \Lambda_\tau)$ we have $N(P, \Lambda_\tau)/\langle \mu \rangle = N(P, (\Lambda_\tau)_\mu)$, where $(\Lambda_\tau)_\mu$ is constant on all the facets of P . Hence, $\mathcal{C}(P, (\Lambda_\tau)_\mu) \simeq \mathcal{C}(3, 1)$, and $N(P, \Lambda_\tau)/\langle \mu \rangle \simeq S^3$. \square

Lemma 4.18. *For each $\tau \in \{\mathbf{v}_1 + \mathbf{v}_2, \mathbf{v}_1 + \mathbf{v}_3, \mathbf{v}_2 + \mathbf{v}_3\}$ the complex $\mathcal{C}(P, \Lambda_\tau)$ is a bipartite Hamiltonian subcomplex in P defined by a set of disjoint simple edge-cycles containing all the vertices of P .*

Proof. The subcomplex is bipartite and Hamiltonian by Proposition 4.14. Since $N(P, \Lambda_\tau)$ is a closed manifold and Λ_τ has rank 2, the complex $\mathcal{C}(P, \Lambda_\tau)$ has no vertices (at a vertex there should be three linearly independent vectors). Thus, $\mathcal{C}^1(P, \Lambda_\tau)$ consists of a disjoint set of circles, and each vertex of P lies on exactly one circle since $\mathcal{C}(P, \Lambda_\tau) \subset \partial P$ is a Hamiltonian subcomplex. \square

Proposition 4.19. *A disjoint set of simple edge-cycles containing all the vertices of P defines a bipartite Hamiltonian subcomplex C in ∂P if and only if for any cycle γ and each connected component of $\partial P \setminus \gamma$ the number of vertices on γ such that the edge of P incident to this vertex and not lying on γ lies in the corresponding component is even.*

Proof. Indeed, if C is Hamiltonian, then the facets of P lying in each facet G of C can be nicely colored in two colors (nicely means that adjacent facets have different colors). Then the colors along each component γ of ∂G alter, therefore there is an even number of vertices on γ with the edge going inside G . On the other hand, if for each component γ of ∂G there is an even number of such vertices, we can join these vertices outside G by a set of simple piecewise linear paths. We obtain a disjoint set of simple piecewise linear closed curves on ∂P . Each curve divides ∂P into two connected components homeomorphic to disks, hence the adjacency graph of the complement to this set of curves is a tree. Thus, the complement can be nicely colored in two colors, and this coloring restricts to a nice coloring of G . \square

Corollary 4.20. *For a simple 3-polytope P the following conditions are equivalent:*

- (1) *P has a coloring of facets in at most 4 colors such that adjacent facets have different colors;*
- (2) *there is a disjoint set of simple edge-cycles such that*
 - *any vertex of P lies in exactly one cycle;*
 - *for any cycle γ from the set and any of the two connected components of $\partial P \setminus \gamma$ the number of vertices on γ with the edge going inside this component is even.*

Remark 4.21. In [B1913] G. D. Birkhoff reduced the four color problem to the family of simple 3-polytopes P such that P is different from the simplex, has no 3- and 4-belts and each 5-belt surrounds a facet, where a k -belt is a cyclic sequence of k facets such that two facets of this sequence are adjacent if and only if they are successive and no three facets have a common

vertex. We call such polytopes *strongly Pogorelov*. Then Corollary 4.20 implies that the four color theorem is equivalent to the fact that any strongly Pogorelov polytope satisfies condition (2) of this corollary.

4.4. Subspaces of $N(P, \Lambda)$ corresponding to faces of $\mathcal{C}(P, \Lambda)$. As it was mentioned in Lemma 2.9 any k -face G of $\mathcal{C}(P, c)$ is an orientable topological k -manifold, perhaps with a boundary. Moreover, Lemma 2.10 implies that ∂G consists of faces of $\mathcal{C}(P, c)$ lying in G . If G is a connected component of the intersection $G_{i_1} \cap \cdots \cap G_{i_{n-k}}$, then ∂G consists of connected components of nonempty intersections $G \cap G_{j_1} \cap \cdots \cap G_{j_l}$, $\{i_1 < \cdots < i_{n-k}\} \cap \{j_1 < \cdots < j_l\} = \emptyset$.

Lemma 4.22. *Connected components of $G \cap G_{j_1} \cap \cdots \cap G_{j_l}$ are exactly connected components of $G_{i_1} \cap \cdots \cap G_{i_{n-k}} \cap G_{j_1} \cap \cdots \cap G_{j_l}$ lying in G .*

Proof. Let $G_{i_1} \cap \cdots \cap G_{i_{n-k}} = \bigsqcup_s G_{\alpha_s}$, $G_{j_1} \cap \cdots \cap G_{j_l} = \bigsqcup_t G_{\beta_t}$, and $G_{\alpha_s} \cap G_{\beta_t} = \bigsqcup_w G_{s,t,w}$ be the decompositions into connected components. Then

$$G_{i_1} \cap \cdots \cap G_{i_{n-k}} \cap G_{j_1} \cap \cdots \cap G_{j_l} = \bigsqcup_{s,t,w} G_{s,t,w}$$

is a decomposition into a disjoint union of closed connected sets. Each set in each union is a union of faces of P , hence the number of sets in each union is finite. Therefore, each set $G_{s,t,w}$ is open in the topology induced to $G_{i_1} \cap \cdots \cap G_{i_{n-k}} \cap G_{j_1} \cap \cdots \cap G_{j_l}$ and it is a connected component of this set. If $G = G_{\alpha_1}$, then by the same argument $G \cap G_{j_1} \cap \cdots \cap G_{j_l} = \bigsqcup_{t,w} G_{1,t,w}$ is the decomposition

into connected components. This finishes the proof. \square

Lemma 4.23. *For any faces G' and G'' of $\mathcal{C}(P, c)$ if their intersection is nonempty, then it is a disjoint union of faces $\mathcal{C}(P, c)$ of equal dimensions.*

Proof. Indeed, if G' is a connected component of $G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{a+1}} \cap \cdots \cap G_{i_b}$, and G'' is a connected component of $G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{b+1}} \cap \cdots \cap G_{i_c}$, where $G_{i_1}, \dots, G_{i_a}, \dots, G_{i_b}, \dots, G_{i_c}$ are different facets of $\mathcal{C}(P, c)$, then $G' \cap G'' \subset G_{i_1} \cap \cdots \cap G_{i_c}$, where the latter set is a disjoint union of its connected components – faces of $\mathcal{C}(P, c)$ of the same dimension. Again, as in the proof of Lemma 4.22 let $G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{a+1}} \cap \cdots \cap G_{i_b} = \bigsqcup_s G_{\alpha_s}$, $G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{b+1}} \cap \cdots \cap G_{i_c} =$

$\bigsqcup_t G_{\beta_t}$, and $G_{\alpha_s} \cap G_{\beta_t} = \bigsqcup_w G_{s,t,w}$ be the decompositions into connected components. Then

$$G_{i_1} \cap \cdots \cap G_{i_c} = (G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{a+1}} \cap \cdots \cap G_{i_b}) \cap (G_{i_1} \cap \cdots \cap G_{i_a} \cap G_{i_{b+1}} \cap \cdots \cap G_{i_c}) = \bigsqcup_{s,t,w} G_{s,t,w}$$

is a decomposition into a disjoint union of closed connected sets. Each set in each union is a union of faces of P , hence the number of sets in each union is finite. Therefore, each set $G_{s,t,w}$ is open in the topology induced to $G_{i_1} \cap \cdots \cap G_{i_c}$ and it is a connected component of this set. If $G' = G_{\alpha_1}$ and $G'' = G_{\beta_1}$ then by the same argument $G' \cap G'' = \bigsqcup_w G_{1,1,w}$ is the decomposition into connected components. This finishes the proof. \square

Definition 4.24. For a k -face G of $\mathcal{C}(P, c)$ we will call by facets of G *connected components* of nonempty intersections of $G \cap G_j$, $G \not\subset G_j$, and by faces of G connected components of intersection of its facets.

Corollary 4.25. *Faces of G are exactly faces of $\mathcal{C}(P, c)$ lying in G .*

The vector-coloring $\Lambda: \{F_1, \dots, F_m\} \rightarrow \mathbb{Z}_2^r$ of P induces the vector-coloring $\Lambda_G: \{\tilde{G}_1, \dots, \tilde{G}_q\} \rightarrow \mathbb{Z}_2^r \rightarrow \mathbb{Z}_2^r / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle$ of facets of any k -face $G \subset \mathcal{C}(P, \Lambda)$: a connected component of $G \cap G_j$ is mapped to $[\Lambda_j]$.

Definition 4.26. Define $V_G = \langle \Lambda_G(\tilde{G}_j), j = 1, \dots, q \rangle \subset \mathbb{Z}_2^r / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle$ and

$$N(G, \Lambda_G) = G \times V_G / \sim, \text{ where } (p, t) \sim (q, s) \Leftrightarrow p = q \text{ and } t - s \in \langle \Lambda_G(\tilde{G}_j) : p \in \tilde{G}_j \rangle.$$

Proposition 4.27. *Let Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold, and let $\pi_\Lambda: N(P, \Lambda) \rightarrow P$ be the projection. Then for any k -face G of $\mathcal{C}(P, \Lambda)$ the preimage $\pi_\Lambda^{-1}(G)$ is a closed topological k -dimensional submanifold (locally defined in some coordinate system as the intersection of $(n - k)$ coordinate hyperplanes) in $N(P, \Lambda)$ homeomorphic to a disjoint union of $|\mathbb{Z}_2^r / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle| / V_G| = 2^{r-(n-k)-\dim V_G}$ manifolds $N(G, \Lambda_G)$.*

Proof. Indeed, $N(P, \Lambda) = P \times \mathbb{Z}_2^r / \sim$, where $(p, a) \sim (q, b)$ if and only if $p = q$ and $a - b \in \langle \Lambda_i : p \in F_i \rangle = \langle \Lambda_j : p \in G_j \rangle$. Also $\pi_\Lambda^{-1}(G) = G \times \mathbb{Z}_2^r / \sim$, where $(p, a) \sim (q, b)$ if and only if $p = q$ and $a - b \in \langle \Lambda_j : p \in G_j \rangle$. But each point $p \in G$ lies in $G_{i_1} \cap \dots \cap G_{i_{n-k}}$. Hence,

$$\mathbb{Z}_2^r / \langle \Lambda_j : p \in G_j \rangle \simeq (\mathbb{Z}_2^r / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle) / (\langle \Lambda_j : p \in G_j \rangle / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle).$$

This space is a disjoint union of cosets modulo V_G . Starting from the point $[p, a] \in \pi_\Lambda^{-1}(G)$ and moving inside this space we can reach by a path only the points $[q, b]$, where $a - b \in V_G$. Hence, $\pi_\Lambda^{-1}(G)$ is a disjoint union of $|\mathbb{Z}_2^r / \langle \Lambda_{i_1}, \dots, \Lambda_{i_{n-k}} \rangle| / V_G|$ connected components, and each component is homeomorphic to $N(G, \Lambda_G)$. Since $N(P, \Lambda)$ is a closed manifold, for each point $p \in \partial P$, which belongs to exactly l facets G_{j_1}, \dots, G_{j_l} , the vectors $\Lambda_{j_1}, \dots, \Lambda_{j_l}$ are linearly independent. By Lemma 2.10 p has a neighbourhood in P homeomorphic to $\mathbb{R}_{\geq}^l \times \mathbb{R}^{n-l}$. Then in $N(P, \Lambda)$ for the point $p \times a$ these neighbourhoods are glued to the neighbourhood U homeomorphic to $\mathbb{R}^l \times \mathbb{R}^{n-l}$. Indeed, in $p \times a$ the copies $P \times (a + \varepsilon_1 \Lambda_{j_1} + \dots + \varepsilon_l \Lambda_{j_l})$, $\varepsilon_s = \pm 1$, are glued locally as the sets $\{\varepsilon_1 y_1 \geq 0, \dots, \varepsilon_l y_l \geq 0\}$, where the addition of the vector Λ_{j_s} corresponds to the operation $y_s \rightarrow -y_s$. At each point of $\pi_\Lambda^{-1}(G)$ we may take $j_1 = i_1, \dots, j_{n-k} = i_{n-k}$ to see that $\pi_\Lambda^{-1}(G) \cap U$ is defined by equations $y_1 = \dots = y_{n-k} = 0$. This finishes the proof. \square

Proposition 4.28. *Let $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ be a proper Hamiltonian subcomplex and M_1, \dots, M_s be the set of its defining $(n - 2)$ -faces. Then facets of each M_q are connected components of intersections of M_q with facets of C not containing M_q . Moreover, each k -face G of M_q , $0 \leq k \leq n - 2$, is a connected component of intersection of M_q with a unique $(k + 1)$ -face \tilde{G} of C containing G .*

Proof. By definition facets of $M_q \subset G_i \cap G_j$ are connected components of intersections of M_q with facets G_k of $\mathcal{C}(P, c_1)$ different from G_i and G_j . By Lemma 4.4 for $G_i \cap G_j \cap G_k \neq \emptyset$ the facets G_i and G_j lie in the same facet \tilde{G}_a of $\mathcal{C}(P, c_2)$, and G_k lies in another facet \tilde{G}_b . Then

$$M_q \cap G_k \subset M_q \cap \tilde{G}_b = M_q \cap \left(\bigcup_{G_l \subset \tilde{G}_b} G_l \right) = \bigcup_{G_l \subset \tilde{G}_b: M_q \cap G_l \neq \emptyset} M_q \cap G_l.$$

The latter union is disjoint since $(M_q \cap G_{l_1}) \cap (M_q \cap G_{l_2}) \subset G_i \cap G_j \cap G_{l_1} \cap G_{l_2} = \emptyset$ by Lemma 4.4(3). Each $M_q \cap G_l$ has a finite set of connected components since it is a union of faces of P . Then we have a disjoint finite union of a finite set of connected components of $M \cap G_l$, $G_l \subset \tilde{G}_b$. Then each connected component is also a connected component of the union. This finishes the proof of the first statement.

Each k -face G of $M_q \subset G_i \cap G_j$ is a connected component of $M_q \cap G_{i_3} \cap \dots \cap G_{i_{n-k}}$ by Lemma 4.22. By Lemma 4.4 $G_i, G_j \subset \tilde{G}_{j_2}$, $G_{i_3} \subset \tilde{G}_{j_2}$, \dots , $G_{i_{n-k}} \subset \tilde{G}_{j_{n-k}}$ for different facets $\tilde{G}_{j_2}, \dots, \tilde{G}_{j_{n-k}}$ of $\mathcal{C}(P, c_2)$. Then $M_q \cap \tilde{G}_{j_2} \cap \dots \cap \tilde{G}_{j_{n-k}}$ is equal to the intersection of M_q with a connected component \tilde{G} of $\tilde{G}_{j_2} \cap \dots \cap \tilde{G}_{j_{n-k}}$ and it is equal to

$$M_q \cap \tilde{G}_{j_3} \cap \dots \cap \tilde{G}_{j_{n-k}} = M_q \cap \left(\bigcup_{G_{l_3} \subset \tilde{G}_{j_3}} G_{l_3} \right) \cap \dots \cap \left(\bigcup_{G_{l_{n-k}} \subset \tilde{G}_{j_{n-k}}} G_{l_{n-k}} \right) = \bigcup_{G_{l_3} \subset \tilde{G}_{j_3}, \dots, G_{l_{n-k}} \subset \tilde{G}_{j_{n-k}}} M_q \cap G_{l_3} \cap \dots \cap G_{l_{n-k}},$$

where any two nonempty sets in the union are disjoint, since at some position j the indices l'_j and l''_j are different and $G_i \cap G_j \cap G_{l'_j} \cap G_{l''_j} = \emptyset$. Then each connected component of each set is a connected component of the union. In particular, for $l_3 = i_3, \dots, l_{n-k} = i_{n-k}$. Thus, G is a connected component of intersection of the $(k+1)$ -face \tilde{G} of C with M_q , and $G \subset \tilde{G}$. On the other hand, let G be a connected component of intersection of some $(k+1)$ -face \tilde{G}' of C with M_q , where $G \subset \tilde{G}'$. Then \tilde{G}' is a connected component of some intersection $\tilde{G}_{u_2} \cap \dots \cap \tilde{G}_{u_{n-k}}$. Then by the argument in the beginning of the proof of Lemma 4.4 without loss of generality we may assume that $G_i, G_j \subset \tilde{G}_{u_2}$, $G_{i_3} \subset \tilde{G}_{u_3}, \dots, G_{i_{n-k}} \subset \tilde{G}_{u_{n-k}}$. Then $u_2 = j_2, \dots, u_{n-k} = j_{n-k}$, and $\tilde{G} = \tilde{G}'$. \square

Proposition 4.29. *Let $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ be a proper Hamiltonian subcomplex. Then any k -face $\tilde{G} \subset \mathcal{C}(P, c_2)$ is a union $\tilde{G} = \bigcup_{\alpha} G_{\alpha}$ of k -faces of $\mathcal{C}(P, c_1)$, where the intersection of any three faces in the union is empty, while each nonempty intersection of two faces in the union is a disjoint union of $(q-1)$ -faces of defining faces. In particular, the adjacency graph $\Gamma(\tilde{G})$ is well-defined. Its vertices are faces G_{α} and edges correspond to connected components of intersections of two such faces. The $(k-1)$ -faces of defining faces corresponding to the edges of $\Gamma(\tilde{G})$ are pairwise disjoint.*

Proof. By definition \tilde{G} is a connected component of the intersection $\tilde{G}_{j_1} \cap \cdots \cap \tilde{G}_{j_{n-k}}$ of pairwise different facets. We have

$$\tilde{G}_{j_1} \cap \cdots \cap \tilde{G}_{j_{n-k}} = \left(\bigcup_{G_{l_1} \subset \tilde{G}_{j_1}} G_{l_1} \right) \cap \cdots \cap \left(\bigcup_{G_{l_{n-k}} \subset \tilde{G}_{j_{n-k}}} G_{l_{n-k}} \right) = \bigcup_{G_{l_1} \subset \tilde{G}_{j_1}, \dots, G_{l_{n-k}} \subset \tilde{G}_{j_{n-k}}} G_{l_1} \cap \cdots \cap G_{l_{n-k}}.$$

The union on the right is a union of k -faces of $\mathcal{C}(P, c_1)$, which are connected components of nonempty intersections. Moreover, if two such faces intersect, then they are connected components of two different intersections $G_{l_1} \cap \cdots \cap G_{l_{n-k}}$ and $G_{l'_1} \cap \cdots \cap G_{l'_{n-k}}$. If $l_a \neq l'_a$ and $l_b \neq l'_b$, then $(G_{l_1} \cap \cdots \cap G_{l_{n-k}}) \cap (G_{l'_1} \cap \cdots \cap G_{l'_{n-k}}) \subset (G_{l_a} \cap G_{l'_a}) \cap (G_{l_b} \cap G_{l'_b}) = \emptyset$. Thus, if faces intersect, then $l_a = l'_a$ for all indices a but one, say b . Then the intersection is a disjoint union of $(k-1)$ -faces of defining faces lying in $G_{l_b} \cap G_{l'_b}$. If three faces intersect, then either for all a but one $l_a = l'_a = l''_a$, and $l_b \neq l'_b \neq l''_b \neq l_b$, or there are two indices $b_1 \neq b_2$ such that $l_{b_1} \neq l'_{b_1}$ and $l_{b_2} \neq l''_{b_2}$. In the first case the intersection lies in $(G_{l_{b_1}} \cap G_{l'_{b_1}}) \cap (G_{l_{b_1}} \cap G_{l''_{b_1}}) = \emptyset$, and in the second – in $(G_{l_{b_1}} \cap G_{l'_{b_1}}) \cap (G_{l_{b_2}} \cap G_{l''_{b_2}}) = \emptyset$. \square

Corollary 4.30. *Let $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ be a proper Hamiltonian subcomplex. If a k -face $G \subset \mathcal{C}(P, c_1)$ does not intersect defining faces, then G is also a k -face of $\mathcal{C}(P, c_2)$ of the same combinatorial type.*

Proof. Indeed, G lies in some k -face \tilde{G} of $\mathcal{C}(P, c_2)$. Since G does not intersect defining faces, we have $G = \tilde{G}$. By the same argument each face of G is a face of \tilde{G} . On the other hand each face of \tilde{G} is a subset of G not intersecting defining faces. Hence, it is a face of G . \square

4.5. Bipartite Hamiltonian subcomplexes and two-sheeted branched coverings. Remind that by π_Λ we denote the projection $N(P, \Lambda) \rightarrow P$.

Proposition 4.31. *Let Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold and let $\tau \in \mathbb{Z}_2^r \setminus \{0\}$ be an involution such that $N(P, \Lambda)/\langle \tau \rangle = N(P, \Lambda_\tau)$ is also a closed topological manifold. Let $M_1^{n-2}, \dots, M_s^{n-2}$ be defining faces of the bipartite Hamiltonian subcomplex $\mathcal{C}(P, \Lambda_\tau) \subset \mathcal{C}(P, \Lambda)$ and $M = M_1^{n-2} \sqcup \cdots \sqcup M_s^{n-2}$. Then for the projection $\pi: N(P, \Lambda) \rightarrow N(P, \Lambda_\tau)$*

- *the restriction $N(P, \Lambda) \setminus \pi_\Lambda^{-1}(M) \rightarrow N(P, \Lambda_\tau) \setminus \pi_{\Lambda_\tau}^{-1}(M)$ is a 2-sheeted covering;*
- *the restriction $\pi_\Lambda^{-1}(M) \rightarrow \pi_{\Lambda_\tau}^{-1}(M)$ is one-to-one and for each point $x \in \pi_\Lambda^{-1}(M)$ and its image y there are neighbourhoods such that*
 - *each neighbourhood is homeomorphic to $\mathbb{C} \times \mathbb{R}^{n-2}$;*
 - *the preimage of M corresponds to the set $\{0\} \times \mathbb{R}^{n-2}$;*
 - *the mapping $N(P, \Lambda) \rightarrow N(P, \Lambda_\tau)$ has the form $(\mathbf{z}, \mathbf{x}) \rightarrow (\mathbf{z}^2, \mathbf{x})$.*

In particular, π is a 2-sheeted branched covering with the branch set $\pi_\Lambda^{-1}(M)$ (see the definition in [G19]). Moreover, $\pi_\Lambda^{-1}(M) \simeq \pi_\Lambda^{-1}(M) = \bigsqcup_{q=1}^s \pi_\Lambda^{-1}(M_q)$, where $\pi_\Lambda^{-1}(M_q)$ is a disjoint union of $2^{r-2-\dim V_{M_q}}$ copies of the closed $(n-2)$ -manifold $N(M_q, \Lambda_{M_q})$.

Proof. Indeed, for each point $p \notin M$ all the different facets G_i of $\mathcal{C}(P, \Lambda)$ containing p lie in different facets \tilde{G}_j of $\mathcal{C}(P, \Lambda_\tau)$. As it was mentioned in the proof of Proposition 4.27 each point $[p \times a] \in N(P, \Lambda)$ such that p belongs to exactly l facets G_{j_1}, \dots, G_{j_l} has a neighbourhood $U([p \times a])$ homeomorphic to \mathbb{R}^n . Moreover, there are 2^{r-l} such neighbourhoods corresponding to cosets in $\mathbb{Z}_2^r / \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$ and they can be chosen to be disjoint. For $[p \times [a]] \in N(P, \Lambda_\tau)$ we have similar 2^{r-1-l} neighbourhoods corresponding to cosets in $(\mathbb{Z}_2^r / \langle \tau \rangle) / \langle [\Lambda_{j_1}], \dots, [\Lambda_{j_l}] \rangle$. Each neighbourhood of $N(P, \Lambda)$ corresponding to a coset $b + \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$ is mapped to the neighbourhood corresponding to the coset $[b] + \langle [\Lambda_{j_1}], \dots, [\Lambda_{j_l}] \rangle$ and this mapping is a homeomorphism. Moreover, the coset $[b] + \langle [\Lambda_{j_1}], \dots, [\Lambda_{j_l}] \rangle$ corresponds to exactly two cosets $b + \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$ and $(b + \tau) + \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$.

Now consider a point $p \in M_q^{n-2} \subset G_{j_1} \cap G_{j_2}$ such that G_{j_1} and G_{j_2} lie in the same facet \tilde{G}_{i_2} of $\mathcal{C}(P, \Lambda_\tau)$ and p lies in exactly l facets $G_{j_1}, G_{j_2}, \dots, G_{j_l}$. By Lemma 4.4 the sets $G_{j_1} \cup G_{j_2}, G_{j_3}, \dots, G_{j_l}$ lie in $l-1$ different facets $\tilde{G}_{i_2}, \tilde{G}_{i_3}, \dots, \tilde{G}_{i_l}$. By Lemma 2.10 the point p in P has a neighbourhood

$$U \simeq \mathbb{R}_{\geq}^l \times \mathbb{R}^{n-l} = \{(y_1, \dots, y_n) \in \mathbb{R}^n : y_1 \geq 0, \dots, y_l \geq 0\},$$

corresponding to $\mathcal{C}(P, \Lambda)$, where the facet G_{j_p} corresponds to the hyperplane $y_p = 0$. Set $\mathbf{z} = y_1 + iy_2$ and $\mathbf{x} = (y_3, \dots, y_n)$. The mapping $(\mathbf{z}, \mathbf{x}) \rightarrow (\mathbf{z}^2, \mathbf{x})$ defines a homeomorphism

$$\mathbb{R}_{\geq}^l \times \mathbb{R}^{n-l} \rightarrow \mathbb{R} \times \mathbb{R}_{\geq} \times \mathbb{R}_{\geq}^{l-2} \times \mathbb{R}^{n-l} = \{(\tilde{y}_1, \dots, \tilde{y}_n) \in \mathbb{R}^n : \tilde{y}_2 \geq 0, \dots, \tilde{y}_l \geq 0\} \simeq \mathbb{R}_{\geq}^{l-1} \times \mathbb{R}^{n-l-1},$$

and under the composition of homeomorphisms the facets \tilde{G}_{i_p} are mapped to the hyperplanes $\tilde{y}_p = 0$, $p = 2, \dots, l$. In both coordinate systems M_q^{n-2} is defined by the condition $y_1 = y_2 = 0$ and $\tilde{y}_1 = \tilde{y}_2 = 0$. In $N(P, \Lambda)$ the neighbourhoods U are glued to 2^{r-l} neighbourhoods $U([p, a])$ corresponding to cosets in $\mathbb{Z}_2^r / \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$. In $N(P, \Lambda_\tau)$ these neighbourhoods are glued to $2^{r-l} = 2^{(r-1)-(l-1)}$ neighbourhoods $U([p, [a]])$ corresponding to cosets in $(\mathbb{Z}_2^r / \langle \tau \rangle) / \langle [\Lambda_{j_2}], \dots, [\Lambda_{j_l}] \rangle$. We have $\mathbb{Z}_2^r / \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle \simeq (\mathbb{Z}_2^r / \langle \tau \rangle) / \langle [\Lambda_{j_2}], \dots, [\Lambda_{j_l}] \rangle$ since $\tau = \Lambda_{j_1} + \Lambda_{j_2}$. Thus, a neighbourhood corresponding to a coset $b + \langle \Lambda_{j_1}, \dots, \Lambda_{j_l} \rangle$ is mapped to the neighbourhood corresponding to the coset $[b] + \langle [\Lambda_{j_2}], \dots, [\Lambda_{j_l}] \rangle$ and in the above coordinates the sets $\pi_\Lambda^{-1}(M)$ and $\pi_{\Lambda_\tau}^{-1}(M)$ are defined by the equations $\mathbf{z} = 0$ and $\tilde{\mathbf{z}} = 0$, and the mapping has the form $(\tilde{\mathbf{z}}, \tilde{\mathbf{x}}) = (\mathbf{z}^2, \mathbf{x})$. The last statement follows from Proposition 4.27. \square

4.6. $\mathcal{C}(n, k)$ -subcomplexes and hyperelliptic involutions.

Definition 4.32. We call by a $\mathcal{C}(n, k)$ -subcomplex C of $\mathcal{C}(P, c)$ a subcomplex $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c)$ such that $\mathcal{C}(P, c_2) \simeq \mathcal{C}(n, k)$. A $\mathcal{C}(n, k)$ -subcomplex is *Hamiltonian*, if $\mathcal{C}(P, c_2)$ is Hamiltonian.

Corollary 4.33. Any $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$ corresponds to a subgroup $H(C) \subset \mathbb{Z}_2^m$ of rank $m-k$ such that $\mathbb{R}\mathcal{Z}_P / H(C) \simeq S^n$. The subgroup is defined in \mathbb{Z}_2^m by equations $\sum_{F_j \subset G_i} x_j = 0$, where G_i , $i = 1, \dots, k$, are facets of the subcomplex.

Theorem 3.14 implies the following result.

Corollary 4.34. *For $n \leq 4$ the correspondence $C \rightarrow H(C)$ is a bijection between $\mathcal{C}(n, k)$ -subcomplexes $C \subset \partial P$ and subgroups $H \subset \mathbb{Z}_2^m$ of rank $m - k$ such that $\mathbb{R}\mathcal{Z}_P/H \simeq S^n$.*

Proposition 4.35. *Let $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ be a proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex. Then for any facet \tilde{G} of C the adjacency graph $\Gamma(\tilde{G})$ is a tree. In particular, the subcomplex C is bipartite.*

Proof. For $n \leq 2$ this is trivial. Assume that $n \geq 3$. Any facet \tilde{G} of C is a topological disk. Consider a defining $(n - 2)$ -face $M \subset G_i \cap G_j$, where $G_i, G_j \subset \tilde{G}$ are facets of $\mathcal{C}(P, c_1)$. M is a connected orientable $(n - 2)$ -manifold, perhaps with a boundary. If M has a boundary, then ∂M is a union of $(n - 3)$ -faces. Since C is Hamiltonian, any such a face lies in the $(n - 2)$ -skeleton of $\mathcal{C}(P, c_2)$. In particular, $\partial M \subset \partial \tilde{G}$, which is a topological sphere. Consider a point $p \in M$. Let p belong to exactly l facets G_{j_1}, \dots, G_{j_l} , where $G_{j_1} = G_i$ and $G_{j_2} = G_j$. By Lemma 4.4 the sets $G_{j_1} \cup G_{j_2}, G_{j_3}, \dots, G_{j_l}$ lie in $l - 1$ different facets $\tilde{G}_{i_2}, \tilde{G}_{i_3}, \dots, \tilde{G}_{i_l}$. As in the proof of Proposition 4.31 the point p in P has a neighbourhood

$$U \simeq \{(\tilde{y}_1, \dots, \tilde{y}_n) \in \mathbb{R}^n : \tilde{y}_2 \geq 0, \dots, \tilde{y}_l \geq 0\} \simeq \mathbb{R}_{\geq}^{l-1} \times \mathbb{R}^{n-l-1},$$

where the facets \tilde{G}_{i_p} correspond to the hyperplanes $\tilde{y}_p = 0$, $p = 2, \dots, l$, and M is defined by the equations $\tilde{y}_1 = \tilde{y}_2 = 0$. Thus, M is an orientable polyhedral $(n - 2)$ -manifold locally flat embedded to the polyhedral $(n - 1)$ -disk \tilde{G} with $\partial M = M \cap \partial \tilde{G}$.

Lemma 4.36. *The complement $\tilde{G} \setminus M$ has exactly two connected components.*

Proof. It is easy to see that the complement $\tilde{G} \setminus M$ has at most two connected components, since it is valid locally at each point of M , and from each point of the complement we can reach such a point by a simple piecewise linear path intersecting M at one point.

On the other hand, assume that there is only one connected component. If $\partial M \neq \emptyset$, then this is valid also for the double manifolds $DM = M \cup_{\partial M} M \subset D\tilde{G} = \tilde{G} \cup_{\partial \tilde{G}} \tilde{G} \simeq S^{n-1}$. But DM is an orientable $(n - 2)$ -manifold, hence $H_{n-2}(DM) = \mathbb{Z}$. By the Alexander duality $\tilde{H}^0(\tilde{G} \cup_{\partial \tilde{G}} \tilde{G} \setminus M \cup_{\partial M} M) \simeq \mathbb{Z}$. Hence, there are two connected components. A contradiction.

If $\partial M = \emptyset$, then $M \cap \partial \tilde{G} = \emptyset$ and for the space $\tilde{G}' = \tilde{G}/\partial \tilde{G} \simeq S^n$ the complement $\tilde{G}' \setminus M$ also has one connected component. But this contradicts the Alexander duality. \square

Corollary 4.37. *We have $M = G_i \cap G_j$.*

Proof. Indeed, by Lemma 4.36 $\tilde{G} \setminus M$ has two connected components C_1 and C_2 , where $\text{int } G_i \subset C_1$ and $\text{int } G_j \subset C_2$. Moreover, $\overline{C_1} \cap \overline{C_2} = M$ since M is locally flat embedded to \tilde{G} . Then G_i and G_j have no common points lying outside M . \square

Lemma 4.36 and Corollary 4.37 imply that the adjacency graph $\Gamma(\tilde{G})$ is a tree. Since it is valid for each \tilde{G} , the subcomplex C is bipartite. \square

Construction 4.38 (A vector-coloring induced by a Hamiltonian $\mathcal{C}(n, k)$ -subcomplex). Proposition 4.35 and Example 4.13 imply that any proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C =$

$\mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ induces a vector-coloring $\tilde{\Lambda}_C$ of P of rank $k+1$ defined up to a linear change of coordinates in \mathbb{Z}_2^{k+1} . We have $\mathcal{C}(P, \tilde{\Lambda}_C) = \mathcal{C}(P, c_1)$ and $N(P, \tilde{\Lambda}_C)$ is a hyperelliptic manifold with the hyperelliptic involution $(0, 0, \dots, 1)$ (in terms of Construction 4.11).

Theorem 3.14 implies the following result.

Theorem 4.39. *Let $n \leq 4$ and Λ be a vector-coloring of rank r of a simple n -polytope P such that $N(P, \Lambda)$ is a closed topological manifold. Then nonzero hyperelliptic involutions $\tau \in \mathbb{Z}_2^r \setminus \{0\}$ are in bijection with proper Hamiltonian $\mathcal{C}(n, r-1)$ -subcomplexes $C \subset \mathcal{C}(P, \Lambda)$ inducing Λ (that is $\Lambda = \tilde{\Lambda}_C$ up to a change of coordinates).*

Definition 4.40. For a complex $C = \mathcal{C}(P, c)$ set $f_i(C)$ to be the number of its i -faces. By definition $f_n(C) = 1$. We have $f_{n-1}(C) = M$.

Proposition 4.41. *Let $C = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1)$ be a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex. If a k -face \tilde{G} of C is not a circle, then the adjacency graph $\Gamma(\tilde{G})$ of k -faces G of $\mathcal{C}(P, c_1)$ lying in \tilde{G} is a tree, where we call the faces adjacent if they have a nonempty intersection.*

Proof. Indeed, for $k = 0$ this is trivial. For $k = 1$ if \tilde{G} is not a circle, then it is an edge subdivided by vertices of $\mathcal{C}(P, c_1)$ into edges, and $\Gamma(\tilde{G})$ is a path. Assume that $k > 1$. Each face of C is either a topological disk or a sphere. Let \tilde{G} be a connected component of $\tilde{G}_{j_1} \cap \dots \cap \tilde{G}_{j_{n-k}}$.

Lemma 4.42. *If the intersection of two k -faces G' and G'' of $\mathcal{C}(P, c_1)$ lying in \tilde{G} is nonempty, then $G' \cap G''$ is a $(k-1)$ -face of $\mathcal{C}(P, c_1)$ lying in a defining $(n-2)$ -face. Moreover, $\tilde{G} \setminus (G' \cap G'')$ consists of two connected components C_1 and C_2 such that $G' \cap G'' = \overline{C_1} \cap \overline{C_2}$, and $G' \subset \overline{C_1}$, $G'' \subset \overline{C_2}$.*

Let G' and G'' be connected components of $G_{a_1} \cap \dots \cap G_{a_{n-k}}$ and $G_{b_1} \cap \dots \cap G_{b_{n-k}}$. Then up to a renumbering of indices $G_{a_i}, G_{b_i} \subset \tilde{G}_{j_i}$ for all i . By Lemma 4.4 $a_i \neq b_i$ only for one i , say for $i = 1$. Then $G' \cap G'' \subset G_{a_1} \cap G_{b_1} \cap G_{b_2} \cap \dots \cap G_{b_{n-k}}$. In particular, each connected component G of $G' \cap G''$ lies in a defining $(n-2)$ -face.

The argument in the proof of Proposition 4.35 shows that $\tilde{G} \setminus G$ has two connected components C_1 and C_2 with $G = \overline{C_1} \cap \overline{C_2}$ and $G' \subset \overline{C_1}$, $G'' \subset \overline{C_2}$. Then $G' \cap G'' = G$ and the adjacency graph $\Gamma(\tilde{G})$ is a tree. \square

Proposition 4.43. *Let $C_2 = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1) = C_1$ be a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex with the set of defining faces M_1, \dots, M_s . Then for $0 \leq k \leq n-1$*

$$(2) \quad f_k(C_1) = f_k(C_2) - \delta_{r, n-1} \delta_{k, 1} + \sum_{q=1}^s (f_k(M_q) + f_{k-1}(M_q)) =$$

$$(3) \quad \binom{r}{n-k} + \delta_{r, n} \delta_{k, 0} - \delta_{r, n-1} \delta_{k, 1} + \sum_{q=1}^s (f_k(M_q) + f_{k-1}(M_q)).$$

where $\delta_{i, j} = 1$ if $i = j$, and $\delta_{i, j} = 0$ if $i \neq j$.

Proof. Indeed, each k -face G of C_1 either lies in some M_q or it does not lie in defining faces but lies in a unique k -face \tilde{G} of C_2 . By Proposition 4.41 if $(r, k) \neq (n-1, 1)$ the k -faces G of the latter type lying in \tilde{G} form a tree with edges corresponding to $(k-1)$ -faces of defining faces lying in \tilde{G} . By Proposition 4.28 each $(k-1)$ -face of a defining face lies in a unique k -face \tilde{G} of C_2 . Thus, for $(r, k) \neq (n-1, 1)$ the number of k -faces $G \subset \tilde{G}$ is one greater than the number of $(k-1)$ -faces inside \tilde{G} lying in defining faces. For $(r, k) = (n-1, 1)$ the number of 1-faces of C_1 lying in a unique 1-face of C_2 (which is a circle) is equal to the number of vertices of defining faces. Also we have $f_k(C_2) = \binom{r}{n-k} + \delta_{r,n}\delta_{k,0}$. This finishes the proof. \square

Proposition 4.44. *Let $C_2 = \mathcal{C}(P, c_2) \subset \mathcal{C}(P, c_1) = C_1$ be a proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex with the set of defining faces M_1, \dots, M_s . Then for any defining face M_q its facets can be colored in $(r-1)$ colors in such a way that if the intersection of a set of facets is nonempty, then their colors are pairwise different.*

Proof. Indeed, any defining face M_q lies in some facet \tilde{G}_i of C_2 and its facets are connected components of intersections of M_q with facets $\tilde{G}_j \neq \tilde{G}_i$. Then we can assign to each connected component of $M_q \cap \tilde{G}_j$ the color j . If the intersection of facets of M_q is nonempty, then by construction they have different colors. \square

4.7. Geometric hyperelliptic manifolds $N(P, \Lambda)$. If P is a right-angled n -polytope in some geometry \mathbb{X} and Λ is a linearly independent vector-coloring of rank r , then $N(P, \Lambda)$ is a manifold with a geometric structure modelled on \mathbb{X} .

Construction 4.45. Let P be a right-angled n -polytope in some geometry \mathbb{X} . If $C \subset P$ is a proper Hamiltonian $\mathcal{C}(n, k)$ -subcomplex, then there is a canonical linearly independent vector-coloring $\tilde{\Lambda}_C$ of rank $k+1$ induced by C . It is defined up to a linear change of coordinates in \mathbb{Z}_2^{k+1} . Then $N(P, \tilde{\Lambda}_C)$ is a geometric hyperelliptic n -manifold with a hyperelliptic involution in \mathbb{Z}_2^{k+1} corresponding to C .

Remark 4.46. Construction 4.45 is a direct generalization to dimensions $n > 3$ of the construction of geometric hyperelliptic 3-manifolds in [M90, VM99M, VM99S2] based on Hamiltonian cycles, theta- and K_4 -subgraphs in right-angled 3-polytopes.

Remark 4.47. Theorem 4.39 implies that for $n \leq 4$ and any linearly independent vector-coloring Λ of a right-angled n -polytope P if $N(P, \Lambda)$ admits a hyperelliptic involution in \mathbb{Z}_2^r , then this involution, the coloring Λ and $N(P, \Lambda)$ can be obtained by Construction 4.45.

In this section we will discuss which geometries \mathbb{X} admit hyperelliptic manifolds obtained by Construction 4.45.

Corollary 4.48. *Let $n > 2$ and C be a Hamiltonian $\mathcal{C}(n, r)$ -subcomplex in ∂P . Then $n-1 \leq r \leq n+1$ and the vertex set of P is a disjoint union of vertices of C (their number $V_{n,r}$ is: $V_{n,n-1} = 0$, $V_{n,n} = 2$, $V_{n,n+1} = n+1$) and vertices of defining $(n-2)$ -faces M_1, \dots, M_s .*

The number of defining faces is equal to $m - r$. Moreover, for each $0 \leq k \leq n - 1$

$$f_k(P) = \binom{r}{n-k} + \delta_{r,n}\delta_{k,0} - \delta_{r,n-1}\delta_{k,1} + \sum_{q=1}^s (f_k(M_q) + f_{k-1}(M_q)).$$

Proof. This follows directly from Proposition 4.43.

In particular, each vertex of P either is a vertex of C or lies on its 1-face. Thus, C should have 1-faces. This is possible only for $k \in \{n-1, n, n+1\}$. Moreover, $\mathcal{C}^1(n, n-1)$ is a circle, $\mathcal{C}^1(n, n-1)$ consists of two vertices and n multiple edges, and $\mathcal{C}^1(n, n-1)$ is the complete graph on n vertices (see [E24, Example 8.17]). If a vertex v of P is a vertex of C , then it is the intersection of n different facets of C , and it does not lie in defining faces. If v lies in a 1-skeleton of C , then two facets of P containing v lie in the same facet of C . Then their intersection is a defining face.

For $k = n - 1 > 1$ we have $m = f_{n-1}(P) = \binom{r}{1} + \sum_{q=1}^s f_{n-2}(M_q) = r - s$. Thus, $s = m - r$ is the total number of defining faces. \square

Corollary 4.49. *The n -cube I^n does not admit Hamiltonian $\mathcal{C}(n, k)$ -subcomplexes for $n > 3$. In particular, there are no locally Euclidean hyperelliptic n -manifolds $N(P, \Lambda)$, $n > 3$, obtained by Construction 4.45.*

Proof. The cube has 2^n vertices and $2n$ facets. Any $(n-2)$ -face is I^{n-2} and has 2^{n-2} vertices. If I^n has a Hamiltonian $\mathcal{C}(n, k)$ -subcomplex, then $2^n = V_k + (2n-k)2^{n-2}$, where $n-1 \leq k \leq n+1$. We have $2n-k \geq n-1$. Thus, the right part is at least $V_k + (n-1)2^{n-2}$. If $n \geq 5$, then it is at least $V_k + 4 \cdot 2^{n-2} = V_k + 2^n \geq 2^n$, where the equality holds only if $n = 5$ and $k = n+1$. But in this case $V_k = n+1 = 6$ and we obtain a contradiction. If $n = 4$, then we have $16 = V_k + (8-k) \cdot 4$. For $k = 3$ we have $16 = 0 + 5 \cdot 4 = 20$, for $k = 4$ we have $16 = 2 + 4 \cdot 4 = 18$, and for $k = 5$ we have $16 = 5 + 3 \cdot 4 = 17$. A contradiction. \square

Remark 4.50. For $n \leq 3$ the cube I^n admits Hamiltonian $\mathcal{C}(n, k)$ -subcomplexes.

Corollary 4.51. *Let and C be a Hamiltonian $\mathcal{C}(n, n-1)$ -subcomplex in ∂P . Then any its defining face is an $(n-2)$ -face of P admitting a coloring in $(n-2)$ colors such that adjacent facets have different colors.*

Remark 4.52. As is was proved in [J01] a simple n -polytope P admits a coloring of its facets in n colors such that adjacent facets have different colors if and only if any 2-face of P has an even number of edges.

Corollary 4.53. *Let and C be a Hamiltonian $\mathcal{C}(n, n-1)$ -subcomplex in ∂P . Then the vertices of P lie on a disjoint set of even-gonal 2-faces of defining faces.*

Proof. Indeed, by Corollary 4.51 and Remark 4.52 each defining face M_q has a coloring in $(n-2)$ colors such that adjacent facets have different colors and each its 2-gonal face has an even number of edges. Moreover, for each choice of $(n-4)$ colors any nonempty intersection of facets of these colors is an even-gonal 2-face of M_q , and any vertex of M_q lies on exactly one such a 2-face. \square

Corollary 4.54. *If a small cover $N(P, \Lambda)$ over a 4-polytope P has a hyperelliptic involution in \mathbb{Z}_2^4 , then this involution corresponds to a Hamiltonian $\mathcal{C}(4, 3)$ -subcomplex inducing Λ and the vertices of P lie on a disjoint set of $(m - 3)$ defining even-gons.*

Remark 4.55. The first example of a small cover $N(P, \Lambda)$ over a 4-polytope P with a hyperelliptic involution in \mathbb{Z}_2^4 was build by Alexei Koretskii, see [K24].

Proposition 4.56. *If a 4-polytope P admits a Hamiltonian $\mathcal{C}(4, r)$ -subcomplex, then P has at least one triangular or quadrangular 2-face. In particular, there are no hyperbolic ($\mathbb{X} = \mathbb{L}^4$) hyperelliptic 4-manifolds $N(P, \Lambda)$ obtained by Construction 4.45. Moreover, for all $n \geq 4$ there are no hyperbolic ($\mathbb{X} = \mathbb{L}^n$) n -manifolds $N(P, \Lambda)$ obtained by Construction 4.45.*

Proof. Let p_k be the number of k -gonal 2-faces of P , and f_i be the total number of its i -faces (in particular, $f_3 = m$). We have the Euler formula $f_0 - f_1 + f_2 - f_3 = 0$. Also $4f_0 = 2f_1$ since P is simple. Also $\sum_k k p_k = \binom{4}{2} f_0 = 6f_0$. Then $f_2 = f_1 - f_0 + f_3 = f_0 + f_3 = f_0 + m$, and

$$\sum_k p_k = f_2 = f_0 + m = \frac{1}{6} \sum_k k p_k + m.$$

Thus, $\sum_k 6p_k = \sum_k k p_k + 6m$, $\sum_k (k - 6)p_k + 6m = 0$, and

$$(4) \quad 3p_3 + 2p_4 + p_5 = 6m + \sum_{k \geq 7} (k - 6)p_k$$

Assume that P has no triangles and quadrangles. Then $p_5 = 6m + \sum_{k \geq 7} (k - 6)p_k$ and $f_2 = \sum_{k \geq 5} p_k = 6m + \sum_{k \geq 6} (k - 5)p_k$. Let k_i be the number of edges of i -th defining 2-face. Then

$$f_0 = V_{4,r} + \sum_{i=1}^{m-r} k_i = f_2 - f_3 = 5m + \sum_{k \geq 6} (k - 5)p_k.$$

Thus,

$$\sum_{i=1}^{m-r} (k_i - 5) = 5m + \sum_{k \geq 6} (k - 5)p_k - 5(m - r) - V_{4,r} = 5r - V_{4,r} + \sum_{k \geq 6} (k - 5)p_k \geq 5r - V_{4,r} + \sum_{i=1}^{m-r} (k_i - 5).$$

Then $V_{4,r} \geq 5r$. For $r = 3$ we have $0 \geq 15$, for $r = 4$ we have $2 \geq 20$, and for $r = 5$ we have $5 \geq 25$. In all cases this is a contradiction.

Since any right-angled hyperbolic 4-polytope has no triangular and quadrangular 2-faces, it does not admit Hamiltonian $\mathcal{C}(4, r)$ -subcomplexes. Moreover, it follows from the paper [N82] by V.V. Nikulin that for $n > 4$ in the hyperbolic n -space \mathbb{L}^n there are no compact right-angled polytopes. This finishes the proof. \square

Proposition 4.57. *If a 4-polytope $P = Q \times I$ admits a Hamiltonian $\mathcal{C}(4, r)$ -subcomplex, then at least one of the defining 2-faces of P is a triangle. In particular, there are no hyperelliptic 4-manifolds $N(P, \Lambda)$ with geometries $\mathbb{L}^3 \times \mathbb{R}$, $\mathbb{L}^2 \times \mathbb{R}^2$, and \mathbb{R}^4 obtained by Construction 4.45.*

Proof. Let q be the number of facets of Q . Then $f_0(Q) = 2(q - 2)$, $m = f_3(P) = q + 2$, and $f_0(P) = 2f_0(Q) = 4(m - 4)$. Let k_i be the number of edges of the i -th defining 2-face. We have $f_0(P) = V_{4,r} + \sum_{i=1}^{m-r} k_i = 4(m - 4) = 4m - 16$. Then the average number of edges in defining 2-faces is

$$\frac{\sum_{i=1}^{m-r} k_i}{m-r} = \frac{4m - 16 - V_{4,r}}{m-r} = \frac{4(m-r) + 4r - 16 - V_{4,r}}{m-r} = 4 - \frac{16 + V_{4,r} - 4r}{m-r} = \begin{cases} 4 - \frac{4}{m-3} & \text{if } r = 3; \\ 4 - \frac{2}{m-4} & \text{if } r = 4; \\ 4 - \frac{1}{m-5} & \text{if } r = 5; \end{cases}$$

This number is strictly less than 4. Therefore, at least one defining face is a triangle. \square

Proposition 4.58. *For $n \geq 4$ the simplex Δ^n up to symmetries has a unique proper Hamiltonian $\mathcal{C}(n, r)$ -subcomplex defined by a single $(n - 2)$ -face Δ^{n-2} . For this subcomplex $r = n$. It corresponds to a hyperelliptic involution on the manifold $\mathbb{R}\mathcal{Z}_{\Delta^n} \simeq S^n$. In particular, the geometry S^n arises in Construction 4.45. The branch set of the covering $S^n \rightarrow S^n$ is the sphere S^{n-2} .*

Remark 4.59. For $n = 3$ the simplex Δ^3 admits also a Hamiltonian $\mathcal{C}(n, n - 1)$ -subcomplex corresponding to a Hamiltonian cycle.

Proof. Indeed, for $n \geq 4$ any two $(n - 2)$ -faces of Δ^n intersect. Also by definition any $(n - 2)$ -face of Δ^n is a defining face a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex. The structure of the branch set follows from the following fact.

Lemma 4.60. *Let F be one of the defining $(n - 2)$ -faces of a Hamiltonian $\mathcal{C}(n, k)$ -subcomplex $C \subset \partial P$. If the facets of F correspond to different facets of C (equivalently, if $F \cap F_i$ and $F \cap F_j$ are facets of F , then F_i and F_j lie in different facet of C), then in the branch set of the covering $N(P, \tilde{\Lambda}_C) \rightarrow S^n$ the preimage of F is a disjoint union of 2^{k-1-m_F} copies of $\mathbb{R}\mathcal{Z}_F$, where m_F is the number of facets of F .*

Proof. This follows from Proposition 4.31. \square

\square

Proposition 4.61. *For $n \geq 4$ the prism $\Delta^{n-1} \times I$ up to symmetries admits exactly 3 Hamiltonian $\mathcal{C}(n, r)$ -subcomplexes: a unique $\mathcal{C}(n, n + 1)$ -subcomplex and two $\mathcal{C}(n, n)$ -subcomplexes. In particular, the geometry $S^{n-1} \times \mathbb{R}$ arises in Construction 4.45. For the $\mathcal{C}(n, n + 1)$ -subcomplex and the $\mathcal{C}(n, n)$ -subcomplexes the branch sets of the coverings $S^{n-1} \times S^1 \rightarrow S^n$ and $N(P, \tilde{\Lambda}_C) \rightarrow S^n$ are disjoint unions of two spheres S^{n-2} .*

Proof. Indeed, up to symmetries $\Delta^{n-1} \times I$ has two types of $(n - 2)$ -faces: $\Delta^{n-3} \times I$ and Δ^{n-2} . In the Hamiltonian subcomplex corresponding to $\Delta^{n-3} \times I$ the facets corresponding to $\Delta^{n-1} \times 0$ and $\Delta^{n-1} \times 1$ do not intersect. Therefore, this subcomplex is not equivalent to $\mathcal{C}(n, r)$ for all r . The face Δ^{n-2} corresponds to a Hamiltonian $\mathcal{C}(n, n + 1)$ -subcomplex.

Any face $\Delta^{n-3} \times I$ intersects any face of the type Δ^{n-2} . For $n \geq 5$ it also intersects any other face of the type $\Delta^{n-3} \times I$. Hence it can not be a defining face of a Hamiltonian $\mathcal{C}(n, r)$ -subcomplex. For $n = 4$ and any face $I \times I$ there is a unique face $I \times I$ such that these faces

are disjoint. In the corresponding Hamiltonian subcomplex the facets corresponding to $\Delta^3 \times 0$ and $\Delta^3 \times 1$ do not intersect. Therefore, this subcomplex is not equivalent to $\mathcal{C}(n, r)$ for all r . Any face $\Delta^{n-2} \times \mathbf{x}$ intersects any other face $\Delta^{n-2} \times \mathbf{x}$. Two faces $\Delta_1^{n-2} \times 0$ and $\Delta_2^{n-2} \times 1$ do not intersect. Up to symmetries there can be two types of such faces. In the first case $\Delta_1^{n-2} = \Delta_2^{n-2}$. In the second case $\Delta_1^{n-2} \cap \Delta_2^{n-2}$ is an $(n-3)$ -simplex. Both these pairs of faces define Hamiltonian $\mathcal{C}(n, n)$ -subcomplexes. From the above argument there can not be more than two defining faces. The structure of the branch set follows from Lemma 4.60. \square

Construction 4.62 (Cutting off a face). Let $P = \{\mathbf{a}_i \mathbf{x} + b_i \geq 0, i = 1, \dots, m\} \subset \mathbb{R}^n$ be a simple n -polytope and $G = F_{i_1} \cap \dots \cap F_{i_k}$ be its $(n-k)$ -face, $k > 1$. Set $\mathbf{a}_G = \sum_{s=1}^k \mathbf{a}_{i_s}$ and $b_G = \sum_{s=1}^k b_{i_s}$. Take the halfspace $\mathcal{H}_{\geq \varepsilon} = \{\mathbf{a}_G \mathbf{x} + b_G \geq \varepsilon\}$. For small $\varepsilon \geq 0$ the intersection $P_{G, \varepsilon} = P \cap \mathcal{H}_{\geq \varepsilon}$ is a simple n -polytope. It has an additional facet F corresponding to the intersection of P with the hyperplane $\mathcal{H}_\varepsilon = \partial \mathcal{H}_{\geq \varepsilon}$. We have $F \cap F_{j_1} \cap \dots \cap F_{j_l} \neq \emptyset$ if and only if $F_{j_1} \cap \dots \cap F_{j_l}$ is a face of P intersecting G and not lying in G . That is, $F_{j_1} \cap \dots \cap F_{j_l} \cap F_{i_1} \cap \dots \cap F_{i_k} \neq \emptyset$ and $\{i_1, \dots, i_k\} \not\subset \{j_1, \dots, j_l\}$.

Lemma 4.63. *The facet F of $P_{G, \varepsilon}$ is combinatorially equivalent to $G \times \Delta^{k-1}$.*

Proof. Indeed, facets of F are in bijection with facets of P intersecting G . These are F_{i_1}, \dots, F_{i_k} , and facets F_j such that $F_j \cap G$ is a facet of G . The facets $F \cap F_{i_{a_1}}, \dots, F \cap F_{i_{a_l}}, F \cap F_{j_1}, \dots, F \cap F_{j_s}$ intersect if and only if $\{i_{a_1}, \dots, i_{a_l}\} \neq \{i_1, \dots, i_k\}$, and $G \cap F_{j_1} \cap \dots \cap F_{j_s} = (G \cap F_{j_1}) \cap \dots \cap (G \cap F_{j_s}) \neq \emptyset$. Thus, $F \simeq G \times \Delta^{k-1}$. \square

Lemma 4.64. *The other part $P \cap \mathcal{H}_{\leq \varepsilon}$ of the polytope P is combinatorially equivalent to $G \times \Delta^k$.*

Proof. Indeed, by the same argument as above the facets of the polytope $P \cap \mathcal{H}_{\leq \varepsilon}$ are in bijection with the facet F , facets F_{i_1}, \dots, F_{i_k} , and facets F_j such that $F_j \cap G$ is a facet of G . Moreover, its collection of facets $\{F, F_{i_{a_1}}, \dots, F_{i_{a_l}}, F_{j_1}, \dots, F_{j_s}\}$ intersects if any only if $\{i_{a_1}, \dots, i_{a_l}\} \neq \{i_1, \dots, i_k\}$ and $G \cap F_{j_1} \cap \dots \cap F_{j_s} = (G \cap F_{j_1}) \cap \dots \cap (G \cap F_{j_s}) \neq \emptyset$, while for $\{F_{i_{a_1}}, \dots, F_{i_{a_l}}, F_{j_1}, \dots, F_{j_s}\}$ the criterion of intersection is just $G \cap F_{j_1} \cap \dots \cap F_{j_s} \neq \emptyset$. \square

Lemma 4.65. *Any $(n-2)$ -face $F \cap F_{i_q} \simeq G \times \Delta^{k-2}$ of $P_{G, \varepsilon}$ defines a Hamiltonian subcomplex $C \simeq \partial P$.*

Proof. Let us rotate the hyperplane \mathcal{H}_ε around the $(n-2)$ -plane containing the face $F \cap F_{i_q}$. The rotating plane $\mathcal{H}(\varphi)$ is defined by the formula

$$\cos \varphi (\mathbf{a}_G \mathbf{x} + b_G - \varepsilon) + \sin \varphi (\mathbf{a}_{i_q} \mathbf{x} + b_{i_q}) = 0.$$

We have $\mathcal{H}(0) = \mathcal{H}_\varepsilon = \text{aff}(F)$ and $\mathcal{H}(\frac{\pi}{2}) = \text{aff}(F_{i_q})$. Moreover, for small $\delta > 0$ at each moment $-\delta \leq \varphi < \frac{\pi}{2}$ the polytope $P \cap \mathcal{H}_{\geq 0}(\varphi)$ has the same combinatorial type P_ε and for any $-\delta \leq \varphi_1 < \varphi_2 \leq \frac{\pi}{2}$ the polytope $P \cap \mathcal{H}_{\leq 0}(\varphi_1) \cap \mathcal{H}_{\geq 0}(\varphi_2)$ has the same combinatorial type $G \times \Delta^k \simeq P \cap \mathcal{H}_{\leq \varepsilon}$. In particular, the polytope $P \cap \mathcal{H}_{\leq 0}(-\delta) \cap \mathcal{H}_{\geq 0}(0)$ is combinatorially equivalent to $P \cap \mathcal{H}_{\leq 0}(-\delta) \cap \mathcal{H}_{\geq 0}(\frac{\pi}{2})$. Then the piecewise linear homeomorphism defined using the barycentric subdivisions preserves the face structures and is identical on $P \cap \mathcal{H}(-\delta)$. This homeomorphism together with the identical mapping on $P \cap \mathcal{H}_{\geq 0}(-\delta)$ defines the desired equivalence $C \simeq \partial P$. \square

Corollary 4.66. *For any set G_1, \dots, G_k of pairwise disjoint faces of the simplex Δ^n the polytope obtained from Δ^n by cutting off all these faces by different hyperplanes has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex given by a set of k defining $(n-2)$ -faces lying in different cutting hyperplanes.*

Example 4.67. Any hyperplane separating a face Δ^k of the simplex Δ^n from the other vertices leaves a face Δ^{n-k-1} on the other side. Then Lemma 4.64 implies that if we cut off Δ^k we obtain combinatorially the polytope $\Delta^{n-k-1} \times \Delta^{k+1}$. Moreover, the defining face $F \cap F_{i_q}$ from Lemma 4.65 has the form $\Delta^{n-k-2} \times \Delta^k$.

Corollary 4.68. *For any $p, q \geq 1$ the face $\Delta^{p-1} \times \Delta^{q-1}$ defines a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex in $P^n = \Delta^p \times \Delta^q$. In particular, for $p, q \geq 2$ the geometry $\mathbb{S}^p \times \mathbb{S}^q$ arises in Construction 4.45. (For $p = 1$ or $q = 1$ we obtain the polytope $\Delta^{n-1} \times I$ and the geometry $\mathbb{S}^{n-1} \times \mathbb{R}$ already covered by Proposition 4.61.) For $p, q \geq 2$ the branch set of the coverings $S^p \times S^q \rightarrow S^n$ is homeomorphic to $S^{p-1} \times S^{q-1}$.*

Remark 4.69. The structure of the branch set follows from Lemma 4.60. Moreover, this implies that in Corollary 4.66 the branch set is a disjoint union of the products $S^{n-k-2} \times S^k$ corresponding to faces Δ^k , $0 \leq k \leq n-2$.

Proposition 4.70. *If an n -polytope P has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex such that its defining faces $\{M_1, \dots, M_s\}$ do not intersect a facet $F_i \simeq \Delta^{n-1}$, then for any $k \geq 1$ the polytope $\Delta^k \times P$ has a Hamiltonian $\mathcal{C}(n+k, n+k+1)$ -subcomplex with defining faces $\Delta^{k-1} \times F_i$ and $\Delta^k \times M_1, \dots, \Delta^k \times M_s$.*

Proof. Indeed, the faces $\Delta^k \times M_1, \dots, \Delta^k \times M_s$ define the subcomplex equivalent to $\partial(\Delta^k \times \Delta^n)$, and the face $\Delta^{k-1} \times F_i \simeq \Delta^{k-1} \times \Delta^{n-1}$ transforms it to $\partial\Delta^{n+k}$. \square

Corollary 4.71. *For any $p, q \geq 1$ the polytope $P^n = \Delta^p \times \Delta^q \times I$ has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex defined by two faces $\Delta^{p-1} \times \Delta^q \times \{0\}$ and $\Delta^p \times \Delta^{q-1} \times \{1\}$. In particular, the geometries $\mathbb{S}^p \times \mathbb{S}^q \times \mathbb{R}$, $p, q \geq 2$, $\mathbb{S}^p \times \mathbb{R}^2$, $p \geq 2$, and \mathbb{R}^3 arise in Construction 4.45. The branch set of the covering $N(P, \tilde{\Lambda}_C) \rightarrow S^n$ is $S^{p-1} \times S^q \sqcup S^p \times S^{q-1}$.*

Proof. Indeed, $\Delta^{q-1} \times \{1\} \cap \Delta^p \times \{0\} = \emptyset$. Hence, we can apply Proposition 4.70 to $P = \Delta^q \times I$. The structure of the branch set follows from Lemma 4.60. \square

Proposition 4.72. *If an n -polytope P has a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex C such that its defining faces $\{M_1, \dots, M_s\}$ do not intersect an $(n-2)$ -face $G \subset P$, then $G \simeq \Delta^{n-2}$, and the faces $\{M_1, \dots, M_s, G\}$ define a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex in ∂P .*

Proof. By Corollary 4.30 G is an $(n-2)$ -face of C , hence $G \simeq \Delta^{n-2}$ and it defines in C the Hamiltonian $\mathcal{C}(n, n)$ -subcomplex. Then the faces $\{M_1, \dots, M_s, G\}$ define the corresponding Hamiltonian $\mathcal{C}(n, n)$ -subcomplex in ∂P . \square

Corollary 4.73. *Let $\Delta^2 = \text{conv}\{v_1, v_2, v_3\}$. Then the faces $\text{conv}\{v_1, v_2\} \times \Delta^{n-3}$ and $v_3 \times \Delta^{n-2}$ define a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex C in $\Delta^2 \times \Delta^{n-2}$ for $n \geq 3$. The branch set of the covering $N(P, \tilde{\Lambda}_C) \rightarrow S^n$ is a disjoint union of S^{n-2} and $S^1 \times S^{n-3}$.*

Proof. The structure of the branch set over $v_3 \times \Delta^{n-2}$ follows from Lemma 4.60. For the face $F = \text{conv}\{v_1, v_2\} \times \Delta^{n-3}$ its facets corresponding to Δ^{n-3} lie in different facets of C , while the facets $v_1 \times \Delta^{n-3}$ and $v_2 \times \Delta^{n-3}$ lie in the same facet of C different from the above facets. Hence, by Proposition 4.31 the branch set over F is homeomorphic to $S^1 \times S^{n-3}$. \square

Corollary 4.74. *Let P_k be a k -gon, $k \geq 3$. Then for $p \geq 1$ the polytope $P^n = \Delta^p \times P_k$ admits Hamiltonian $\mathcal{C}(n, n)$ - and $\mathcal{C}(n, n+1)$ -subcomplexes C_n and C_{n+1} . In particular, taking a right-angled triangle in \mathbb{S}^2 , a square in \mathbb{R}^2 and a right-angled k -gon, $k \geq 5$, in \mathbb{L}^2 we see that the geometries $\mathbb{S}^p \times \mathbb{S}^2$, $\mathbb{S}^p \times \mathbb{R}^2$ and $\mathbb{S}^p \times \mathbb{L}^2$, $p \geq 2$, arise in Construction 4.45. The branch set of the covering $N(P, \tilde{\Lambda}_{C_{n+1}}) \rightarrow S^n$ is a disjoint union of $2(k-3)$ copies of S^{n-2} and one $S^{n-3} \times S^1$, and for the covering $N(P, \tilde{\Lambda}_{C_n}) \rightarrow S^n$ it is a disjoint union of $(k-2)$ -copies of S^{n-2} and one $S^{n-3} \times S^1$.*

Proof. Indeed, let $P_k = \text{conv}\{v_1, \dots, v_k\}$. Then the vertices v_1, \dots, v_{k-3} define a Hamiltonian $\mathcal{C}(2, 3)$ -subcomplex in P_k , and the edge $\text{conv}\{v_{k-2}, v_{k-1}\}$ does not intersect these vertices. By Proposition 4.70 the faces $\Delta^p \times v_1, \dots, \Delta^p \times v_{k-3}, \Delta^{p-1} \times \text{conv}\{v_{k-2}, v_{k-1}\}$ define a Hamiltonian $\mathcal{C}(n, n+1)$ -subcomplex C_{n+1} . By Proposition 4.72 the addition of the face $\Delta^p \times v_k$ defines a Hamiltonian $\mathcal{C}(n, n)$ -subcomplex C_n . For each defining face of C_{n+1} its facets correspond to different facets of C_{n+1} , hence the structure of the branch set follows from Lemma 4.60. For defining faces $\Delta^p \times v_j$ of C_n the same argument works. For the defining face $\Delta^{p-1} \times \text{conv}\{v_{k-2}, v_{k-1}\}$ of C_n its facets corresponding to Δ^{p-1} lie in different facets of C_n , while the facets $\Delta^{p-1} \times v_{k-2}$ and $\Delta^{p-1} \times v_{k-1}$ lie in the same facet of C_n different from the above facets. Hence, by Proposition 4.31 the branch set over this facet is homeomorphic to $S^{p-1} \times S^1$. \square

Example 4.75. On Fig. 1 we show a set of five disjoint quadrangles defining a Hamiltonian $\mathcal{C}(4, 5)$ -subcomplex in $P_5 \times P_5$. In particular, the geometry $\mathbb{L}^2 \times \mathbb{L}^2$ arises in Construction 4.45. It follows from Lemma 4.60 that the branch set of the covering $N(P, \tilde{\Lambda}_C) \rightarrow S^4$ is a disjoint union of five tori $\mathbb{T}^2 = S^1 \times S^1$.

In dimension $n = 4$ all the products of Euclidean, spherical and hyperbolic geometries (including these geometries) are 10 geometries: \mathbb{S}^4 , \mathbb{R}^4 , \mathbb{L}^4 , $\mathbb{S}^3 \times \mathbb{R}$, $\mathbb{S}^2 \times \mathbb{S}^2$, $\mathbb{S}^2 \times \mathbb{R}^2$, $\mathbb{S}^2 \times \mathbb{L}^2$, $\mathbb{L}^3 \times \mathbb{R}$, $\mathbb{L}^2 \times \mathbb{R}^2$, and $\mathbb{L}^2 \times \mathbb{L}^2$.

Theorem 4.76. *In dimension $n = 4$ among all products of Euclidean, spherical and hyperbolic geometries (including these geometries) the geometries \mathbb{S}^4 , $\mathbb{S}^3 \times \mathbb{R}$, $\mathbb{S}^2 \times \mathbb{S}^2$, $\mathbb{S}^2 \times \mathbb{R}^2$, $\mathbb{S}^2 \times \mathbb{L}^2$, and $\mathbb{L}^2 \times \mathbb{L}^2$ admit hyperelliptic manifolds build by Construction 4.45, and the geometries \mathbb{R}^4 , \mathbb{L}^4 , $\mathbb{L}^3 \times \mathbb{R}$, $\mathbb{L}^2 \times \mathbb{R}^2$ do not admit.*

Proof. The cases of \mathbb{S}^4 , $\mathbb{S}^3 \times \mathbb{R}$, $\mathbb{S}^2 \times \mathbb{S}^2$, $\mathbb{S}^2 \times \mathbb{R}^2$, $\mathbb{S}^2 \times \mathbb{L}^2$, $\mathbb{L}^2 \times \mathbb{L}^2$ are covered by Propositions 4.58, 4.61, Corollaries 4.68, 4.74, and Example 4.75.

The cases of \mathbb{R}^4 , \mathbb{L}^4 , $\mathbb{L}^3 \times \mathbb{R}$, $\mathbb{L}^2 \times \mathbb{R}^2$ are covered by Corollary 4.49, and Propositions 4.56, 4.57. \square

FIGURE 1. A set of disjoint quadrangles defining a Hamiltonian $\mathcal{C}(4, 5)$ -subcomplex in $P_5 \times P_5$

5. ACKNOWLEDGEMENTS

The author is grateful to V.M. Buchstaber for his permanent attention, to A.D. Mednykh for motivating discussions, in particular for the suggestion to consider geometries arising on hyperelliptic 4-manifolds $N(P, \Lambda)$ and the corresponding branch sets, and to D.V. Gugin for useful discussions.
