Abstract

We develop structure-preserving numerical methods for the Serre-Green-Naghdi equations, a model for weakly dispersive free-surface waves. We consider both the classical form, requiring the inversion of a nonlinear elliptic operator, and a hyperbolic approximation of the equations, allowing fully explicit time stepping. Systems for both flat and variable topography are studied. Our novel numerical methods conserve both the total water mass and the total energy. In addition, the methods for the original Serre-Green-Naghdi equations conserve the total momentum for flat bathymetry. For variable topography, all the methods proposed are well-balanced for the lake-at-rest state. We provide a theoretical setting allowing us to construct schemes of any kind (finite difference, finite element, discontinuous Galerkin, spectral, etc.) as long as summation-by-parts operators are available in the chosen setting. Energy-stable variants are proposed by adding a consistent high-order artificial viscosity term. The proposed methods are validated through a large set of benchmarks to verify all the theoretical properties. Whenever possible, comparisons with exact, reference numerical, or experimental data are carried out. The impressive advantage of structure preservation, and in particular energy preservation, to resolve accurately dispersive wave propagation on very coarse meshes is demonstrated by several of the tests.

1 Introduction

This paper is devoted to the structure-preserving numerical approximation of the fully nonlinear, weakly dispersive Serre-Green-Naghdi (SGN) equations for free-surface hydrodynamics. Dispersive free-surface waves occur in a wide variety of phenomena going from the propagation of tsunamis [52, 73, 3], to estuarine dynamics and wave propagation in natural as well as man made environments [128, 9, 17, 39, 60]. Many of these applications involve multi-scale wave physics, with often large domains and long-time/distance propagation. Depth averaged Boussinesq-type equations are used in many existing operational codes for hazard assessment (see e.g. [68, 64] and references therein). These models can be written as a perturbation of the hyperbolic shallow water equations with a dispersive term, which accounts for some of the vertical kinematic lost in the depth averaging [71]. Among these models, the SGN system [119, 53, 131] accounts for the full nonlinearity of the wave propagation and transformation, and is endowed with a rigorous estimate of the energy associated to the wave dynamics (see e.g. [37, 50, 71, 63]) which can be used as a rigorous criterion to estimate the dissipation during the propagation process. In the literature, two main writings of the SGN equations have been used for the purpose of numerical approximation: a classical one involving the inversion of a nonlinear elliptic operator to evaluate the time variation of the velocity [71, 63, 50], and a system based on a hyperbolic relaxation of the dispersion operator [37, 34]. Both forms are considered here.

Realistic operational applications require being able to run multi-scale simulations on reasonably coarse meshes to obtain fast predictions. A lot of focus is being put on deploying operational codes on modern high-performance parallel architectures [134, 125, 20]. In this work, we consider the other end of the process, and propose improved numerical methods. In the literature we find many different numerical approaches to approximate Boussinesq-type, dispersive shallow water equations. Many such techniques involve some high-order approximation in space and time, with possibly ad-hoc treatments for the dispersive terms (hyperbolization, or some lower-order approximation) to combine efficiency and good numerical dispersion [131, 35, 62, 116, 94, 72, 83, 41, 29, 74, 13, 15, 127, 63]. Some authors also propose methods with some strong energy stability/dissipation property [122, 95], by imitation of what is usually done for hyperbolic conservation laws with entropy stability. Few recent works focus on approximations guaranteeing exact energy conservation [108, 84, 70] at the discrete level.

The theoretical and numerical results discussed in [33, 31, 12, 8] show that there is a very delicate interaction between dissipation, dispersion, and non-linearity. In particular, while in the purely dispersive setting many initial conditions lead to appearance of solitary wave fission, in presence of finite dissipation one obtains travelling waves with finite stationary wavelength and much lower amplitudes. In this respect, while recent work has shown that discontinuous solutions for Boussinesq models can be constructed [49, 30, 58], such constructions do not rely, as in the case of hyperbolic balance laws, on the notion of a dissipative solution. Admissibility conditions for these problems are formulated based on geometrical considerations in phase space, and relate to the celerities of the solution fronts. There is no notion on the sign of the energy evolution in such conditions. It is thus unclear whether one should use numerical dissipation when solving non-dissipative dispersive equations as a means of stabilization. This is a major difference between dispersive models and hyperbolic ones. In addition, the recent work by Jouy et al. [60] has shown that numerical dissipation plays in practice the exact same role of a physical dissipative regularization. In particular, when using high-order schemes embedding dissipation a gross underestimation of the wave amplitudes may be obtained on coarse meshes. This is not the case for non-dissipative methods. The results of [60] show that this issue occurs not only for non-dissipative models, but also in presence of physical dissipation terms in the model, e.g., due to friction terms. Our objective is thus to investigate the construction and validation of structure-preserving methods for the SGN equations, namely methods which conserve within machine accuracy as many physical properties as possible, including energy, and which is well-balanced with respect to the well-known lake-at-rest state.

To this end we use the framework of summation-by-parts (SBP) operators and split forms [43] as a systematic approach to build exactly energy-conservative semidiscretizations. The idea is to follow step-by-step the continuous derivation of the energy balance, and combine the use of SBP differentiation operators, which allow to mimic integration by parts, and use appropriate split forms of the differential equations to mimic the product and chain rule. To obtain a fully conservative method, the resulting ordinary differential equations in time can be integrated using relaxation Runge-Kutta (RRK) schemes, which are a small modification of classical Runge-Kutta methods allowing to preserve appropriate invariants [66, 113].

The paper is organized as follows. In the following Section 2, we briefly review the techniques that we use for spatial and temporal discretizations. In particular, we describe how split forms of the equations can be used to derive energy-conserving discretizations using SBP operators. Next, we review such energy-conserving split forms of the classical shallow water equations in Section 3. In Section 4, we review the classical SGN equations in flat bathymetry as well as their hyperbolic approximation. To prepare the remainder of this article, we also explain how to pass from the hyperbolic approximation to the original system. Next, we derive a structure-preserving split form and discretization of the hyperbolic approximation with flat bathymetry in Section 5. We begin with the hyperbolic approximation since there are less complicated higher-derivative terms in this case, making it easier to derive an energy-conserving split form. Using the previously established translation rules, we use these results to derive corresponding structure-preserving methods for the original SGN equations in Section 6. We extend the investigations to the case of variable bathymetry first for the hyperbolic approximation in Section 7 and to the classical SGN equations in Sections 8 and 9. We describe how to add stabilizing artificial viscosity/dissipation in Section 10. Afterwards, we validate our implementation and present numerical experiments in Section 11. Finally, we summarize our results and give an outlook on future work in Section 12.

2 Brief review of split forms and discretization techniques

In this section, we briefly review the techniques that we use for spatial and temporal discretizations. In general, we will use the method of lines, starting with a semidiscretization in space followed by a time integration.

2.1 Split forms

Consider Burgers' equation

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0 \quad (1)$$

with periodic boundary conditions. As is well known, a smooth solution satisfies the energy equality

$$\left(\frac{1}{2}u^2\right)_t + \left(\frac{1}{3}u^3\right)_x = 0. \quad (2)$$

Thus, the total energy (squared L^2 norm) is conserved. To prove this, one would typically multiply the PDE by u and use the chain rule. However, discrete derivative operators can in general not satisfy a discrete version of the chain rule, in particular for higher-order operators [100]. Thus, we will use the split form [117, eq. (6.40)]

$$u_t + \frac{1}{3}(u^2)_x + \frac{1}{3}uu_x = 0. \quad (3)$$

Indeed, multiplying Burgers' equation by the solution u and integrating over the domain yields

$$\frac{1}{2} \frac{d}{dt} \int u^2 dx = \int uu_t dx = -\frac{1}{3} \int u(u^2)_x dx - \frac{1}{3} \int u^2 u_x dx = 0. \quad (4)$$

Hence, energy conservation can be shown using only integration by parts. To obtain a semidiscretization satisfying the energy conservation law at the discrete level, we just need to use the split form derived at the continuous level and apply discrete derivative operators satisfying a discrete equivalent of integration by parts.

Although the split form looks like it results in a non-conservative discretization, one can show that the total mass is still conserved since

$$\frac{d}{dt} \int u dx = -\frac{1}{3} \int (u^2)_x dx - \frac{1}{3} \int u_x u dx = 0, \quad (5)$$

using again only integration by parts. Moreover, it can be shown that the discretization of the split form is even locally conservative when discretized with SBP operators [43]. This also holds for more general flux differencing discretizations that can be entropy-stable but do not need to be related to a split form [42].

2.2 Summation-by-parts operators

SBP operators are discrete derivative operators designed to mimic integration by parts at the discrete level. Originally, SBP operators were introduced for finite difference methods [69, 120], but they can also be used for finite volume [88, 89], continuous finite element [57, 56, 1], discontinuous Galerkin [47, 14, 16], and flux reconstruction methods [59, 110]. A good overview can be obtained from the review articles [123, 38] and the application of various methods from the SBP framework to dispersive wave equations in [108].

We consider periodic boundary conditions in this article. Thus, we will only briefly recap the corresponding properties of periodic SBP operators. Further discussions and examples can be found in [123, 38, 108]. We use a nodal collocation approach and discretize the spatial domain using point values of the unknowns at given grid points x_i . The discretized version of a function u is denoted by \mathbf{u} with $\mathbf{u}_i = u(x_i)$. In particular, $\mathbf{1} = (1, \dots, 1)^T$. Nonlinear operations are performed pointwise, e.g., $(\mathbf{u}^2)_i = \mathbf{u}_i^2$.

Definition 1. A periodic SBP operator on the domain $[x_{\min}, x_{\max}]$ consists of a grid \mathbf{x} , a symmetric and positive definite mass/norm matrix M satisfying $\mathbf{1}^T M \mathbf{1} = x_{\max} - x_{\min}$, and a consistent derivative operator D such that

$$MD + D^T M = 0. \quad (6)$$

It is called diagonal-norm operator if M is diagonal.

A consistent derivative operator D differentiates constants exactly, i.e., $D\mathbf{1} = \mathbf{0}$. A classical example of a periodic SBP operator is given by central second-order finite differences, where mass matrix is the identity matrix scaled by the grid spacing Δx and the stencil coefficients of the derivative operator are $\Delta x^{-1}(-1/2, 0, 1/2)$.

The definition above introduces first-derivative SBP operators. Since we also need higher derivatives for the dispersive terms, we will use second-derivative SBP operators [82, 80] as well. Since the second-derivative terms of the Serre-Green-Naghdi equations have variable coefficients, we will use upwind operators to construct them in a general way [81]. See also [108, 92] for discussions of upwind SBP operators and discontinuous Galerkin methods for second-derivative terms.

Definition 2. A periodic upwind SBP operator on the domain $[x_{\min}, x_{\max}]$ consists of a grid \mathbf{x} , a symmetric and positive definite mass/norm matrix M satisfying $\mathbf{1}^T M \mathbf{1} = x_{\max} - x_{\min}$, and two consistent derivative operators D_{\pm} such that

$$MD_+ + D_-^T M = 0, \quad M(D_+ - D_-) \text{ is negative semidefinite.} \quad (7)$$

It is called diagonal-norm operator if M is diagonal.

We will frequently use that the average $D = (D_+ + D_-)/2$ of upwind SBP operators is a central SBP operator [81]. A classical example of periodic upwind SBP operators is given by the one-sided first-order finite differences, where the mass matrix is again the identity matrix scaled by the grid spacing Δx and the stencil coefficients of the upwind derivative operator are $\Delta x^{-1}(-1, 1, 0)$ and $\Delta x^{-1}(0, -1, 1)$. Thus, the corresponding central SBP operator is given by the coefficients $\Delta x^{-1}(-1/2, 0, 1/2)$.

To get a second-derivative operator, one can apply a first-derivative operator twice. For the classical second-order central SBP operator, this results in the wide-stencil operator with coefficients $\Delta x^{-2}(1/4, 0, -1/2, 0, 1/4)$. A better approximation is usually given by the combination of upwind operators, e.g., $D_+ D_-$ with stencil coefficients $\Delta x^{-2}(1, -2, 1)$.

In this article, we will only use diagonal-normal SBP operators. We will use the quadrature rule induced by the mass matrix to compute discrete versions of integrals or the discrete L^2 error.

2.3 Time integration methods using relaxation

We will use explicit Runge-Kutta methods for time integration. Since such explicit time integration methods cannot guarantee conservation (or dissipation) of nonlinear invariants such as the energy [101, 90, 105, 61, 76, 109, 121], we will use relaxation to enforce the conservation of the energy [66, 114, 107]. This approach has its origins in an idea of Sanz-Serna [118]. It has been applied successfully to compressible flows [133, 103, 130] and various other systems conserving or dissipating an energy/entropy functional. It is particularly useful for long-time simulations of dispersive wave equations and Hamiltonian systems [108, 106, 84, 111, 7, 135].

The basic idea is as follows. Consider an ODE $u' = f(u)$ and assume that the ODE conserves an energy $\eta(u)$, i.e., $\forall u: \eta'(u)f(u) = 0$. Given a one-step method computing $u^{n+1} \approx u(t^{n+1})$ from $u^n \approx u(t^n)$, we enforce conservation of the energy η by projecting the numerical solution along the secant line connecting u^n and u^{n+1} onto the level set $\eta(u) = \eta(u^n)$. Thus, we need to solve the scalar root finding problem

$$\eta(u_{\gamma}^{n+1}) = \eta(u^n), \quad u_{\gamma}^{n+1} = u^n + \gamma(u^{n+1} - u^n), \quad (8)$$

for the relaxation parameter γ . The general theory of relaxation methods shows that there is a unique solution $\gamma = 1 + \mathcal{O}(\Delta t^{p-1})$ under rather general assumptions [107], where p is the order of accuracy of the time integration method. Continuing the numerical integration with u_{γ}^{n+1} instead of u^{n+1} guarantees conservation of the energy η , of all linear invariants, and at least the same order of accuracy p as the original method if the relaxed solution is interpreted as $u_{\gamma}^{n+1} \approx u(t_{\gamma}^{n+1})$, where the relaxed time is $t_{\gamma}^{n+1} = t^n + \gamma \Delta t$.

3 Split forms of the classical shallow water equations

The Serre-Green-Naghdi equations [119, 53, 131] (see also [71] and references therein) and their hyperbolic approximation [37, 13] are extensions of the classical shallow water equations by additional terms modeling dispersive effects. To prepare deriving structure-preserving discretizations, we first consider some split forms of the classical shallow water (Saint-Venant) equations.

3.1 Flat bathymetry

Consider the classical shallow water equations with constant bathymetry

$$\begin{aligned} h_t + (hu)_x &= 0, \\ (hu)_t + \left(hu^2 + \frac{1}{2}gh^2\right)_x &= 0, \end{aligned} \tag{9}$$

where h denotes the water height, u the velocity, and g the gravitational constant. The system admits the energy conservation law [10, 44]

$$\underbrace{\left(\frac{1}{2}gh^2 + \frac{1}{2}hu^2\right)}_{=E}_t + \underbrace{\left(gh^2u + \frac{1}{2}hu^3\right)}_{=F}_x = 0. \tag{10}$$

A split form of the equations can be used to prove energy conservation using only integration by parts, e.g., [48, 132]. Indeed, there is even a two-parameter family of energy-conserving split forms of the classical shallow water equations [99]. A simplified version discarding some higher-order terms of [99, Section 4.2] reads¹

$$\begin{aligned} h_t + \alpha(hu)_x + (1-\alpha)h_xu + (1-\alpha)hu_x &= 0, \\ (hu)_t + (1-\alpha)g(h^2)_x - (1-2\alpha)ghh_x & \\ + \frac{\alpha}{2}(hu^2)_x + \frac{1-\alpha}{2}h(u^2)_x + \frac{1-\alpha}{2}h_xu^2 + \frac{1}{2}(hu)_xu + \frac{1}{2}hhu_x &= 0. \end{aligned} \tag{11}$$

To simplify the following derivation, we focus on the split form (11) with $\alpha = 0$, i.e.,

$$\begin{aligned} h_t + h_xu + hu_x &= 0, \\ (hu)_t + g(h^2)_x - ghh_x + \frac{1}{2}h(u^2)_x + \frac{1}{2}h_xu^2 + \frac{1}{2}(hu)_xu + \frac{1}{2}hhu_x &= 0. \end{aligned} \tag{12}$$

Furthermore, to simplify the treatment of the elliptic terms in the Serre-Green-Naghdi equations, we will use primitive variables (h, u) instead of the conservative variables (h, hu) in the following. Thus, using the product rule in time

$$(hu)_t = hu_t + h_tu = hu_t - h_xu^2 - hhu_x, \tag{13}$$

the split form (12) becomes

$$\begin{aligned} h_t + h_xu + hu_x &= 0, \\ hu_t + g(h^2)_x - ghh_x + \frac{1}{2}h(u^2)_x - \frac{1}{2}h_xu^2 + \frac{1}{2}(hu)_xu - \frac{1}{2}hhu_x &= 0. \end{aligned} \tag{14}$$

To prepare the following arguments, we will demonstrate how to obtain conservation of total water mass, momentum, and energy.

¹ $a_1 = 3 - 4\alpha$ and $a_2 = (2 - a_1)/3$ in the notation of [99, Section 4.2].

3.1.1 Flat bathymetry: conservation of the total water mass

The spatial terms of the first equation of (14) cancel when integrated over the periodic domain due to integration by parts, i.e.,

$$0 = \int h_t dx + \int h_x u dx + \int hu_x dx = \frac{d}{dt} \int h dx. \quad (15)$$

Note that the two terms vanishing via integration by parts yield exactly the difference of the flux hu at the periodic boundaries.

3.1.2 Flat bathymetry: conservation of the total momentum

The time derivative of the momentum is

$$(hu)_t = h_t u + hu_t. \quad (16)$$

Thus, we multiply the first equation of (14) by u , add it to the second equation, integrate over the periodic domain, and obtain

$$\begin{aligned} 0 &= \int (hu)_t dx + \int h_x u^2 dx + \int hu u_x dx + \int g(h^2)_x dx - \int gh h_x dx \\ &\quad + \frac{1}{2} \int h(u^2)_x dx - \frac{1}{2} \int h_x u^2 dx + \frac{1}{2} \int (hu)_x u dx - \frac{1}{2} \int hu u_x dx \\ &= \int (hu)_t dx + \int g(h^2)_x dx - \int gh h_x dx \\ &\quad + \frac{1}{2} \int h(u^2)_x dx + \frac{1}{2} \int h_x u^2 dx + \frac{1}{2} \int (hu)_x u dx + \frac{1}{2} \int hu u_x dx. \end{aligned} \quad (17)$$

Using integration by parts, the two gh^2 terms yield a boundary term $gh^2/2$. The first two terms of the last line as well as the last two terms cancel due to integration by parts, respectively, resulting in the boundary terms $hu^2/2$ and $hu^2/2$. Thus, all terms canceling via integration by parts sum up to the expected flux $gh^2/2 + hu^2$. This shows that *for exact time integration* momentum is conserved.

3.1.3 Flat bathymetry: conservation of the total energy

The time derivative of the energy E (10) is

$$E_t = \left(\frac{1}{2} gh^2 + \frac{1}{2} hu^2 \right)_t = gh h_t + hu u_t. \quad (18)$$

Thus, we multiply the first equation of (14) by gh , the second equation by u , add them, and obtain

$$\begin{aligned} 0 &= E_t + gh h_x u + gh^2 u_x + g(h^2)_x u - gh h_x u + \frac{1}{2} hu(u^2)_x - \frac{1}{2} h_x u^3 + \frac{1}{2} (hu)_x u^2 - \frac{1}{2} hu^2 u_x \\ &= E_t + g \left(h^2 u_x + (h^2)_x u \right) + \frac{1}{2} \left(hu(u^2)_x + (hu)_x u^2 \right) - \frac{1}{2} \left(h_x u^3 + hu^2 u_x \right). \end{aligned} \quad (19)$$

We see that all pairs of terms in parentheses cancel when integrating over the periodic domain due to integration by parts, resulting in the expected flux terms $F = gh^2 u + hu^3/2$. Thus, the total energy is conserved, *if the time integration is exact*.

3.2 Variable bathymetry

The classical shallow water equations with variable bathymetry are

$$\begin{aligned} h_t + (hu)_x &= 0, \\ (hu)_t + \left(hu^2 + \frac{1}{2} gh^2 \right)_x + gh b_x &= 0, \end{aligned} \quad (20)$$

where b denotes the bathymetry (bottom topography). The system admits the energy conservation law [10, 44, 48]

$$\underbrace{\left(\frac{1}{2}gh^2 + ghb + \frac{1}{2}hu^2\right)}_{=E}_t + \underbrace{\left(gh^2u + ghbu + \frac{1}{2}hu^3\right)}_{=F}_x = 0. \quad (21)$$

The generalization to variable bathymetry of the split form (14) of [99, Section 5.3] is

$$\begin{aligned} h_t + h_x u + hu_x &= 0, \\ hu_t + g(h(h+b))_x - g(h+b)h_x + \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}huu_x &= 0. \end{aligned} \quad (22)$$

Conservation of the total water mass follows as in the case of flat bathymetry. Since (22) is the same as the previous split form (14) for flat bathymetry $b = 0$, conservation of the total momentum follows for constant bottom topography as well. In the energy rate of change E_t , we get the new term gbh_t , leading to the additional terms

$$gh_x bu + ghbu_x + g(hb)_x u - gh_x bu = g(hbu_x + (hb)_x u), \quad (23)$$

which vanish due to integration by parts when integrating over the periodic domain. Thus, the total energy is conserved for variable bathymetry as well.

Moreover, the split form (22) is well-balanced, i.e., it preserves the lake-at-rest steady state $h+b = \text{const}$, $u = 0$. Indeed, the time derivative of h vanishes for $u = 0$, and the time derivative of the velocity is given by

$$0 = hu_t + g(h(h+b))_x - g(h+b)h_x = hu_t g(h+b)h_x - g(h+b)h_x = hu_t \quad (24)$$

if $h+b = \text{const}$ additionally. All of these properties still hold for semidiscretizations using periodic SBP operators.

4 Review of the Serre-Green-Naghdi equations for flat bathymetry

In this section, we review the classical form of the Serre-Green-Naghdi equations for flat bathymetry as well as their hyperbolic approximation. We present the associated energy conservation laws and describe how to pass from one set of equations to the other to prepare the derivations later in this paper.

4.1 Equations in classical form and elliptic operator

On a flat bathymetry, the SGN equations can be written as

$$\begin{aligned} h_t + (hu)_x &= 0, \\ (hu)_t + \left(hu^2 + \frac{1}{2}gh^2 + \tilde{p}\right)_x &= 0, \\ \tilde{p} &= -\frac{1}{3}\left(h^3(\dot{u})_x - 2h^3u_x^2\right), \end{aligned} \quad (25)$$

with the classical notation for the material derivative $\dot{a} = a_t + ua_x$. As in Section 3, h is the water height, u the velocity, and g the gravitational constant. Compared to the shallow water equations (9), the SGN equations (25) contain an additional non-hydrostatic pressure \tilde{p} . This system is known to admit an energy conservation law reading

$$\underbrace{\left(\frac{1}{2}gh^2 + \frac{1}{2}hu^2 + \frac{1}{6}h(\dot{h})^2\right)}_{=E}_t + \underbrace{\left(gh^2u + \frac{1}{2}hu^3 + \frac{1}{6}h(\dot{h})^2u + \tilde{p}u\right)}_{=F}_x = 0. \quad (26)$$

Note that both the energy E and the energy flux F are extensions of the corresponding quantities for the shallow water equations (10). Our objective is to construct discrete approximations of the SGN system preserving exactly the energy conservation law (26).

Note that to advance in time system (25) requires the inversion of the operator $\mathcal{T}(u_t)$, where

$$\mathcal{T}(v) = hv - \frac{1}{3}(h^3 v_x)_x. \quad (27)$$

Indeed, writing system (25) in primitive variables we have

$$\begin{aligned} h_t + (hu)_x &= 0, \\ hu_t - \frac{1}{3}(h^3 u_{tx})_x + \frac{1}{2}g(h^2)_x + huu_x + p_x &= 0, \\ p &= \frac{1}{3}h^3 u_x^2 - \frac{1}{3}h^3 uu_{xx}, \end{aligned} \quad (28)$$

where we have rewritten the non-hydrostatic pressure as

$$\tilde{p} = -\frac{1}{3}(h^3 u_{tx})_x + p, \quad (29)$$

and calculated

$$\begin{aligned} \tilde{p} &= -\frac{1}{3} \left(h^3 (\dot{u})_x - 2h^3 u_x^2 \right) = -\frac{1}{3} \left(h^3 (u_t + uu_x)_x - 2h^3 u_x^2 \right) \\ &= -\frac{1}{3} h^3 u_{tx} - \frac{1}{3} h^3 uu_{xx} + \frac{1}{3} h^3 u_x^2. \end{aligned} \quad (30)$$

This shows the appearance of the elliptic operator $\mathcal{T}(u_t)$ (27) whose inversion is required to obtain u_t .

4.2 1-D augmented Lagrangian hyperbolic system

In this work we will also study the structure-preserving approximation of the hyperbolic augmented Lagrangian formulation of the fully-nonlinear SGN equations reading [37, 126]

$$\begin{aligned} h_t + (hu)_x &= 0, \\ (hu)_t + \left(hu^2 + \frac{1}{2}gh^2 + \frac{\lambda}{3}\eta(1 - \eta/h) \right)_x &= 0, \\ (hw)_t + (hwu)_x &= \lambda(1 - \eta/h), \\ (h\eta)_t + (h\eta u)_x &= hw. \end{aligned} \quad (31)$$

For $\lambda = 0$, we recover the usual hyperbolic shallow water system (9) from the first two equations. In compact form, we can write the above system as (with obvious definitions)

$$\mathbf{U}_t + \mathbf{F}_x = \mathbf{S}.$$

This system is hyperbolic, with characteristic speeds $\lambda_{1/4} = u \mp c$ and $\lambda_{2/3} = u$, where the celerity is given by

$$c^2 = gh + \lambda \frac{\eta^2}{h^2}.$$

The model can be shown to admit the mathematical entropy (energy) conservation law

$$\underbrace{\left(\frac{1}{2}gh^2 + \frac{1}{2}hu^2 + \frac{1}{6}hw^2 + \frac{\lambda}{6}h(1 - \eta/h)^2 \right)}_{=E}_t + \underbrace{\left(gh^2u + \frac{1}{2}hu^3 + \frac{1}{6}hw^2u + \frac{\lambda}{6}h(1 - \eta^2/h^2)u \right)}_{=F}_x = 0. \quad (32)$$

Please note again that the energy E and the energy flux F are extensions of the corresponding quantities for the shallow water equations (10). In primitive variables, the system (31) reads

$$\begin{aligned}
h_t + (hu)_x &= 0, \\
hu_t + \frac{1}{2}g(h^2)_x + hu u_x + \left(\frac{\lambda}{3}\eta(1 - \eta/h)\right)_x &= 0, \\
hw_t + hu w_x &= \lambda(1 - \eta/h), \\
\eta_t + \eta_x u &= w.
\end{aligned} \tag{33}$$

4.3 Passing from the hyperbolic to the classical form

It will be very useful later in the paper to use the existing relations between the hyperbolic and classical systems. In particular, we can easily pass from the hyperbolic approximation (33) to the classical system (28) as follows. First, we note that

$$\begin{cases} \eta_t + u\eta_x = \dot{\eta} = w, \\ hw_t + hu w_x = h\dot{w} = \lambda(1 - \eta/h) \end{cases} \implies \lambda(1 - \eta/h) = h\dot{\eta}.$$

We then set

$$\pi = \lambda(1 - \eta/h)/3 = \frac{h}{3}\ddot{\eta} \tag{34}$$

and note that the hyperbolic system (33) can also be written as

$$\begin{aligned}
h_t + (hu)_x &= 0, \\
hu_t + gh h_x + hu u_x + (\eta\pi)_x &= 0, \\
hw_t + hu w_x &= 3\pi, \\
h\eta_t + h\eta_x u &= hw.
\end{aligned} \tag{35}$$

Considering the relaxed limit $\lambda \rightarrow \infty$ in which $\eta \rightarrow h$ [37, 126], we set

$$\tilde{p} = \lim_{\eta \rightarrow h} \eta\pi = \frac{h^2}{3}\ddot{h},$$

which can be readily shown to be equivalent to the last equation in (25). Note that we also have $w = \dot{h}$ in the limit $\eta \rightarrow h$. Using this, we can write the classical system (28) in the alternative first-order form (see also [95])

$$\begin{aligned}
h_t + (hu)_x &= 0, \\
hu_t + gh h_x + hu u_x + (h\pi)_x &= 0, \\
hw_t + hu w_x &= 3\pi, \\
w + hu_x &= 0,
\end{aligned} \tag{36}$$

in which the last two equations define w and π . System (36) can be directly obtained from (33) in the limit $\eta \rightarrow h$ (or simply replacing η by h), and using the mass equation to express \dot{h} . Note that to march the system in time, we still need to combine the last two equations and replace π in the momentum equation, which at the continuous level still leads to the need to invert operator (27). However, given a discretization for the hyperbolic system, with this correspondence we can deduce one for the classical system in first order form (36). Moreover, the SGN energy from (26) can be written as

$$E = \frac{1}{2}gh^2 + \frac{1}{2}hu^2 + \frac{1}{6}hw^2 \tag{37}$$

and we have that

$$dE = \left(gh + \frac{1}{2}u^2 + \frac{1}{2}w^2\right)dh + u(h du) + w(h dw)$$

and

$$F_x = \left(gh + \frac{1}{2}u^2 + \frac{1}{2}w^2 \right) (hu)_x + u (hu_x + gh h_x + (h\pi)_x) + w (huw_x - 3\pi) + \pi (w + hu_x). \quad (38)$$

So from (36), one obtains energy conservation using only integration by parts by multiplying by the transpose of the dual variables \mathbf{W}^*

$$(\mathbf{W}^*)^T := \left(gh + \frac{1}{2}u^2 + \frac{1}{2}w^2, u, w, \pi \right). \quad (39)$$

5 Hyperbolic approximation with flat bathymetry

In this section, we will derive an energy-conservative split form and corresponding structure-preserving numerical methods for the hyperbolic approximation (33) of the Serre-Green-Naghdi equations with flat bathymetry. We will first derive the split form and then present the numerical methods.

5.1 Energy equation

The energy conservation law (32) can be obtained as usual by multiplying the equations (31) by the entropy variables

$$\mathbf{U}^* = \frac{\partial E}{\partial \mathbf{U}} = \begin{pmatrix} gh - \frac{1}{2}hu^2 - \frac{1}{6}hw^2 + \frac{\lambda}{2}(1 - \frac{\eta}{h}) \left(\frac{1}{3} + \frac{\eta}{h} \right) \\ u \\ \frac{1}{3}w \\ -\frac{\lambda}{3h}(1 - \frac{\eta}{h}) \end{pmatrix} \quad (40)$$

and summing them up since

$$dE = (\mathbf{U}^*)^T d\mathbf{U}. \quad (41)$$

A similar expression can be obtained for the physical/primitive variables $\mathbf{V} := (h, u, w, \eta)^T$:

$$dE = (\mathbf{V}^*)^T \text{diag}(1, h, h, 1) d\mathbf{V}, \quad \mathbf{V}^* = \begin{pmatrix} gh + \frac{1}{2}u^2 + \frac{1}{6}w^2 + \frac{\lambda}{6}(1 - \eta^2/h^2) \\ u \\ \frac{1}{3}w \\ -\frac{\lambda}{3}(1 - \eta/h) \end{pmatrix}. \quad (42)$$

Setting $P_h = \text{diag}(1, h, h, 1)$, we have that

$$(\mathbf{V}^*)^T P_h \mathbf{V}_t = (\mathbf{U}^*)^T \mathbf{U}_t = E_t = -F_x. \quad (43)$$

Indeed, multiplying (33) by \mathbf{V}^* and summing up, we get

$$\begin{aligned}
-E_t &= -(\mathbf{V}^*)^T P_h \mathbf{V}_t \\
&= \left(gh + \frac{1}{2}u^2 + \frac{1}{6}w^2 + \frac{\lambda}{6}(1 - \eta^2/h^2) \right) (hu)_x \\
&\quad + u \left(\frac{1}{2}g(h^2)_x + hu u_x + \frac{\lambda}{3}(\eta(1 - \eta/h))_x \right) + \frac{w}{3} (hu w_x - \lambda(1 - \eta/h)) - \frac{\lambda}{3}(1 - \eta/h)(\eta_x u - w) \\
&= \left(gh(hu)_x + \frac{1}{2}g(h^2)_{xu} \right) + \left(\frac{1}{2}(hu)_x u^2 + hu^2 u_x \right) + \left(\frac{1}{6}(hu)_x w^2 + \frac{1}{3}hu w w_x \right) \\
&\quad + \frac{\lambda}{6} \left((1 - \eta^2/h^2)(hu)_x + 2(\eta(1 - \eta/h))_x u - 2(1 - \eta/h)\eta_x u \right) \\
&= \left(gh^2 u + \frac{1}{2}hu^3 + \frac{1}{6}hu w^2 + \frac{\lambda}{6}h(1 - \eta^2/h^2)u \right)_x = F_x.
\end{aligned} \tag{44}$$

5.2 Split form

To develop an energy-conservative split form of the hyperbolic system (33), we rewrite each nonlinear term as a linear combination of terms equivalent when using the product/chain rule. To reduce the number of parameters we have to deal with simultaneously, we start by looking at a split form of the mass terms and non-hydrostatic pressure terms allowing to obtain boundary terms upon integration by parts. Thus, we start from the hyperbolic system (33) and introduce parameters $\alpha, \beta, \gamma \in \mathbb{R}$ to obtain the split form

$$\begin{aligned}
h_t + \alpha(hu)_x + (1 - \alpha)h_x u + (1 - \alpha)hu_x &= 0, \\
hu_t + \frac{1}{2}g(h^2)_x + hu u_x + \frac{\lambda}{3}\beta(\eta(1 - \eta/h))_x + \frac{\lambda}{3}(1 - \beta)\frac{\eta^2}{h^2}h_x + \frac{\lambda}{3}(1 - \beta)(1 - 2\eta/h)\eta_x &= 0, \\
hw_t + hu w_x &= \lambda(1 - \eta/h), \\
\eta_t + \gamma\eta_x u + (1 - \gamma)(\eta u)_x - (1 - \gamma)\eta u_x &= w.
\end{aligned} \tag{45}$$

Multiplying the equations by the corresponding entropy variables \mathbf{V}^* in primitive variables and summing up the terms contributing to the non-hydrostatic pressure part of the energy flux F , we obtain

$$\begin{aligned}
&\frac{\lambda}{6}(1 - \eta^2/h^2) (\alpha(hu)_x + (1 - \alpha)h_x u + (1 - \alpha)hu_x) \\
&\quad + \frac{\lambda}{3}\beta(\eta(1 - \eta/h))_x u + \frac{\lambda}{3}(1 - \beta)\frac{\eta^2}{h^2}h_x u + \frac{\lambda}{3}(1 - \beta)(1 - 2\eta/h)\eta_x u \\
&\quad - \frac{\lambda}{3}(1 - \eta/h)\gamma\eta_x u - \frac{\lambda}{3}(1 - \eta/h)(1 - \gamma)(\eta u)_x + \frac{\lambda}{3}(1 - \eta/h)(1 - \gamma)\eta u_x \\
&= \alpha\frac{\lambda}{6}(hu)_x - \alpha\frac{\lambda}{6}\frac{\eta^2}{h^2}(hu)_x + (1 - \alpha)\frac{\lambda}{6}(h_x u + hu_x) + (1 + \alpha - 2\beta)\frac{\lambda}{6}\frac{\eta^2}{h^2}h_x u \\
&\quad + (2(1 - \gamma) - (1 - \alpha))\frac{\lambda}{6}\frac{\eta^2}{h}u_x - \beta\frac{\lambda}{3}\left(\frac{\eta^2}{h}\right)_x u + (\beta + (1 - \beta) - \gamma - (1 - \gamma))\frac{\lambda}{3}\eta_x u \\
&\quad + (\gamma - 2(1 - \beta))\frac{\lambda}{3}\frac{\eta}{h}\eta_x u + (1 - \gamma)\frac{\lambda}{3}\frac{\eta}{h}(\eta u)_x.
\end{aligned} \tag{46}$$

We can compare terms involving the same monomials, which gives the conditions to be verified to obtain only boundary terms upon integration by parts of one of them:

$$\begin{aligned}
(hu)_x &: \text{ok} \\
\frac{\eta^2}{h^2}(hu)_x &: \alpha = 0 \\
uh_x &: \text{ok} \\
\frac{\eta^2}{h^2}h_xu &: 1 + \alpha - 2\beta = 0 \\
\frac{\eta^2}{h}u_x &: -(1 - \alpha) + 2\beta - 2(1 - \gamma) = 0 \\
\eta_xu &: \beta + (1 - \beta) - \gamma - (1 - \gamma) = 0 \\
\frac{\eta}{h}\eta_xu &: -2(1 - \beta) + \gamma = 0 \\
(\eta u)_x &: 1 - \gamma = 0
\end{aligned}$$

Luckily enough, the above system admits the unique solution

$$\alpha = 0, \quad \beta = 1/2, \quad \gamma = 1,$$

giving the split forms

$$\begin{aligned}
(hu)_x &\rightarrow h_xu + hu_x, \\
\frac{\lambda}{3}\frac{\eta^2}{h^2}h_x + \frac{\lambda}{3}\left(1 - 2\frac{\eta}{h}\right)\eta_x &\rightarrow \frac{\lambda}{6}\frac{\eta^2}{h^2}h_x + \frac{\lambda}{6}\left(1 - 2\eta/h\right)\eta_x + \frac{\lambda}{6}(\eta(1 - \eta/h))_x, \\
\eta_xu &\rightarrow \eta_xu.
\end{aligned}$$

We are thus left now with the shallow water terms plus the vertical mass equation on w . We can choose the split form of the shallow water equation (22) of [99] for the remaining shallow water terms. Finally, we need to consider the terms leading to the $huw^2/6$ term of the energy flux (10). We use the ansatz

$$\delta huw_x + (1 - \delta)((huw)_x - \varepsilon(hu)_xw - (1 - \varepsilon)h_xuw - (1 - \varepsilon)hu_xw) \quad (47)$$

for the term huw_x in the third equation of (33). Assembling the terms resulting in the energy equation we get

$$\begin{aligned}
&\frac{1}{6}h_xuw^2 + \frac{1}{6}hu_xw^2 + \delta\frac{1}{3}huww_x + (1 - \delta)\frac{1}{3}(huw)_xw \\
&- (1 - \delta)\varepsilon\frac{1}{3}(hu)_xw^2 - (1 - \delta)(1 - \varepsilon)\frac{1}{3}h_xuw^2 - (1 - \delta)(1 - \varepsilon)\frac{1}{3}hu_xw^2 \\
&= \frac{1}{6}(1 - 2(1 - \delta)(1 - \varepsilon))h_xuw^2 + \frac{1}{6}(1 - 2(1 - \delta)(1 - \varepsilon))hu_xw^2 \\
&+ \delta\frac{1}{3}huww_x + (1 - \delta)\frac{1}{3}(huw)_xw - (1 - \delta)\varepsilon\frac{1}{3}(hu)_xw^2.
\end{aligned} \quad (48)$$

To get only boundary terms from integration by parts, we need to solve the system

$$\begin{aligned}
h_xuw^2: & \quad 1 - 2(1 - \delta)(1 - \varepsilon) = 0, \\
hu_xw^2: & \quad 1 - 2(1 - \delta)(1 - \varepsilon) = 0, \\
huww_x: & \quad \delta - (1 - \delta) = 0, \\
(hu)_xw^2: & \quad (1 - \delta)\varepsilon = 0,
\end{aligned} \quad (49)$$

with unique solution $(\delta, \varepsilon) = (1/2, 0)$. Assembling all the results, we obtain the following split form for (33):

$$\begin{aligned}
& h_t + h_x u + h u_x = 0, \\
& h u_t + g(h^2)_x - g h h_x + \frac{1}{2} h (u^2)_x - \frac{1}{2} h_x u^2 + \frac{1}{2} (h u)_x u - \frac{1}{2} h u u_x \\
& \quad + \frac{\lambda \eta^2}{6 h^2} h_x + \frac{\lambda}{6} (1 - 2\eta/h) \eta_x + \frac{\lambda}{6} (\eta(1 - \eta/h))_x = 0, \\
& h w_t + \frac{1}{2} (h w)_x + \frac{1}{2} h u w_x - \frac{1}{2} h_x u w - \frac{1}{2} h u_x w = \lambda(1 - \eta/h), \\
& \eta_t + \eta_x u = w.
\end{aligned} \tag{50}$$

By grouping terms that appear multiple times, we obtain

$$\begin{aligned}
& h_t + h_x u + h u_x = 0, \\
& h u_t + g(h^2)_x - g h h_x + \frac{1}{2} h (u^2)_x - \frac{1}{2} h_x u^2 + \frac{1}{2} (h u)_x u - \frac{1}{2} h u u_x \\
& \quad + \frac{\lambda \eta^2}{6 h^2} h_x + \frac{\lambda}{3} \eta_x - \frac{\lambda \eta}{3 h} \eta_x - \frac{\lambda}{6} \left(\frac{\eta^2}{h} \right)_x = 0, \\
& h w_t + \frac{1}{2} (h w)_x + \frac{1}{2} h u w_x - \frac{1}{2} h_x u w - \frac{1}{2} h u_x w = \lambda - \lambda \frac{\eta}{h}, \\
& \eta_t + \eta_x u = w.
\end{aligned} \tag{51}$$

5.3 Semidiscretization

We now consider the semidiscrete form of the non-conservative system (51), which reads

$$\begin{aligned}
& \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} = \mathbf{0}, \\
& \mathbf{h} \partial_t \mathbf{u} + g D \mathbf{h}^2 - g \mathbf{h} D \mathbf{h} + \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} \\
& \quad + \frac{\lambda \eta^2}{6 \mathbf{h}^2} D \mathbf{h} + \frac{\lambda}{3} D \eta - \frac{\lambda \eta}{3 \mathbf{h}} D \eta - \frac{\lambda}{6} D \frac{\eta^2}{\mathbf{h}} = \mathbf{0}, \\
& \mathbf{h} \partial_t \mathbf{w} + \frac{1}{2} D \mathbf{h} \mathbf{w} + \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{w} - \frac{1}{2} \mathbf{u} \mathbf{w} D \mathbf{h} - \frac{1}{2} \mathbf{h} \mathbf{w} D \mathbf{u} = \lambda - \lambda \frac{\eta}{\mathbf{h}}, \\
& \partial_t \eta + \mathbf{u} D \eta = \mathbf{w}.
\end{aligned} \tag{52}$$

Here, the discretized functions are again denoted in boldface. The operator D is the discrete differentiation operator. Multiplication and division of vectors is defined pointwise. The discrete total energy for (52) is $\mathbf{1}^T M \mathbf{E}$, where $\mathbf{1}^T = (1, \dots, 1)$ is the vector of ones, M is the mass matrix, and

$$\mathbf{E} = \frac{1}{2} g \mathbf{h}^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h} \mathbf{w}^2 + \frac{\lambda}{6} \mathbf{h} - \frac{\lambda}{3} \eta + \frac{\lambda \eta^2}{6 \mathbf{h}} \tag{53}$$

is the discrete equivalent of the energy E in (32).

Theorem 3. *Consider the semidiscretization (52) of the hyperbolic approximation of the Serre-Green-Naghdi equations (31) with a periodic first-derivative SBP operator D with diagonal mass/norm matrix.*

1. *The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved.*
2. *The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.*

Proof. The discrete total water mass is $\mathbf{1}^T M \mathbf{h}$, and its rate of change is

$$\partial_t (\mathbf{1}^T M \mathbf{h}) = \mathbf{1}^T M \partial_t \mathbf{h} = -\mathbf{1}^T M \mathbf{u} D \mathbf{h} - \mathbf{1}^T M \mathbf{h} D \mathbf{u} = -\mathbf{u}^T M D \mathbf{h} - \mathbf{h}^T M D \mathbf{u} = 0, \tag{54}$$

hence the result. Here, we have used again that M is diagonal and applied the periodic SBP property (6). We now evaluate the rate of change of energy. First we note that

$$\begin{aligned}
\partial_{\mathbf{h}}\mathbf{E} &= g\mathbf{h} + \frac{1}{2}\mathbf{u}^2 + \frac{1}{6}\mathbf{w}^2 + \frac{\lambda}{6}\mathbf{1} - \frac{\lambda}{6}\frac{\boldsymbol{\eta}^2}{\mathbf{h}^2}, \\
\partial_{\mathbf{u}}\mathbf{E} &= \mathbf{h}\mathbf{u}, \\
\partial_{\mathbf{w}}\mathbf{E} &= \frac{1}{3}\mathbf{h}\mathbf{w}, \\
\partial_{\boldsymbol{\eta}}\mathbf{E} &= -\frac{\lambda}{3}\mathbf{1} + \frac{\lambda}{3}\frac{\boldsymbol{\eta}}{\mathbf{h}}.
\end{aligned} \tag{55}$$

So the semidiscrete rate of change of the energy satisfies

$$\begin{aligned}
-\partial_t(\mathbf{1}^T M \mathbf{E}) &= -\left(\mathbf{1}^T M \partial_{\mathbf{h}}\mathbf{E} \cdot \partial_t \mathbf{h} + \mathbf{1}^T M \partial_{\mathbf{u}}\mathbf{E} \cdot \partial_t \mathbf{u} + \mathbf{1}^T M \partial_{\mathbf{w}}\mathbf{E} \cdot \partial_t \mathbf{w} + \mathbf{1}^T M \partial_{\boldsymbol{\eta}}\mathbf{E} \cdot \partial_t \boldsymbol{\eta}\right) \\
&= g(\mathbf{h}\mathbf{u})^T M D \mathbf{h} + g(\mathbf{h}^2)^T M D \mathbf{u} + \frac{1}{2}(\mathbf{u}^3)^T M D \mathbf{h} + \frac{1}{2}(\mathbf{h}\mathbf{u}^2)^T M D \mathbf{u} \\
&\quad + \frac{1}{6}(\mathbf{u}\mathbf{w}^2)^T M D \mathbf{h} + \frac{1}{6}(\mathbf{h}\mathbf{w}^2)^T M D \mathbf{u} + \frac{\lambda}{6}(\mathbf{u})^T M D \mathbf{h} + \frac{\lambda}{6}(\mathbf{h})^T M D \mathbf{u} \\
&\quad - \frac{\lambda}{6}\left(\frac{\boldsymbol{\eta}^2}{\mathbf{h}^2}\mathbf{u}\right)^T M D \mathbf{h} - \frac{\lambda}{6}\left(\frac{\boldsymbol{\eta}^2}{\mathbf{h}}\right)^T M D \mathbf{u} \\
&\quad + g\mathbf{u}^T M D \mathbf{h}^2 - g(\mathbf{h}\mathbf{u})^T M D \mathbf{h} + \frac{1}{2}(\mathbf{h}\mathbf{u})^T M D \mathbf{u}^2 - \frac{1}{2}(\mathbf{u}^3)^T M D \mathbf{h} + \frac{1}{2}(\mathbf{u}^2)^T M D \mathbf{h}\mathbf{u} \\
&\quad - \frac{1}{2}(\mathbf{h}\mathbf{u}^2)^T M D \mathbf{u} + \frac{\lambda}{6}\frac{\boldsymbol{\eta}^2}{\mathbf{h}^2}\mathbf{u} D \mathbf{h} + \frac{\lambda}{3}\mathbf{u} D \boldsymbol{\eta} - \frac{\lambda}{3}\frac{\boldsymbol{\eta}}{\mathbf{h}}\mathbf{u} D \boldsymbol{\eta} - \frac{\lambda}{6}\mathbf{u} D \frac{\boldsymbol{\eta}^2}{\mathbf{h}} \\
&\quad + \frac{1}{6}\mathbf{w}^T M D \mathbf{h}\mathbf{u}\mathbf{w} + \frac{1}{6}(\mathbf{h}\mathbf{u}\mathbf{w})^T M D \mathbf{w} - \frac{1}{6}(\mathbf{u}\mathbf{w}^2)^T M D \mathbf{h} - \frac{1}{6}(\mathbf{h}\mathbf{w}^2)^T M D \mathbf{u} \\
&\quad - \frac{\lambda}{3}\mathbf{w}^T M \mathbf{1} + \frac{\lambda}{3}\left(\frac{\boldsymbol{\eta}}{\mathbf{h}}\right)^T M \mathbf{w} - \frac{\lambda}{3}\mathbf{u}^T M D \boldsymbol{\eta} + \frac{\lambda}{3}\mathbf{1}^T M \mathbf{w} + \frac{\lambda}{3}\left(\frac{\boldsymbol{\eta}}{\mathbf{h}}\mathbf{u}\right)^T M D \boldsymbol{\eta} - \frac{\lambda}{3}\left(\frac{\boldsymbol{\eta}}{\mathbf{h}}\right)^T M \mathbf{w}.
\end{aligned} \tag{56}$$

Here, we have used that the mass matrix M is diagonal to simplify terms such as

$$g\mathbf{1}^T M \mathbf{h}\mathbf{u} D \mathbf{h} = g(\mathbf{h}\mathbf{u})^T M D \mathbf{h}. \tag{57}$$

Canceling and grouping terms, we obtain

$$\begin{aligned}
-\partial_t E &= \left(g\mathbf{u}^T M D \mathbf{h}^2 + g(\mathbf{h}^2)^T M D \mathbf{u}\right) + \frac{1}{2}\left((\mathbf{u}^2)^T M D \mathbf{h}\mathbf{u} + (\mathbf{h}\mathbf{u})^T M D \mathbf{u}^2\right) + \frac{\lambda}{6}\left(\mathbf{u}^T M D \mathbf{h} + \mathbf{h}^T M D \mathbf{u}\right) \\
&\quad - \frac{\lambda}{6}\left(\left(\frac{\boldsymbol{\eta}^2}{\mathbf{h}}\right)^T M D \mathbf{u} + \mathbf{u}^T M D \frac{\boldsymbol{\eta}^2}{\mathbf{h}}\right) + \frac{1}{6}\left(\mathbf{w}^T M D \mathbf{h}\mathbf{u}\mathbf{w} + (\mathbf{h}\mathbf{u}\mathbf{w})^T M D \mathbf{w}\right).
\end{aligned} \tag{58}$$

All terms on the right-hand side are of the general form

$$\mathbf{a}^T M D \mathbf{b} + \mathbf{b}^T M D \mathbf{a}, \tag{59}$$

and cancel for periodic first-derivative SBP operators D , due to (6). Hence, the conservation of total energy. \square

Remark 4. *The total momentum is not conserved in general by the semidiscretization (52) of the hyperbolic approximation of the Serre-Green-Naghdi equations. This is due to the split form of the non-hydrostatic pressure term — the other terms conserve the total momentum since they are the same as for the classical shallow water equations, see Section 3 and [99]. We have so far not been able to derive a split form of the non-hydrostatic pressure term that conserves the total momentum (using only integration by parts). For the same reason, there is no advantage in considering a split form using conservative variables.*

6 Original Serre-Green-Naghdi equation with flat bathymetry

In this section, we use the results from the previous Section 5 to derive an energy-conserving split form of the original Serre-Green-Naghdi equations with flat bathymetry. Afterwards, we will present corresponding structure-preserving semidiscretizations.

6.1 Deriving a split form from the hyperbolic approximation

As discussed in Section 5 we are going to apply the results for the split form (51) and the connections between the hyperbolic and classical model to devise a split form for the latter. In practice we can start from the first three in (50), we replace the $1 - \eta/h$ terms using the definition of π (34), and replace η by h in the remaining ones. The resulting split form reads (28):

$$\begin{aligned} h_t + h_x u + h u_x &= 0, \\ h u_t + g(h^2)_x - g h h_x + \frac{1}{2} h (u^2)_x - \frac{1}{2} h_x u^2 + \frac{1}{2} (h u)_x u - \frac{1}{2} h u u_x + (h \pi)_x &= 0, \\ h w_t + \frac{1}{2} (h u w)_x + \frac{1}{2} h u w_x - \frac{1}{2} h_x u w - \frac{1}{2} h u_x w &= 3\pi, \\ w + h u_x &= 0. \end{aligned} \tag{60}$$

One can easily check that the conservation of energy (26) can be obtained only using summation by parts, upon integration with the dual variables (39), as discussed in Section 4.3.

To clarify the structure of the elliptic operator, we compute the part of the non-hydrostatic pressure $h\pi$ containing a time derivative of u and obtain

$$h^2 w_t = -h^3 u_{tx} - h^2 h_t u_x = -h^3 u_{tx} + h^2 h_x u u_x + h^3 u_x^2. \tag{61}$$

Moreover, we have

$$h(h u w)_x + h^2 u w_x - h_x^2 u w - h^2 u_x w = -h(h^2 u u_x)_x - h^2 u (h u_x)_x + h^2 h_x u u_x + h^3 u_x^2, \tag{62}$$

using which we can recast the split form of the original Serre-Green-Naghdi equations as

$$\begin{aligned} h_t + h_x u + h u_x &= 0, \\ h u_t - \frac{1}{3} (h^3 u_{tx})_x + g(h^2)_x - g h h_x + \frac{1}{2} h (u^2)_x - \frac{1}{2} h_x u^2 + \frac{1}{2} (h u)_x u - \frac{1}{2} h u u_x + p_x &= 0, \\ p &= \frac{1}{2} h^3 (u_x)^2 + \frac{1}{2} h^2 h_x u u_x - \frac{1}{6} h (h^2 u u_x)_x - \frac{1}{6} h^2 u (h u_x)_x. \end{aligned} \tag{63}$$

Remark 5. *The split form (63) of the original Serre-Green-Naghdi equations conserves not only the total water mass and the energy but also the total momentum, since the non-hydrostatic pressure is written in a conservative form and the remaining terms are the same as in the split form (14) of the classical shallow water equations.*

6.2 More general split forms of the non-hydrostatic pressure

As described in the previous subsection, the split form (51) of the hyperbolic approximation induces an energy-conservative split form of the original Serre-Green-Naghdi equations (28). However, such energy-conserving split form is not unique. Indeed, we can derive other splittings of the non-hydrostatic pressure. We can start with

$$\begin{aligned} h_t + h_x u + h u_x &= 0, \\ h u_t - \frac{1}{3} (h^3 u_{tx})_x + g(h^2)_x - g h h_x + \frac{1}{2} h (u^2)_x - \frac{1}{2} h_x u^2 + \frac{1}{2} (h u)_x u - \frac{1}{2} h u u_x + p_x &= 0, \end{aligned} \tag{64}$$

where p is a general non-hydrostatic pressure term consistent with

$$p = \frac{1}{2}h^3(u_x)^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{6}h(h^2uu_x)_x - \frac{1}{6}h^2u(hu_x)_x = \frac{1}{3}h^3(u_x)^2 - \frac{1}{3}h^3uu_{xx}. \quad (65)$$

Note again that the energy (26) is the shallow water energy plus the term $h(hu_x)^2/6$. Its rate of change is

$$E_t = \left(gh + \frac{1}{2}u^2h_t + \frac{1}{2}h^2u_x^2\right)h_t + uhu_t + \frac{1}{3}h^3u_xu_{tx}. \quad (66)$$

Thus, we multiply the first equation of the split form by $(gh + u^2/2 + h^2u_x^2/2)$, the second equation by u , add them and integrate over the periodic domain to obtain

$$0 = \int E_t dx + \left[gh^2u + \frac{1}{2}hu^3 - \frac{1}{3}h^3uu_{tx} + pu\right] + \int \left(\frac{1}{2}h^3u_x^3 + \frac{1}{2}h^2h_xuu_x^2 - pu_x\right), \quad (67)$$

where the term $[\cdot]$ is a boundary flux term vanishing for periodic domains. Thus, we want to choose p such we can use integration by parts on the last volume term to obtain the missing boundary flux term, i.e.,

$$\int \left(\frac{1}{2}h^3u_x^3 + \frac{1}{2}h^2h_xuu_x^2 - pu_x\right) = \left[\frac{1}{6}h^3uu_x^2\right] = \left[\frac{1}{6}h(\dot{h})^2u\right]. \quad (68)$$

This is satisfied by the general pressure term

$$p = \frac{1}{2}h^3u_x^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{6}\mathbf{a}(\mathbf{b}u_x)_x - \frac{1}{6}\mathbf{b}(\mathbf{a}u_x)_x, \quad (69)$$

where

$$\mathbf{a}\mathbf{b} = h^3u. \quad (70)$$

All of these choices yield a consistent pressure term since

$$\begin{aligned} p &= \frac{1}{2}h^3u_x^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{6}\mathbf{a}(\mathbf{b}u_x)_x - \frac{1}{6}\mathbf{b}(\mathbf{a}u_x)_x = \frac{1}{2}h^3u_x^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{3}\mathbf{a}\mathbf{b}u_{xx} - \frac{1}{6}\mathbf{a}\mathbf{b}_x u_x - \frac{1}{6}\mathbf{a}_x\mathbf{b}u_x \\ &= \frac{1}{2}h^3u_x^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{3}h^3uu_{xx} - \frac{1}{6}(h^3u)_{xx} \\ &= \frac{1}{2}h^3u_x^2 + \frac{1}{2}h^2h_xuu_x - \frac{1}{3}h^3uu_{xx} - \frac{1}{2}h^2h_xuu_x - \frac{1}{6}h^3u_x^2 = \frac{1}{3}h^3u_x^2 - \frac{1}{3}h^3uu_{xx}. \end{aligned} \quad (71)$$

Remark 6. Many choices are possible, here. We take any in $(\mathbf{a}, \mathbf{b}) = (h^m u^n, h^{3-m} u^{1-n})$, with non-negative integers $m \leq 3, n \leq 1$. The split form (63) uses $(\mathbf{a}, \mathbf{b}) = (h, h^2u)$. Preliminary tests do not show any significant differences when making other choices. Investigating this further is left for future work.

6.3 Spatial semidiscretizations

Replacing continuous derivatives in the split form (63) by periodic SBP operators results in the semidiscretization

$$\begin{aligned} \partial_t \mathbf{h} + \mathbf{u}D\mathbf{h} + \mathbf{h}D\mathbf{u} &= \mathbf{0}, \\ \mathbf{h}\partial_t \mathbf{u} - \frac{1}{3}D\mathbf{h}^3D\partial_t \mathbf{u} + gD\mathbf{h}^2 - g\mathbf{h}D\mathbf{h} + \frac{1}{2}\mathbf{h}D\mathbf{u}^2 - \frac{1}{2}\mathbf{u}^2D\mathbf{h} + \frac{1}{2}\mathbf{u}D\mathbf{h}\mathbf{u} - \frac{1}{2}\mathbf{h}\mathbf{u}D\mathbf{u} + D\mathbf{p} &= \mathbf{0}, \\ \mathbf{p} &= \frac{1}{2}\mathbf{h}^3(D\mathbf{u})^2 + \frac{1}{2}\mathbf{h}^2(D\mathbf{h})\mathbf{u}D\mathbf{u} - \frac{1}{6}\mathbf{h}D\mathbf{h}^2\mathbf{u}D\mathbf{u} - \frac{1}{6}\mathbf{h}^2\mathbf{u}D\mathbf{h}D\mathbf{u}. \end{aligned} \quad (72)$$

The discrete total energy for (72) is $\mathbf{1}^T M \mathbf{E}$ with

$$\mathbf{E} = \frac{1}{2}g\mathbf{h}^2 + \frac{1}{2}\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{h}^3(D\mathbf{u})^2. \quad (73)$$

Theorem 7. Consider the semidiscretization (72) of the original Serre-Green-Naghdi equations (25) with a periodic first-derivative SBP operator D with diagonal mass/norm matrix.

1. The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved.
2. The total momentum $\mathbf{1}^T M \mathbf{h} \mathbf{u}$ is conserved.
3. The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.

Proof. This is a specialization of the more general result Theorem 10 below with $D = D_- = D_+$. \square

If the semidiscretization (72) is discretized in time with an explicit method (like an explicit Runge-Kutta method), it requires the solution of discretized elliptic problems of the form

$$\left(\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D \right) \partial_t \mathbf{u} = \mathbf{y}, \quad (74)$$

where

$$\mathbf{y} = -g D \mathbf{h}^2 + g \mathbf{h} D \mathbf{h} - \frac{1}{2} \mathbf{h} D \mathbf{u}^2 + \frac{1}{2} \mathbf{u}^2 D \mathbf{h} - \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} + \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} - D \mathbf{p}. \quad (75)$$

Lemma 8. If if the water height is positive, the discrete operator

$$\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D \quad (76)$$

of (72) is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. We have

$$M \left(\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D \right) = \mathbf{h} M + \frac{1}{3} D^T M \mathbf{h}^3 D \quad (77)$$

due to the SBP property (6) for diagonal M . \square

Thus, the discrete elliptic problem can be solved uniquely. However, the second derivative is discretized using a wide-stencil operator (with variable coefficients). This can lead to stability issues (for under-resolved) grids and a loss of efficiency. Thus, it would be better to use narrow-stencil second-derivative operators [80] or upwind SBP operators [81]. Here, we choose the second option with upwind SBP operators D_{\pm} and their corresponding central operator $D = (D_+ + D_-)/2$, leading to the semidiscretization

$$\begin{aligned} \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} &= \mathbf{0}, \\ \mathbf{h} \partial_t \mathbf{u} - \frac{1}{3} D_+ \mathbf{h}^3 D_- \partial_t \mathbf{u} + g D \mathbf{h}^2 - g \mathbf{h} D \mathbf{h} + \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} + D_+ \mathbf{p}_+ + D \mathbf{p}_0 &= \mathbf{0}, \\ \mathbf{p}_+ &= \frac{1}{2} \mathbf{h}^3 (D \mathbf{u}) D_- \mathbf{u} + \frac{1}{2} \mathbf{h}^2 (D \mathbf{h}) \mathbf{u} D_- \mathbf{u}, \\ \mathbf{p}_0 &= -\frac{1}{6} \mathbf{h} D \mathbf{h}^2 \mathbf{u} D \mathbf{u} - \frac{1}{6} \mathbf{h}^2 \mathbf{u} D \mathbf{h} D \mathbf{u}. \end{aligned} \quad (78)$$

Lemma 9. If if the water height is positive, the discrete operator

$$\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- \quad (79)$$

of (78) is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. We have

$$M \left(\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- \right) = \mathbf{h} M + \frac{1}{3} D_-^T M \mathbf{h}^3 D_- \quad (80)$$

due to the upwind SBP property (7) for diagonal M . \square

The corresponding discrete total energy for (78) is

$$\frac{1}{2}g\mathbf{1}^T M\mathbf{h}^2 + \frac{1}{2}\mathbf{1}^T M\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{u}^T D_-^T M\mathbf{h}^3 D_- \mathbf{u} = \mathbf{1}^T M \left(\frac{1}{2}g\mathbf{h}^2 + \frac{1}{2}\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{h}^3(D_- \mathbf{u})^2 \right) = \mathbf{1}^T M\mathbf{E}. \quad (81)$$

There could be more options to use upwind SBP operators in (78). Here, we have chosen the simplest version avoiding the wide-stencil second-derivative operator for the elliptic problem.

Theorem 10. *Consider the semidiscretization (78) of the original Serre-Green-Naghdi equations (25) with periodic first-derivative upwind SBP operators D_{\pm} inducing the central operator $D = (D_+ + D_-)/2$ with diagonal mass/norm matrix.*

1. The total water mass $\mathbf{1}^T M\mathbf{h}$ is conserved.
2. The total momentum $\mathbf{1}^T M\mathbf{h}\mathbf{u}$ is conserved.
3. The total energy $\mathbf{1}^T M\mathbf{E}$ is conserved.

Proof. Conservation of the total water mass follows from the first equation of (78) as in the proof of Theorem 3. Conservation of the total momentum follows since the split form of the shallow water part is the same as in Section 3 and the non-hydrostatic pressure term is discretized in a conservative way, i.e.,

$$\mathbf{1}^T M D_+ \mathbf{p}_+ + \mathbf{1}^T M D \mathbf{p}_0 = -\mathbf{1}^T D_-^T M \mathbf{p}_+ - \mathbf{1}^T D^T M \mathbf{p}_0 = 0 \quad (82)$$

for consistent derivative operators D_{\pm} and D . Concerning energy, its rate of change is

$$\begin{aligned} & \partial_t \left(\frac{1}{2}g\mathbf{1}^T M\mathbf{h}^2 + \frac{1}{2}\mathbf{1}^T M\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{u}^T D_-^T M\mathbf{h}^3 D_- \mathbf{u} \right) \\ &= g\mathbf{h}^T M \partial_t \mathbf{h} + \frac{1}{2}(\mathbf{u}^2)^T M \partial_t \mathbf{h} + \mathbf{u}^T M \mathbf{h} \partial_t \mathbf{u} + \frac{1}{2} \left(\mathbf{h}^2(D_- \mathbf{u})^2 \right)^T M \partial_t \mathbf{h} + \frac{1}{3}\mathbf{u}^T D_-^T M \mathbf{h}^3 D_- \partial_t \mathbf{u}. \end{aligned} \quad (83)$$

To evaluate it we thus multiply the first of (78) by $g\mathbf{h}^T M + (1/2)(\mathbf{u}^2)^T M + (1/2)(\mathbf{h}^2(D_- \mathbf{u})^2)^T M$, the second by $\mathbf{u}^T M$, and add the two equations to get

$$\begin{aligned} & g\mathbf{h}^T M \partial_t \mathbf{h} + \frac{1}{2}(\mathbf{u}^2)^T M \partial_t \mathbf{h} + \frac{1}{2} \left(\mathbf{h}^2(D_- \mathbf{u})^2 \right)^T M \partial_t \mathbf{h} + \mathbf{u}^T M \mathbf{h} \partial_t \mathbf{u} + \frac{1}{3}\mathbf{u}^T D_-^T M \mathbf{h}^3 D_- \partial_t \mathbf{u} \\ &= -g\mathbf{h}^T M \mathbf{u} D \mathbf{h} - g\mathbf{h}^T M \mathbf{h} D \mathbf{u} - \frac{1}{2}(\mathbf{u}^2)^T M \mathbf{u} D \mathbf{h} - \frac{1}{2}(\mathbf{u}^2)^T M \mathbf{h} D \mathbf{u} \\ & \quad - \frac{1}{2} \left(\mathbf{h}^2(D_- \mathbf{u})^2 \right)^T M \mathbf{u} D \mathbf{h} - \frac{1}{2} \left(\mathbf{h}^2(D_- \mathbf{u})^2 \right)^T M \mathbf{h} D \mathbf{u} - \mathbf{u}^T M g D \mathbf{h}^2 + \mathbf{u}^T M g \mathbf{h} D \mathbf{h} \\ & \quad - \frac{1}{2}(\mathbf{h}\mathbf{u})^T M D \mathbf{u}^2 + \frac{1}{2}(\mathbf{u}^3)^T M D \mathbf{h} - \frac{1}{2}(\mathbf{u}^2)^T M D \mathbf{h}\mathbf{u} + \frac{1}{2}(\mathbf{h}\mathbf{u}^2)^T M D \mathbf{u} - \mathbf{u}^T M D_+ \mathbf{p}_+ - \mathbf{u}^T M D \mathbf{p}_0 \\ &= -g(\mathbf{h}\mathbf{u})^T M D \mathbf{h} - g(\mathbf{h}^2)^T M D \mathbf{u} - \frac{1}{2}(\mathbf{u}^3)^T M D \mathbf{h} - \frac{1}{2}(\mathbf{h}\mathbf{u}^2)^T M D \mathbf{u} \\ & \quad - \frac{1}{2} \left(\mathbf{h}^2 \mathbf{u}(D_- \mathbf{u})^2 \right)^T M D \mathbf{h} - \frac{1}{2} \left(\mathbf{h}^3(D_- \mathbf{u})^2 \right)^T M D \mathbf{u} - g\mathbf{u}^T M D \mathbf{h}^2 + g(\mathbf{h}\mathbf{u})^T M D \mathbf{h} \\ & \quad - \frac{1}{2}(\mathbf{h}\mathbf{u})^T M D \mathbf{u}^2 + \frac{1}{2}(\mathbf{u}^3)^T M D \mathbf{h} - \frac{1}{2}(\mathbf{u}^2)^T M D \mathbf{h}\mathbf{u} + \frac{1}{2}(\mathbf{h}\mathbf{u}^2)^T M D \mathbf{u} - \mathbf{u}^T M D_+ \mathbf{p}_+ - \mathbf{u}^T M D \mathbf{p}_0 \\ &= -\frac{1}{2} \left(\mathbf{h}^2 \mathbf{u}(D_- \mathbf{u})^2 \right)^T M D \mathbf{h} - \frac{1}{2} \left(\mathbf{h}^3(D_- \mathbf{u})^2 \right)^T M D \mathbf{u} + \mathbf{p}_+^T M D_- \mathbf{u} + \mathbf{p}_0^T M D \mathbf{u}. \end{aligned} \quad (84)$$

Inserting the pressure terms \mathbf{p}_+ and \mathbf{p}_0 yields

$$\begin{aligned} \partial_t(\mathbf{1}^T M\mathbf{E}) &= -\frac{1}{2} \left(\mathbf{h}^2 \mathbf{u}(D_- \mathbf{u})^2 \right)^T M D \mathbf{h} - \frac{1}{2} \left(\mathbf{h}^3(D_- \mathbf{u})^2 \right)^T M D \mathbf{u} + \frac{1}{2} \left(\mathbf{h}^3(D \mathbf{u}) D_- \mathbf{u} \right)^T M D_- \mathbf{u} \\ & \quad + \frac{1}{2} \left(\mathbf{h}^2(D \mathbf{h}) \mathbf{u} D_- \mathbf{u} \right)^T M D_- \mathbf{u} - \frac{1}{6} \left(\mathbf{h} D \mathbf{h}^2 \mathbf{u} D \mathbf{u} \right)^T M D \mathbf{u} - \frac{1}{6} \left(\mathbf{h}^2 \mathbf{u} D \mathbf{h} D \mathbf{u} \right)^T M D \mathbf{u} \\ &= -\frac{1}{6} \left(\mathbf{h}^2 \mathbf{u} D \mathbf{u} \right)^T D^T M (\mathbf{h} D \mathbf{u}) - \frac{1}{6} (\mathbf{h} D \mathbf{u})^T D^T M (\mathbf{h}^2 \mathbf{u} D \mathbf{u}) = 0, \end{aligned}$$

since after using the SBP property (6) the first and the fourth as well as the second and the third terms in the first right hand side cancel for a diagonal mass matrix M , and similarly the last two terms in the last step. \square

There are even more possibilities to discretize the non-hydrostatic pressure terms with upwind operators. Consider for example the central pressure term

$$D\mathbf{p}_0 = -\frac{1}{6}D\mathbf{h}D\mathbf{h}^2\mathbf{u}D\mathbf{u} - \frac{1}{6}D\mathbf{h}^2\mathbf{u}D\mathbf{h}D\mathbf{u} \quad (85)$$

of (78). The energy contribution of this terms vanishes since

$$-6\mathbf{u}^T MD\mathbf{p}_0 = \mathbf{u}^T MD\mathbf{h}D\mathbf{h}^2\mathbf{u}D\mathbf{u} + \mathbf{u}^T MD\mathbf{h}^2\mathbf{u}D\mathbf{h}D\mathbf{u} = (\mathbf{h}D\mathbf{u})^T MD(\mathbf{h}^2\mathbf{u}D\mathbf{u}) + (\mathbf{h}^2\mathbf{u}D\mathbf{u})^T MD(\mathbf{h}D\mathbf{u}) = 0.$$

Let us now consider a more general form

$$D_\alpha\mathbf{h}D_\beta\mathbf{h}^2\mathbf{u}D_\gamma\mathbf{u} + D_\delta\mathbf{h}^2\mathbf{u}D_\varepsilon\mathbf{h}D_\zeta\mathbf{u}, \quad (86)$$

where $\alpha, \beta, \gamma, \delta, \varepsilon, \zeta \in \{+, -, 0\}$, and $D_0 = D$ is the central operator. The energy contribution of this term is

$$\mathbf{u}^T MD_\alpha\mathbf{h}D_\beta\mathbf{h}^2\mathbf{u}D_\gamma\mathbf{u} + \mathbf{u}^T MD_\delta\mathbf{h}^2\mathbf{u}D_\varepsilon\mathbf{h}D_\zeta\mathbf{u} = (\mathbf{h}D_{\alpha^*}\mathbf{u})^T MD_\beta(\mathbf{h}^2\mathbf{u}D_\gamma\mathbf{u}) + (\mathbf{h}^2\mathbf{u}D_{\delta^*}\mathbf{u})^T MD_\varepsilon(\mathbf{h}D_\zeta\mathbf{u}), \quad (87)$$

where $\pm^* = \mp$ and $0^* = 0$. This term vanishes if

$$\zeta = \alpha^*, \quad \varepsilon = \beta^*, \quad \gamma = \delta^*. \quad (88)$$

Even if we do not want to introduce a clear directional bias by choosing the same number of + and - signs in (α, β, γ) , there are many possibilities different from $\alpha = \beta = \gamma = 0$ as in (78), e.g., $\alpha = +$, $\beta = 0$, and $\gamma = -$.

Preliminary tests do not show any significant differences between the different choices of applying (upwind) derivative operators to the non-hydrostatic pressure term. Investigating this further is left for future work.

7 Hyperbolic approximation with variable bathymetry

Following the notation of [13], we introduce the bottom topography $b = b(x)$ and write the generalization of the hyperbolic system (33) as

$$\begin{aligned} h_t + (hu)_x &= 0, \\ hu_t + gh h_x + hu u_x + (h\Pi)_x + \left(gh + \frac{3}{2}\frac{h}{\eta}\Pi\right) b_x &= 0, \\ hw_t + hu w_x &= \lambda(1 - \eta/h), \\ \eta_t + \eta_x u + \frac{3}{2}b_x u &= w, \\ \Pi &= \frac{\lambda}{3}\frac{\eta}{h}\left(1 - \frac{\eta}{h}\right). \end{aligned} \quad (89)$$

This system satisfies the energy conservation law

$$\begin{aligned} &\overbrace{\left(\frac{1}{2}g(h+b)^2 + \frac{1}{2}hu^2 + \frac{1}{6}hw^2 + \frac{\lambda}{6}h(1-\eta/h)^2\right)}^{=E}_t \\ &+ \underbrace{\left(gh(h+b)u + \frac{1}{2}hu^3 + \frac{1}{6}huw^2 + \frac{\lambda}{6}h(1-\eta/h)^2u + h\Pi u\right)}_{=F}_x = 0. \end{aligned} \quad (90)$$

We will derive an energy-conservative split form of this generalization of (33) in the following.

7.1 Energy equation

The energy conservation law (90) can be derived by multiplying the time derivatives of the primitive variables $\mathbf{V} = (h, u, w, \eta)^T$ by

$$\mathbf{V}^* = \frac{\partial E}{\partial \mathbf{V}} = \begin{pmatrix} g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2 + \frac{\lambda}{6}(1 - \eta^2/h^2) \\ hu \\ hw \\ -\frac{\lambda}{3}(1 - \eta/h) \end{pmatrix}. \quad (91)$$

Indeed, the computation is very similar to the one from Section 5.1; the additional terms are

$$\begin{aligned} & g(hu)_x b + \left(gh + \frac{3}{2} \frac{h}{\eta} \Pi \right) b_x u - \frac{\lambda}{3} (1 - \eta/h) \frac{3}{2} b_x u \\ &= (ghbu)_x + \frac{\lambda}{2} (1 - \eta/h) b_x u - \frac{\lambda}{2} (1 - \eta/h) b_x u = (ghbu)_x. \end{aligned} \quad (92)$$

7.2 Split form

The analysis shows that the bathymetry terms cancel identically when evaluating the energy balance. Hence, the split form (51) generalizes readily to this case if the bathymetry is included appropriately in the hydrostatic pressure term. In particular, the non-conservative split form becomes

$$\begin{aligned} h_t + h_x u + hu_x &= 0, \\ hu_t + g(h(h+b))_x - g(h+b)h_x + \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}huu_x \\ &+ \frac{\lambda}{6} \frac{\eta^2}{h^2} h_x + \frac{\lambda}{3} \eta_x - \frac{\lambda}{3} \frac{\eta}{h} \eta_x - \frac{\lambda}{6} \left(\frac{\eta^2}{h} \right)_x + \frac{\lambda}{2} \left(1 - \frac{\eta}{h} \right) b_x = 0, \\ hw_t + \frac{1}{2}(huw)_x + \frac{1}{2}huw_x - \frac{1}{2}h_x u w - \frac{1}{2}hu_x w &= \lambda - \lambda \frac{\eta}{h}, \\ \eta_t + \eta_x u + \frac{3}{2}b_x u &= w. \end{aligned} \quad (93)$$

7.3 Semidiscretization

The split form (93) induces the semidiscretization

$$\begin{aligned} \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} &= \mathbf{0}, \\ \mathbf{h} \partial_t \mathbf{u} + g D \mathbf{h} (\mathbf{h} + \mathbf{b}) - g (\mathbf{h} + \mathbf{b}) D \mathbf{h} - \frac{1}{2} \mathbf{h} D \mathbf{u}^2 + \frac{1}{2} \mathbf{u}^2 D \mathbf{h} - \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} + \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} \\ &+ \frac{\lambda}{6} \frac{\eta^2}{h^2} D \mathbf{h} + \frac{\lambda}{3} D \eta - \frac{\lambda}{3} \frac{\eta}{h} D \eta - \frac{\lambda}{6} D \frac{\eta^2}{h} + \frac{\lambda}{2} D \mathbf{b} - \frac{\lambda}{2} \frac{\eta}{h} D \mathbf{b} = \mathbf{0}, \\ \mathbf{h} \partial_t \mathbf{w} + \frac{1}{2} D \mathbf{h} \mathbf{u} \mathbf{w} + \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{w} - \frac{1}{2} \mathbf{u} \mathbf{w} D \mathbf{h} - \frac{1}{2} \mathbf{h} \mathbf{w} D \mathbf{u} &= \lambda - \lambda \frac{\eta}{h}, \\ \partial_t \eta + \mathbf{u} D \eta + \frac{3}{2} \mathbf{u} D \mathbf{b} &= \mathbf{w}. \end{aligned} \quad (94)$$

The corresponding discrete total energy is $\mathbf{1}^T M \mathbf{E}$, where

$$\mathbf{E} = \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h} \mathbf{w}^2 + \frac{\lambda}{6} \mathbf{h} - \frac{\lambda}{3} \eta + \frac{\lambda}{6} \frac{\eta^2}{h}. \quad (95)$$

Theorem 11. Consider the semidiscretization (94) of the hyperbolic approximation of the Serre-Green-Naghdi equations with varying bathymetry (89) using a periodic first-derivative SBP operator D with diagonal mass/norm matrix. The following properties are true.

1. The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved.
2. The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.
3. The semidiscretization is well-balanced w.r.t. the steady state $h + b \equiv \text{const}$, $u \equiv 0$, $w \equiv 0$, $\eta \equiv h$.

Proof. Conservation of the total water mass follows as in the proof of Theorem 3. Concerning energy, we compute

$$\partial_{\mathbf{h}} \mathbf{E} = g(\mathbf{h} + \mathbf{b}) + \frac{1}{2} \mathbf{u}^2 + \frac{1}{6} \mathbf{w}^2 + \frac{\lambda}{6} - \frac{\lambda}{6} \frac{\eta^2}{\mathbf{h}^2}. \quad (96)$$

The other derivatives are the same as in the proof of Theorem 3. Thus, the differences in the semidiscrete rate of change of the total energy compared to the case of constant bathymetry in Theorem 3 are as follows:

- additional term $g \mathbf{b}^T M$ multiplied to $\partial_t \mathbf{h}$
- additional term $g D \mathbf{h} \mathbf{b} - g \mathbf{b} D \mathbf{h} + \frac{\lambda}{2} D \mathbf{b} - \frac{\lambda}{2} \frac{\eta}{\mathbf{h}} D \mathbf{b}$ added to $\mathbf{h} \partial_t \mathbf{u}$
- additional term $\frac{3}{2} \mathbf{u} D \mathbf{b}$ added to $\partial_t \eta$

These additional terms assembled give

$$\begin{aligned} & g \mathbf{b}^T M \mathbf{u} D \mathbf{h} + g \mathbf{b}^T M \mathbf{h} D \mathbf{u} + g \mathbf{u}^T M D \mathbf{h} \mathbf{b} - g \mathbf{u}^T M \mathbf{b} D \mathbf{h} \\ & + \frac{\lambda}{2} \mathbf{u}^T M D \mathbf{b} - \frac{\lambda}{2} \mathbf{u}^T M \frac{\eta}{\mathbf{h}} D \mathbf{b} - \frac{\lambda}{2} \mathbf{1}^T M \mathbf{u} D \mathbf{b} + \frac{\lambda}{2} \left(\frac{\eta}{\mathbf{h}} \right)^T M \mathbf{u} D \mathbf{b} \\ = & g(\mathbf{b} \mathbf{u})^T M D \mathbf{h} + g(\mathbf{h} \mathbf{b})^T M D \mathbf{u} + g \mathbf{u}^T M D \mathbf{h} \mathbf{b} - g(\mathbf{b} \mathbf{u})^T M D \mathbf{h} \\ & + \frac{\lambda}{2} \mathbf{u}^T M D \mathbf{b} - \frac{\lambda}{2} \left(\frac{\eta}{\mathbf{h} \mathbf{u}} \right)^T M D \mathbf{b} - \frac{\lambda}{2} \mathbf{u}^T M D \mathbf{b} + \frac{\lambda}{2} \left(\frac{\eta}{\mathbf{h} \mathbf{u}} \right)^T M D \mathbf{b} = 0, \end{aligned}$$

where we have used that the mass matrix M is diagonal in the first step and applied the SBP property (6) in the second step. This plus the elements in the proof of Theorem 3 show that total energy is conserved. Finally, we observe that the method is well-balanced since for $\mathbf{u} = \mathbf{0} = \mathbf{w}$, we have both $\partial_t \mathbf{h} = \mathbf{0}$ and $\partial_t \eta = \mathbf{0}$. Moreover since also $\eta = \mathbf{h}$, we have $\partial_t \mathbf{w} = \mathbf{0}$. Finally,

$$-\mathbf{h} \partial_t \mathbf{u} = \underbrace{g D \mathbf{h}(\mathbf{h} + \mathbf{b}) - g(\mathbf{h} + \mathbf{b}) D \mathbf{h}} + \underbrace{\frac{\lambda}{6} \frac{\eta^2}{\mathbf{h}^2} D \mathbf{h} - \frac{\lambda}{6} D \frac{\eta^2}{\mathbf{h}}} + \underbrace{\frac{\lambda}{3} D \eta - \frac{\lambda}{3} \frac{\eta}{\mathbf{h}} D \eta} + \underbrace{\frac{\lambda}{2} D \mathbf{b} - \frac{\lambda}{2} \frac{\eta}{\mathbf{h}} D \mathbf{b}}. \quad (97)$$

The last three terms grouped in braces cancel due to $\eta = \mathbf{h}$. The first due to the fact that $\mathbf{h} + \mathbf{b}$ is constant. \square

8 Original Serre-Green-Naghdi equations with variable bathymetry: mild-slope approximation

We proceed as before and note that we can pass from the hyperbolic formulation (89) to the standard one using $w = \dot{\eta} + \frac{3}{2} \dot{b}$ and $\Pi = \frac{\eta}{h} \frac{1}{3} h \dot{w}$. Then, we can easily recast the momentum in (89) as

$$h u_t + g h h_x + h u u_x + \left(\frac{h \eta}{3} \dot{w} \right)_x + \left(g h + \frac{1}{2} h \dot{w} \right) b_x = 0. \quad (98)$$

Taking now the relaxed limit $\eta = h$, and simplifying the last in (89) using the mass equation we obtain

$$\begin{aligned}
h_t + (hu)_x &= 0, \\
hu_t + gh h_x + hu u_x + (h\pi)_x + \left(gh + \frac{3}{2}\pi\right) b_x &= 0, \\
hw_t + hu w_x &= 3\pi, \\
w + hu_x - \frac{3}{2}b_x u &= 0,
\end{aligned} \tag{99}$$

where as before the last two equations are merely the definitions of π and w . Note that the above system does not match exactly the SGN equations reported in, e.g., [54, 50]. The form obtained is essentially a mild-slope version of the SGN model in which a quadratic term b_x^2 has been removed, following to the classical mild-slope approximation [78]. This approximation has been made in [13] to simplify the Lagrangian used to derive the hyperbolic formulation. We can nevertheless show that the system obtained admits an energy conservation law

$$\underbrace{\left(\frac{1}{2}g(h+b)^2 + \frac{1}{2}hu^2 + \frac{1}{6}hw^2\right)}_{=E} \Big|_t + \underbrace{\left(gh(h+b)u + \frac{1}{2}hu^3 + \frac{1}{6}huw^2 + h\pi u\right)}_{=F} \Big|_x = 0. \tag{100}$$

Expanding the energy terms, we get

$$E = \frac{1}{2}g(h+b)^2 + \frac{1}{2}hu^2 + \frac{1}{6}h\left(-hu_x + \frac{3}{2}b_x u\right)^2 = \frac{1}{2}g(h+b)^2 + \frac{1}{2}hu^2 + \frac{1}{6}h^3u_x^2 - \frac{1}{2}h^2b_x u u_x + \frac{3}{8}hb_x^2 u^2. \tag{101}$$

We can check easily that a $hb^2/8 = h(ub_x)^2/8$ term is missing compared, e.g., to [54, 50]. This is precisely the quadratic term neglected in [13]. We can check that the following relations hold for the differentials:

$$\begin{aligned}
dE &= \left(g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2\right) dh + hu \, du + h\frac{w}{3} \, dw, \\
dF &= \left(g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2\right) d(hu) + u \left(hu \, du + gh \, dh + d(h\pi) + \left(gh + \frac{3}{2}\pi\right) db\right) \\
&\quad + \frac{w}{3}(hu \, dw - 3\pi) + \pi(w + h \, du - \frac{3}{2}u \, db).
\end{aligned} \tag{102}$$

8.1 Deriving a split form from the hyperbolic approximation

With the same approach as in Section 6, we find that a split form induced by (93) allowing to recover the energy balance using only integration by parts is

$$\begin{aligned}
h_t + h_x u + hu_x &= 0, \\
hu_t + g(h(h+b))_x - g(h+b)h_x + \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}huu_x + (h\pi)_x + \frac{3}{2}\pi b_x &= 0, \\
hw_t + \frac{1}{2}(huw)_x + \frac{1}{2}huw_x - \frac{1}{2}h_x u w - \frac{1}{2}hu_x w &= 3\pi, \\
w + hu_x - \frac{3}{2}b_x u &= 0.
\end{aligned} \tag{103}$$

One can easily check (details omitted for brevity) that the SBP property holds now by multiplying the above system by the transpose of the dual variable $(\mathbf{W}^*)^T$ where from (102) we have

$$(\mathbf{W}^*)^T := \left(g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2, u, w/3, \pi\right).$$

To clarify the structure of the elliptic operator that we need to invert to obtain u_t , we compute the part of the non-hydrostatic pressure $h\pi$ containing a time derivative of u and obtain

$$h^2 w_t = h^2 \left(-hu_x + \frac{3}{2}b_x u \right)_t = -h^3 u_{tx} + \frac{3}{2}h^2 b_x u_t + h^2 h_x u u_x + h^3 u_x^2. \quad (104)$$

Moreover, as in the flat bathymetry case we exploit the relation

$$\begin{aligned} h(huw)_x + h^2 uw_x - hh_x uw - h^2 u_x w = & -h(h^2 uu_x)_x - h^2 u(hu_x)_x + h^2 h_x uu_x + h^3 u_x^2 \\ & + \frac{3}{2}h(hb_x u^2)_x + \frac{3}{2}h^2 u(b_x u)_x - \frac{3}{2}hh_x b_x u^2 - \frac{3}{2}h^2 b_x uu_x, \end{aligned} \quad (105)$$

obtained with some manipulations of the definition of w . This leads to the split form

$$\begin{aligned} h_t + h_x u + hu_x &= 0, \\ hu_t - \frac{1}{3}(h^3 u_{tx})_x + \frac{1}{2}(h^2 b_x u_t)_x - \frac{1}{2}h^2 b_x u_{tx} + \frac{3}{4}hb_x^2 u_t + g(h(h+b))_x - g(h+b)h_x \\ &+ \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}huu_x + p_x + \frac{3}{2}\frac{p}{h}b_x = 0, \\ p &= \frac{1}{2}h^3 u_x^2 + \frac{1}{2}h^2 h_x uu_x - \frac{1}{6}h(h^2 uu_x)_x - \frac{1}{6}h^2 u(hu_x)_x \\ &+ \frac{1}{4}h(hb_x u^2)_x + \frac{1}{4}h^2 u(b_x u)_x - \frac{1}{4}hh_x b_x u^2 - \frac{1}{4}h^2 b_x uu_x. \end{aligned} \quad (106)$$

As described in Remark 6, there are still other options of split forms of the non-hydrostatic pressure terms that could be considered. We will not pursue this further here.

8.2 Semidiscretization

The split form (106) leads to the semidiscretization

$$\begin{aligned} \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} &= \mathbf{0}, \\ \left(\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D + \frac{1}{2} D \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \right) \partial_t \mathbf{u} + g D \mathbf{h} (\mathbf{h} + \mathbf{b}) - g (\mathbf{h} + \mathbf{b}) D \mathbf{h} \\ &+ \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} + D \mathbf{p} + \frac{3}{2} \frac{\mathbf{p}}{\mathbf{h}} D \mathbf{b} = \mathbf{0}, \\ \mathbf{p} &= \frac{1}{2} \mathbf{h}^3 (D \mathbf{u})^2 + \frac{1}{2} \mathbf{h}^2 (D \mathbf{h}) \mathbf{u} D \mathbf{u} - \frac{1}{6} \mathbf{h} D (\mathbf{h}^2 \mathbf{u} D \mathbf{u}) - \frac{1}{6} \mathbf{h}^2 \mathbf{u} D \mathbf{h} D \mathbf{u} \\ &+ \frac{1}{4} \mathbf{h} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{4} \mathbf{h}^2 \mathbf{u} D ((D \mathbf{b}) \mathbf{u}) - \frac{1}{4} \mathbf{h} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2 - \frac{1}{4} \mathbf{h}^2 (D \mathbf{b}) \mathbf{u} D \mathbf{u}. \end{aligned} \quad (107)$$

The discrete total energy for (107) is $\mathbf{1}^T M \mathbf{E}$, where

$$\begin{aligned} \mathbf{E} &= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h} \left(-\mathbf{h} D \mathbf{u} + \frac{3}{2} \mathbf{u} D \mathbf{b} \right)^2 \\ &= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h}^3 (D \mathbf{u})^2 - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) (D \mathbf{u}) \mathbf{u} + \frac{3}{8} \mathbf{h} (D \mathbf{b})^2 \mathbf{u}^2. \end{aligned} \quad (108)$$

Theorem 12. *Consider the semidiscretization (107) of the original Serre-Green-Naghdi equations with mild-slope approximation (99) using a periodic SBP operator D with diagonal mass matrix. The following holds.*

1. The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved.
2. The total momentum $\mathbf{1}^T M \mathbf{h} \mathbf{u}$ is conserved if the bathymetry is constant.

3. The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.

4. The semidiscretization is well-balanced, i.e., it preserves the steady state $h + b \equiv \text{const}$, $u \equiv 0$.

Proof. This is a special case of the more general Theorem 15 below with $D = D_- = D_+$. \square

Lemma 13. *If the water height is positive, then the discrete operator*

$$\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D + \frac{1}{2} D \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \quad (109)$$

of (107) is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. This is a special case of the more general Lemma 14 below with $D = D_- = D_+$. \square

As before, the discrete operator (109) of (107) includes a wide-stencil approximation of the second derivative. Thus, we also use an upwind version.

Lemma 14. *If the water height is positive, then the discrete operator*

$$\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- + \frac{1}{2} D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D_- + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \quad (110)$$

is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. We have

$$\begin{aligned} M \left(\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- + \frac{1}{2} D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D_- + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \right) \\ = \mathbf{h} M + \frac{1}{3} D_-^T M \mathbf{h}^3 D_- + \frac{1}{2} M D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) M D_- + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 M \end{aligned} \quad (111)$$

and

$$\left(M D_+ (\mathbf{h}^2 (D \mathbf{b})) - \mathbf{h}^2 (D \mathbf{b}) M D_- \right)^T = (\mathbf{h}^2 (D \mathbf{b})) D_+^T M - D_-^T M (\mathbf{h}^2 (D \mathbf{b})) = -\mathbf{h}^2 (D \mathbf{b}) M D_- + M D_+ (\mathbf{h}^2 (D \mathbf{b})).$$

Thus, the operator is symmetric with respect to M . Now for any given vector \mathbf{v} , we have

$$\begin{aligned} \mathbf{v}^T M \left(\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- + \frac{1}{2} D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D_- + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \right) \mathbf{v} \\ = \|\mathbf{v}\|_{\mathbf{h} M}^2 + \frac{1}{3} \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M}^2 - \langle \mathbf{h} D_- \mathbf{v}, (D \mathbf{b}) \mathbf{v} \rangle_{\mathbf{h} M} + \frac{3}{4} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M}^2. \end{aligned} \quad (112)$$

By the Cauchy-Schwarz and Young inequalities, we have

$$\begin{aligned} & \|\mathbf{v}\|_{\mathbf{h} M}^2 + \frac{1}{3} \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M}^2 + \frac{3}{4} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M}^2 - \langle \mathbf{h} D_- \mathbf{v}, (D \mathbf{b}) \mathbf{v} \rangle_{\mathbf{h} M} \\ & \geq \|\mathbf{v}\|_{\mathbf{h} M}^2 + \frac{1}{3} \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M}^2 + \frac{3}{4} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M}^2 - \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M} \\ & \geq \|\mathbf{v}\|_{\mathbf{h} M}^2 + \frac{1}{3} \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M}^2 + \frac{3}{4} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M}^2 - \frac{1}{2\varepsilon} \|\mathbf{h} D_- \mathbf{v}\|_{\mathbf{h} M}^2 - \frac{\varepsilon}{2} \|(D \mathbf{b}) \mathbf{v}\|_{\mathbf{h} M}^2 = \|\mathbf{v}\|_{\mathbf{h} M}^2 \end{aligned} \quad (113)$$

for $\varepsilon = 3/2$. \square

The use of the above operators leads to the semidiscretization

$$\begin{aligned}
& \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} = \mathbf{0}, \\
& \left(\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- + \frac{1}{2} D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D_- + \frac{3}{4} \mathbf{h} (D \mathbf{b})^2 \right) \partial_t \mathbf{u} + g D \mathbf{h} (\mathbf{h} + \mathbf{b}) - g (\mathbf{h} + \mathbf{b}) D \mathbf{h} \\
& \quad + \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} + D_+ \mathbf{p}_+ + D \mathbf{p}_0 + \frac{3}{2} \frac{\mathbf{p}_+ + \mathbf{p}_0}{\mathbf{h}} D \mathbf{b} = \mathbf{0}, \\
& \mathbf{p}_+ = \frac{1}{2} \mathbf{h}^3 (D \mathbf{u}) D_- \mathbf{u} + \frac{1}{2} \mathbf{h}^2 (D \mathbf{h}) \mathbf{u} D_- \mathbf{u} - \frac{1}{4} \mathbf{h}^2 (D \mathbf{b}) \mathbf{u} D \mathbf{u} - \frac{1}{4} \mathbf{h} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2, \\
& \mathbf{p}_0 = -\frac{1}{6} \mathbf{h} D (\mathbf{h}^2 \mathbf{u} D \mathbf{u}) - \frac{1}{6} \mathbf{h}^2 \mathbf{u} D (\mathbf{h} D \mathbf{u}) + \frac{1}{4} \mathbf{h} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{4} \mathbf{h}^2 \mathbf{u} D ((D \mathbf{b}) \mathbf{u}).
\end{aligned} \tag{114}$$

The discrete total energy for (114) is $\mathbf{1}^T M \mathbf{E}$, where

$$\begin{aligned}
\mathbf{E} &= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h} \left(-\mathbf{h} D_- \mathbf{u} + \frac{3}{2} \mathbf{u} D \mathbf{b} \right)^2 \\
&= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h}^3 (D_- \mathbf{u})^2 - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) (D_- \mathbf{u}) \mathbf{u} + \frac{3}{8} \mathbf{h} (D \mathbf{b})^2 \mathbf{u}^2.
\end{aligned} \tag{115}$$

Theorem 15. *Consider the semidiscretization (114) of the original Serre-Green-Naghdi equations with mild-slope approximation for varying bathymetry (99) with periodic first-derivative upwind SBP operators D_{\pm} inducing the central operator $D = (D_+ + D_-)/2$ with diagonal mass/norm matrix.*

1. The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved
2. The total momentum $\mathbf{1}^T M \mathbf{h} \mathbf{u}$ is conserved for constant bathymetry.
3. The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.
4. The semidiscretization is well-balanced, i.e., it preserves the steady state $h + b \equiv \text{const}$, $u \equiv 0$.

Proof. Conservation of the total water mass follows as in the proof of Theorem 3 since the equation for \mathbf{h} is the same. Conservation of the total momentum for constant bathymetry follows from Theorem 10 since (114) reduces to (78) in this case. We now evaluate the time derivative of the total energy:

$$\begin{aligned}
& \partial_t (\mathbf{1}^T M \mathbf{E}) \\
&= g (\mathbf{h} + \mathbf{b})^T M \partial_t \mathbf{h} + \frac{1}{2} (\mathbf{u}^2)^T M \partial_t \mathbf{h} + \frac{1}{2} (\mathbf{h}^2 (D_- \mathbf{u})^2)^T M \partial_t \mathbf{h} - (\mathbf{h} (D \mathbf{b}) (D_- \mathbf{u}) \mathbf{u})^T M \partial_t \mathbf{h} \\
& \quad + \frac{3}{8} \left((D \mathbf{b})^2 \mathbf{u}^2 \right)^T M \partial_t \mathbf{h} + \mathbf{u}^T M \mathbf{h} \partial_t \mathbf{u} + \frac{1}{3} \left(\mathbf{h}^3 (D_- \mathbf{u}) \right)^T M D_- \partial_t \mathbf{u} - \frac{1}{2} \left(\mathbf{h}^2 (D \mathbf{b}) (D_- \mathbf{u}) \right)^T M \partial_t \mathbf{u} \\
& \quad - \frac{1}{2} \left(\mathbf{h}^2 (D \mathbf{b}) \mathbf{u} \right)^T M D_- \partial_t \mathbf{u} + \frac{3}{4} \left(\mathbf{h} (D \mathbf{b})^2 \mathbf{u} \right)^T M \partial_t \mathbf{u}.
\end{aligned} \tag{116}$$

Thus, we multiply the first equation of (114) by

$$g (\mathbf{h} + \mathbf{b})^T M + \frac{1}{2} (\mathbf{u}^2)^T M + \frac{1}{2} (\mathbf{h}^2 (D_- \mathbf{u})^2)^T M - (\mathbf{h} (D \mathbf{b}) (D_- \mathbf{u}) \mathbf{u})^T M + \frac{3}{8} \left((D \mathbf{b})^2 \mathbf{u}^2 \right)^T M, \tag{117}$$

the second equation by $\mathbf{u}^T M$, and add them. Compared to the case of flat bathymetry in Theorem 10, the

additional spatial derivative terms are

$$\begin{aligned}
& g\mathbf{b}^T M (\mathbf{u}D\mathbf{h} + \mathbf{h}D\mathbf{u}) - (\mathbf{h}(D\mathbf{b})(D_-\mathbf{u})\mathbf{u})^T M (\mathbf{u}D\mathbf{h} + \mathbf{h}D\mathbf{u}) + \frac{3}{8} \left((D\mathbf{b})^2 \mathbf{u}^2 \right)^T M (\mathbf{u}D\mathbf{h} + \mathbf{h}D\mathbf{u}) \\
& + g\mathbf{u}^T MD\mathbf{h}\mathbf{b} - g(\mathbf{b}\mathbf{u})^T MD\mathbf{h} + \frac{1}{4} \mathbf{u}^T MD\mathbf{h}D(\mathbf{h}(D\mathbf{b})\mathbf{u}^2) + \frac{1}{4} \mathbf{u}^T MD\mathbf{h}^2\mathbf{u}D((D\mathbf{b})\mathbf{u}) \\
& - \frac{1}{4} \mathbf{u}^T MD_+\mathbf{h}(D\mathbf{h})(D\mathbf{b})\mathbf{u}^2 - \frac{1}{4} \mathbf{u}^T MD_+\mathbf{h}^2(D\mathbf{b})\mathbf{u}(D\mathbf{u}) + \frac{3}{4} \mathbf{1}^T M\mathbf{h}^2(D\mathbf{b})\mathbf{u}(D_-\mathbf{u})(D\mathbf{u}) \\
& + \frac{3}{4} \mathbf{1}^T M\mathbf{h}(D\mathbf{h})(D\mathbf{b})\mathbf{u}^2(D_-\mathbf{u}) - \frac{1}{4} ((D\mathbf{b})\mathbf{u})^T MD(\mathbf{h}^2\mathbf{u}D\mathbf{u}) - \frac{1}{4} (\mathbf{h}(D\mathbf{b})\mathbf{u}^2)^T MD(\mathbf{h}D\mathbf{u}) \\
& + \frac{3}{8} ((D\mathbf{b})\mathbf{u})^T MD(\mathbf{h}(D\mathbf{b})\mathbf{u}^2) + \frac{3}{8} (\mathbf{h}(D\mathbf{b})\mathbf{u}^2)^T MD((D\mathbf{b})\mathbf{u}) - \frac{3}{8} \mathbf{1}^T M(D\mathbf{h})(D\mathbf{b})^2\mathbf{u}^3 \\
& - \frac{3}{8} \mathbf{1}^T M\mathbf{h}(D\mathbf{b})^2\mathbf{u}^2(D\mathbf{u}) = 0,
\end{aligned} \tag{118}$$

proving energy conservation. For well-balanced, if $h + b \equiv \text{const}$ and $u \equiv 0$ we have $\partial_t \mathbf{h} = \mathbf{0}$, and $\mathbf{p} = \mathbf{0}$ so

$$\left(\mathbf{h} - \frac{1}{3} D\mathbf{h}^3 D + \frac{1}{2} D\mathbf{h}^2(D\mathbf{b}) - \frac{1}{2} \mathbf{h}^2(D\mathbf{b})D + \frac{3}{4} \mathbf{h}(D\mathbf{b})^2 \right) \partial_t \mathbf{u} + \underbrace{gD\mathbf{h}(\mathbf{h} + \mathbf{b}) - g(\mathbf{h} + \mathbf{b})D\mathbf{h}}_{=0} = \mathbf{0}. \tag{119}$$

□

Remark 16. *One could also choose other non-hydrostatic pressure terms. In addition to the split form versions mentioned in Remark 6, one could distribute the upwind terms differently. For example, one could use*

$$D \left(-\frac{1}{4} \mathbf{h}^2(D\mathbf{b})\mathbf{u}D_-\mathbf{u} \right) \tag{120}$$

in $D\mathbf{p}_0$ instead of

$$D_+ \left(-\frac{1}{4} \mathbf{h}^2(D\mathbf{b})\mathbf{u}D\mathbf{u} \right) \tag{121}$$

in $D_+\mathbf{p}_+$ since the contribution to the energy rate of both choices is the same (when multiplied by $\mathbf{u}^T M$). Investigating this further is left for future work.

9 Original Serre-Green-Naghdi equations with variable bathymetry: full system without mild-slope approximation

As an extension of the previous section, we propose here a split form of the classical SGN system with full bathymetric variations, which we write for the moment as

$$\begin{aligned}
& h_t + (hu)_x = 0, \\
& hu_t + gh h_x + hu u_x + (h\pi)_x + \left(gh + \frac{3}{2}\pi \right) b_x + \phi b_x = 0, \\
& hw_t + hu w_x = 3\pi, \\
& w + hu_x - \frac{3}{2}\omega = 0, \\
& h\omega_t + hu\omega_x = 4\phi, \\
& \omega - ub_x = 0,
\end{aligned} \tag{122}$$

with the last four relations defining π , w , ϕ , and ω . We can now check that the energy conservation law

$$\underbrace{\left(\frac{1}{2}g(h+b)^2 + \frac{1}{2}hu^2 + \frac{1}{6}hw^2 + \frac{1}{8}h\omega^2\right)}_{=E} + \underbrace{\left(gh(h+b)u + \frac{1}{2}hu^3 + \frac{1}{6}huw^2 + \frac{1}{8}hu\omega^2 + h\pi u\right)}_{=F} = 0 \quad (123)$$

holds. We can show that the last two definitions allow to write

$$E_t = \left(g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2 + \frac{1}{8}\omega^2\right) h_t + hu u_t + \frac{1}{3}hw w_t + \frac{1}{4}h\omega\omega_t. \quad (124)$$

As before, the flux variation requires exploiting all the auxiliary variables

$$\begin{aligned} F_x = & \left(g(h+b) + \frac{1}{2}u^2 + \frac{1}{6}w^2 + \frac{1}{8}\omega^2\right) (hu)_x + u (ghh_x + hu u_x + (h\pi)_x + (gh + 3\pi/2)b_x + \phi b_x) \\ & + \frac{w}{3}(huw_x - 3\pi) + \pi(w + hu_x - 3\omega/2) + \frac{\omega}{4}(hu\omega_x - 4\phi) + \phi(\omega - b_x u). \end{aligned} \quad (125)$$

To mimic these relations, using the results obtained so far, we consider the following split form:

$$\begin{aligned} h_t + h_x u + hu_x &= 0, \\ hu_t + g(h(h+b))_x - g(h+b)h_x \\ &+ \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}hu u_x + (h\pi)_x + \frac{3}{2}\pi b_x + \phi b_x = 0, \\ hw_t + \frac{1}{2}(huw)_x + \frac{1}{2}huw_x - \frac{1}{2}h_x u w - \frac{1}{2}hu_x w &= 3\pi, \\ w + hu_x - \frac{3}{2}\omega &= 0, \\ h\omega_t + \frac{1}{2}(hu\omega)_x + \frac{1}{2}hu\omega_x - \frac{1}{2}h_x u \omega - \frac{1}{2}hu_x \omega &= 4\phi, \\ \omega - b_x u &= 0. \end{aligned} \quad (126)$$

One can easily check that this formulation is compatible, up to integration by parts, with mass and energy conservation, as well as well-balanced wrt states at rest and constant $h+b$. Compared to the mild-slope approximation (99), we only have the additional term $+\phi b_x$ in the momentum equation, where

$$\phi = \frac{1}{4}hb_x u_t + \frac{1}{8}(hb_x u^2)_x + \frac{1}{8}hu(b_x u)_x - \frac{1}{8}h_x b_x u^2 - \frac{1}{8}hb_x u u_x. \quad (127)$$

Following a similar procedure as done in the flat and mild slope cases, we can write

$$\begin{aligned} h_t + h_x u + hu_x &= 0, \\ hu_t - \frac{1}{3}(h^3 u_{tx})_x + \frac{1}{2}(h^2 b_x u_t)_x - \frac{1}{2}h^2 b_x u_{tx} + hb_x^2 u_t + g(h(h+b))_x - g(h+b)h_x \\ &+ \frac{1}{2}h(u^2)_x - \frac{1}{2}h_x u^2 + \frac{1}{2}(hu)_x u - \frac{1}{2}hu u_x + p_x + \frac{3}{2}\frac{p}{h}b_x + \psi b_x = 0, \\ p &= \frac{1}{2}h^3 u_x^2 + \frac{1}{2}h^2 h_x u u_x - \frac{1}{6}h(h^2 u u_x)_x - \frac{1}{6}h^2 u (hu_x)_x \\ &+ \frac{1}{4}h(hb_x u^2)_x + \frac{1}{4}h^2 u (b_x u)_x - \frac{1}{4}hh_x b_x u^2 - \frac{1}{4}h^2 b_x u u_x, \\ \psi &= \frac{1}{8}(hb_x u^2)_x + \frac{1}{8}hu(b_x u)_x - \frac{1}{8}h_x b_x u^2 - \frac{1}{8}hb_x u u_x. \end{aligned} \quad (128)$$

Compared to the split form (106) of the mild-slope approximation, we have the following differences:

- the term $hb_x^2 u_t$ has a factor of unity instead of $3/4$
- the terms $(hb_x u^2)_x + hu(b_x u)_x - h_x b_x u^2 - hb_x u u_x$ appearing in $3pb_x/(2h)$ have the factor $1/2$ instead of $3/8$ due to the additional term ψb_x

9.1 Semidiscretization

The split form (128) leads to the semidiscretization

$$\begin{aligned}
& \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} = \mathbf{0}, \\
& \left(\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D + \frac{1}{2} D \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D + \mathbf{h} (D \mathbf{b})^2 \right) \partial_t \mathbf{u} + g D \mathbf{h} (\mathbf{h} + \mathbf{b}) - g (\mathbf{h} + \mathbf{b}) D \mathbf{h} \\
& \quad + \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} + D \mathbf{p} + \frac{3}{2} \frac{\mathbf{p}}{\mathbf{h}} D \mathbf{b} + \psi D \mathbf{b} = \mathbf{0}, \\
& \mathbf{p} = \frac{1}{2} \mathbf{h}^3 (D \mathbf{u})^2 + \frac{1}{2} \mathbf{h}^2 (D \mathbf{h}) \mathbf{u} D \mathbf{u} - \frac{1}{6} \mathbf{h} D (\mathbf{h}^2 \mathbf{u} D \mathbf{u}) - \frac{1}{6} \mathbf{h}^2 \mathbf{u} D \mathbf{h} D \mathbf{u} \\
& \quad + \frac{1}{4} \mathbf{h} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{4} \mathbf{h}^2 \mathbf{u} D ((D \mathbf{b}) \mathbf{u}) - \frac{1}{4} \mathbf{h} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2 - \frac{1}{4} \mathbf{h}^2 (D \mathbf{b}) \mathbf{u} D \mathbf{u}, \\
& \psi = \frac{1}{8} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{8} \mathbf{h} \mathbf{u} D ((D \mathbf{b}) \mathbf{u}) - \frac{1}{8} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2 - \frac{1}{8} \mathbf{h} (D \mathbf{b}) \mathbf{u} D \mathbf{u}.
\end{aligned} \tag{129}$$

Lemma 17. *If the water height is positive, then the discrete operator*

$$\mathbf{h} - \frac{1}{3} D \mathbf{h}^3 D + \frac{1}{2} D \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D + \mathbf{h} (D \mathbf{b})^2 \tag{130}$$

is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. Compared to Lemma 13, we have an additional term $\mathbf{h} (D \mathbf{b})^2 / 4$. □

The discrete total energy for (129) is $\mathbf{1}^T M \mathbf{E}$, where

$$\begin{aligned}
\mathbf{E} &= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h} \left(-\mathbf{h} D \mathbf{u} + \frac{3}{2} \mathbf{u} D \mathbf{b} \right)^2 + \frac{1}{8} \mathbf{h} (\mathbf{u} D \mathbf{b})^2 \\
&= \frac{1}{2} g (\mathbf{h} + \mathbf{b})^2 + \frac{1}{2} \mathbf{h} \mathbf{u}^2 + \frac{1}{6} \mathbf{h}^3 (D \mathbf{u})^2 - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) (D \mathbf{u}) \mathbf{u} + \frac{1}{2} \mathbf{h} (D \mathbf{b})^2 \mathbf{u}^2.
\end{aligned} \tag{131}$$

Theorem 18. *Consider the semidiscretization (129) of the original Serre-Green-Naghdi equations without mild-slope approximation for varying bathymetry (122) using a periodic first-derivative SBP operator D with diagonal mass/norm matrix.*

1. *The total water mass $\mathbf{1}^T M \mathbf{h}$ is conserved.*
2. *The total momentum $\mathbf{1}^T M \mathbf{h} \mathbf{u}$ is conserved if the bathymetry is constant.*
3. *The total energy $\mathbf{1}^T M \mathbf{E}$ is conserved.*
4. *The semidiscretization is well-balanced, i.e., it preserves the steady state $h + b \equiv \text{const}$, $u \equiv 0$.*

Proof. This is a special case of the more general result Theorem 20 below. □

Analogously, we can derive the upwind version of the split form as

$$\begin{aligned}
& \partial_t \mathbf{h} + \mathbf{u} D \mathbf{h} + \mathbf{h} D \mathbf{u} = \mathbf{0}, \\
& \left(\mathbf{h} - \frac{1}{3} D_+ \mathbf{h}^3 D_- + \frac{1}{2} D_+ \mathbf{h}^2 (D \mathbf{b}) - \frac{1}{2} \mathbf{h}^2 (D \mathbf{b}) D_- + \mathbf{h} (D \mathbf{b})^2 \right) \partial_t \mathbf{u} + g D \mathbf{h} (\mathbf{h} + \mathbf{b}) - g (\mathbf{h} + \mathbf{b}) D \mathbf{h} \\
& \quad + \frac{1}{2} \mathbf{h} D \mathbf{u}^2 - \frac{1}{2} \mathbf{u}^2 D \mathbf{h} + \frac{1}{2} \mathbf{u} D \mathbf{h} \mathbf{u} - \frac{1}{2} \mathbf{h} \mathbf{u} D \mathbf{u} + D_+ \mathbf{p}_+ + D \mathbf{p}_0 + \frac{3}{2} \frac{\mathbf{p}_+ + \mathbf{p}_0}{\mathbf{h}} D \mathbf{b} + \psi D \mathbf{b} = \mathbf{0}, \\
& \mathbf{p}_+ = \frac{1}{2} \mathbf{h}^3 (D \mathbf{u}) D_- \mathbf{u} + \frac{1}{2} \mathbf{h}^2 (D \mathbf{h}) \mathbf{u} D_- \mathbf{u} - \frac{1}{4} \mathbf{h}^2 (D \mathbf{b}) \mathbf{u} D \mathbf{u} - \frac{1}{4} \mathbf{h} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2, \\
& \mathbf{p}_0 = -\frac{1}{6} \mathbf{h} D (\mathbf{h}^2 \mathbf{u} D \mathbf{u}) - \frac{1}{6} \mathbf{h}^2 \mathbf{u} D (\mathbf{h} D \mathbf{u}) + \frac{1}{4} \mathbf{h} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{4} \mathbf{h}^2 \mathbf{u} D ((D \mathbf{b}) \mathbf{u}), \\
& \psi = \frac{1}{8} D (\mathbf{h} (D \mathbf{b}) \mathbf{u}^2) + \frac{1}{8} \mathbf{h} \mathbf{u} D ((D \mathbf{b}) \mathbf{u}) - \frac{1}{8} \mathbf{h} (D \mathbf{b}) \mathbf{u} D \mathbf{u} - \frac{1}{8} (D \mathbf{h}) (D \mathbf{b}) \mathbf{u}^2.
\end{aligned} \tag{132}$$

Lemma 19. *If the water height is positive, then the discrete operator*

$$\mathbf{h} - \frac{1}{3}D_+\mathbf{h}^3D_- + \frac{1}{2}D_+\mathbf{h}^2(Db) - \frac{1}{2}\mathbf{h}^2(Db)D_- + \mathbf{h}(Db)^2 \quad (133)$$

is symmetric and positive definite with respect to the diagonal mass matrix M .

Proof. Compared to Lemma 14, we have an additional term $+\mathbf{h}(Db)^2/4$ in the operator, leading to an additional term $+\|(Db)\mathbf{v}\|_{\mathbf{h}M}^2/4 \geq 0$ in (113). \square

The discrete total energy of the semidiscretization is $\mathbf{1}^T M\mathbf{E}$, where

$$\begin{aligned} \mathbf{E} &= \frac{1}{2}g(\mathbf{h} + \mathbf{b})^2 + \frac{1}{2}\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{h} \left(-\mathbf{h}D_-\mathbf{u} + \frac{3}{2}\mathbf{u}Db \right)^2 + \frac{1}{8}\mathbf{h}(\mathbf{u}Db)^2 \\ &= \frac{1}{2}g(\mathbf{h} + \mathbf{b})^2 + \frac{1}{2}\mathbf{h}\mathbf{u}^2 + \frac{1}{6}\mathbf{h}^3(D_-\mathbf{u})^2 - \frac{1}{2}\mathbf{h}^2(Db)(D_-\mathbf{u})\mathbf{u} + \frac{1}{2}\mathbf{h}(Db)^2\mathbf{u}^2. \end{aligned} \quad (134)$$

Theorem 20. *Consider the semidiscretization (132) of the original Serre-Green-Naghdi equations without mild-slope approximation for varying bathymetry (122) with periodic first-derivative upwind SBP operators D_{\pm} inducing the central operator $D = (D_+ + D_-)/2$ with diagonal mass/norm matrix.*

1. *The total water mass $\mathbf{1}^T M\mathbf{h}$ is conserved.*
2. *The total momentum $\mathbf{1}^T M\mathbf{h}\mathbf{u}$ is conserved if the bathymetry is constant.*
3. *The total energy $\mathbf{1}^T M\mathbf{E}$ is conserved.*
4. *The semidiscretization is well-balanced, i.e., it preserves the steady state $h + b \equiv \text{const}$, $u \equiv 0$.*

Proof. Conservation of the total water mass and momentum as well as preservation of the steady state follow as in Theorem 15. Thus, we just check the rate of change of the total energy. Compared to the mild-slope case in Theorem 15, we get the following additional terms

- $+(1/8)((Db)^2\mathbf{u}^2)^T M\partial_t\mathbf{h}$ from the additional energy term and the rate of change of \mathbf{h}
- $+(1/4)\mathbf{u}^T M\mathbf{h}(Db)\partial_t\mathbf{u}$ from the additional energy term and the rate of change of \mathbf{u}
- $+\mathbf{u}^T M\psi Db = ((Db)\mathbf{u})^T M\psi$ from the additional term involving the bottom topography

The additional term involving the time derivative of \mathbf{u} is included in the linear operator that we need to invert. Adding the remaining terms yields

$$\begin{aligned} ((Db)^2\mathbf{u}^2)^T M\partial_t\mathbf{h} + 8\mathbf{u}^T M\psi Db &= ((Db)^2\mathbf{u}^2)^T M\mathbf{h}D\mathbf{u} + ((Db)^2\mathbf{u}^2)^T M\mathbf{u}D\mathbf{h} + ((Db)\mathbf{u})^T MD(\mathbf{h}(Db)\mathbf{u}^2) \\ &\quad + ((Db)\mathbf{u})^T M\mathbf{h}\mathbf{u}D(\mathbf{u}(Db)) - ((Db)\mathbf{u})^T M\mathbf{h}(Db)\mathbf{u}D\mathbf{u} - ((Db)\mathbf{u})^T M(D\mathbf{h})(Db)\mathbf{u}^2 \\ &= \mathbf{1}^T M\mathbf{h}(Db)^2\mathbf{u}^2(D\mathbf{u}) + \mathbf{1}^T M(D\mathbf{h})(Db)^2\mathbf{u}^3 + ((Db)\mathbf{u})^T MD(\mathbf{h}(Db)\mathbf{u}^2) \\ &\quad + (\mathbf{h}(Db)\mathbf{u}^2)^T MD(\mathbf{u}(Db)) - \mathbf{1}^T M\mathbf{h}(Db)^2\mathbf{u}^2(D\mathbf{u}) - \mathbf{1}^T M(D\mathbf{h})(Db)^2\mathbf{u}^3 = 0. \end{aligned}$$

Thus, the total energy is conserved. \square

10 Artificial viscosity stabilization

When considering structure-preserving methods, and in particular entropy/energy-conservative methods, it is quite natural to compare them to methods embedding some form of numerical dissipation. As discussed in the introduction, it is unclear that the notion of a dissipative weak solution should also apply to dispersive equations such as those considered here. However, when working on coarse meshes, as often in operational practice, one must be careful in controlling spurious modes related to under-resolution, and some degree of dissipation may be justified. This is also the motivation to introduce the upwind SBP operators of Section 2. So inspired by classical and more recent works on spectral and high-order approximations with vanishing viscosity [124, 77, 55, 96] we consider the use of artificial viscosity (AV) as a stabilization method. In particular, for all models studied we consider adding to the momentum equation a viscous term using a classical formulation reading [51, 11]

$$hu_t + \dots = (\mu hu_x)_x. \quad (135)$$

The viscosity definition is set having in mind the preservation of the consistency of the underlying operators, and in particular for a method of accuracy order p we set

$$\mu = C \frac{\Delta x^p}{p}, \quad (136)$$

where for simplicity the (dimensional) constant C , has been set to 1 in all experiments.

10.1 Discretization with SBP operators

In general, we will add to the right hand side of our discretization a term \mathbf{F}_μ :

$$\mathbf{h} \partial_t \mathbf{u} + \dots = \mathbf{F}_\mu. \quad (137)$$

When using periodic central SBP operators, the artificial diffusion term is approximated as

$$\mathbf{F}_\mu = D(\mu \mathbf{h} D \mathbf{u}). \quad (138)$$

When using periodic upwind SBP operators, the artificial diffusion term is approximated as

$$\mathbf{F}_\mu = D_+(\mu \mathbf{h} D_- \mathbf{u}). \quad (139)$$

For these additional terms we can prove the following simple result.

Theorem 21. *The discrete artificial viscosity terms (138) and (139) verify the following two properties*

1. *They do not alter momentum conservation: total energy $\mathbf{1}^T M \mathbf{F}_\mu = 0$.*
2. *They provide a dissipative contribution to the energy balance: $\mathbf{u}^T M \mathbf{F}_\mu \geq 0$.*

Proof. Result obtained combining (138) with (6), and (139) with (7) respectively. □

The above proves that energy preserving schemes become energy stable when including the AV term.

11 Numerical experiments

The methods proposed in this work have been implemented in Julia [6], using the packages SummationByPartsOperators.jl [102] for the spatial discretizations and OrdinaryDiffEq.jl [98] for time integration. The Fourier pseudospectral methods use FFTW wrapped in FFTW.jl [45] in Julia. The sparse linear systems are solved using a direct solver of SuiteSparse [19, 2, 22] available in Julia. We use the ITP method [91] implemented in SimpleNonlinearSolve.jl [93] to compute the relaxation parameter γ for energy-conservative time integration

methods. We use Plots.jl [21] to visualize the results. All source code to reproduce our numerical results is available online [112].

Time integration is performed using explicit Runge-Kutta methods with error-based step size control [5, 67, 104, 115]. If not described otherwise, we choose relative and absolute tolerances 10^{-5} . For the original Serre-Green-Naghdi equations, we use the fifth-order Runge-Kutta method of [129]. For the hyperbolic approximation, we use the third-order Runge-Kutta method of [104] that was optimized for discretizations of hyperbolic conservation laws when the time step size is constrained by stability instead of accuracy.

Throughout this article, we use SI units for all quantities. The gravitational constant is set to $g = 9.81 \text{ m/s}^2$. We apply periodic boundary conditions for all experiments since we have not analyzed the energy for other boundary conditions. When necessary larger domain sizes are used avoid the effects of inconsistent values on the left/right domain boundaries. We initialize the hyperbolic approximation with the water height and velocity of the Serre-Green-Naghdi equations, and the auxiliary variables

$$\boldsymbol{\eta} = \mathbf{h}, \quad \mathbf{w} = -\mathbf{h}D\mathbf{u}. \quad (140)$$

11.1 Convergence studies

Since we are interested in the spatial error of the methods, we use the fifth-order Runge-Kutta method of [129] with stricter tolerances 10^{-9} for the convergence experiments reported in this section. To compute the experimental order of convergence (EOC), we use the formula

$$\text{EOC} = -\frac{\log(e_2/e_1)}{\log(N_2/N_1)}, \quad (141)$$

where e_i and N_i are measures of the error and the discretization size for two consecutive grid refinements. For finite difference methods, we use the number of nodes as discretization size N .

11.1.1 Solitary waves of the Serre-Green-Naghdi equations

The exact solitary wave for the Serre-Green-Naghdi equations has depth and depth-averaged velocities given by

$$h_e = h_\infty \left(1 + \varepsilon \operatorname{sech}^2(\kappa(x - Ct))\right), \quad u_e = C \left(1 - \frac{h_\infty}{h}\right), \quad (142)$$

where $\varepsilon = A/h_\infty$ with A the soliton amplitude, and where

$$\kappa^2 = \frac{3\varepsilon}{4h_\infty^2(1 + \varepsilon)}, \quad C^2 = gh_\infty(1 + \varepsilon). \quad (143)$$

This is a solution of the classical Serre-Green-Naghdi equations. When using it for the hyperbolic system, a possible choice to initialize the auxiliary variables, at least for λ large enough, is

$$\eta(t = 0, x) = h_e(0), \quad w(t = 0, x) = -h_e(0)u'_e(0). \quad (144)$$

If not stated otherwise, we use the following parameters for the solitary wave:

$$h_\infty = 1, \quad A = 0.2h_\infty. \quad (145)$$

For the convergence experiments in this section, we choose the domain $[-50, 50]$ with periodic boundary conditions and a time interval such that the wave travels through the domain once.

Figure 1 shows the errors of the numerical solutions measured with respect to the soliton solution of the Serre-Green-Naghdi equations for finite difference methods with different orders of accuracy, including methods with (high order) artificial viscosity. The EOC matches the expected order of accuracy. For this case artificial viscosity leads to an increase in the absolute value of the error by a factor in between ≈ 2 –5.

For the hyperbolic approximation, the EOC matches the expected order of accuracy for the second-order method, when using $\lambda = 10^4$. For the fourth-order method $\lambda = 10^6$, is necessary to obtain the proper rates for the water height, but even with this value the convergence rates are a bit smaller for the velocity. A larger value of λ may allow to correct this. For completeness we also study the convergence when increasing the value of the parameter λ . The results are summarized in Table 1. The EOC of the water height is unity. The velocity converges as well but with a reduced EOC, especially for large λ . The differences due to the artificial diffusion are very small here.

11.1.2 Manufactured solution for the hyperbolic system

We use the method of manufactured solutions to check the implementation. We choose the solution

$$\begin{aligned}
 h(t, x) &= 7 + 2 \cos(2\pi x) + \cos(2\pi x - 4\pi t), \\
 u(t, x) &= \sin(2\pi x - \pi t), \\
 \eta(t, x) &= h(t, x), \\
 w(t, x) &= -h(t, x) \partial_x u(t, x), \\
 b &= -5 - 2 \cos(2\pi x),
 \end{aligned}
 \tag{146}$$

and add source terms to the equations so that the equations are satisfied for the manufactured solutions. We consider the grid convergence of the error at the final time $t = 1$ on a domain of width 1. The results shown in Figure 2 confirm the expected order of accuracy for the finite difference semidiscretizations. For this test, the difference brought by adding artificial dissipation is orders of magnitude smaller than the errors itself, and the convergence curves are essentially superposed.

Figure 2: Grid convergence to the manufactured solution for the hyperbolic system results using finite difference semidiscretizations of different orders and $\lambda = 500$. Left: depth. Right: velocity.

11.2 Qualitative comparison of upwind and central methods

To point out the different behavior of upwind and central finite difference methods for solving the elliptic equations, we compare numerical results for a Gaussian initial condition.

11.2.1 Qualitative comparison: flat bathymetry

First, we consider the initial condition

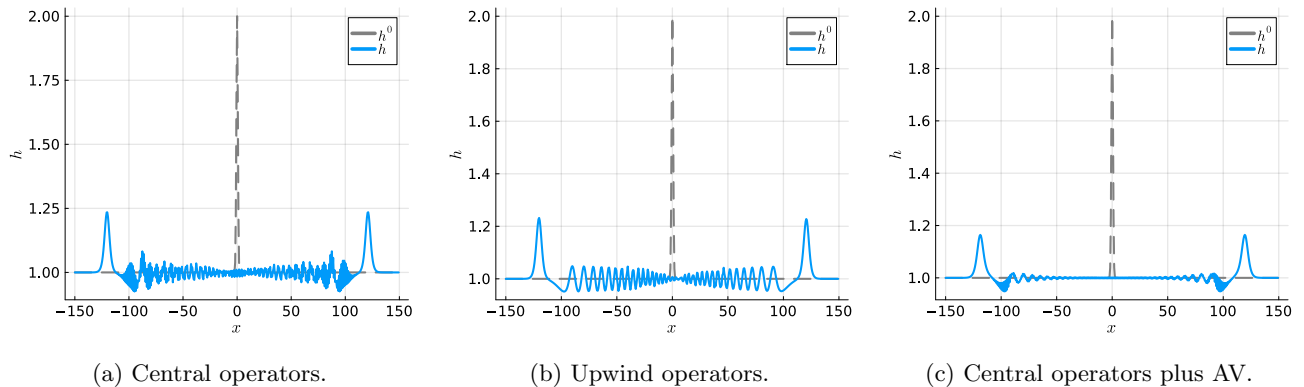

$$h(x, 0) = 1 + \exp(-x^2), \quad u(x, 0) = 10^{-2}, \quad b(x) = 0, \quad (147)$$

and discretize the domain $[-150, 150]$ with second-order finite differences. We use the fifth-order Runge-Kutta method of [129] with tolerances 10^{-5} for the time interval $[0, 35]$. Reference solutions are shown in Figure 3. All the methods considered in this section are visually fully converged with the same number of nodes $N = 3000$.

(a) Hyperbolic approximation with $\lambda = 500$. (b) Original Serre-Green-Naghdi equations. (c) Serre-Green-Naghdi with artificial diffusion.

Figure 3: Numerical solutions for the initial condition (147). These reference solutions are all visually converged on the same grid with $N = 3000$ nodes using second-order central finite difference methods.

(a) Central operators. (b) Upwind operators. (c) Central operators plus AV.

Figure 4: Numerical solutions obtained with second-order finite difference methods with $N = 500$ nodes for the original Serre-Green-Naghdi equations for the same setup as in Figure 3.

Next, we compare three approaches for the original Serre-Green-Naghdi equations with only $N = 500$ nodes: central SBP operators, upwind SBP operators, and central SBP plus artificial viscosity. The results are shown in Figure 4. The central discretization of the Laplacian leads to spurious oscillations due to under-resolution. These oscillations, absent in the mesh resolved solutions, are completely removed by the upwind structure-preserving discretization. Artificial viscosity allows to remove some of the oscillations, but also damps the solution everywhere, as visible from the lower water heights obtained. This qualitative difference is in accordance with the behavior of central (wide-stencil) and upwind (narrow-stencil) discretizations of several time-dependent problems [80, 81] including other systems of dispersive wave equations [70]. For the effects of numerical dissipation one can instead refer to [60].

11.2.2 Qualitative comparison: variable bathymetry

Next, we use a variable bathymetry and

$$h(x, 0) = 1 + \exp(-x^2) - b(x), \quad u(x, 0) = 10^{-2}, \quad b(x) = \frac{\cos(\pi x/75)}{4}. \quad (148)$$

Reference solutions are shown in Figure 5. All methods are visually converged at the same level $N = 3000$ nodes.

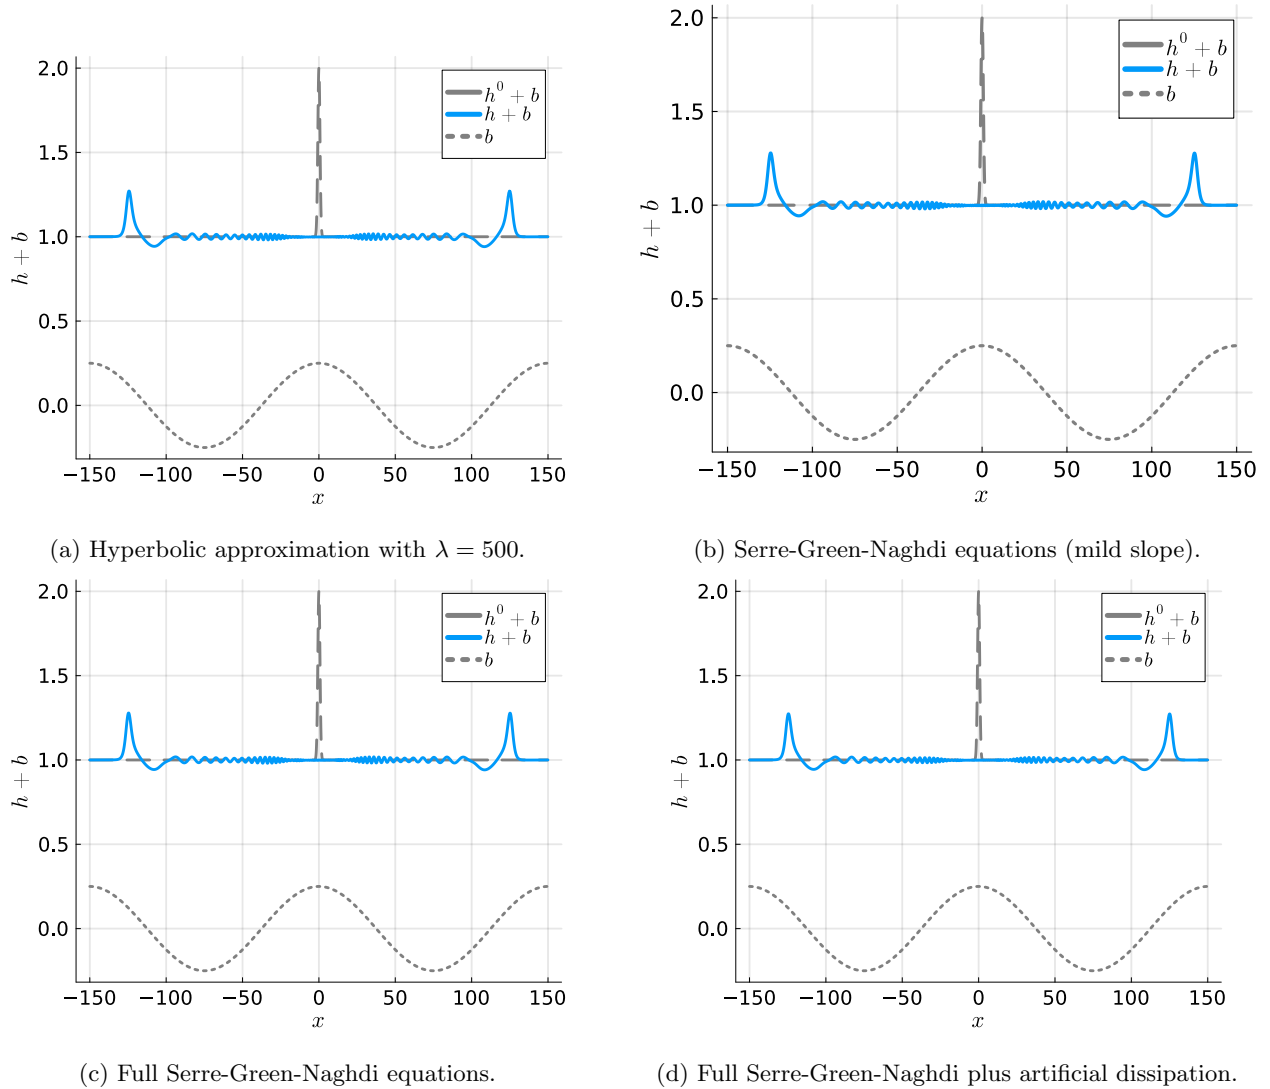

Figure 5: Numerical solutions for the initial condition (148). These reference solutions are all visually converged on the same grid with $N = 3000$ nodes using second-order central finite difference methods.

Numerical solutions obtained with second-order finite difference methods with $N = 500$ nodes for the original Serre-Green-Naghdi equations are shown in Figure 6. As before, the central discretization of the Laplacian leads to spurious oscillations. The oscillations are in this case removed in both the upwind SBP method, which is structure-preserving, and using artificial viscosity. However, as expected, on coarse meshes the latter has dramatic impact on the wave heights obtained, and on the resolution of secondary waves.

(a) Central operators, mild slope.

(b) Central operators, full system.

(c) Upwind operators, mild slope.

(d) Upwind operators, full system.

(e) Central + AV, full system.

11.3 Conservation of invariants

In this section, we check the conservation of the invariants, i.e., the total water mass and the total energy. We use again the initial conditions and setups from Section 11.2 for constant and variable bathymetry.

11.3.1 Conservation of invariants: flat bathymetry

Table 2: Conservation of invariants (error “Er” of water mass $\int h$, momentum $\int hu$, and energy $\int E$) for constant bathymetry.

The conservation of mass, momentum, and energy is measured on the test of Section 11.2. We use second-order finite differences with $N = 1000$ nodes, in the spatial domain $[-150, 150]$, on the time interval $t \in [0, 35]$. The results are shown in Table 2. For all systems, the linear invariant (total water mass) is conserved up to machine accuracy. For the structure-preserving semidiscretizations, the total energy error decreases with the time step size, and the EOC matches the order of accuracy of the time integration method. This is expected since, being a nonlinear invariant, total energy is not conserved exactly by the time integration method. For the original systems we obtain the same result for the momentum, which is a nonlinear invariant due to the formulation using hu_t . As already said, this could be avoided working with $(hu)_t$ but with considerable overheads in the solution of the elliptic problem. In any case, the momentum EOC matches the order of accuracy of the time discretization. Conversely, the momentum error for the hyperbolic approximation is the same for all Δt s since

in this case the semidiscretization in space is non momentum conserving. The results including AV show a finite defect in the energy integral, independent of the time step. This error is given by $\int \mu(\Delta x, p)h(u_x)^2$ at the final time, and reduces when passing from order 2 to order 4 as shown in the tables.

11.3.2 Conservation of invariants: variable bathymetry

Next, we use a variable bathymetry as in (148). The other parameters are still the same as before. The results shown in Table 3 show similar behavior to the constant bathymetry case. To save space we do not report here the errors when including artificial dissipation, which also behave very similarly as in the previous sub-section. We do report a table with the energy errors at final time $t = 35$ for second- and fourth-order schemes showing some small dependence of the error on the formulation, but again mostly on the order (and mesh).

Table 3: Conservation of invariants (errors “Er” of water mass $\int h$ and energy $\int E$) for variable bathymetry. The spatial discretizations use second-order finite differences with $N = 1000$ nodes in the interval $[-150, 150]$.

11.4 Well-balancedness

We also check the well-balancedness of the methods. For this, we use the initial condition

$$h(x, 0) = 1 - b(x), \quad u(x, 0) = 0, \quad b(x) = \frac{\cos(\pi x/75)}{4}, \quad (149)$$

in the interval $[-150, 150]$ with $N = 1000$ nodes. We report in Table 4 the results obtained without artificial viscosity. The ones obtained with this term added are identical down to machine accuracy and are omitted to save space. The results shown confirm the well-balancedness of the semidiscretizations.

Table 4: Discrete L^2 norm of the ODE RHS for the well-balancedness test case discretized with central finite difference methods of different orders of accuracy p .

11.5 Error growth of solitons of the Serre-Green-Naghdi equations

We study the error growth in long-time simulations of solitary waves. We use the setup of Section 11.1.1, and apply Fourier pseudospectral methods in space with $N = 2^7$ nodes. We choose the final time such that the soliton has traveled through the domain 20 times. We solve the nonlinear scalar equation for relaxation to conserve the energy using the ITP method [91]. The results are shown in Figure 7. Energy is only conserved exactly with relaxation, and in this case it is conserved up to the accuracy of the nonlinear scalar solver. In this case we also see a linear growth in time of the error, while the error of the baseline structure-preserving method grows quadratically. This behavior has also been observed for other nonlinear dispersive systems [23, 28, 108]. It can be explained using the theory of relative equilibrium solutions [27]: the SGN equations can be expressed as Hamiltonian system [75] with the total energy as Hamiltonian \mathcal{H} . However, there is another invariant \mathcal{Q} of the SGN equations and solitary wave solutions are critical points of the functional $\mathcal{H} - c\mathcal{Q}$ [75]. Thus, the basic structure of relative equilibrium solutions of [27] is satisfied and we can expect a quadratic error growth for general time integration methods and a linear error growth for methods conserving the total energy.

11.6 Riemann problem

We consider a Riemann problem following the setup by [126]. We use a smoothed initial profile

$$h(x, 0) = h_R + \frac{h_L - h_R}{2} (1 - \tanh(x/\alpha)), \quad u(x, 0) = 0, \quad (150)$$

with $\alpha = 2$. The analysis of Riemann invariants of the shallow-water system, coupled with the analysis of the Whitham system for the SGN equations [31, 49, 126, 33] allow to recover the approximate values (h^*, u^*) of the mean flow dividing the rarefaction wave and the dispersive shock zones as

$$h^* = \frac{(\sqrt{h_L} + \sqrt{h_R})^2}{4}, \quad u^* = 2(\sqrt{gh^*} - \sqrt{gh_R}), \quad a^+ = \delta_0 - \frac{1}{12}\delta_0^2 + O(\delta_0^3), \quad (151)$$

where a^+ is the second-order asymptotic approximation of the amplitude of the leading soliton and $\delta_0 = |h_R - h_L|$. We take $h_L = 1.8$ and $h_R = 1.0$, and solve the problem until time $t = 47.434$ on a large domain $[-600, 600]$. Only

(a) Error without relaxation.

(b) Error with relaxation.

(c) Energy without relaxation.

(d) Energy with relaxation.

Figure 7: Long-time soliton propagation for the Serre-Green-Naghdi equations. Energy-conserving Fourier pseudospectral methods, and fifth-order Runge-Kutta method of [129] with and without relaxation to conserve the energy. Top: discrete L^2 errors of the numerical solutions. Bottom: energy error after 20 periods.

the results in the interval $[-300, 300]$ are retained. Figure 8 shows solutions for the hyperbolic approximation and the original SGN equations obtained with structure-preserving central finite difference operators. The results from the two systems agree very well with each other, the analytical predictions, and the numerical results of [49, 97].

(a) Hyperbolic approximation with $\lambda = 500$.

(b) Serre-Green-Naghdi equations.

Figure 8: Riemann problem using structure-preserving second-order finite differences with $\Delta x = 0.3$. The intermediate water height $h^* = 1.37$ and amplitude $h^m = 1.74$ of the leading dispersive wave are in accordance with analytical predictions and numerical results [49, 97].

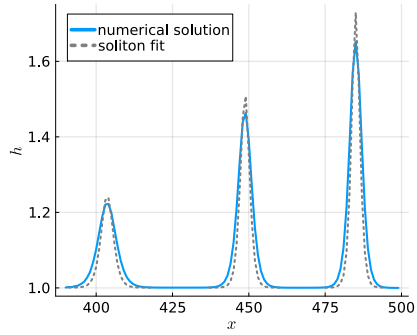

11.7 Soliton fission

Next, we study the long-time behavior of a dispersive shock wave. We use the initial condition

$$h(x, 0) = \begin{cases} 1.8, & |x| < 1, \\ 1.0, & \text{otherwise,} \end{cases} \quad u(x, 0) = 0, \quad (152)$$

and discretize the spatial domain $[-500, 500]$ with 10^3 nodes using central second-order finite differences. We integrate the numerical solutions until $t = 118$, and analyze the leading waves in the interval $[390, 500]$. We take the values where the water height h is greater than a threshold of 1.001 and fit analytical Serre-Green-Naghdi solitons to them. For this, we take the median of the remaining values of h as baseline and use a Nelder-Mead method [86, 46] implemented in Optim.jl/Optimization.jl [85, 26] to compute a least-squares solution.

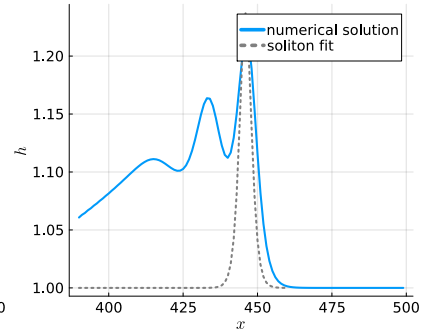

The results are shown in Figure 9. For both the hyperbolic approximation and the discretization of the original SGN equations, the numerical solutions agree very well with the fitted analytical soliton waves. The differences between the numerical solutions and the fits are roughly two orders of magnitude smaller than the amplitude of the waves. To show the impact of numerical viscosity on such long-time computations, we also plot the results of the the original SGN equations plus artificial diffusion. The corresponding results with the hyperbolic model are visually identical. We can see that not only the height of the first wave is much underestimated, but also its position, certainly due to the dependence of the celerity of the leading wave on its amplitude. The optimization method does recognize a half soliton shape in the leading front. This behaviour is further investigated and commented in the following section.

11.8 Favre waves

The propagation of undular bores, also known as Favre waves, is a classical problem, see, e.g., [131, 17] and references therein, for which well-known experiments exist [36, 128]. The initial setup considered here follows, e.g., [17, 60]. The initial solution is obtained by a smoothed discontinuity (cf. also Figure 10)

$$h(x, t = 0) := h_0 + \frac{[[h]]}{2} \left\{ 1 - \tanh \left(\frac{x - x_0}{\alpha} \right) \right\},$$

$$u(x, t = 0) := u_0 + \frac{[[u]]}{2} \left\{ 1 - \tanh \left(\frac{x - x_0}{\alpha} \right) \right\},$$

where

$$[[h]] := \varepsilon h_0,$$

with ε the nonlinearity, and with $[[u]]$ satisfying the shallow-water Rankine-Hugoniot relations, and in particular

$$[[u]] = \sqrt{g \frac{h_1 + h_0}{2h_0h_1}} [[h]].$$

We refer the reader to [17, 60] for further details on the setup.

Figure 10: Favre waves: undular bore sketch, and definition of amplitudes $a_{\min/\max}$ and wavelength λ .

As in [17, 60] we consider at first the short-time bore evolution for three values of the non-linearity $\varepsilon \in \{0.1, 0.2, 0.3\}$. The free-surface elevation for different values of the dimensionless time $\tilde{t} := t\sqrt{g/h_0}$ is compared to fully nonlinear potential solutions from [131]. The results obtained with fourth-order structure-preserving finite differences on a relatively coarse mesh with $\Delta x = 0.125$ are shown in Figures 11 and 12. Our results compare well with the fully nonlinear potential solutions, and to those of [17]. For larger values like $\varepsilon = 0.3$ some limitations, related to the weakly dispersive character of the model itself, can be seen. The value $\lambda = 500$ seems again large enough for the hyperbolic approximation and the original formulations to give visually indistinguishable results. For completeness, we also report in each picture the results obtained with artificial viscosity. For these short-time simulations we cannot see any impact of numerical dissipation.

11.8.1 Long-time propagation

As shown in [60, 12, 8] this problem is extremely sensitive to the presence of dissipative processes such as friction or viscous regularization. In absence of dissipation, soliton fission occurs. Dissipation generates undular bores of lower amplitudes and finite wavelength. This fact is also known, for simpler models such as KdV and BBM, from the modulation theory [32]. As it turns out, numerical dissipation plays exactly the same role,

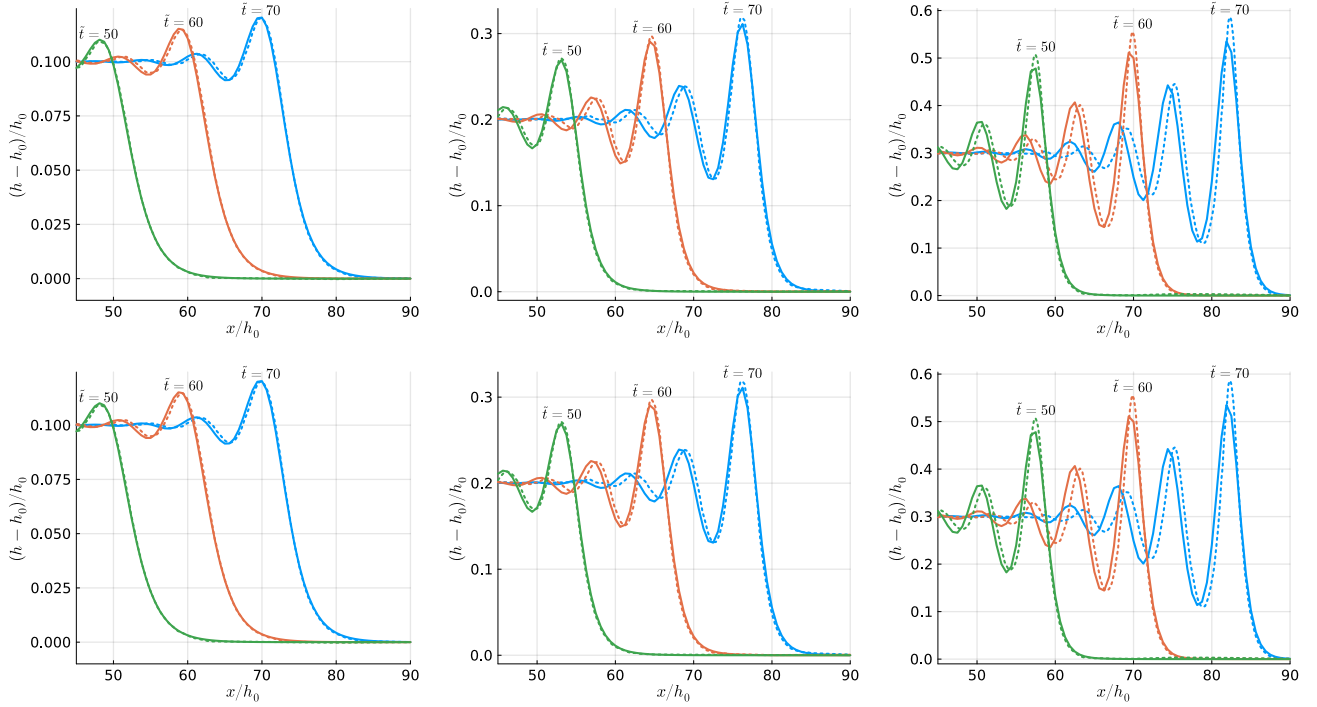

Figure 11: Favre wave: hyperbolic formulation with $\lambda = 500$, and grid spacing $\Delta x = 0.125$. Numerical solutions (solid lines) with nonlinearity $\varepsilon = 0.1$ (left), $\varepsilon = 0.2$ (center), and $\varepsilon = 0.3$ (right). Top: energy-conservative fourth-order finite differences with central operators. Bottom: fourth-order finite differences with central operators and artificial viscosity. The dashed lines show the fully nonlinear potential solutions from [131].

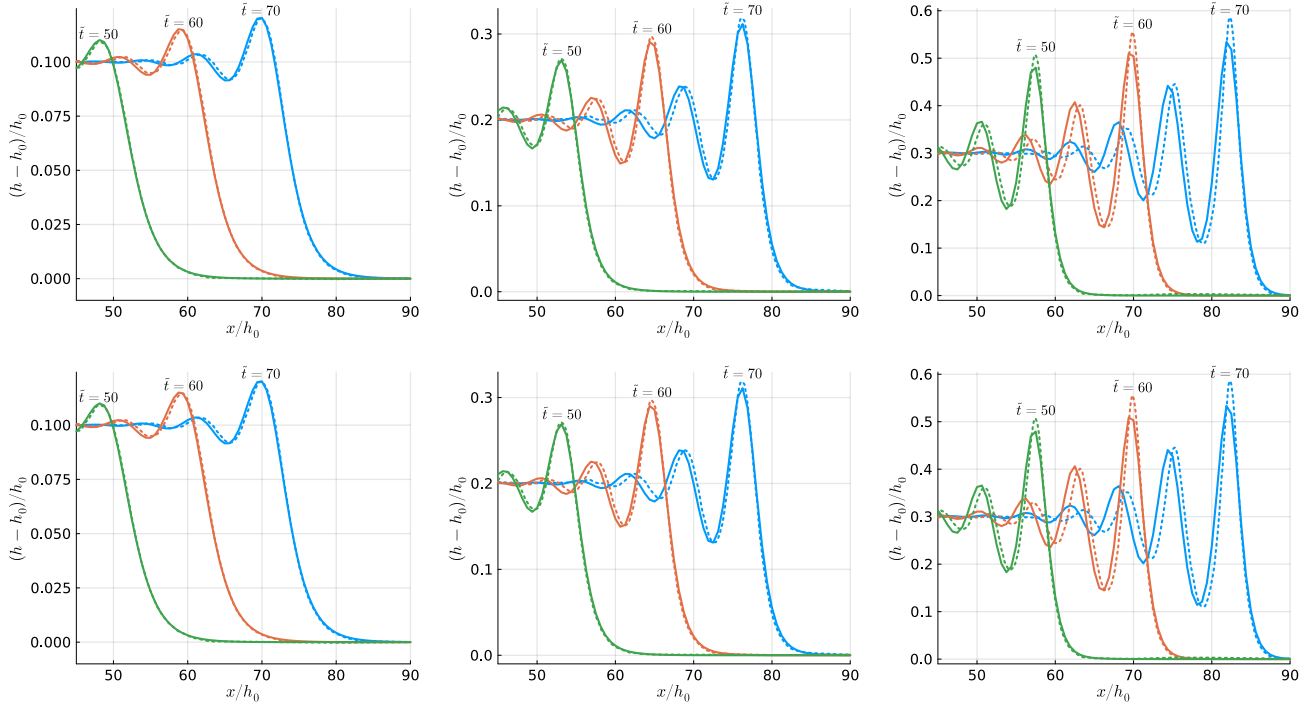

Figure 12: Favre wave: original SGN system, and grid spacing $\Delta x = 0.125$. Numerical solutions (solid lines) with nonlinearity $\varepsilon = 0.1$ (left), $\varepsilon = 0.2$ (center), and $\varepsilon = 0.3$ (right). Top : energy-conservative fourth-order finite differences with central operators. Bottom : fourth-order finite differences with central operators and artificial viscosity. The dashed lines show the fully nonlinear potential solutions from [131].

which may lead to gross underestimations of the wave heights on coarse meshes as the results in [60] demonstrate.

To investigate this aspect we consider the propagation for a large dimensionless time $\tilde{t} = 1500$. To save space we only consider the solution of the system in its original formulation, but similar conclusion are obtained when solving the hyperbolic approximation. The spatial domain considered is now $[-3000, 3000]$ and the initial discontinuity is set at $x_0 = -1000$. We plot two sets of results using second- and fourth-order schemes. The bore front is visualized in Figures 13 for second-order schemes, and 14 for fourth-order ones. From these figures we can see that the first solitary wave is already resolved on the coarsest mesh for the structure-preserving schemes. In the second-order case, a phase error is observed for the secondary waves, as one might expect due to the impact of discrete dispersion. However, the amplitudes are close to the finer mesh solution.

The fourth-order structure-preserving schemes have already resolved the solution on the coarsest mesh. The schemes with artificial viscosity behave much like in presence of a viscous regularization [12, 8], with much lower amplitudes and no fission of solitons. In the fourth-order case, doubling the number of nodes allows to obtain a reasonable prediction of wave height and position. In the second-order case even with two refinements the dissipative method still provides large amplitude underestimations.

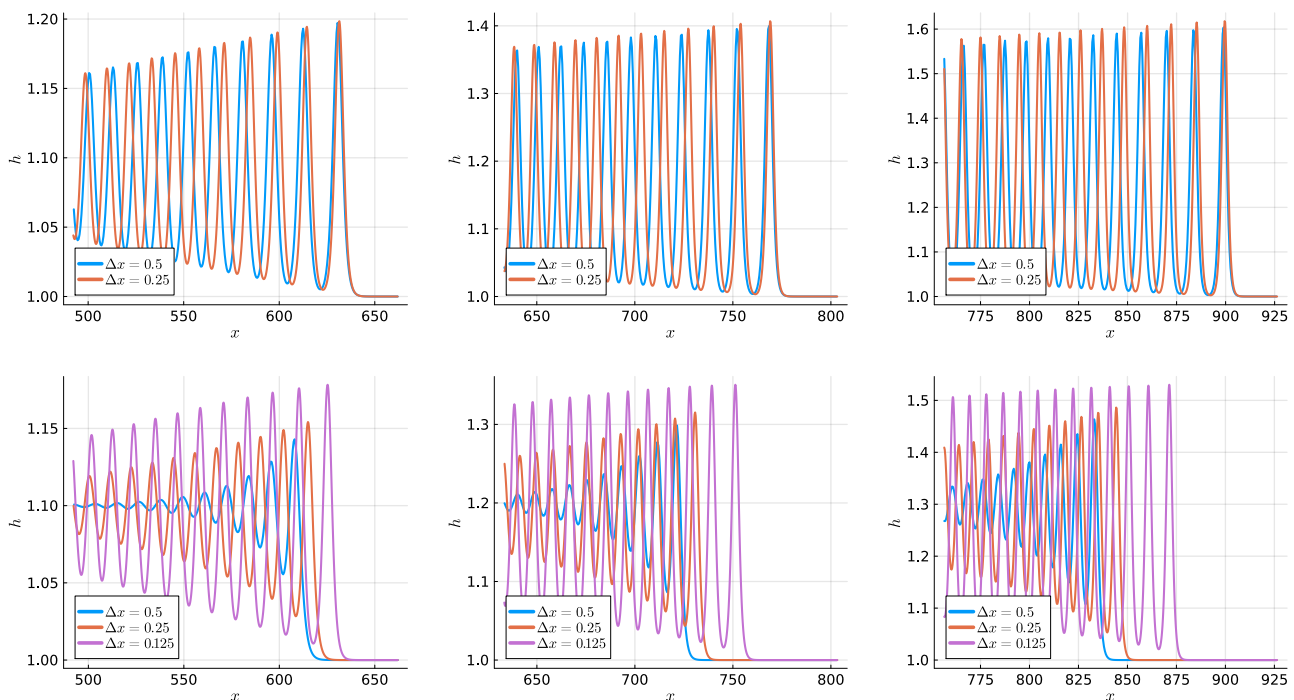

Figure 13: Favre waves. Solutions of the original SGN system at dimensionless time $\tilde{t} = 1500$ for nonlinearities $\varepsilon = 0.1$ (left), $\varepsilon = 0.2$ (center), and $\varepsilon = 0.3$ (right). Top: structure-preserving second-order finite difference scheme. Bottom: second-order finite difference with artificial viscosity.

These observations are confirmed by the plots of the maximum amplitude in Figures 15–16. The structure-preserving schemes provide already on the coarsest mesh an excellent approximation of the converged height. We can see that two more refinements would be required with a second-order scheme to match this value, while one refinement is required when using a fourth-order method. These results are qualitatively in line with those of [60]. They generalize such results to genuinely structure-preserving discretizations of the Serre-Green-Naghdi equations. We refer to the last reference for similar results when physical dissipation (friction) is included.

We do not show the wave lengths λ of the Favre waves, since they increase over time (in the absence of fric-

Figure 14: Favre waves. tion/dissipation). This is in accordance with the results we have observed for the soliton fission problem in Section 11.7. However, we compare for completeness the numerical maximal amplitudes a_{\max} with the data by [36, 128]. To this end, we compute a_{\max} for different Froude numbers

$$\text{Fr} = \frac{\sigma}{\sqrt{gh_0}} = \sqrt{(1+\varepsilon)(1+\varepsilon/2)}$$

by choosing $\varepsilon \in \{0.02, 0.06, 0.10, \dots, 0.30\}$ for $\Delta x = 0.02$, where σ is the non-dispersive/average bore speed. We stop the simulations when the first wave (with amplitude a_{\max}) has travelled roughly the same distance as in the experiments, i.e., 63.5 m. The results are shown in Figure 17. The numerical and experimental data agree very well for Froude numbers $\text{Fr} < 1.25$. For larger Froude numbers, wave breaking modelling is required to capture the correct amplitudes.

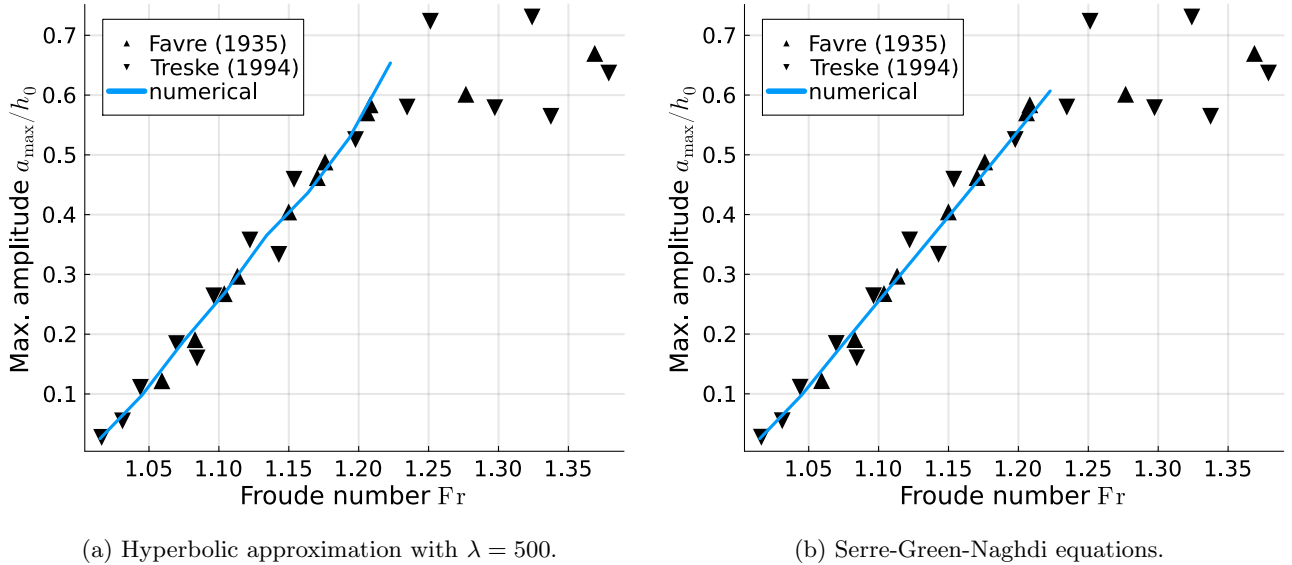

Figure 17: Favre waves: maximal amplitude a_{\max} against Froude number $\text{Fr} = \sigma/\sqrt{gh_0}$. Comparison with experimental data of Favre [36] and Treske [128]. Numerical results with fourth-order structure-preserving finite differences with central operators for the hyperbolic approximation and upwind operators for the original Serre-Green-Naghdi equations.

11.9 Dingemans experiment

In this section, we compare numerical results obtained with our new energy-conserving methods with experimental data from [24, 25]. This setup is similar to classical test cases such as [4] that have been used to validate numerical models for water waves, e.g., [79, 65].

The initial setup as well as a numerical solution of the mild-slope approximation are shown in Figure 18. The original experiment of Dingemans [24, 25] used a wave maker at $x = 0$ to produce water waves with an initial amplitude of $A = 0.02$ moving to the right. For the numerical simulations, choose the spatial domain $[-140, 100]$ and initialize the numerical solution with a sinusoidal perturbation of the still water height $h = 0.8$ with amplitude $A = 0.02$. The phase of the perturbations and the corresponding velocity perturbation are chosen based on the dispersion relation of the Euler equations as in [122, 70]. The offset of the perturbation is chosen manually such that the phase at the first wave gauge matches the experimental data reasonably well.

The bottom is flat except a trapezoidal bar starting at $x = 11.01$. Between $x = 11.01$ and $x = 23.04$, the bottom increases linearly from $b = 0$ to $b = 0.6$. The bottom has a small plateau between $x = 23.04$ and $x = 27.04$ with $b = 0.6$ and decreases linearly from $b = 0.6$ to $b = 0$ between $x = 27.04$ and $x = 33.07$.

Figure 18: Initial setup and numerical solution at time $t = 40$ obtained with fourth-order accurate upwind finite difference methods with $\Delta x = 0.24$ applied to the mild-slope approximation of the Serre-Green-Naghdi equations for the Dingemans experiment.

The values of the numerical solutions are compared to the experimental data at six wave gauges in Figure 19. First, we observe that the numerical solutions agree very well with each other — the results obtained using the hyperbolic approximation and the original SGN equations with/without mild-slope approximation are nearly indistinguishable. Moreover, the numerical results agree very well with the experimental data at the first three wave gauges. The agreement is less good but still qualitatively correct at the remaining wave gauges above and to the right of the plateau of the trapezoidal bar. This is within the limitations of the model used in terms of dispersion relation [116, 40]. However, the amplitudes of the numerical solutions are still in agreement with the experiments.

11.10 Preliminary comparison of runtime efficiency

The relative computational costs of discretizations of the hyperbolic approximation and the original SGN equations depend strongly on the parameter λ . For most numerical results presented above, we have chosen $\lambda = 500$ as a compromise between accuracy and computational costs since the numerical solutions obtained with the hyperbolic approximation and this value of the parameter λ are visually (nearly) indistinguishable from the results obtained with the original SGN equations. The only exception is the Riemann problem in Section 11.6, where a value of $\lambda = 1000$ is required to obtain visually indistinguishable results.

To give a first impression of the computational costs of the methods, we benchmark the total runtime (wallclock time) required to compute the numerical solutions from Sections 11.2 and 11.8 on a single core of a MacBook (M2 chip) using the Julia package BenchmarkTools.jl [18]. The results are reported in Table 5. While we do not aim to present a detailed performance study including the effects of various constraints and effects, the results show that there is no significant difference between the two versions of the original Serre-Green-Naghdi equations with variable bathymetry. Moreover, the computational costs of the hyperbolic approximation appear to increase faster with the number of grid nodes than the costs of the original system. In particular, the hyperbolic approximation with $\lambda = 500$ is faster than the original system (by a factor of roughly three) for

Figure 19: Experimental data of [24, 25] and total water height $h + b$ of the numerical solutions at the wave gauges over time obtained with fourth-order accurate finite difference methods with $\Delta x = 0.24$. The hyperbolic approximation uses $\lambda = 500$.

Table 5: Benchmarks of the total runtime of the numerical solutions obtained with the hyperbolic approximation and the original Serre-Green-Naghdi equations using finite differences with N nodes.

(a) Setup of the conservation tests with variable bathymetry and second-order central operators (Sections 11.2 and 11.3).

N	hyperbolic ($\lambda = 500$)	hyperbolic ($\lambda = 1000$)	original (mild slope)	original (full system)
1000	73.0 ± 21.0 ms	94.0 ± 3.3 ms	178.3 ± 2.3 ms	189.7 ± 4.2 ms
2000	234.0 ± 38.0 ms	301.1 ± 7.2 ms	359.1 ± 8.5 ms	378.0 ± 11.0 ms
3000	441.4 ± 4.9 ms	611.0 ± 18.0 ms	536.2 ± 7.4 ms	581.0 ± 29.0 ms

(b) Setup of the Favre waves with $\varepsilon = 0.2$ and fourth-order central/upwind operators for the hyperbolic/original equations (Section 11.8).

N	hyperbolic ($\lambda = 500$)	hyperbolic ($\lambda = 1000$)	original (flat bottom)	original (mild slope)	original (full system)
1000	68.3 ± 2.5 ms	96.6 ± 5.2 ms	132.8 ± 4.1 ms	163.5 ± 6.1 ms	162.3 ± 1.9 ms
2000	236.0 ± 11.0 ms	339.0 ± 23.0 ms	300.1 ± 4.3 ms	358.5 ± 6.6 ms	382.0 ± 12.0 ms
3000	517.0 ± 40.0 ms	741.3 ± 3.9 ms	517.6 ± 5.8 ms	667.5 ± 4.8 ms	664.0 ± 13.0 ms
4000	1.1796 ± 0.0073 s	1.895 ± 0.014 s	753.0 ± 10.0 ms	964.0 ± 12.0 ms	971.4 ± 8.3 ms
5000	2.0021 ± 0.0060 s	3.128 ± 0.025 s	1.109 ± 0.003 s	1.338 ± 0.009 s	1.368 ± 0.012 s

$N = 1000$ nodes. For $N \in \{2000, 3000\}$, the runtimes of the hyperbolic approximation with $\lambda = 500$ are still smaller than the runtimes of the original systems. This changes around $N = 4000$ nodes; for $N = 5000$ nodes, the original systems are faster than the hyperbolic approximation.

However, these performance benchmarks are done with the research code we have implemented for this article. This code is not optimized for performance. While we expect that the efficiency of the hyperbolic version should be reasonably good, the elliptic solves required for the original system are likely to be suboptimal. In particular, most of the total runtime is spent assembling (multiplying sparse/diagonal matrices) and solving (Cholesky factorization of SuiteSparse) the elliptic problems.

12 Summary and conclusions

We have developed structure-preserving numerical methods for the Serre-Green-Naghdi equations in their original formulation and the first-order hyperbolic approximation of [37, 13]. Starting with the hyperbolic approximation for flat bathymetry in Section 5, we have derived the methods for models with increasing complexity, including variable bathymetry for the hyperbolic approximation (Section 7) and the original Serre-Green-Naghdi equations (Sections 8 and 9). All methods conserve the total water mass, the total energy, and are well-balanced with respect to the lake-at-rest steady state. Moreover, the numerical methods discretizing the original Serre-Green-Naghdi equations conserve the total momentum for flat bathymetry.

We have demonstrated the suitability of the novel structure-preserving numerical methods in a range of numerical experiments, including academic test cases such as convergence tests. We have also demonstrated the importance of energy-conserving methods for long-time simulations of solitary waves in Section 11.5, where energy conservation reduces the error growth in time from quadratic to linear. Even without exact preservation in time, we have also shown the impact of energy conservation in providing correct predictions of wave heights in long-time propagation. Moreover, we have shown that our numerical methods reproduce experimental data,

e.g., for Favre waves (Section 11.8) and the flow over a trapezoidal bar (Section 11.9).

Preliminary performance benchmarks show that the hyperbolic approximation can be very efficient on coarse meshes. On finer meshes, the original formulations of the Serre-Green-Naghdi equations are more efficient (cf. Section 11.10).

Similar to Jouy et al. [60], we have found that structure-preserving numerical methods for the Serre-Green-Naghdi equations can efficiently capture the qualitatively correct behavior of water waves in a range of scenarios. Compared to methods including artificial dissipation/viscosity, the energy-preserving methods show the correct long-time behavior of the amplitude and shape of waves even on coarse meshes with low-order discretizations. This poses the question of the appropriateness of using entropy/energy dissipation as a stability criterion. Certainly, structure-preserving methods are a promising approach for the numerical simulation of water waves on coarse meshes (required in practice) and long-time simulations, typical of the operational context.

Our investigations can be extended in several directions. For example, we could check whether there are more energy-conservative split forms starting from the two-parameter family of energy-conservative split forms of the classical shallow water equations of [99]. Moreover, we could investigate the influence of possible other split forms of the non-hydrostatic pressure term of the Serre-Green-Naghdi equations, other upwind versions of the non-hydrostatic pressure term, and more general narrow-stencil second-derivative SBP operators instead of upwind operators, e.g., in Lemma 14. Further extensions include other boundary conditions, e.g., a reflective/wall boundary condition [87].
